This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.PutFile Overload List

HttpClient.PutFile Method (String, HttpTransferOptions)

Transfer a file from the local system to the web server.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal options As HttpTransferOptions _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   HttpTransferOptions options
);
```

Parameters

localFile
: A string that specifies the file on the local system that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

options
: An HttpTransferOptions enumeration value which specifies one or more file transfer options.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method is used to transfer a file from the local system to a remote server. Not all servers permit files to be uploaded using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself by setting the **UserName** and **Password** properties prior to uploading the file.

This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.PutFile Method (String, String, HttpTransferOptions)

Transfer a file from the local system to the web server.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As HttpTransferOptions _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string remoteFile,
   HttpTransferOptions options
);
```

Parameters

localFile
A string that specifies the file on the local system that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the server that will contain the data being transferred. If the file already exists, it will be overwritten. The file name should be specified using an absolute path that begins with a leading slash character.

options
An HttpTransferOptions enumeration value which specifies one or more file transfer options.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method is used to transfer a file from the local system to a remote server. Not all servers permit files to be uploaded using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself by setting the **UserName** and **Password** properties prior to uploading the file.

This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient Class | SocketTools Namespace | HttpClient.PutFile Overload List

HttpClient.PutFile Method (String, String, HttpTransferOptions, Int64)

Transfer a file from the local system to the web server.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As HttpTransferOptions, _
   ByVal offset As Long _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string remoteFile,
   HttpTransferOptions options,
   long offset
);
```

Parameters

localFile
A string that specifies the file on the local system that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

remoteFile
A string that specifies the file on the server that will contain the data being transferred. If the file already exists, it will be overwritten. The file name should be specified using an absolute path that begins with a leading slash character.

options
An HttpTransferOptions enumeration value which specifies one or more file transfer options.

offset
A integer value which specifies the offset where the file transfer should begin. A value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the option to restart file transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method is used to transfer a file from the local system to a remote server. Not all servers permit files to be uploaded using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself by setting the **UserName** and **Password** properties prior to uploading the file.

This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.PutFile Method (String, String, HttpTransferOptions, Int32)

Transfer a file from the local system to the web server.

[Visual Basic]

```
Overloads Public Function PutFile( _
   ByVal localFile As String, _
   ByVal remoteFile As String, _
   ByVal options As HttpTransferOptions, _
   ByVal offset As Integer _
) As Boolean
```

[C#]

```
public bool PutFile(
   string localFile,
   string remoteFile,
   HttpTransferOptions options,
   int offset
);
```

Parameters

localFile

A string that specifies the file on the local system that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

remoteFile

A string that specifies the file on the server that will contain the data being transferred. If the file already exists, it will be overwritten. The file name should be specified using an absolute path that begins with a leading slash character.

options

An HttpTransferOptions enumeration value which specifies one or more file transfer options.

offset

A integer value which specifies the offset where the file transfer should begin. A value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the option to restart file transfers.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **PutFile** method is used to transfer a file from the local system to a remote server. Not all servers permit files to be uploaded using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself by setting the **UserName** and **Password** properties prior to uploading the file.

This method will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.Read Method

Read data from the server and store it in a byte array.

Overload List

Read data from the server and store it in a byte array.

public int Read(byte[]);

Read data from the server and store it in a byte array.

public int Read(byte[],int);

Read data from the server and store it in a string.

public int Read(ref string);

Read data from the server and store it in a string.

public int Read(ref string,int);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Read Method (Byte[])

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the size of the byte array passed to the method. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Read Overload List

HttpClient.Read Method (Byte[], Int32)

Read data from the server and store it in a byte array.

[Visual Basic]

```
Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Read Overload List

HttpClient.Read Method (String)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer

A string that will contain the data read from the client.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to a maximum of 4096 bytes. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Read Overload List

HttpClient.Read Method (String, Int32)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer
A string that will contain the data read from the client.

length
An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

HttpClient.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.SetCookie Method

Send the specified cookie to the server when a resource is requested.

[Visual Basic]

```
Public Function SetCookie( _
   ByVal cookieName As String, _
   ByVal cookieValue As String _
) As Boolean
```

[C#]

```
public bool SetCookie(
   string cookieName,
   string cookieValue
);
```

Parameters

cookieName

A string which specifies the name of the cookie that will be sent to the server when the next resource is requested.

cookieValue

A string which specifies the value of the cookie. To delete a cookie that has been previously set, this parameter should be an empty string.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SetCookie** method submits the cookie name and value to the server when a resource is requested or data is posted to a script. For more information about cookies and how they are used, refer to the **GetCookie** method.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.SetHeader Method

Set the value of a request header field.

[Visual Basic]

```
Public Function SetHeader( _
   ByVal headerName As String, _
   ByVal headerValue As String _
) As Boolean
```

[C#]

```
public bool SetHeader(
   string headerName,
   string headerValue
);
```

Parameters

headerName
A string that specifies the name of the request header.

headerValue
A string that specifies the value associated with the request header. If this argument is set to an empty string, the request header is and its previous value are deleted.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SetHeader** method is used to set the values of specific fields in the HTTP request header. This method should be called before the client has requested the resource.

Some headers are generated by methods that send resource requests. Some of these are supplied by the requesting methods only if the application has not previously defined the header. For others, the requesting method overrides what the application may have defined. The affected headers include:

Header	Description
Accept	This header field specifies the type of content that the client will accept. By default, all content types will be accepted by the client.
Authorization	This header field specifies the authentication information required to access the resource. By default, this header field is only defined if the client specifies a username and password.
Connection	This header field is automatically defined based on the value specified by the **KeepAlive** property.
Content-Length	This header field is automatically defined when data is being posted to the server or a file is being uploaded.
Content-Type	This header field is automatically defined when data is being posted to the server or a file is being

	uploaded.
Host	This header field defines the hostname of the server. By default, the hostname provided to the **Connect** method will be used.
Proxy-Authorization	This header field specifies the proxy authentication information required to access the resource. By default, this header field is only defined if a proxy server has been specified, along with a username and password.

HttpClient Class | SocketTools Namespace

HttpClient.SubmitForm Method ()

Submits the current form data to the server for processing.

[Visual Basic]

```
Overloads Public Function SubmitForm() As Boolean
```

[C#]

```
public bool SubmitForm();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SubmitForm** method submits the current form data to a script on the remote server and returns the result in a byte array provided by the caller. This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. During the operation, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Any data returned by the server will be discarded.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.SubmitForm Overload List

HttpClient.SubmitForm Method (Byte[], Int32)

Submits the current form data to the server for processing.

[Visual Basic]

```
Overloads Public Function SubmitForm( _
   ByVal resultBuffer As Byte(), _
   ByRef resultLength As Integer _
) As Boolean
```

[C#]

```
public bool SubmitForm(
   byte[] resultBuffer,
   ref int resultLength
);
```

Parameters

resultBuffer
A byte array which will contain the data returned by the server.

resultLength
An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SubmitForm** method submits the current form data to a script on the remote server and returns the result in a byte array provided by the caller. This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. During the operation, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Overloads Public Function SubmitForm( _
   ByVal resultBuffer As Byte(), _
   ByRef resultLength As Integer, _
   ByVal options As HttpSubmitOptions _
) As Boolean
```

[C#]

```
public bool SubmitForm(
   byte[] resultBuffer,
   ref int resultLength,
   HttpSubmitOptions options
);
```

Parameters

resultBuffer
A byte array which will contain the data returned by the server.

resultLength
An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

options
An HttpSubmitOptions enumeration value which specifies one or more options for submitting form data to the server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SubmitForm** method submits the current form data to a script on the remote server and returns the result in a byte array provided by the caller. This method will cause the current thread to block until the operation completes, a timeout occurs or the post is canceled. During the operation, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

HttpClient.TaskAbort Method

Abort all asynchronous tasks that are currently active.

Overload List

Abort all asynchronous tasks that are currently active.

public bool TaskAbort();

Abort the specified asynchronous task.

public bool TaskAbort(int);

Abort the specified asynchronous task.

public bool TaskAbort(int,int);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TaskAbort Method ()

Abort all asynchronous tasks that are currently active.

[Visual Basic]

```
Overloads Public Function TaskAbort() As Boolean
```

[C#]

```
public bool TaskAbort();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskAbort** method signals all background worker threads created by this instance of the class to abort their current operation and terminate as soon as possible. This version of the method will signal each active task and return immediately to the caller.

The **Reset** and **Uninitialize** methods will abort all active background transfers and wait for those tasks to complete before returning to the caller. It is recommended that your application explicitly wait for background transfers to complete or abort them using this method before allowing the program to terminate. This will ensure that your program can perform any necessary cleanup operations. If there are active background tasks running at the time that the class instance is disposed, it can force the instance to stop those worker threads immediately without waiting for them to terminate gracefully.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.TaskAbort Overload List

HttpClient.TaskAbort Method (Int32)

Abort the specified asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskAbort( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskAbort(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskAbort** method signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. This version of the method returns immediately after the background thread has been signaled.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.TaskAbort Overload List

HttpClient.TaskAbort Method (Int32, Int32)

Abort the specified asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskAbort( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer _
) As Boolean
```

[C#]

```
public bool TaskAbort(
   int taskId,
   int timeWait
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

timeWait

An integer value that specifies the number of milliseconds to wait for the background task to abort.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskAbort** method signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the ***timeWait*** parameter has a value of zero, the method returns immediately after the background thread has been signaled. If the ***timeWait*** parameter is non-zero, the method will wait that amount of time for the background thread to terminate.

The **Reset** and **Uninitialize** methods will abort all active background transfers and wait for those tasks to complete before returning to the caller. It is recommended that your application explicitly wait for background transfers to complete or abort them using this method before allowing the program to terminate. This will ensure that your program can perform any necessary cleanup operations. If there are active background tasks running at the time that the class instance is disposed, it can force the instance to stop those worker threads immediately without waiting for them to terminate gracefully.

HttpClient.TaskDone Method

Determine if the current asynchronous task has completed.

Overload List

Determine if the current asynchronous task has completed.

public bool TaskDone();

Determine if an asynchronous task has completed.

public bool TaskDone(int);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TaskDone Method ()

Determine if the current asynchronous task has completed.

[Visual Basic]

```
Overloads Public Function TaskDone() As Boolean
```

[C#]

```
public bool TaskDone();
```

Return Value

This method returns a Boolean value. If the task has finished, the return value is **true**. If the background task is still active, the return value is **false**.

Remarks

The **TaskDone** method is used to determine if the current asynchronous task has completed. This overloaded version of the method is functionally equivalent to providing the value of the **TaskId** property as the unique task identifier.

If you use this method to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this method rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **TaskWait** method will provide the last error code associated with the task. Note that if this method returns **true**, it is guaranteed that calling **TaskWait** using the same task ID will return the error code to the caller immediately without causing the current thread to block.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.TaskDone Overload List

HttpClient.TaskDone Method (Int32)

Determine if an asynchronous task has completed.

[Visual Basic]

```
Overloads Public Function TaskDone( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskDone(
   int taskId
);
```

Parameters

taskId

An optional integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the task has finished, the return value is **true**. If the background task is still active, the return value is **false**.

Remarks

The **TaskDone** method is used to determine if the specified asynchronous task has completed.

If you use this method to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this method rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **TaskWait** method will provide the last error code associated with the task. Note that if this method returns **true**, it is guaranteed that calling **TaskWait** using the same task ID will return the error code to the caller immediately without causing the current thread to block.

HttpClient.TaskResume Method

Resume execution of the current asynchronous task.

Overload List

Resume execution of the current asynchronous task.

public bool TaskResume();

Resume execution of an asynchronous task.

public bool TaskResume(int);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TaskResume Method ()

Resume execution of the current asynchronous task.

[Visual Basic]
```
Overloads Public Function TaskResume() As Boolean
```

[C#]
```
public bool TaskResume();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskResume** method resumes execution of the current background task that was previously suspended using the **TaskSuspend** method. This overloaded version of the method is functionally equivalent to providing the value of the **TaskId** property as the unique task identifier.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.TaskResume Overload List

HttpClient.TaskResume Method (Int32)

Resume execution of an asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskResume( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskResume(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskResume** method resumes execution of the background worker thread that was previously suspended using the **TaskSuspend** method.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.TaskResume Overload List

HttpClient.TaskSuspend Method

Suspend execution of the current asynchronous task.

Overload List

Suspend execution of the current asynchronous task.

public bool TaskSuspend();

Suspend execution of an asynchronous task.

public bool TaskSuspend(int);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TaskSuspend Method ()

Suspend execution of the current asynchronous task.

[Visual Basic]
```
Overloads Public Function TaskSuspend() As Boolean
```

[C#]
```
public bool TaskSuspend();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskSuspend** method will suspend execution of the background worker thread associated with the current task. This overloaded version of the method is functionally equivalent to providing the value of the **TaskId** property as the unique task identifier.

Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **TaskResume** method. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.TaskSuspend Overload List

HttpClient.TaskSuspend Method (Int32)

Suspend execution of an asynchronous task.

[Visual Basic]

```
Overloads Public Function TaskSuspend( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskSuspend(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskSuspend** method will suspend execution of the background worker thread associated with the task.

Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **TaskResume** method. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

HttpClient.TaskWait Method

Wait for all asynchronous tasks to complete.

Overload List

Wait for all asynchronous tasks to complete.

public bool TaskWait();

Wait for an asynchronous task to complete.

public bool TaskWait(int);

Wait for an asynchronous task to complete.

public bool TaskWait(int,int);

Wait for an asynchronous task to complete.

public bool TaskWait(int,int,ref ErrorCode);

Wait for an asynchronous task to complete.

public bool TaskWait(int,int,ref int,ref ErrorCode);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.TaskWait Method ()

Wait for all asynchronous tasks to complete.

[Visual Basic]

```
Overloads Public Function TaskWait() As Boolean
```

[C#]

```
public bool TaskWait();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This overloaded version of the **TaskWait** method will cause the current working thread to block until all background tasks created by this instance of the class have completed. If there are no active background tasks, this method will return to the caller immediately.

You should not call this version of the method from the main UI thread. Windows messages will not be processed while this method is blocked waiting for the background tasks to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if all tasks have completed, create a timer to periodically check the value of the **TaskCount** property. When it returns zero, there are no active background tasks executing.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.TaskWait Overload List

HttpClient.TaskWait Method (Int32)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block for an indefinite period of time until the task completes. If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block.

You should not call this overloaded version of the method from the main UI thread. Windows messages will not be processed while this method is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.TaskWait Overload List

HttpClient.TaskWait Method (Int32, Int32)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId,
   int timeWait
);
```

Parameters

taskId

An integer value that specifies the unique identifier associated with a background task.

timeWait

An integer value that specifies the number of milliseconds to wait for the background task to complete.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *timeWait* parameter is zero, then this method will poll the status of the task and return immediately to the caller. If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block.

You should not call this method from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this method is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.TaskWait Overload List

HttpClient.TaskWait Method (Int32, Int32, ErrorCode)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer, _
   ByRef taskError As ErrorCode _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId,
   int timeWait,
   ref ErrorCode taskError
);
```

Parameters

taskId
An integer value that specifies the unique identifier associated with a background task.

timeWait
An integer value that specifies the number of milliseconds to wait for the background task to complete.

taskError
An ErrorCode value passed by reference that will contain the last error code set by the asynchronous task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *timeWait* parameter is zero, then this method will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block. The *taskError* parameter will contain the last error code value that was set by the worker thread before it terminated. If the *taskError* value is zero, that means that the background task was successful and no error occurred. A non-zero value will indicate that the background task has failed.

You should not call this method from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this method is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

HttpClient.TaskWait Method (Int32, Int32, Int32, ErrorCode)

Wait for an asynchronous task to complete.

[Visual Basic]

```
Overloads Public Function TaskWait( _
   ByVal taskId As Integer, _
   ByVal timeWait As Integer, _
   ByRef timeElapsed As Integer, _
   ByRef taskError As ErrorCode _
) As Boolean
```

[C#]

```
public bool TaskWait(
   int taskId,
   int timeWait,
   ref int timeElapsed,
   ref ErrorCode taskError
);
```

Parameters

taskId
An integer value that specifies the unique identifier associated with a background task.

timeWait
An integer value that specifies the number of milliseconds to wait for the background task to complete.

timeElapsed
An integer value passed by reference that will contain the elapsed time for the task in milliseconds when the method returns.

taskError
An ErrorCode value passed by reference that will contain the last error code set by the asynchronous task.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **TaskWait** method waits for the specified task to complete. This method will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *timeWait* parameter is zero, then this method will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this method is called, the method will return immediately without causing the current thread to block. The *timeElapsed* parameter contain the number of milliseconds that it took for the task to complete. The *taskError* parameter will contain the last error code value that was set by the worker thread before it terminated. If the *taskError* value is zero, that means that the background task was successful and no error occurred. A non-zero value will indicate that the background task has failed.

You should not call this method from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this method is blocked

waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to determine if a background task has finished, create a timer to periodically call the **TaskDone** method. When it returns **true** (indicating that the task has completed), you can safely call **TaskWait** to obtain the elapsed time and last error code without blocking the current thread.

HttpClient Class | SocketTools Namespace | HttpClient.TaskWait Overload List

HttpClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

HttpClient Class | SocketTools Namespace | Initialize Method

HttpClient.Write Method

Write one or more bytes of data to the server.

Overload List

Write one or more bytes of data to the server.

public int Write(byte[]);

Write one or more bytes of data to the server.

public int Write(byte[],int);

Write a string of characters to the server.

public int Write(string);

Write a string of characters to the server.

public int Write(string,int);

See Also

HttpClient Class | SocketTools Namespace

HttpClient.Write Method (Byte[])

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Write Overload List

HttpClient.Write Method (Byte[], Int32)

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Write Overload List

HttpClient.Write Method (String)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

HttpClient Class | SocketTools Namespace | HttpClient.Write Overload List

HttpClient.Write Method (String, Int32)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer

A string which contains the data to be written to the server.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

HttpClient Events

The events of the **HttpClient** class are listed below. For a complete list of **HttpClient** class members, see the HttpClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnCommand	Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an client operation fails.
⚡ OnProgress	Occurs as a data stream is being read or written to the client.
⚡ OnRead	Occurs when data is available to be read from the client.
⚡ OnRedirect	Occurs when the server indicates a resource has been moved.
⚡ OnTaskBegin	Occurs when an asynchronous task begins execution.
⚡ OnTaskEnd	Occurs when an asynchronous task completes.
⚡ OnTaskRun	Occurs while a background task is active.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the client.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.OnCommand Event

Occurs when the client sends a command to the remote host and receives a reply indicating the result of that command.

[Visual Basic]

```
Public Event OnCommand As OnCommandEventHandler
```

[C#]

```
public event OnCommandEventHandler OnCommand;
```

Event Data

The event handler receives an argument of type HttpClient.CommandEventArgs containing data related to this event. The following **HttpClient.CommandEventArgs** properties provide information specific to this event.

Property	Description
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Remarks

The **OnCommand** event is generated when the client receives a reply from the server after some action has been taken.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.CommandEventArgs Class

Provides data for the OnCommand event.

For a list of all members of this type, see HttpClient.CommandEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.HttpClient.CommandEventArgs

[Visual Basic]
```
Public Class HttpClient.CommandEventArgs
    Inherits EventArgs
```

[C#]
```
public class HttpClient.CommandEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

CommandEventArgs specifies the result code and result string for the last command executed by the server.

The OnCommand event occurs whenever a command is executed on the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

See Also

HttpClient.CommandEventArgs Members | SocketTools Namespace

HttpClient.CommandEventArgs Members

HttpClient.CommandEventArgs overview

Public Instance Constructors

HttpClient.CommandEventArgs Constructor	Initializes a new instance of the HttpClient.CommandEventArgs class.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

HttpClient.CommandEventArgs Class | SocketTools Namespace

HttpClient.CommandEventArgs Constructor

Initializes a new instance of the HttpClient.CommandEventArgs class.

[Visual Basic]
```
Public Sub New()
```

[C#]
```
public HttpClient.CommandEventArgs();
```

See Also

HttpClient.CommandEventArgs Class | SocketTools Namespace

HttpClient.CommandEventArgs Properties

The properties of the **HttpClient.CommandEventArgs** class are listed below. For a complete list of **HttpClient.CommandEventArgs** class members, see the HttpClient.CommandEventArgs Members topic.

Public Instance Properties

ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.

See Also

HttpClient.CommandEventArgs Class | SocketTools Namespace

HttpClient.CommandEventArgs.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]
```
Public ReadOnly Property ResultCode As Integer
```

[C#]
```
public int ResultCode {get;}
```

Property Value

An integer value which specifies the last result code returned by the server.

Remarks

This property should be checked after the **Command** method is used to execute a command on the server to determine if the operation was successful. Result codes are three-digit numeric values returned by the remote server and may be broken down into the following ranges:

ResultCode	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

It is important to note that while some result codes have become standardized, not all servers respond to commands using the same result codes. For example, one server may respond with a result code of 221 to indicate success, while another may respond with a value of 235. It is recommended that applications check for ranges of values to determine if a command was successful, not a specific value.

See Also

HttpClient.CommandEventArgs Class | SocketTools Namespace

HttpClient.CommandEventArgs.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]

```
Public ReadOnly Property ResultString As String
```

[C#]

```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

This string is generated by the remote server, and typically is used to describe the result code. For example, if an error is indicated by the result code, the result string may describe the condition that caused the error.

See Also

HttpClient.CommandEventArgs Class | SocketTools Namespace

HttpClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its connection, terminating the client session with the application. Because there may still be data in the client receive buffers, you should continue to read data from the client until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and release the resources allocated for the client.

This event is only generated if the client is in non-blocking mode.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type HttpClient.ErrorEventArgs containing data related to this event. The following **HttpClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see HttpClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.HttpClient.ErrorEventArgs

[Visual Basic]

```
Public Class HttpClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class HttpClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

See Also

HttpClient.ErrorEventArgs Members | SocketTools Namespace

HttpClient.ErrorEventArgs Members

HttpClient.ErrorEventArgs overview

Public Instance Constructors

HttpClient.ErrorEventArgs Constructor	Initializes a new instance of the HttpClient.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

HttpClient.ErrorEventArgs Class | SocketTools Namespace

HttpClient.ErrorEventArgs Constructor

Initializes a new instance of the HttpClient.ErrorEventArgs class.

[Visual Basic]
```
Public Sub New()
```

[C#]
```
public HttpClient.ErrorEventArgs();
```

See Also

HttpClient.ErrorEventArgs Class | SocketTools Namespace

HttpClient.ErrorEventArgs Properties

The properties of the **HttpClient.ErrorEventArgs** class are listed below. For a complete list of **HttpClient.ErrorEventArgs** class members, see the HttpClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

HttpClient.ErrorEventArgs Class | SocketTools Namespace

HttpClient.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

HttpClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

HttpClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public HttpClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

HttpClient.ErrorEventArgs Class | SocketTools Namespace | Description Property

HttpClient.OnProgress Event

Occurs as a data stream is being read or written to the client.

[Visual Basic]
```
Public Event OnProgress As OnProgressEventHandler
```

[C#]
```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type HttpClient.ProgressEventArgs containing data related to this event. The following **HttpClient.ProgressEventArgs** properties provide information specific to this event.

Property	Description
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.
Resource	Gets a value which specifies the resource or file name.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the client. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.ProgressEventArgs Class

Provides data for the OnProgress event.

For a list of all members of this type, see HttpClient.ProgressEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.HttpClient.ProgressEventArgs

[Visual Basic]
```
Public Class HttpClient.ProgressEventArgs
    Inherits EventArgs
```

[C#]
```
public class HttpClient.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes copied from the data stream, the total number of bytes in the data stream and a completion percentage.

The OnProgress event occurs as a data stream is being read or written to the client. This event only occurs when the **GetData, GetFile**, **PostData, PostFile, PutData, PutFile** or **SubmitForm** methods are called.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

See Also

HttpClient.ProgressEventArgs Properties

The properties of the **HttpClient.ProgressEventArgs** class are listed below. For a complete list of **HttpClient.ProgressEventArgs** class members, see the HttpClient.ProgressEventArgs Members topic.

Public Instance Properties

BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.
Resource	Gets a value which specifies the resource or file name.

See Also

HttpClient.ProgressEventArgs Class | SocketTools Namespace

HttpClient.ProgressEventArgs.BytesCopied Property

Gets a value which specifies the number of bytes of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property BytesCopied As Long
```

[C#]

```
public long BytesCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesCopied** property specifies the number of bytes that have been read from the client and stored in the local stream buffer, or written from the stream buffer to the client.

See Also

HttpClient.ProgressEventArgs Class | SocketTools Namespace | BytesTotal Property | Percent Property

HttpClient.ProgressEventArgs.BytesTotal Property

Gets a value which specifies the total number of bytes in the data stream.

[Visual Basic]

```
Public ReadOnly Property BytesTotal As Long
```

[C#]

```
public long BytesTotal {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesTotal** property specifies the total amount of data being read from the client and stored in the data stream, or written from the data stream to the client. If the amount of data was unknown or unspecified at the time the method call was made, then this value will always be the same as the **BytesCopied** property.

See Also

HttpClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | Percent Property

HttpClient.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

See Also

HttpClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | BytesTotal Property

HttpClient.OnRead Event

Occurs when data is available to be read from the client.

[Visual Basic]

```
Public Event OnRead As EventHandler
```

[C#]

```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the client. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the client. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the server and store it in a local buffer for processing. See the example below.

This event is only generated if the client is in non-blocking mode.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.OnRedirect Event

Occurs when the server indicates a resource has been moved.

[Visual Basic]
```
Public Event OnRedirect As OnRedirectEventHandler
```

[C#]
```
public event OnRedirectEventHandler OnRedirect;
```

Event Data

The event handler receives an argument of type HttpClient.RedirectEventArgs containing data related to this event. The following **HttpClient.RedirectEventArgs** property provides information specific to this event.

Property	Description
Location	Gets the location of the redirected resource.

Remarks

The **OnRedirect** event is generated when the server indicates that the requested resource has been moved to a new location. This new location is typically on the same server, however it may specify another server.

If the **AutoRedirect** property is set to **true**, then the class will automatically retrieve the resource from its new location. If the property is set to **false**, then the application is responsible for handling the redirection.

HttpClient Class | SocketTools Namespace

HttpClient.RedirectEventArgs Class

Provides data for the OnRedirect event.

For a list of all members of this type, see HttpClient.RedirectEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.HttpClient.RedirectEventArgs

[Visual Basic]

```
Public Class HttpClient.RedirectEventArgs
    Inherits EventArgs
```

[C#]

```
public class HttpClient.RedirectEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

RedirectEventArgs provides the location of the redirected resource.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

See Also

HttpClient.RedirectEventArgs Class | SocketTools Namespace

HttpClient.OnTaskBegin Event

Occurs when an asynchronous task begins execution.

[Visual Basic]

```
Public Event OnTaskBegin As OnTaskBeginEventHandler
```

[C#]

```
public event OnTaskBeginEventHandler OnTaskBegin;
```

Event Data

The event handler receives an argument of type HttpClient.TaskBeginEventArgs containing data related to this event. The following **HttpClient.TaskBeginEventArgs** property provides information specific to this event.

Property	Description
TaskId	Get the unique task identifier associated with the event.

Remarks

The **OnTaskBegin** event occurs when a background task associated with an asynchronous file transfer begins executing. This event can be used in conjunction with the **OnTaskEnd** event to monitor one or more background tasks that are created to perform asynchronous file transfers.

This event and the related asynchronous task events are invoked from the context of the thread that is managing the background task, and not the thread that created the class instance. If a handler is implemented for this event, its code will be executing in a different thread than the main UI thread. You should never attempt to update your application's user interface directly from within this event handler. Instead, you must create a delegate and use the **Invoke** method to ensure that any changes to the user interface are done within the context of the main UI thread.

Because background tasks are managed in separate threads, this has the effect of making your application multi-threaded, even if you do not explicitly create any worker threads in your own code. If the code in your event handler modifies a public member variable or shared object, you must ensure that access to that object is synchronized. For example, if your event handler updates a shared instance of a **Hashtable** object, you should ensure that all operations are performed through the thread-safe wrapper returned by the **Synchronized** method for that class. Refer to the MSDN documentation for more information about creating thread-safe applications.

HttpClient.TaskBeginEventArgs Class | SocketTools Namespace

HttpClient.TaskBeginEventArgs.TaskId Property

Get the unique task identifier associated with the event.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

[C#]

```
public int TaskId {get;}
```

Property Value

An integer value that uniquely identifies the task that invoked the event handler.

See Also

HttpClient.TaskBeginEventArgs Class | SocketTools Namespace

HttpClient.OnTaskEnd Event

Occurs when an asynchronous task completes.

[Visual Basic]
```
Public Event OnTaskEnd As OnTaskEndEventHandler
```

[C#]
```
public event OnTaskEndEventHandler OnTaskEnd;
```

Event Data

The event handler receives an argument of type HttpClient.TaskEndEventArgs containing data related to this event. The following **HttpClient.TaskEndEventArgs** properties provide information specific to this event.

Property	Description
Error	Get the last error code for the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

Remarks

The **OnTaskEnd** event occurs when a file transfer completes and the background task has terminated. Refer to the **OnTaskBegin** event for additional information about implementing a handler for this event.

See Also

HttpClient.TaskEndEventArgs Class | SocketTools Namespace

HttpClient.TaskEndEventArgs Properties

The properties of the **HttpClient.TaskEndEventArgs** class are listed below. For a complete list of **HttpClient.TaskEndEventArgs** class members, see the HttpClient.TaskEndEventArgs Members topic.

Public Instance Properties

Error	Get the last error code for the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

See Also

HttpClient.TaskEndEventArgs Class | SocketTools Namespace

HttpClient.TaskEndEventArgs.Error Property

Get the last error code for the background task.

[Visual Basic]
```
Public ReadOnly Property Error As ErrorCode
```

[C#]
```
public HttpClient.ErrorCode Error {get;}
```

Property Value

An **ErrorCode** enumeration that specifies the last error code set by the background task.

See Also

HttpClient.TaskEndEventArgs Class | SocketTools Namespace

HttpClient.TaskEndEventArgs.TaskId Property

Get the unique task identifier associated with the event.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

[C#]

```
public int TaskId {get;}
```

Property Value

An integer value that uniquely identifies the task that invoked the event handler.

See Also

HttpClient.TaskEndEventArgs Class | SocketTools Namespace

HttpClient.TaskEndEventArgs.TimeElapsed Property

Gets the amount of time that has elapsed in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TimeElapsed As Integer
```

[C#]

```
public int TimeElapsed {get;}
```

Property Value

An integer value that specifies the number of milliseconds that the background task has executed.

See Also

HttpClient.TaskEndEventArgs Class | SocketTools Namespace

HttpClient.OnTaskRun Event

Occurs while a background task is active.

[Visual Basic]
```
Public Event OnTaskRun As OnTaskRunEventHandler
```

[C#]
```
public event OnTaskRunEventHandler OnTaskRun;
```

Event Data

The event handler receives an argument of type HttpClient.TaskRunEventArgs containing data related to this event. The following **HttpClient.TaskRunEventArgs** properties provide information specific to this event.

Property	Description
Completed	Gets an estimate of the progress of the background task.
TaskId	Get the unique task identifier associated with the event.
TimeElapsed	Gets the amount of time that has elapsed in milliseconds.

Remarks

The **OnTaskRun** event is generated periodically during a file transfer while the background task is active. The rate and number of times that this event will be generated depends on the task being performed. This event is generally analogous to the **OnProgress** event for file transfers that are performed in the current working thread, however the **OnTaskRun** event will occur for each individual background task that is active.

Refer to the **OnTaskBegin** event for additional information about implementing a handler for this event.

HttpClient.TaskRunEventArgs Class | SocketTools Namespace

HttpClient.TaskRunEventArgs.Completed Property

Gets an estimate of the progress of the background task.

[Visual Basic]

```
Public ReadOnly Property Completed As Integer
```

[C#]

```
public int Completed {get;}
```

Property Value

An integer value that returns a number between 0 and 100 inclusive that specifies the estimated percentage of completion for the task. A value of zero indicates that the task has just begun executing, while a value of 100 indicates that the task is at or near completion.

See Also

HttpClient.TaskRunEventArgs Class | SocketTools Namespace

HttpClient.TaskRunEventArgs.TaskId Property

Get the unique task identifier associated with the event.

[Visual Basic]

```
Public ReadOnly Property TaskId As Integer
```

[C#]

```
public int TaskId {get;}
```

Property Value

An integer value that uniquely identifies the task that invoked the event handler.

See Also

HttpClient.TaskRunEventArgs Class | SocketTools Namespace

HttpClient.TaskRunEventArgs.TimeElapsed Property

Gets the amount of time that has elapsed in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TimeElapsed As Integer
```

[C#]

```
public int TimeElapsed {get;}
```

Property Value

An integer value that specifies the number of milliseconds that the background task has been executing.

See Also

HttpClient.TaskRunEventArgs Class | SocketTools Namespace

HttpClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.OnWrite Event

Occurs when data can be written to the client.

[Visual Basic]

```
Public Event OnWrite As EventHandler
```

[C#]

```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the client. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the client send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the client is in non-blocking mode.

See Also

HttpClient Class | SocketTools Namespace

HttpClient.CookieFlags Enumeration

Specifies the cookie flags supported by the HttpClient class.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpClient.CookieFlags
```

[C#]

```
[Flags]
public enum HttpClient.CookieFlags
```

Remarks

The HttpClient class uses the **CookieFlags** enumeration to specify one or more cookie flags when a cookie is set by the server. Multiple options may be specified.

Members

Member Name	Description	Value
cookieDefault	This flag specifies that the cookie can be stored on the local system and may be provided to the server over a standard, non-secure connection.	0
cookieSecure	This flag specifies that the cookie should only be provided to the server if the connection is secure.	1
cookieSession	This flag specifies that the cookie should only be used for the current application session and should not be stored permanently on the local system.	2

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

See Also

SocketTools Namespace

HttpClient.ErrorCode Enumeration

Specifies the error codes returned by the HttpClient class.

[Visual Basic]

```
Public Enum HttpClient.ErrorCode
```

[C#]

```
public enum HttpClient.ErrorCode
```

Remarks

The HttpClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

HttpClient.HttpFormMethod Enumeration

Specifies the methods supported by the HttpClient class when submitting form data to a server.

[Visual Basic]

```
Public Enum HttpClient.HttpFormMethod
```

[C#]

```
public enum HttpClient.HttpFormMethod
```

Remarks

The HttpClient class uses the **HttpFormMethod** enumeration to specify the method that should be used when submitting form data to a server for processing.

Members

Member Name	Description
methodDefault	The form data should be submitted using the default method, using the GET command.
methodGet	The form data should be submitted using the GET command. This method should be used when the amount of form data is relatively small. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used instead.
methodPost	The form data should be submitted using the POST command. This is the preferred method of submitting larger amounts of form data. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

SocketTools Namespace

HttpClient.HttpEncoding Enumeration

Specifies the encoding types supported by the HttpClient class.

[Visual Basic]

```
Public Enum HttpClient.HttpEncoding
```

[C#]

```
public enum HttpClient.HttpEncoding
```

Remarks

The HttpClient class uses the **HttpEncoding** enumeration to specify the type of encoding to be used when data is submitted to the server for processing.

Members

Member Name	Description
encodingNone	No encoding will be applied to the content of a request, and no Content-Type header will be generated.
encodingURL	Standard URL encoding will be applied to the content of a request, and a Content-Type header will be generated with the value "application/x-www-form-urlencoded". This is the default encoding type.
encodingXML	Standard URL encoding will be applied to the content of a request, except that spaces will not be replaced by '+'. This encoding type is intended for use with XML parsers that do not recognize '+' as a space. A Content-Type header will be generated with the value "application/x-www-form-urlencoded".

HttpClient.HttpFormType Enumeration

Specifies the form types supported by the HttpClient class when submitting form data to a server.

[Visual Basic]

```
Public Enum HttpClient.HttpFormType
```

[C#]

```
public enum HttpClient.HttpFormType
```

Remarks

The HttpClient class uses the **HttpFormType** enumeration to specify how form data that should be submitted to a server for processing.

Members

Member Name	Description
formDefault	The form data should be submitted using the default encoding method.
formEncoded	The form data should be submitted as URL encoded values. This is typically used when the GET method is used to submit the data to the server.
formMultipart	The form data should be submitted as multipart form data. This is typically used when the POST method is used to submit a file to the server. Note that the script must understand how to process multipart form data if this form type is specified.

HttpClient.HttpOptions Enumeration

Specifies the options that the HttpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum HttpClient.HttpOptions
```

[C#]
```
[Flags]
public enum HttpClient.HttpOptions
```

Remarks

The HttpClient class uses the **HttpOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionNoCache	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.	1
optionKeepAlive	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested. If the server does not support the keep-alive option, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers.	2
optionRedirect	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.	4
optionProxy	This option specifies the client should use the default proxy configuration for	8

	the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.	
optionErrorData	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with optionRedirect.	16
optionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.	1024
optionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.	2048
optionSecure	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.	4096
optionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768
optionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an	262144

	IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.	
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288
optionHiResTimer	This option specifies that elapsed time values should be returned in milliseconds rather than seconds. This option is intended to provide greater accuracy with smaller data transfers over a high speed network connection.	1048576

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

HttpClient.HttpPostOptions Enumeration

Specifies options that the HttpClient class supports when posting data to a server.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpClient.HttpPostOptions
```

[C#]

```
[Flags]
public enum HttpClient.HttpPostOptions
```

Remarks

The HttpClient class uses the **HttpPostOptions** enumeration to specify one or more options to be used when posting data to the server. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
postDefault	The default post mode with appropriate encoding used for the type of data which is being submitted to the server. The response from the server will be returned in the result buffer without any end-of-line text conversion.	0
postConvert	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the data being submitted to the server, only on the data returned by the server.	1
postMultipart	The contents of the buffer being sent to the server consists of multipart form data and will be sent as-is without any encoding.	2
postErrorData	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the method to fail. Instead, the response is returned to the client and the method will succeed. If this option is used, your application should check the value of	4

	the **ResultCode** property to obtain the actual HTTP status code returned by the server. This will enable you to determine if the operation was successful.	

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

HttpClient.HttpProxyType Enumeration

Specifies the proxy server types supported by the HttpClient class.

[Visual Basic]
```
Public Enum HttpClient.HttpProxyType
```

[C#]
```
public enum HttpClient.HttpProxyType
```

Remarks

The HttpClient class uses the **HttpProxyType** enumeration to specify the type of proxy server the client is connecting to.

Members

Member Name	Description
proxyNone	A direct connection will be established with the remote host. When this value is specified the proxy-related properties are ignored.
proxyStandard	A standard connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard connections.
proxySecure	A secure connection is established through the specified proxy server. This proxy type should only be used with secure connections and the Secure property should also be set to a value of true.
proxyWindows	The configuration options for the current system should be used. These options are found in the Network and Internet settings for Windows.
proxyDefault	The default proxy type. This value is the same as the **proxyWindows** proxy type.

HttpClient.HttpStatus Enumeration

Specifies the status values that may be returned by the HttpClient class.

[Visual Basic]

```
Public Enum HttpClient.HttpStatus
```

[C#]

```
public enum HttpClient.HttpStatus
```

Remarks

The HttpClient class uses the **HttpStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client session is being closed and subsequent attempts to access the client will result in an error.
statusGetData	The client is downloading data from the server to the local system.
statusPutData	The client is uploading data from the local system to the server.
statusPostData	The client is posting form data to the server.

HttpClient.HttpSubmitOptions Enumeration

Specifies the options that the HttpClient class supports when submitting form data to a server.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpClient.HttpSubmitOptions
```

[C#]

```
[Flags]
public enum HttpClient.HttpSubmitOptions
```

Remarks

The HttpClient class uses the **HttpSubmitOptions** enumeration to specify one or more options to be used when submitting form data to a server for processing. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
submitDefault	The default post mode. The contents of the buffer are encoded and sent as standard form data. The response from the server will be returned in the result buffer without any end-of-line text conversion.	0
submitConvert	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.	1

HttpClient.HttpTransferOptions Enumeration

Specifies the data transfer options that the HttpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpClient.HttpTransferOptions
```

[C#]

```
[Flags]
public enum HttpClient.HttpTransferOptions
```

Remarks

The HttpClient class uses the **HttpTransferOptions** enumeration to specify one or more options to be used when transferring data between the local system and the server. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
transferDefault	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.	0
transferConvert	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.	1
transferCompress	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled by setting the Compression property to True.	2
transferErrorData	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the method to fail. Instead, the response is returned to the client and the method will succeed. If this option is used, your application should check the value of the **ResultCode** property to obtain the	4

	actual HTTP status code returned by the server. This will enable you to determine if the operation was successful.

HttpClient.HttpVersion Enumeration

Specifies the protocol versions supported by the HttpClient class.

[Visual Basic]

```
Public Enum HttpClient.HttpVersion
```

[C#]

```
public enum HttpClient.HttpVersion
```

Remarks

The HttpClient class uses the **HttpVersion** enumeration to specify the protocol version to be used when establishing a connection to the server.

Members

Member Name	Description
version09	Version 0.9 of the protocol. This value specifies that the client should use the preliminary protocol version which only supports the use of the GET command. Header fields are not supported with this version of the protocol.
version10	Version 1.0 of the protocol.
version11	Version 1.1 of the protocol.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

HttpClient.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the HttpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum HttpClient.SecureCipherAlgorithm
```

[C#]
```
[Flags]
public enum HttpClient.SecureCipherAlgorithm
```

Remarks

The HttpClient class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128

HttpClient.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the HttpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum HttpClient.SecureHashAlgorithm
```

[C#]
```
[Flags]
public enum HttpClient.SecureHashAlgorithm
```

Remarks

The HttpClient class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

HttpClient.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the HttpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpClient.SecureKeyAlgorithm
```

[C#]

```
[Flags]
public enum HttpClient.SecureKeyAlgorithm
```

Remarks

The HttpClient class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

See Also

SocketTools Namespace

HttpClient.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the HttpClient class.

[Visual Basic]
```
Public Enum HttpClient.SecurityCertificate
```

[C#]
```
public enum HttpClient.SecurityCertificate
```

Remarks

The HttpClient class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the remote host when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the remote host. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

SocketTools Namespace

HttpClient.SecurityProtocols Enumeration

Specifies the security protocols that the HttpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum HttpClient.SecurityProtocols
```

[C#]
```
[Flags]
public enum HttpClient.SecurityProtocols
```

Remarks

The HttpClient class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

SocketTools Namespace

HttpClient.TraceOptions Enumeration

Specifies the logging options that the HttpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpClient.TraceOptions
```

[C#]

```
[Flags]
public enum HttpClient.TraceOptions
```

Remarks

The HttpClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

HttpClient.OnCommandEventHandler Delegate

Represents the method that will handle the OnCommand event.

[Visual Basic]

```
Public Delegate Sub HttpClient.OnCommandEventHandler( _
   ByVal sender As Object, _
   ByVal e As CommandEventArgs _
)
```

[C#]

```
public delegate void HttpClient.OnCommandEventHandler(
      object sender,
      CommandEventArgs e
   );
```

Parameters

sender
The source of the event.

e
A CommandEventArgs object that contains the event data.

Remarks

When you create an **OnCommandEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnCommandEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

SocketTools Namespace

HttpClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub HttpClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void HttpClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

HttpClient.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

[Visual Basic]

```
Public Delegate Sub HttpClient.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

[C#]

```
public delegate void HttpClient.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A ProgressEventArgs that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

SocketTools Namespace

HttpClient.OnRedirectEventHandler Delegate

Represents the method that will handle the OnRedirect event.

[Visual Basic]

```
Public Delegate Sub HttpClient.OnRedirectEventHandler( _
   ByVal sender As Object, _
   ByVal e As RedirectEventArgs _
)
```

[C#]

```
public delegate void HttpClient.OnRedirectEventHandler(
      object sender,
      RedirectEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A RedirectEventArgs that contains the event data.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

SocketTools Namespace

HttpClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see HttpClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.HttpClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class HttpClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class HttpClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the HttpClient class.

Example

```
<Assembly: SocketTools.HttpClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.HttpClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

See Also

HttpClient.RuntimeLicenseAttribute Members | SocketTools Namespace

HttpClient.RuntimeLicenseAttribute Members

HttpClient.RuntimeLicenseAttribute overview

Public Instance Constructors

HttpClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

HttpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

HttpClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public HttpClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the HttpClient class.

See Also

HttpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

HttpClient.RuntimeLicenseAttribute Properties

The properties of the **HttpClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **HttpClient.RuntimeLicenseAttribute** class members, see the HttpClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

HttpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

HttpClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

HttpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

HttpClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see HttpClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.HttpClientException

[Visual Basic]
```
Public Class HttpClientException
    Inherits ApplicationException
```

[C#]
```
public class HttpClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A HttpClientException is thrown by the HttpClient class when an error occurs.

The default constructor for the HttpClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpClient (in SocketTools.HttpClient.dll)

See Also

HttpClientException Members | SocketTools Namespace

HttpClientException Members

HttpClientException overview

Public Instance Constructors

HttpClientException	Overloaded. Initializes a new instance of the HttpClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

HttpClientException Class | SocketTools Namespace

HttpClientException Constructor

Initializes a new instance of the HttpClientException class with the last network error code.

Overload List

Initializes a new instance of the HttpClientException class with the last network error code.

```
public HttpClientException();
```

Initializes a new instance of the HttpClientException class with a specified error number.

```
public HttpClientException(int);
```

Initializes a new instance of the HttpClientException class with a specified error message.

```
public HttpClientException(string);
```

Initializes a new instance of the HttpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
public HttpClientException(string,Exception);
```

See Also

HttpClientException Class | SocketTools Namespace

HttpClientException Constructor ()

Initializes a new instance of the HttpClientException class with the last network error code.

[Visual Basic]
```
Overloads Public Sub New()
```

[C#]
```
public HttpClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the HttpClient.ErrorCode enumeration.

See Also

HttpClientException Class | SocketTools Namespace | HttpClientException Constructor Overload List

HttpClientException Constructor (String)

Initializes a new instance of the HttpClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public HttpClientException(
   string message
);
```

Parameters

message
The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

HttpClientException Class | SocketTools Namespace | HttpClientException Constructor Overload List

HttpClientException Constructor (String, Exception)

Initializes a new instance of the HttpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

```
[Visual Basic]
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

```
[C#]
public HttpClientException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

HttpClientException Class | SocketTools Namespace | HttpClientException Constructor Overload List

HttpClientException Constructor (Int32)

Initializes a new instance of the HttpClientException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public HttpClientException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the HttpClient.ErrorCode enumeration.

See Also

HttpClientException Class | SocketTools Namespace | HttpClientException Constructor Overload List

HttpClientException Properties

The properties of the **HttpClientException** class are listed below. For a complete list of **HttpClientException** class members, see the HttpClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

HttpClientException Class | SocketTools Namespace

HttpClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]
```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]
```
public HttpClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a HttpClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the HttpClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the HttpClient.ErrorCode enumeration.

See Also

HttpClientException Class | SocketTools Namespace

HttpClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

HttpClientException Class | SocketTools Namespace

HttpClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

HttpClientException Class | SocketTools Namespace

HttpClientException Methods

The methods of the **HttpClientException** class are listed below. For a complete list of **HttpClientException** class members, see the HttpClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

HttpClientException Class | SocketTools Namespace

HttpClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

See Also

HttpClientException Class | SocketTools Namespace

HttpServer Class

Implements a server that enables the application to send and receive files using the Hypertext Transfer Protocol.

For a list of all members of this type, see HttpServer Members.

System.Object
  SocketTools.HttpServer

[Visual Basic]
```
Public Class HttpServer
    Implements IDisposable
```

[C#]
```
public class HttpServer : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **SocketTools.HttpServer** class provides an interface for implementing an embedded, lightweight server that can be used to provide access to documents and other resources using the Hypertext Transfer Protocol. The server can accept connections from any standard web browser, third-party applications or programs developed using the **SocketTools.HttpClient** class.

The application specifies an initial server configuration and then responds to events that are generated when the client sends a request to the server. An application may implement only minimal handlers for most events, in which case the default actions are performed for most standard HTTP commands. However, an application may also use the event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

The server includes support for CGI scripting, virtual hosting, client authentication and the creation of virtual directories and files. The server also supports secure connections using TLS 1.2. Secure connections require that a valid server certificate be installed on the system.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

See Also

HttpServer Members | SocketTools Namespace

HttpServer Members

HttpServer overview

Public Static (Shared) Fields

defaultHost	Defines the ID used to specify the default virtual host.
invalidHost	Defines an invalid virtual host identifier.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Constructors

HttpServer Constructor	Initializes a new instance of the HttpServer class.

Public Instance Fields

AdapterAddress	Returns the IP address associated with the specified network adapter.

Public Instance Properties

AdapterCount	Get the number of available local and remote network adapters.
CacheTime	Gets and sets a value that specifies the current cache time period.
CertificateName	Gets and sets a value that specifies the name of the server certificate.
CertificatePassword	Gets and sets the password associated with the server certificate.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateUser	Gets and sets the user that owns the server certificate.
ClientAccess	Gets and sets the access rights that have been granted to the client session.
ClientAddress	Return the Internet address of the current client connection.
ClientCount	Return the number of active client sessions connected to the server.
ClientDirectory	Return the current working directory for the active client session.
ClientHost	Return the host name that the client used to establish the connection.
ClientId	Gets the unique client identifier for the current

	client session.
ClientIdle	Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.
ClientPort	Gets a value that specifies the port number used by the current client session.
ClientThread	Gets the thread ID for the current client session.
ClientUser	Return the user name associated with the specified client session.
CommandLine	Return the complete command line issued by the client.
Directory	Get and set the full path to the root directory assigned to the server.
ExecTime	Get and set maximum number of seconds that the server will permit an external script handler to execute.
ExternalAddress	Return the external IP address for the local system.
HiddenFiles	Determine if the server should permit access to hidden files.
Identity	Gets and sets a string that identifies the server to the client.
IdleTime	Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.
IsActive	Gets a value which indicates if the server is active.
IsAuthenticated	Determine if the active client session has been authenticated.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsListening	Gets a value which indicates if the server is listening for client connections.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalPath	Return the full path to the local file or directory that is the target of the current command.
LocalUser	Determines if the server should perform user authentication using the Windows local account database.
LockFiles	Determines if files should be exclusively locked when a client attempts to upload or download a file.

LogFile	Gets and sets the name of the server log file.
LogFormat	Gets and sets the format used when updating the server log file.
LogLevel	Gets and sets the level of detail included in the server log file.
MaxClients	Gets and sets the maximum number of clients that can connect to the server.
MemoryUsage	Gets the amount of unmanaged memory currently allocated by the server.
MultiUser	Determine if the server should be started in multi-user mode.
NoIndex	Determine if the server should search for a default index page.
Options	Gets and sets the options that may be specified for the server instance.
Priority	Gets and sets a value which specifies the server priority.
ReadOnly	Determine if the server should prevent clients from uploading files.
Restricted	Determine if the server should be started in restricted mode, limiting client access to the server.
Secure	Determine if the server should accept secure client connections.
ServerAddress	Gets and sets the address that will be used by the server to listen for connections.
ServerHandle	Gets the handle to the server created to listen for client connections.
ServerName	Gets a value which specifies the host name for the local system.
ServerPort	Gets and sets the port number that will be used by the server to listen for connections.
ServerThread	Gets the thread ID for the current server.
ServerUuid	Gets and sets the Universally Unique Identifier (UUID) associated with the server.
StackSize	Gets and sets the size of the stack allocated for threads created by the server.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of

	the network function tracing logfile.
TraceFlags	Gets and sets a value which specifies the network function tracing flags.
Version	Gets a value which returns the current version of the HttpServer class library.
VirtualPath	Return the virtual path to the local file or directory that is the target of the current command.

Public Instance Methods

AddHost	Overloaded. Add a new virtual host to the server virtual host table.
AddPath	Overloaded. Add a new virtual path for the specified host.
AddUser	Overloaded. Add a new virtual user to the specified host.
Authenticate	Overloaded. Authenticate the client and assign access rights for the session.
CheckPath	Overloaded. Determine if the client has permission to access the specified virtual path.
ClearHeaders	Overloaded. Delete all of the response headers for the specified client session.
DeleteHost	Overloaded. Delete a virtual host associated with the specified server.
DeletePath	Overloaded. Delete a virtual path from the specified virtual host.
DeleteUser	Overloaded. Remove a virtual user from the server.
Disconnect	Overloaded. Disconnect the specified client session from the server.
Dispose	Overloaded. Releases all resources used by HttpServer.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetAllHeaders	Overloaded. Return all of the request header values in the specified string buffer.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Return the value of a request header for the specified client session.
GetType (inherited from Object)	Gets the Type of the current instance.
GetVariable	Overloaded. Return the value of a CGI environment variable for the specified client.

Initialize	Overloaded. Initialize an instance of the HttpServer class.
ReceiveRequest	Overloaded. Receive the request that was sent by the client to the server.
RedirectRequest	Overloaded. Redirect the request from the client to another URL.
RegisterHandler	Overloaded. Register a CGI program for use and associate it with a file name extension.
RegisterProgram	Overloaded. Register a CGI program for use and associate it with a virtual path on the server.
RequireAuthentication	Overloaded. Send a response to the client indicating that authentication is required.
Reset	Reset the internal state of the object, resetting all properties to their default values.
ResolvePath	Overloaded. Resolve a path to its full virtual or local file name.
Restart	Restarts the server and terminates all active client connections.
Resume	Resume accepting new client connections.
SendError	Overloaded. Send an error result code and message to the client in response to a command.
SendResponse	Overloaded. Send a result code and message to the client in response to a command.
SetHeader	Overloaded. Create or change the value of a response header for the client session.
SetVariable	Overloaded. Create or change the value of a CGI environment variable for the specified client.
Start	Overloaded. Start listening for client connections on the specified IP address and port number.
Stop	Stop listening for new client connections and terminate all active clients already connected to the server.
Suspend	Suspend accepting new client connections.
Throttle	Overloaded. Limit the maximum number of client connections, connections per IP address and connection rate.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the server.

Public Instance Events

OnAuthenticate	Occurs when the client has requested

	authentication with the specified username and password.
OnCommand	Occurs when a client has issued a command to the server.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnDownload	Occurs when a connection is established with the remote host.
OnError	Occurs when an network operation fails.
OnExecute	Occurs when the client has executed an external script handler on the server.
OnIdle	Occurs when the there are no clients connected to the server.
OnResult	Occurs when the command issued by the client has been processed by the server.
OnStart	Occurs when the server starts accepting connections.
OnStop	Occurs when the server stops accepting connections.
OnTimeout	Occurs when the client has exceeded the maximum allowed idle time.
OnUpload	Occurs when the client has successfully uploaded a file to the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the HttpServer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

HttpServer Class | SocketTools Namespace

HttpServer Constructor

Initializes a new instance of the HttpServer class.

[Visual Basic]
```
Public Sub New()
```

[C#]
```
public HttpServer();
```

See Also

HttpServer Class | SocketTools Namespace

HttpServer Fields

The fields of the **HttpServer** class are listed below. For a complete list of **HttpServer** class members, see the HttpServer Members topic.

Public Static (Shared) Fields

defaultHost	Defines the ID used to specify the default virtual host.
invalidHost	Defines an invalid virtual host identifier.

Public Instance Fields

AdapterAddress	Returns the IP address associated with the specified network adapter.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.AdapterAddress Field

Returns the IP address associated with the specified network adapter.

[Visual Basic]

```
Public ReadOnly AdapterAddress As AdapterAddressArray
```

[C#]

```
public readonly AdapterAddressArray AdapterAddress;
```

Remarks

The **AdapterAddress** array returns the IP addresses that are associated with the local network or remote dial-up network adapters configured on the system. The **AdapterCount** property can be used to determine the number of adapters that are available.

Multihomed systems with more than one local network adapter, or a combination of local and dial-up adapters will not be listed in a specific order. An application should not make the assumption that the first address returned by **AdapterAddress** always refers to a local network adapter.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress** property will return the IP address allocated for that connection.

See Also

HttpServer Class | SocketTools Namespace | AdapterAddressArray Class | AdapterCount Property

HttpServer Properties

The properties of the **HttpServer** class are listed below. For a complete list of **HttpServer** class members, see the HttpServer Members topic.

Public Instance Properties

AdapterCount	Get the number of available local and remote network adapters.
CacheTime	Gets and sets a value that specifies the current cache time period.
CertificateName	Gets and sets a value that specifies the name of the server certificate.
CertificatePassword	Gets and sets the password associated with the server certificate.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateUser	Gets and sets the user that owns the server certificate.
ClientAccess	Gets and sets the access rights that have been granted to the client session.
ClientAddress	Return the Internet address of the current client connection.
ClientCount	Return the number of active client sessions connected to the server.
ClientDirectory	Return the current working directory for the active client session.
ClientHost	Return the host name that the client used to establish the connection.
ClientId	Gets the unique client identifier for the current client session.
ClientIdle	Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.
ClientPort	Gets a value that specifies the port number used by the current client session.
ClientThread	Gets the thread ID for the current client session.
ClientUser	Return the user name associated with the specified client session.
CommandLine	Return the complete command line issued by the client.
Directory	Get and set the full path to the root directory assigned to the server.

ExecTime	Get and set maximum number of seconds that the server will permit an external script handler to execute.
ExternalAddress	Return the external IP address for the local system.
HiddenFiles	Determine if the server should permit access to hidden files.
Identity	Gets and sets a string that identifies the server to the client.
IdleTime	Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.
IsActive	Gets a value which indicates if the server is active.
IsAuthenticated	Determine if the active client session has been authenticated.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsListening	Gets a value which indicates if the server is listening for client connections.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalPath	Return the full path to the local file or directory that is the target of the current command.
LocalUser	Determines if the server should perform user authentication using the Windows local account database.
LockFiles	Determines if files should be exclusively locked when a client attempts to upload or download a file.
LogFile	Gets and sets the name of the server log file.
LogFormat	Gets and sets the format used when updating the server log file.
LogLevel	Gets and sets the level of detail included in the server log file.
MaxClients	Gets and sets the maximum number of clients that can connect to the server.
MemoryUsage	Gets the amount of unmanaged memory currently allocated by the server.
MultiUser	Determine if the server should be started in multi-user mode.
NoIndex	Determine if the server should search for a default index page.

Options	Gets and sets the options that may be specified for the server instance.
Priority	Gets and sets a value which specifies the server priority.
ReadOnly	Determine if the server should prevent clients from uploading files.
Restricted	Determine if the server should be started in restricted mode, limiting client access to the server.
Secure	Determine if the server should accept secure client connections.
ServerAddress	Gets and sets the address that will be used by the server to listen for connections.
ServerHandle	Gets the handle to the server created to listen for client connections.
ServerName	Gets a value which specifies the host name for the local system.
ServerPort	Gets and sets the port number that will be used by the server to listen for connections.
ServerThread	Gets the thread ID for the current server.
ServerUuid	Gets and sets the Universally Unique Identifier (UUID) associated with the server.
StackSize	Gets and sets the size of the stack allocated for threads created by the server.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the network function tracing logfile.
TraceFlags	Gets and sets a value which specifies the network function tracing flags.
Version	Gets a value which returns the current version of the HttpServer class library.
VirtualPath	Return the virtual path to the local file or directory that is the target of the current command.

HttpServer Class | SocketTools Namespace

HttpServer.AdapterCount Property

Get the number of available local and remote network adapters.

[Visual Basic]
```
Public ReadOnly Property AdapterCount As Integer
```

[C#]
```
public int AdapterCount {get;}
```

Property Value

Returns the number of available local and remote network adapters.

Remarks

The **AdapterCount** property returns the number of local and remote dial-up networking adapters available on the local system. This value can be used in conjunction with the **AdapterAddress** array to enumerate the IP addresses assigned to the various network adapters.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress** property will return the IP address allocated for that connection.

HttpServer Class | SocketTools Namespace | AdapterAddress Field

HttpServer.CertificateName Property

Gets and sets a value that specifies the name of the server certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the server certificate name.

Remarks

The **CertificateName** property sets the common name or friendly name of the certificate that should be used when starting a secure server. If the **Secure** property is set to True, this property must be specify a valid certificate name. The certificate must have a private key associated with it, otherwise client connections will fail because the class will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

HttpServer Class | SocketTools Namespace | CertificateStore Property | Secure Property

HttpServer.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]

```
Public Property CertificateStore As String
```

[C#]

```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when security is enabled for the server. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the server certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the server certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in

PKCS12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

HttpServer Class | SocketTools Namespace | CertificatePassword Property | Secure Property

HttpServer.ClientAccess Property

Gets and sets the access rights that have been granted to the client session.

[Visual Basic]

```
Public Property ClientAccess As UserAccess
```

[C#]

```
public HttpServer.UserAccess ClientAccess {get; set;}
```

Property Value

A UserAccess enumeration that specifies on or more user access permissions.

Remarks

The **ClientAccess** property is used to determine all of the access permissions that are currently granted to an authenticated client session and optionally change those permissions. For a list of user access rights that can be granted to the client, see the UserAccess enumeration.

When modifying the value of this property, it is recommended that you use bitwise OR and AND operands to set and clear specific bitflags. The exception is when using the **httpAccessDefault** permission. If you wish to reset the client session to use the default permissions based on the server configuration and client authentication, then you should assign this value directly to the **ClientAccess** property.

This property should only be accessed within an event handler such as **OnCommand** because its value is specific to the client session that raised the event. This property will always return a value of zero outside of an event handler, and an exception will be raised if you attempt to modify this property outside of an event handler.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClientAddress Property

Return the Internet address of the current client connection.

[Visual Basic]

```
Public ReadOnly Property ClientAddress As String
```

[C#]

```
public string ClientAddress {get;}
```

Property Value

A string that specifies the client Internet Protocol address.

Remarks

The **ClientAddress** property returns the address of the current client session which has connected to the server. This property should only be accessed within an event handler such as **OnConnect** because its value is specific to the client session that raised the event. This property will always return an empty string when accessed outside of an event handler.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClientCount Property

Return the number of active client sessions connected to the server.

[Visual Basic]
```
Public ReadOnly Property ClientCount As Integer
```

[C#]
```
public int ClientCount {get;}
```

Property Value

An integer value that specifies the number of active client sessions.

Remarks

The **ClientCount** read-only property returns the number of active client sessions that have been established with the server. The value includes both authenticated and unauthenticated client sessions.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClientDirectory Property

Return the current working directory for the active client session.

[Visual Basic]
```
Public ReadOnly Property ClientDirectory As String
```

[C#]
```
public string ClientDirectory {get;}
```

Property Value

A string that specifies the full path to a local directory on the server.

Remarks

The **ClientDirectory** property returns the current working directory for the active client session. Initially this value will be the absolute path on the local system that maps to an authenticated client's home directory. The client can change its current working directory using the CWD command. The **ClientHome** property will return the home directory that has been assigned to the client.

It is important to note that the current working directory for client sessions is virtual, and does not reflect the current working directory for the server process. This property should only be accessed within an event handler after the client session has been authenticated. Unauthenticated clients are not assigned a current working directory. This property will always return an empty string when accessed outside of an event handler.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClientHost Property

Return the host name that the client used to establish the connection.

[Visual Basic]
```
Public ReadOnly Property ClientHost As String
```

[C#]
```
public string ClientHost {get;}
```

Property Value

A string that specifies the host name used by the client to connect to the server.

Remarks

The **ClientHost** property returns the host name that the client used to establish the connection. If the client does not explicitly specify the host name, then this property will return the same host name that was assigned to the server when it started.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClientId Property

Gets the unique client identifier for the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which uniquely identifies the client session.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be used by the application to identify that client session, and is different than the socket handle allocated for the client. While it is possible for a client socket handle to be reused by the operating system, client IDs are unique throughout the life of the server session and are never duplicated.

It is important to note that the actual value of the client ID should be considered opaque. It is only guaranteed that the value will be greater than zero, and that it will be unique to the client session.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClientIdle Property

Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.

[Visual Basic]

```
Public Property ClientIdle As Integer
```

[C#]

```
public int ClientIdle {get; set;}
```

Property Value

An integer value that specifies the idle timeout period in seconds.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClientPort Property

Gets a value that specifies the port number used by the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientPort As Integer
```

[C#]

```
public int ClientPort {get;}
```

Property Value

An integer value which specifies the peer port number.

Remarks

The **ClientPort** property returns the port number that the current client has used when establishing a connection with the server. This property value is only meaningful when accessed within an event handler such as the **OnConnect** event.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClientThread Property

Gets the thread ID for the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientThread As Integer
```

[C#]

```
public int ClientThread {get;}
```

Property Value

An integer value which identifies the client thread that was created to manage the client session.

Remarks

Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClientUser Property

Return the user name associated with the specified client session.

[Visual Basic]

```
Public ReadOnly Property ClientUser As String
```

[C#]

```
public string ClientUser {get;}
```

Property Value

A string that specifies the user name associated with the active client session.

Remarks

The **ClientUser** property returns the user name that the client used to authenticate the client session. This property should only be accessed within an event handler after the client session has been authenticated. Unauthenticated clients are not assigned a user name. This property will always return an empty string when accessed outside of an event handler.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Directory Property

Get and set the full path to the root directory assigned to the server.

[Visual Basic]

```
Public Property Directory As String
```

[C#]

```
public string Directory {get; set;}
```

Property Value

A string that specifies the full path to a local directory on the server.

Remarks

The **Directory** property returns the path to the root directory for the server. If this property is set to the name of a valid directory before the server is started, that directory will be considered the root directory for the server. If this property is not set, or is set to an empty string, then the server will use the current working directory as its root directory, however this is not recommended. It is recommended that you specify an absolute path to the directory, otherwise the path will be relative to the current working directory. You may include environment variables in the path surrounded by percent (%) symbols and they will be expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. If the root directory does not exist at the time that the server is started, it will be created.

If the **MultiUser** property is **False**, all authenticated clients will have their current working directory initialized to the server root directory. If the **MultiUser** property is **True**, then the Public and User subdirectories will be created in the root directory, and each authenticated client will have their current working directory initialized to their individual home directory.

This property can be read after the server has started and it will return the full path to the root directory. However, attempting to change the value of this property after the server has started will cause an exception to be raised. To change the root directory for the server, you must first call the **Stop** method which will terminate all active client connections.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ExternalAddress Property

Return the external IP address for the local system.

[Visual Basic]

```
Public ReadOnly Property ExternalAddress As String
```

[C#]

```
public string ExternalAddress {get;}
```

Property Value

A string that specifies the external Internet Protocol address for the local system.

Remarks

The **ExternalAddress** property returns the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **ServerAddress** property will only return the IP address for the local system on the LAN side of the network. The **ExternalAddress** property can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router. Note that you should not assign the **ServerAddress** property to the value returned by the **ExternalAddress** property. If the server is running behind a NAT router, the router must be configured to forward incoming connections to the appropriate address on the LAN.

Using this property requires that you have an active connection to the Internet; checking the value of this property on a system that uses dial-up networking may cause the operating system to automatically connect to the Internet service provider. The control may be unable to determine the external IP address for the local host for a number of reasons, particularly if the system is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the external address for the local host cannot be determined, the property will return an empty string.

If the control is able to obtain a valid external address for the local host, that address will be cached for sixty minutes. Because dial-up connections typically have different IP addresses assigned to them each time the system is connected to the Internet, it is recommended that this property only be used in conjunction with persistent broadband connections.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.HiddenFiles Property

Determine if the server should permit access to hidden files.

[Visual Basic]
```
Public Property HiddenFiles As Boolean
```

[C#]
```
public bool HiddenFiles {get; set;}
```

Property Value

A Boolean value that specifies if hidden files can be accessed by clients.

Remarks

The **HiddenFiles** property determines if the server should allow clients to access files with the hidden and/or system attribute. If this property is **True**, then hidden files are included in directory listings and clients may download or replace hidden files. If the property is **False**, hidden files are not included in directory listings and any attempt to access, delete or modify a hidden file will result in an error.

The default value for this property is **False.**

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Identity Property

Gets and sets a string that identifies the server to the client.

[Visual Basic]

```
Public Property Identity As String
```

[C#]

```
public string Identity {get; set;}
```

Property Value

A string that identifies the server instance.

Remarks

The **Identity** property returns a string that is used to identify the server. It is used for informational purposes only and does not affect the operation of the server. Typically the string specifies the name of the application and a version number, and is displayed whenever a client establishes its initial connection to the server. This property can be set to assign an identity to the server, however after the server has started this property becomes read-only.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.IdleTime Property

Gets and sets the maximum number of seconds a client can be idle before the server terminates the session.

[Visual Basic]

```
Public Property IdleTime As Integer
```

[C#]

```
public int IdleTime {get; set;}
```

Property Value

An integer value that specifies the idle timeout period in seconds.

Remarks

The **IdleTime** property specifies the maximum number of seconds that a client session may be idle before the server closes the control connection to the client. A value of zero specifies the default value of 60 seconds. If the value is non-zero, the minimum value is 10 seconds and the maximum value is 300 seconds (5 minutes). This value is used to initialize the default idle timeout period for each client session. The server determines if a client is idle based on the time the last command was issued and whether or not a data transfer is in progress.

The **ClientIdle** property can be used to determine the idle timeout period for a specific client. When the timeout period for the client has elapsed, the **OnTimeout** event will fire prior to the client being disconnected from the server.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.IsActive Property

Gets a value which indicates if the server is active.

[Visual Basic]

```
Public ReadOnly Property IsActive As Boolean
```

[C#]

```
public bool IsActive {get;}
```

Property Value

A Boolean value that specifies if the server instance is currently active.

Remarks

The **IsActive** property returns **True** if the server has been started using the **Start** method. If the server has not been started, the property will return **False**.

To determine if the server is accepting client connections, use the **IsListening** property. This property will only indicate if the server has been started. For example, if the server has been suspended using the **Suspend** method, this property will return a value of **True**, while the **IsListening** property will return a value of **False**.

An application should not depend on this property returning **False** immediately after the **Stop** method has been called to shutdown the server. This property will continue to return **True** until all clients have disconnected from the server and the server thread has terminated. To determine when the server has stopped, implement a handler for the **OnStop** event.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.IsAuthenticated Property

Determine if the active client session has been authenticated.

[Visual Basic]

```
Public ReadOnly Property IsAuthenticated As Boolean
```

[C#]

```
public bool IsAuthenticated {get;}
```

Property Value

A Boolean value that specifies if the active client session has been authenticated.

Remarks

The **IsAuthenticated** property returns **True** if the active client session has successfully authenticated with a valid username and password. This property should only be accessed within an event handler such as **OnCommand** because its value is specific to the client session that raised the event. This property will always return a value of **False** outside of an event handler.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.IsListening Property

Gets a value which indicates if the server is listening for client connections.

[Visual Basic]

```
Public ReadOnly Property IsListening As Boolean
```

[C#]

```
public bool IsListening {get;}
```

Property Value

Returns **true** if the server is listening for client connections; otherwise returns **false**.

Remarks

The **IsListening** property will return **true** if the **Start** method was called and the server is currently accepting incoming client connections. In all other situations, this property will return **false**.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public HttpServer.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.LocalPath Property

Return the full path to the local file or directory that is the target of the current command.

[Visual Basic]
```
Public Property LocalPath As String
```

[C#]
```
public string LocalPath {get; set;}
```

Property Value

A string that specifies the full path to a local file or directory on the server.

Remarks

The **LocalPath** property returns the full path to a local file name or directory specified by the client as an argument to a standard HTTP command. For example, if the client sends the GET command to the server, this property will return the complete path to the local file that the client wants to download. This property will only return a value for those standard commands that perform some action on a file or directory, otherwise it will return an empty string.

Setting this property allows you to effectively redirect the client to use a different file than the one that was actually requested. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the current working directory for the active client session. The full path to this file is not limited to the server root directory or its subdirectory, it can specify a file anywhere on the local system. If this property is set to an empty string, then the server will revert to using the actual file or directory name specified by the command.

This property should only be set within an **OnCommand** event handler, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, setting this property will cause an exception to be raised by the control. Exercise caution when using this property to redirect the server to use a different file than the one requested by the client; changing the target file may cause the client to behave in unexpected ways.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.LocalUser Property

Determines if the server should perform user authentication using the Windows local account database.

[Visual Basic]
```
Public Property LocalUser As Boolean
```

[C#]
```
public bool LocalUser {get; set;}
```

Property Value

A Boolean value that specifies if the server should authenticate local users.

Remarks

The **LocalUser** property determines if the server should perform user authentication using the Windows local account database. If this option is not specified, the application is responsible for creating virtual users using the **AddUser** method or implementing an **OnAuthenticate** event handler and authenticating client sessions individually.

If this property is set to **True**, a client can authenticate as a local user, however the session will not inherit that user's access rights. All files that are accessed or created by the server will continue to use the permissions of the process that started the server. For example, consider a server application that was started by local user ***A***. Next, a client connects to the server and authenticates itself as local user ***B***. When that client uploads a file to the server, the file that is created will be owned by user ***A***, not user ***B***. This ensures that the server application retains ownership and control of the files that have been created or modified.

The default value for this property is **False**.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.LockFiles Property

Determines if files should be exclusively locked when a client attempts to upload or download a file.

[Visual Basic]
```
Public Property LockFiles As Boolean
```

[C#]
```
public bool LockFiles {get; set;}
```

Property Value

A Boolean value that specifies if files should be locked during file transfers.

Remarks

The **LocalTime** property determines if files should be exclusively locked when a client attempts to upload or download a file. If another client attempts to access the same file, the operation will fail. By default, the server will permit multiple clients to access the same file, although it will still write-lock files that are in the process of being uploaded..

The default value for this property is **False**.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.LogFile Property

Gets and sets the name of the server log file.

[Visual Basic]
```
Public Property LogFile As String
```

[C#]
```
public string LogFile {get; set;}
```

Property Value

A string that specifies the full path to a local log file.

Remarks

The **LogFile** property is used to specify the name of a file that will contain a log of all client activity. The **LogFormat** and **LogLevel** properties affect the specific format for the file and the level of detail included in the log. It is recommended that you specify an absolute path to the log file, otherwise the path will be relative to the current working directory. You may include environment variables in the path surrounded by percent (%) symbols and they will be expanded.

If the log file does not exist it will be created when the server is started. If file already exists, the server will append the new logging data to the file. The server must have permission to create and/or modify the specified file.

Setting this property to an empty string after the server has been started will have the effect of disabling logging, setting the logging level to 0 and the logging format to **FormatType.formatNone**.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.LogFormat Property

Gets and sets the format used when updating the server log file.

[Visual Basic]

```
Public Property LogFormat As FormatType
```

[C#]

```
public HttpServer.FormatType LogFormat {get; set;}
```

Property Value

A FormatType enumeration that specifies the log file format.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.LogLevel Property

Gets and sets the level of detail included in the server log file.

[Visual Basic]
```
Public Property LogLevel As Integer
```

[C#]
```
public int LogLevel {get; set;}
```

Property Value

An integer value that specifies the amount of information the server writes to the log file.

Remarks

The **LogLevel** property is used to specify the level of detail that should generated in the log file. The minimum value is 1 and the maximum value is 10. If this parameter is zero, it is the same as specifying a log file format of **httpLogNone** and will disable logging by the server.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.MaxClients Property

Gets and sets the maximum number of clients that can connect to the server.

[Visual Basic]

```
Public Property MaxClients As Integer
```

[C#]

```
public int MaxClients {get; set;}
```

Property Value

An integer value which specifies the maximum number of client sessions that will be accepted by the server. A value of zero specifies that there is no fixed limit to the maximum number of clients.

Remarks

The **MaxClients** property specifies the maximum number of client connections that will be accepted by the server. Once the maximum number of connections has been established, the server will reject any subsequent connections until the number of active client connections drops below the specified value. A value of zero specifies that there should be no limit on the number of clients.

Changing the value of this property while a server is actively listening for connections will modify the maximum number of client connections permitted, but it will not affect connections that have already been established.

By default, there are no limits on the number of client connections or the connection rate when a server is started. Use the **Throttle** method to change the maximum number of client connections per IP address or the overall connection rate threshold for the server.

It is important to note that regardless of the maximum number of clients specified by this property, the actual number of client connections that can be managed by the server depends on the number of sockets that can be allocated from the operating system. The amount of physical memory installed on the system affects the number of connections that can be maintained because each connection allocates memory for the socket context from the non-paged memory pool.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.MemoryUsage Property

Gets the amount of unmanaged memory currently allocated by the server.

[Visual Basic]

```
Public ReadOnly Property MemoryUsage As Long
```

[C#]

```
public long MemoryUsage {get;}
```

Property Value

A long integer which specifies the number of bytes of memory allocated.

Remarks

This read-only property returns the amount of memory allocated by the server and all active client sessions. It enumerates all unmanaged memory allocations made by the server process and client session threads, returning the total number of bytes allocated for the server. This value reflects the amount of memory explicitly allocated by the class and does not reflect the total working set size of the process, or the memory allocated on the managed heap which is used by the .NET garbage collector.

Getting the value of this property forces the server into a locked state, and all client sessions will block while the memory usage is being calculated. Because this enumerates all unmanaged heaps allocated for the server process, it can be an expensive operation, particularly when there are a large number of active clients connected to the server. Frequently checking the value of this property can significantly degrade the performance of the server. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by this property remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

See Also

HttpServer Class | SocketTools Namespace | StackSize Property

HttpServer.MultiUser Property

Determine if the server should be started in multi-user mode.

[Visual Basic]

```
Public Property MultiUser As Boolean
```

[C#]

```
public bool MultiUser {get; set;}
```

Property Value

A Boolean value that specifies if the server should be started in multi-user mode.

Remarks

The **MultiUser** property determines if the server should be started in multi-user mode. If this property is set to **True**, each user will be assigned their own home directory which will be based on their user name. When a client authenticates as that user, its current working directory is set to the user's home directory. If this property is set to **False**, then all users will share the server root directory by default. This property does not affect the maximum number of simultaneous client connections to the server. To isolate users to their own individual home directory, set the **Restricted** property to **True**.

Setting this property to **True** will cause the server to create two subdirectories under the server root directory named Public and Users. The Public subdirectory is where public files should be stored, and also serves as the home directory for anonymous (guest) users. The Users subdirectory is where the home directories for each user will be created.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

The default value for this property is **False**.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.NoIndex Property

Determine if the server should search for a default index page.

[Visual Basic]

```
Public Property NoIndex As Boolean
```

[C#]

```
public bool NoIndex {get; set;}
```

Property Value

A boolean value that specifies if the server should search for default index pages. The default value for this property is **false**.

Remarks

The **NoIndex** property determines if the server should should search for a default index file if the client requests a resource that maps to a local directory on the server. If this property is set to **true**, the server will not search for an index file. If this property is set to **false**, the server will search for a file named index.htm, index.html, default.htm, default.html or index.txt in the directory. If a file by one of those names is found, it will return the contents of that file rather than a list of files in the directory.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

HttpServer Class | SocketTools Namespace

HttpServer.Options Property

Gets and sets the options that may be specified for the server instance.

[Visual Basic]
```
Public Property Options As ServerOptions
```

[C#]
```
public HttpServer.ServerOptions Options {get; set;}
```

Property Value

A ServerOptions enumeration that specifies one or more server options.

Remarks

The **Options** property is used to specify one or more server options as bitflags using the ServerOptions enumeration. Each option has a corresponding property, and it is recommended that you use those properties, such as **LocalUser** and **UnixMode**, to specify whether a particular server option should be enabled or disabled. Using the class properties will make your code more readable and ensure forward compatibility.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Priority Property

Gets and sets a value which specifies the server priority.

[Visual Basic]
```
Public Property Priority As ServerPriority
```

[C#]
```
public HttpServer.ServerPriority Priority {get; set;}
```

Property Value

Returns a ServerPriority enumeration value which specifies the current server priority. The default value for this property is **priorityNormal**.

Remarks

The **Priority** property can be used to control the processor usage, memory and network bandwidth allocated by the server for client sessions. The default priority balances resource utilization and client throughput while ensuring that the user interface remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of throughput.

Higher priority values increases the thread priority and processor utilization for the client sessions. It is not recommended that you increase the server priority unless you understand the implications of doing so and have thoroughly tested your application. Raising the priority of the server can have a negative impact on the responsiveness of the user interface.

See Also

HttpServer Class | SocketTools Namespace | ServerPriority Enumeration

HttpServer.ReadOnly Property

Determine if the server should prevent clients from uploading files.

[Visual Basic]

```
Public Property ReadOnly As Boolean
```

[C#]

```
public bool ReadOnly {get; set;}
```

Property Value

A Boolean value that specifies if clients have read-only access to the server.

Remarks

The **ReadOnly** property determines if the server should only allow read-only access to files by default, changing the default permissions granted to authenticated users. If this property is set to **True**, anonymous users will not be able to upload, rename or delete files and cannot create subdirectories. This is recommended if the server is publicly accessible over the Internet and guest logins are permitted.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

The default value for this property is **False**.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Restricted Property

Determine if the server should be started in restricted mode, limiting client access to the server.

[Visual Basic]
```
Public Property Restricted As Boolean
```

[C#]
```
public bool Restricted {get; set;}
```

Property Value

A boolean value that specifies if the server should be started in restricted mode. The default value for this property is **false**.

Remarks

The **Restricted** property determines if the server should be initialized in a restricted mode that isolates the server and limits the ability for clients to access files on the host system. If this property is set to **True**, the only commands accepted by the server will be the GET and HEAD commands. The server will never return a list of files if the client provides a URL that maps to a local directory and there is no default index page. Clients will not be able to execute CGI programs or scripts, and cannot access files outside of the server root directory or its subdirectories.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Secure Property

Determine if the server should accept secure client connections.

[Visual Basic]
```
Public Property Secure As Boolean
```

[C#]
```
public bool Secure {get; set;}
```

Property Value

A Boolean value that specifies if the server should accept secure connections.

Remarks

The **Secure** property determines if client connections are encrypted using the standard SSL or TLS security protocols. The default value for this property is **False**, which specifies that clients will use a standard, unencrypted connection to the server. To enable secure connections, the application should set this property value to **True** prior to calling the **Start** method.

When secure connections are enabled, the server will accept the client connection and then wait for the client to initiate the handshake where both the client and server negotiate the various encryption options available. This process is handled automatically by the server, and all that is required is that the application specify the server certificate which should be used. This is done by setting the **CertificateName** property, and optionally the **CertificateStore** property if required.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ServerAddress Property

Gets and sets the address that will be used by the server to listen for connections.

[Visual Basic]

```
Public Property ServerAddress As String
```

[C#]

```
public string ServerAddress {get; set;}
```

Property Value

A string which specifies the IP address that the server will use to listen for incoming client connections. An empty string indicates that the server will accept connections on any valid network interface configured for the local system.

Remarks

The **ServerAddress** property is used to specify the default address that the server will use when listening for connections. Setting this property to the value 0.0.0.0 or an empty string indicates that the server should listen for client connections using any valid network interface. If an address is specified, it must be a valid Internet address that is bound to a network adapter configured on the local system. Clients will only be able to connect to the server using that specific address.

It is common to set this property to the value 127.0.0.1 for testing purposes. It is a non-routable address that specifies the local system, and most software firewalls are configured so they do not block applications using this address.

See Also

HttpServer Class | SocketTools Namespace | ServerName Property | ServerPort Property

HttpServer.ServerName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public Property ServerName As String
```

[C#]

```
public string ServerName {get; set;}
```

Property Value

A string which specifies the local host name.

Remarks

The **ServerName** property returns the fully-qualified host name assigned to the local system. This consists of the local computer name and its domain name. The actual value returned depends on the system configuration. If no domain has been specified for the system, then only the machine name will be returned.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ServerPort Property

Gets and sets the port number that will be used by the server to listen for connections**.**

[Visual Basic]

```
Public Property ServerPort As Integer
```

[C#]

```
public int ServerPort {get; set;}
```

Property Value

An integer value which specifies the port number.

Remarks

The **ServerPort** property is used to set the port number that server will use to listen for incoming client connections. Valid port numbers are in the range of 1 to 65535. It is recommended that most custom servers specify a port number larger than 5000 to avoid potential conflicts with standard Internet services and ephemeral ports used by client applications.

If a port number is specified that is already in use by another application, the **OnError** event will fire and the background server thread will terminate. To enable a server to be stopped and immediately restarted using the same address and port number, make sure that the **ReuseAddress** property is set to a value of **true**.

See Also

HttpServer Class | SocketTools Namespace | ServerAddress Property | ServerName Property

HttpServer.ServerThread Property

Gets the thread ID for the current server.

[Visual Basic]

```
Public ReadOnly Property ServerThread As Integer
```

[C#]

```
public int ServerThread {get;}
```

Property Value

An integer value which identifies the server thread that was created. A return value of zero specifies that no server has been started.

Remarks

Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ServerUuid Property

Gets and sets the Universally Unique Identifier (UUID) associated with the server.

[Visual Basic]

```
Public Property ServerUuid As String
```

[C#]

```
public string ServerUuid {get; set;}
```

Property Value

A string that specifies the UUID assigned to the server instance.

Remarks

The **ServerUuid** property returns the UUID that uniquely identifies this instance of the server. If the application does not set this property, a temporary UUID will be assigned to the server. If a value is assigned to this property, it must be a valid UUID string. A permanent UUID can be generated using a utility such as **uuidgen** which is included with Visual Studio.

Attempting to change the value of this property after the server has started will cause an exception to be raised. To change this property value, you must first call the **Stop** method which will terminate all active client connections.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.StackSize Property

Gets and sets the size of the stack allocated for threads created by the server.

[Visual Basic]

```
Public Property StackSize As Integer
```

[C#]

```
public int StackSize {get; set;}
```

Property Value

An integer value that specifies the initial amount of memory that is committed to the stack for each thread created by the server.

Remarks

The default stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the method parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the method calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.TraceFile Property

Gets and sets a value which specifies the name of the network function tracing logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the method being called, the arguments passed to the method and the method's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.TraceFlags Property

Gets and sets a value which specifies the network function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public HttpServer.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Version Property

Gets a value which returns the current version of the HttpServer class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the HttpServer class library. This value can be used by an application for validation and debugging purposes.

HttpServer Class | SocketTools Namespace

HttpServer.VirtualPath Property

Return the virtual path to the local file or directory that is the target of the current command.

[Visual Basic]

```
Public Property VirtualPath As String
```

[C#]

```
public string VirtualPath {get; set;}
```

Property Value

A string that specifies the virtual path to the local file accessed by the active client session.

Remarks

The **VirtualPath** property returns the virtual path to a local file name or directory specified by the client as an argument to a standard HTTP command. For example, if the client sends the GET command to the server, this property will return the complete virtual path to the resource that the client wants to access. This property will only return a value for those standard commands that perform some action on a file or directory, otherwise it will return an empty string.

Setting this property allows you to effectively redirect the client to use a different file than the one that was actually requested. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the current working directory for the active client session. If this property is set to an empty string, then the server will revert to using the actual file or directory name specified by the command.

This property should only be set within an **OnCommand** event handler, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, setting this property will cause an exception to be raised by the control. Exercise caution when using this property to redirect the server to use a different file than the one requested by the client; changing the target file may cause the client to behave in unexpected ways.

HttpServer Methods

The methods of the **HttpServer** class are listed below. For a complete list of **HttpServer** class members, see the HttpServer Members topic.

Public Static (Shared) Methods

ErrorText	Returns the description of an error code.

Public Instance Methods

AddHost	Overloaded. Add a new virtual host to the server virtual host table.
AddPath	Overloaded. Add a new virtual path for the specified host.
AddUser	Overloaded. Add a new virtual user to the specified host.
Authenticate	Overloaded. Authenticate the client and assign access rights for the session.
CheckPath	Overloaded. Determine if the client has permission to access the specified virtual path.
ClearHeaders	Overloaded. Delete all of the response headers for the specified client session.
DeleteHost	Overloaded. Delete a virtual host associated with the specified server.
DeletePath	Overloaded. Delete a virtual path from the specified virtual host.
DeleteUser	Overloaded. Remove a virtual user from the server.
Disconnect	Overloaded. Disconnect the specified client session from the server.
Dispose	Overloaded. Releases all resources used by HttpServer.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetAllHeaders	Overloaded. Return all of the request header values in the specified string buffer.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Return the value of a request header for the specified client session.
GetType (inherited from Object)	Gets the Type of the current instance.
GetVariable	Overloaded. Return the value of a CGI environment variable for the specified client.

Initialize	Overloaded. Initialize an instance of the HttpServer class.
ReceiveRequest	Overloaded. Receive the request that was sent by the client to the server.
RedirectRequest	Overloaded. Redirect the request from the client to another URL.
RegisterHandler	Overloaded. Register a CGI program for use and associate it with a file name extension.
RegisterProgram	Overloaded. Register a CGI program for use and associate it with a virtual path on the server.
RequireAuthentication	Overloaded. Send a response to the client indicating that authentication is required.
Reset	Reset the internal state of the object, resetting all properties to their default values.
ResolvePath	Overloaded. Resolve a path to its full virtual or local file name.
Restart	Restarts the server and terminates all active client connections.
Resume	Resume accepting new client connections.
SendError	Overloaded. Send an error result code and message to the client in response to a command.
SendResponse	Overloaded. Send a result code and message to the client in response to a command.
SetHeader	Overloaded. Create or change the value of a response header for the client session.
SetVariable	Overloaded. Create or change the value of a CGI environment variable for the specified client.
Start	Overloaded. Start listening for client connections on the specified IP address and port number.
Stop	Stop listening for new client connections and terminate all active clients already connected to the server.
Suspend	Suspend accepting new client connections.
Throttle	Overloaded. Limit the maximum number of client connections, connections per IP address and connection rate.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources

	allocated by the HttpServer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

HttpServer.AddHost Method

Add a new virtual host to the server virtual host table.

Overload List

Add a new virtual host to the server virtual host table.

public int AddHost(string);

Add a new virtual host to the server virtual host table.

public int AddHost(string,string);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.AddHost Method (String, String)

Add a new virtual host to the server virtual host table.

[Visual Basic]

```
Overloads Public Function AddHost( _
   ByVal hostName As String, _
   ByVal rootDirectory As String _
) As Integer
```

[C#]

```
public int AddHost(
   string hostName,
   string rootDirectory
);
```

Parameters

hostName
A string which specifies the hostname that will be added to the virtual host table. This parameter must specify a valid hostname and cannot be a zero-length string.

rootDirectory
An optional string that specifies the root document directory for the virtual host. If this parameter is omitted or a zero-length string, the virtual host will use the same root directory that was specified when the server was started. This parameter may contain environment variables enclosed in % symbols.

Return Value

An integer value that uniquely identifies the virtual host that was added to the server. This value may be used with other methods that require a virtual host identifier. If the method fails, the return value will be -1 and the **LastError** property will be updated to indicate the cause of the failure.

Remarks

Virtual hosting is a method for sharing multiple domain names on a single instance of a server. The client provides the server with the hostname that it has used to establish the connection, and that name is compared against a table of virtual hosts configured for the server. If the hostname matches a virtual host, the client will use the root directory and any virtual paths that have been assigned to that host.

When the server is first started, a default virtual host with an ID of zero is automatically created and is identified as **httpHostDefault**. This virtual host uses the same hostname, port number and root directory that the server instance was created with. The application should treat all other host IDs as opaque values and never make assumptions about how they are allocated.

The virtual host ID returned by this method can be used with the **AddPath** method to create a virtual path assigned to the host, the **AddUser** to create a virtual user, and the **RegisterHandler** and **RegisterProgram** methods which are used to register script handlers and CGI programs.

HttpServer Class | SocketTools Namespace | HttpServer.AddHost Overload List

HttpServer.AddHost Method (String)

Add a new virtual host to the server virtual host table.

[Visual Basic]

```
Overloads Public Function AddHost( _
   ByVal hostName As String _
) As Integer
```

[C#]

```
public int AddHost(
   string hostName
);
```

Parameters

hostName

A string which specifies the hostname that will be added to the virtual host table. This parameter must specify a valid hostname and cannot be a zero-length string.

Return Value

An integer value that uniquely identifies the virtual host that was added to the server. This value may be used with other methods that require a virtual host identifier. If the method fails, the return value will be -1 and the **LastError** property will be updated to indicate the cause of the failure.

Remarks

Virtual hosting is a method for sharing multiple domain names on a single instance of a server. The client provides the server with the hostname that it has used to establish the connection, and that name is compared against a table of virtual hosts configured for the server. If the hostname matches a virtual host, the client will use the root directory and any virtual paths that have been assigned to that host.

When the server is first started, a default virtual host with an ID of zero is automatically created and is identified as **httpHostDefault**. This virtual host uses the same hostname, port number and root directory that the server instance was created with. The application should treat all other host IDs as opaque values and never make assumptions about how they are allocated.

The virtual host ID returned by this method can be used with the **AddPath** method to create a virtual path assigned to the host, the **AddUser** to create a virtual user, and the **RegisterHandler** and **RegisterProgram** methods which are used to register script handlers and CGI programs.

This version of the method will share the same root directory that was specified when this instance of the server was started.

HttpServer Class | SocketTools Namespace

HttpServer.AddPath Method (Int32, String, String, FileAccess)

Add a new virtual path for the specified host.

[Visual Basic]

```
Overloads Public Function AddPath( _
   ByVal hostId As Integer, _
   ByVal virtualPath As String, _
   ByVal localPath As String, _
   ByVal accessFlags As FileAccess _
) As Boolean
```

[C#]

```
public bool AddPath(
   int hostId,
   string virtualPath,
   string localPath,
   FileAccess accessFlags
);
```

Parameters

hostId
: An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

virtualPath
: A string which specifies the virtual path that will be created. This parameter cannot be an empty string and the maximum length of the virtual path is 1024 characters.

localPath
: A string which specifies the local directory or file name that the virtual path will be mapped to. This path must exist and can be no longer than 260 characters. This parameter cannot be an empty string.

accessFlags
: One or more FileAccess enumeration values which designates the access clients will be given to the virtual path.

Return Value

A boolean value which specifies if the virtual path was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddPath** method maps a virtual path name to a directory or file name on the local system. Virtual paths are assigned to specific hosts and if multiple virtual hosts are created for the server, each can have its own virtual paths which map to different files. To create a virtual path for the default server, the caller should specify the *HostId* parameter as **HttpServer.hostDefault** which has a value of zero.

It is recommended that the *localPath* parameter always specify the full path to the local file or directory. If the path is relative, it will be considered relative to the current working directory for the process and expanded to its full path name. The local path can include environment variables surrounded by % symbols. For example, if the value %ProgramData% is included in the path, it will be expanded to the full path for the common application data folder. The local path cannot specify a Windows system folder or the root directory of a mounted drive volume.

The local file or directory does not need to located in the document root directory for the server or virtual host. It can specify any valid local path that the server process has the appropriate permissions to access. You should exercise caution when creating virtual paths to files or directories outside of the server root directory. If the ***LocalPath*** parameter specifies a directory, clients will have access to that directory and all subdirectories using its virtual path.

If you wish to password protect the virtual file or directory, include the **accessProtected** flag in the file permissions. The default command handlers will recognize this flag and require that the client authenticate itself to grant access to the resource. If the server application implements a custom command handler, it is responsible for checking for the presence of this flag and perform the appropriate checks to ensure that the client session has been authenticated.

If the server was started in restricted mode, the client will be unable to access documents outside of the server root directory and its subdirectories. This restriction also applies to virtual paths that reference documents or other resources outside of the root directory. To allow a client to access a document outside of the server root directory, the **ClientAccess** property should be used to grant the client **accessRead** permission.

HttpServer Class | SocketTools Namespace | HttpServer.AddPath Overload List

HttpServer.AddPath Method (Int32, String, String)

Add a new virtual path for the specified host.

[Visual Basic]

```
Overloads Public Function AddPath( _
   ByVal hostId As Integer, _
   ByVal virtualPath As String, _
   ByVal localPath As String _
) As Boolean
```

[C#]

```
public bool AddPath(
   int hostId,
   string virtualPath,
   string localPath
);
```

Parameters

hostId
An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

virtualPath
A string which specifies the virtual path that will be created. This parameter cannot be an empty string and the maximum length of the virtual path is 1024 characters.

localPath
A string which specifies the local directory or file name that the virtual path will be mapped to. This path must exist and can be no longer than 260 characters. This parameter cannot be an empty string.

Return Value

A boolean value which specifies if the virtual path was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddPath** method maps a virtual path name to a directory or file name on the local system. Virtual paths are assigned to specific hosts and if multiple virtual hosts are created for the server, each can have its own virtual paths which map to different files. To create a virtual path for the default server, the caller should specify the ***HostId*** parameter as **HttpServer.hostDefault** which has a value of zero.

It is recommended that the *localPath* parameter always specify the full path to the local file or directory. If the path is relative, it will be considered relative to the current working directory for the process and expanded to its full path name. The local path can include environment variables surrounded by % symbols. For example, if the value %ProgramData% is included in the path, it will be expanded to the full path for the common application data folder. The local path cannot specify a Windows system folder or the root directory of a mounted drive volume.

The local file or directory does not need to located in the document root directory for the server or virtual host. It can specify any valid local path that the server process has the appropriate permissions to access. You should exercise caution when creating virtual paths to files or directories outside of the server root directory. If the *LocalPath* parameter specifies a directory, clients will have access to that directory and all subdirectories using its virtual path.

If you wish to password protect the virtual file or directory, include the **accessProtected** flag in the file permissions. The default command handlers will recognize this flag and require that the client authenticate itself to grant access to the resource. If the server application implements a custom command handler, it is responsible for checking for the presence of this flag and perform the appropriate checks to ensure that the client session has been authenticated.

If the server was started in restricted mode, the client will be unable to access documents outside of the server root directory and its subdirectories. This restriction also applies to virtual paths that reference documents or other resources outside of the root directory. To allow a client to access a document outside of the server root directory, the **ClientAccess** property should be used to grant the client **accessRead** permission.

HttpServer Class | SocketTools Namespace

HttpServer.AddUser Method (String, String)

Add a new virtual user to the default host.

[Visual Basic]

```
Overloads Public Function AddUser( _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool AddUser(
   string userName,
   string userPassword
);
```

Parameters

userName

A string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the method will fail with an error indicating the username is invalid. The username must be at least three characters in length. Usernames are not case sensitive.

userPassword

A string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the method will fail with an error indicating the password is invalid. The password must be at least one character in length. Passwords are case sensitive.

Return Value

A boolean value which specifies if the virtual user was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddUser** method creates a virtual user that is associated with the server. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this method. If a match is found, the client access rights will be updated.

If you wish to modify the information for an existing user, it is not necessary to delete the username first. If this method is called with a username that already exists, that record is replaced with the values passed to this method.

The virtual users created by this method exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this method for each user that is listed.

HttpServer Class | SocketTools Namespace | HttpServer.AddUser Overload List

HttpServer.AddUser Method (String, String, String)

Add a new virtual user to the default host.

[Visual Basic]

```
Overloads Public Function AddUser( _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal homeDirectory As String _
) As Boolean
```

[C#]

```
public bool AddUser(
   string userName,
   string userPassword,
   string homeDirectory
);
```

Parameters

userName

A string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the method will fail with an error indicating the username is invalid. The username must be at least three characters in length. Usernames are not case sensitive.

userPassword

A string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the method will fail with an error indicating the password is invalid. The password must be at least one character in length. Passwords are case sensitive.

homeDirectory

A string which specifies the directory that will be the virtual user's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created the first time that the virtual user successfully logs in to the server. If this parameter is an empty string, a default home directory will be created for the virtual user.

Return Value

A boolean value which specifies if the virtual user was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddUser** method creates a virtual user that is associated with the server. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this method. If a match is found, the client access rights will be updated.

If you wish to modify the information for an existing user, it is not necessary to delete the username first. If this method is called with a username that already exists, that record is replaced with the values passed to this method.

The virtual users created by this method exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this method for each user that is listed.

HttpServer.AddUser Method (String, String, UserAccess, String)

Add a new virtual user to the default host.

[Visual Basic]

```
Overloads Public Function AddUser( _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal accessFlags As UserAccess, _
   ByVal homeDirectory As String _
) As Boolean
```

[C#]

```
public bool AddUser(
   string userName,
   string userPassword,
   UserAccess accessFlags,
   string homeDirectory
);
```

Parameters

userName

A string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the method will fail with an error indicating the username is invalid. The username must be at least three characters in length. Usernames are not case sensitive.

userPassword

A string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the method will fail with an error indicating the password is invalid. The password must be at least one character in length. Passwords are case sensitive.

accessFlags

A UserAccess enumeration which specifies the access clients will be given when authenticated as this user.

homeDirectory

A string which specifies the directory that will be the virtual user's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created the first time that the virtual user successfully logs in to the server. If this parameter is an empty string, a default home directory will be created for the virtual user.

Return Value

A boolean value which specifies if the virtual user was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddUser** method creates a virtual user that is associated with the server. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this method. If a match is found, the client access rights will be updated.

If you wish to modify the information for an existing user, it is not necessary to delete the username first. If this method is called with a username that already exists, that record is replaced with the values passed to this method.

The virtual users created by this method exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this method for each user that is listed.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.AddUser Overload List

HttpServer.AddUser Method (Int32, String, String)

Add a new virtual user to the specified host.

[Visual Basic]

```
Overloads Public Function AddUser( _
   ByVal hostId As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool AddUser(
   int hostId,
   string userName,
   string userPassword
);
```

Parameters

hostId

An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

userName

A string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the method will fail with an error indicating the username is invalid. The username must be at least three characters in length. Usernames are not case sensitive.

userPassword

A string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the method will fail with an error indicating the password is invalid. The password must be at least one character in length. Passwords are case sensitive.

Return Value

A boolean value which specifies if the virtual user was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddUser** method creates a virtual user that is associated with the server. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this method. If a match is found, the client access rights will be updated.

If you wish to modify the information for an existing user, it is not necessary to delete the username first. If this method is called with a username that already exists, that record is replaced with the values passed to this method.

The virtual users created by this method exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this method for each user that is listed.

HttpServer Class | SocketTools Namespace | HttpServer.AddUser Overload List

HttpServer.AddUser Method (Int32, String, String, String)

Add a new virtual user to the specified host.

[Visual Basic]

```
Overloads Public Function AddUser( _
   ByVal hostId As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal homeDirectory As String _
) As Boolean
```

[C#]

```
public bool AddUser(
   int hostId,
   string userName,
   string userPassword,
   string homeDirectory
);
```

Parameters

hostId

An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

userName

A string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the method will fail with an error indicating the username is invalid. The username must be at least three characters in length. Usernames are not case sensitive.

userPassword

A string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the method will fail with an error indicating the password is invalid. The password must be at least one character in length. Passwords are case sensitive.

homeDirectory

A string which specifies the directory that will be the virtual user's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created the first time that the virtual user successfully logs in to the server. If this parameter is an empty string, a default home directory will be created for the virtual user.

Return Value

A boolean value which specifies if the virtual user was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddUser** method creates a virtual user that is associated with the server. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this method. If a match is found, the client access rights will be updated.

If you wish to modify the information for an existing user, it is not necessary to delete the username first. If this method is called with a username that already exists, that record is replaced with the values passed to this method.

The virtual users created by this method exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this method for each user that is listed.

HttpServer.AddUser Method (Int32, String, String, UserAccess, String)

Add a new virtual user to the specified host.

[Visual Basic]

```
Overloads Public Function AddUser( _
   ByVal hostId As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal accessFlags As UserAccess, _
   ByVal homeDirectory As String _
) As Boolean
```

[C#]

```
public bool AddUser(
   int hostId,
   string userName,
   string userPassword,
   UserAccess accessFlags,
   string homeDirectory
);
```

Parameters

hostId

An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

userName

A string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the method will fail with an error indicating the username is invalid. The username must be at least three characters in length. Usernames are not case sensitive.

userPassword

A string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the method will fail with an error indicating the password is invalid. The password must be at least one character in length. Passwords are case sensitive.

accessFlags

A UserAccess enumeration which specifies the access clients will be given when authenticated as this user.

homeDirectory

A string which specifies the directory that will be the virtual user's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created the first time that the virtual user successfully logs in to the server. If this parameter is an empty string, a default home directory will be created for the virtual user.

Return Value

A boolean value which specifies if the virtual user was added to the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **AddUser** method creates a virtual user that is associated with the server. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this method. If a match is found, the client access rights will be updated.

If you wish to modify the information for an existing user, it is not necessary to delete the username first. If this method is called with a username that already exists, that record is replaced with the values passed to this method.

The virtual users created by this method exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this method for each user that is listed.

HttpServer.Authenticate Method

Authenticate the active client and assign access rights for the session.

Overload List

Authenticate the active client and assign access rights for the session.

public bool Authenticate(UserAccess);

Authenticate the client and assign access rights for the session.

public bool Authenticate(int,UserAccess);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Authenticate Method (Int32, UserAccess)

Authenticate the client and assign access rights for the session.

[Visual Basic]

```
Overloads Public Function Authenticate( _
   ByVal clientId As Integer, _
   ByVal accessFlags As UserAccess _
) As Boolean
```

[C#]

```
public bool Authenticate(
   int clientId,
   UserAccess accessFlags
);
```

Parameters

clientId
: An integer that identifies the client session.

accessFlags
: One or more UserAccess enumeration values that specifies the access clients will be given when authenticated as this user.

Return Value

A boolean value which specifies if the client session was authenticated. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Authenticate** method is used to authenticate a specific client session, typically in response to an **OnAuthenticate** event that indicates a client has provided authentication credentials as part of the request for a document or other resource.

To enable the server to automatically authenticate a client session, use the **AddUser** method to add one or more virtual users. The server will search the list of virtual users for a match to the credentials provided by the client and will set the appropriate permissions for the session without requiring a event handler to manually authenticate the session using this method.

If the server was started with the **LocalUser** property set to **True** and the client session is not authenticated using this method, the server will attempt to authenticate the client session using the local Windows user database. Although this option can be convenient because it does not require the implementation of an event handler for the **OnAuthenticate** event, it can be used by clients to attempt to discover valid usernames and passwords for the local system. It is recommended that you use the **AddUser** method to create virtual users rather than using the local user database.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.Authenticate Overload List

HttpServer.Authenticate Method (UserAccess)

Authenticate the active client and assign access rights for the session.

[Visual Basic]

```
Overloads Public Function Authenticate( _
   ByVal accessFlags As UserAccess _
) As Boolean
```

[C#]

```
public bool Authenticate(
   UserAccess accessFlags
);
```

Parameters

accessFlags

One or more UserAccess enumeration values that specifies the access clients will be given when authenticated as this user.

Return Value

A boolean value which specifies if the client session was authenticated. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Authenticate** method is used to authenticate the active client session, typically in response to an **OnAuthenticate** event that indicates a client has provided authentication credentials as part of the request for a document or other resource.

To enable the server to automatically authenticate a client session, use the **AddUser** method to add one or more virtual users. The server will search the list of virtual users for a match to the credentials provided by the client and will set the appropriate permissions for the session without requiring a event handler to manually authenticate the session using this method.

If the server was started with the **LocalUser** property set to **True** and the client session is not authenticated using this method, the server will attempt to authenticate the client session using the local Windows user database. Although this option can be convenient because it does not require the implementation of an event handler for the **OnAuthenticate** event, it can be used by clients to attempt to discover valid usernames and passwords for the local system. It is recommended that you use the **AddUser** method to create virtual users rather than using the local user database.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

public bool CheckPath(string,FileAccess);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.CheckPath Method (String)

Determine if the active client has read access to the specified virtual path.

[Visual Basic]

```
Overloads Public Function CheckPath( _
   ByVal virtualPath As String _
) As Boolean
```

[C#]

```
public bool CheckPath(
   string virtualPath
);
```

Parameters

virtualPath

A string which specifies the virtual path that will be created. The path must be absolute and cannot be an empty string. The maximum length of the virtual path is 1024 characters.

Return Value

A boolean value which specifies if the virtual path can be accessed by the client. A return value of **true** specifies that the file or directory can be accessed. If the file or directory cannot be accessed, the method returns false and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **CheckPath** method is used to determine if the client has permission to read the virtual file or directory. The method will return a non-zero value if the client does have the requested permission, or zero if it does not.

Applications that implement their own custom handlers for standard HTTP commands should use this method to ensure that the client has the appropriate permissions to access the requested resource. Failure to check the access permissions for the client can result in the client being able to access restricted documents and other resources. It is recommended that most applications use the default command handlers.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

To obtain the path to the local file or directory that the virtual path is mapped to, use the **ResolvePath** method.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.CheckPath Overload List

HttpServer.CheckPath Method (String, FileAccess)

Determine if the active client has permission to access the specified virtual path.

[Visual Basic]

```
Overloads Public Function CheckPath( _
   ByVal virtualPath As String, _
   ByVal accessFlags As FileAccess _
) As Boolean
```

[C#]

```
public bool CheckPath(
   string virtualPath,
   FileAccess accessFlags
);
```

Parameters

virtualPath
A string which specifies the virtual path that will be created. The path must be absolute and cannot be an empty string. The maximum length of the virtual path is 1024 characters.

accessFlags
One or more FileAccess enumerations that specifies the access permissions that should be checked.

Return Value

A boolean value which specifies if the virtual path can be accessed by the client. A return value of **true** specifies that the file or directory can be accessed with the requested permissions. If the file or directory cannot be accessed, the method returns false and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **CheckPath** method is used to determine if the client has permission to access the virtual file or directory, based on the value of the ***accessFlags*** parameter. For example, if the ***accessFlags*** parameter has the value **accessWrite**, this method will check if the client has write permission for the file or directory. The method will return a non-zero value if the client does have the requested permission, or zero if it does not.

Applications that implement their own custom handlers for standard HTTP commands should use this method to ensure that the client has the appropriate permissions to access the requested resource. Failure to check the access permissions for the client can result in the client being able to access restricted documents and other resources. It is recommended that most applications use the default command handlers.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

To obtain the path to the local file or directory that the virtual path is mapped to, use the **ResolvePath** method.

HttpServer.CheckPath Method (Int32, String)

Determine if the client has read access to the specified virtual path.

[Visual Basic]
```
Overloads Public Function CheckPath( _
   ByVal clientId As Integer, _
   ByVal virtualPath As String _
) As Boolean
```

[C#]
```
public bool CheckPath(
   int clientId,
   string virtualPath
);
```

Parameters

clientId

An integer value which identifies the client session.

virtualPath

A string which specifies the virtual path that will be created. The path must be absolute and cannot be an empty string. The maximum length of the virtual path is 1024 characters.

Return Value

A boolean value which specifies if the virtual path can be accessed by the client. A return value of **true** specifies that the file or directory can be accessed. If the file or directory cannot be accessed, the method returns false and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **CheckPath** method is used to determine if the client has permission to read the virtual file or directory. The method will return a non-zero value if the client does have the requested permission, or zero if it does not.

Applications that implement their own custom handlers for standard HTTP commands should use this method to ensure that the client has the appropriate permissions to access the requested resource. Failure to check the access permissions for the client can result in the client being able to access restricted documents and other resources. It is recommended that most applications use the default command handlers.

To obtain the path to the local file or directory that the virtual path is mapped to, use the **ResolvePath** method.

HttpServer.CheckPath Method (Int32, String, FileAccess)

Determine if the client has permission to access the specified virtual path.

[Visual Basic]

```
Overloads Public Function CheckPath( _
   ByVal clientId As Integer, _
   ByVal virtualPath As String, _
   ByVal accessFlags As FileAccess _
) As Boolean
```

[C#]

```
public bool CheckPath(
   int clientId,
   string virtualPath,
   FileAccess accessFlags
);
```

Parameters

clientId

An integer value which identifies the client session.

virtualPath

A string which specifies the virtual path that will be created. The path must be absolute and cannot be an empty string. The maximum length of the virtual path is 1024 characters.

accessFlags

One or more FileAccess enumerations that specifies the access permissions that should be checked.

Return Value

A boolean value which specifies if the virtual path can be accessed by the client. A return value of **true** specifies that the file or directory can be accessed with the requested permissions. If the file or directory cannot be accessed, the method returns false and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **CheckPath** method is used to determine if the client has permission to access the virtual file or directory, based on the value of the ***accessFlags*** parameter. For example, if the ***accessFlags*** parameter has the value **accessWrite**, this method will check if the client has write permission for the file or directory. The method will return a non-zero value if the client does have the requested permission, or zero if it does not.

Applications that implement their own custom handlers for standard HTTP commands should use this method to ensure that the client has the appropriate permissions to access the requested resource. Failure to check the access permissions for the client can result in the client being able to access restricted documents and other resources. It is recommended that most applications use the default command handlers.

To obtain the path to the local file or directory that the virtual path is mapped to, use the **ResolvePath** method.

public bool ClearHeaders();

Delete all of the response headers for the specified client session.

public bool ClearHeaders(int);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ClearHeaders Method (Int32)

Delete all of the response headers for the specified client session.

[Visual Basic]

```
Overloads Public Function ClearHeaders( _
   ByVal clientId As Integer _
) As Boolean
```

[C#]

```
public bool ClearHeaders(
   int clientId
);
```

Parameters

clientId

An integer value which identifies the client session.

Return Value

A boolean value which specifies if the response headers were cleared. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ClearHeaders** method is used to delete all of the current response header values and automatically generate a new set of default response headers. This method can be useful if the client application wants to clear any custom headers that were specified prior to sending a response to the client. In most cases it is not necessary to use this method because the server will automatically clear the response headers when a session terminates.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.ClearHeaders Overload List

HttpServer.ClearHeaders Method ()

Delete all of the response headers for the active client session.

[Visual Basic]

```
Overloads Public Function ClearHeaders() As Boolean
```

[C#]

```
public bool ClearHeaders();
```

Return Value

A boolean value which specifies if the response headers were cleared. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ClearHeaders** method is used to delete all of the current response header values and automatically generate a new set of default response headers. This method can be useful if the client application wants to clear any custom headers that were specified prior to sending a response to the client. In most cases it is not necessary to use this method because the server will automatically clear the response headers when a session terminates.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer.DeleteHost Method

Delete a virtual host associated with the specified server.

Overload List

Delete a virtual host associated with the specified server.

public bool DeleteHost(int);

Delete a virtual host associated with the specified server.

public bool DeleteHost(string);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.DeleteHost Method (Int32)

Delete a virtual host associated with the specified server.

[Visual Basic]

```
Overloads Public Function DeleteHost( _
   ByVal hostId As Integer _
) As Boolean
```

[C#]

```
public bool DeleteHost(
   int hostId
);
```

Parameters

hostId

An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

Return Value

A boolean value which specifies if the virtual host was deleted from the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **DeleteHost** method removes a virtual host that was created by a previous call to the **AddHost** method. All virtual paths and users associated with the specified host are no longer valid. It is not necessary to call this method to delete any of the virtual hosts prior to stopping the server. Part of the normal shutdown process is releasing the resources allocated for each virtual host that was added to the server.

This method cannot be used to delete the virtual host with an ID of zero, which is the default virtual host that is allocated when the server is started.

```
Overloads Public Function DeleteHost( _
   ByVal hostName As String _
) As Boolean
```

[C#]
```
public bool DeleteHost(
   string hostName
);
```

Parameters

hostName

A string that specifies the name of the virtual host that was previous added to the server. This value must match the complete virtual host name.

Return Value

A boolean value which specifies if the virtual host was removed from the server. A return value of true specifies that the operation was successful. If an error occurs, the method returns false and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **DeleteHost** method removes a virtual host that was created by a previous call to the **AddHost** method. All virtual paths and users associated with the specified host are no longer valid. It is not necessary to call this method to delete any of the virtual hosts prior to stopping the server. Part of the normal shutdown process is releasing the resources allocated for each virtual host that was added to the server.

This method cannot be used to delete the default virtual host that is created when the server is started.

```
public bool DeletePath(
   int hostId,
   string virtualPath
);
```

Parameters

hostId
An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

virtualPath
A string that specifies the virtual path to be removed. This path must be absolute and cannot be an empty string.

Return Value

A boolean value which specifies if the virtual path was removed from the server. A return **value** of true specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remove a virtual user from the server.

[Visual Basic]

```
Overloads Public Function DeleteUser( _
   ByVal hostId As Integer, _
   ByVal userName As String _
) As Boolean
```

[C#]

```
public bool DeleteUser(
   int hostId,
   string userName
);
```

Parameters

hostId

An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

userName

A string which specifies the user name to be deleted. Usernames are not case sensitive.

Return Value

A boolean value which specifies if the virtual user has been deleted. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **DeleteUser** method removes a virtual user that was created by a previous call to the **AddUser** method. This method will not match partial usernames and wildcard characters cannot be used to delete multiple users. Usernames are not case sensitive. You cannot use this method to delete the "anonymous" user.

Disconnect the specified client session from the server.

public void Disconnect();

Disconnect the specified client session from the server.

public void Disconnect(int);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Disconnect Method (Int32)

Disconnect the specified client session from the server.

[Visual Basic]
```
Overloads Public Sub Disconnect( _
   ByVal clientId As Integer _
)
```

[C#]
```
public void Disconnect(
   int clientId
);
```

Parameters

clientId
An integer that identifies the client session.

Return Value

A boolean value which specifies if the client has been signaled to disconnect from the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Disconnect** method terminates the specified client session, releasing the socket handle other resources that were allocated for the session. It is only necessary to use this method if you want the server to explicitly terminate a client connection. Normally the client will close its connection to the server, the **OnDisconnect** event will fire and the server will automatically disconnect the client.

This method signals the thread that is managing the client that it should disconnect from the server, and it will begin the process of terminating the session. This is an asynchronous process and it is not guaranteed that the client will have actually disconnected from the server at the time that this method returns to the caller.

HttpServer Class | SocketTools Namespace | HttpServer.Disconnect Overload List

HttpServer.Disconnect Method ()

Disconnect the specified client session from the server.

[Visual Basic]

```
Overloads Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Return Value

A boolean value which specifies if the client has been signaled to disconnect from the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Disconnect** method terminates the active client session, releasing the socket handle other resources that were allocated for the session. It is only necessary to use this method if you want the server to explicitly terminate a client connection. Normally the client will close its connection to the server, the **OnDisconnect** event will fire and the server will automatically disconnect the client.

This method signals the thread that is managing the client that it should disconnect from the server, and it will begin the process of terminating the session. This is an asynchronous process and it is not guaranteed that the client will have actually disconnected from the server at the time that this method returns to the caller.

HttpServer.Dispose Method

Releases all resources used by HttpServer.

Overload List

Releases all resources used by HttpServer.

public void Dispose();

Releases the unmanaged resources allocated by the HttpServer class and optionally releases the managed resources.

protected void Dispose(bool);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the HttpServer class and optionally releases the managed resources.

[Visual Basic]

```
Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **HttpServer** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.Dispose Overload List

HttpServer.Dispose Method ()

Releases all resources used by HttpServer.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method stops the server, terminates all active client sessions and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

HttpServer.GetAllHeaders Method

Return all of the request header values in the specified string buffer.

Overload List

Return all of the request header values in the specified string buffer.

public bool GetAllHeaders(int,ref string);

Return all of the request header values in the specified string buffer.

public bool GetAllHeaders(ref string);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.GetAllHeaders Method (Int32, String)

Return all of the request header values in the specified string buffer.

[Visual Basic]

```
Overloads Public Function GetAllHeaders( _
   ByVal clientId As Integer, _
   ByRef requestHeaders As String _
) As Boolean
```

[C#]

```
public bool GetAllHeaders(
   int clientId,
   ref string requestHeaders
);
```

Parameters

clientId

An integer that identifies the client session.

requestHeaders

A string variable that is passed by reference which will contain the request headers when the method returns.

Return Value

A boolean value which specifies if the request headers were copied to the string buffer. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **GetAllHeaders** method is used to obtain all of the request headers that were provided by the client. Each header name is separated from its value by the colon (:) and each header is terminated with a carriage return and linefeed (CRLF) sequence. Typically this method would be used within an **OnCommand** event handler. To get the value of a specific request header, use the **GetHeader** method.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.GetAllHeaders Overload List

HttpServer.GetAllHeaders Method (String)

Return all of the request header values in the specified string buffer.

```
[Visual Basic]
Overloads Public Function GetAllHeaders( _
   ByRef requestHeaders As String _
) As Boolean
```

```
[C#]
public bool GetAllHeaders(
   ref string requestHeaders
);
```

Parameters

requestHeaders
A string variable that is passed by reference which will contain the request headers when the method returns.

Return Value

A boolean value which specifies if the request headers were copied to the string buffer. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **GetAllHeaders** method is used to obtain all of the request headers that were provided by the client. Each header name is separated from its value by the colon (:) and each header is terminated with a carriage return and linefeed (CRLF) sequence. Typically this method would be used within an **OnCommand** event handler. To get the value of a specific request header, use the **GetHeader** method.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer.GetHeader Method

Return the value of a request header for the specified client session.

Overload List

Return the value of a request header for the specified client session.

public bool GetHeader(int,string,ref string);

Return the value of a request header for the active client session.

public bool GetHeader(string,ref string);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.GetHeader Method (Int32, String, String)

Return the value of a request header for the specified client session.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal clientId As Integer, _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   int clientId,
   string headerName,
   ref string headerValue
);
```

Parameters

clientId

An integer that identifies the client session.

headerName

A string that specifies the name of the header field. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value.

headerValue

A string variable that is passed by reference which will contain the value of the header when the method returns.

Return Value

A boolean value which specifies if the header value was copied to the string buffer. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **GetHeader** method will return the value of a specific header field included in the request sent by the client. Typically this is used within an **OnCommand** event handler when the server application needs to process a custom command. The **GetAllHeaders** method can be used to obtain a copy of the complete request header block submitted by the client.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.GetHeader Overload List

HttpServer.GetHeader Method (String, String)

Return the value of a request header for the active client session.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   string headerName,
   ref string headerValue
);
```

Parameters

headerName

A string that specifies the name of the header field. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value.

headerValue

A string variable that is passed by reference which will contain the value of the header when the method returns.

Return Value

A boolean value which specifies if the header value was copied to the string buffer. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **GetHeader** method will return the value of a specific header field included in the request sent by the client. Typically this is used within an **OnCommand** event handler when the server application needs to process a custom command. The **GetAllHeaders** method can be used to obtain a copy of the complete request header block submitted by the client.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer Class | SocketTools Namespace | HttpServer.GetHeader Overload List

HttpServer.GetVariable Method

Return the value of a CGI environment variable for the specified client.

Overload List

Return the value of a CGI environment variable for the specified client.

public bool GetVariable(int,string,ref string);

Return the value of a CGI environment variable for the active client.

public bool GetVariable(string,ref string);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.GetVariable Method (Int32, String, String)

Return the value of a CGI environment variable for the specified client.

[Visual Basic]
```
Overloads Public Function GetVariable( _
   ByVal clientId As Integer, _
   ByVal variableName As String, _
   ByRef variableValue As String _
) As Boolean
```

[C#]
```
public bool GetVariable(
   int clientId,
   string variableName,
   ref string variableValue
);
```

Parameters

clientId
An integer that identifies the client session.

variableName
A string that that specifies the name of the environment variable. Variable names are not case-sensitive and should not include the equal sign which acts as a delimiter that separates the variable name from its value.

variableValue
A string variable that is passed by reference which will contain the value of the environment variable when the method returns.

Return Value

A boolean value which specifies if the header value was copied to the string buffer. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **GetVariable** method will return the value of an environment variable that has been defined for the client. Each client session inherits a copy of the process environment block, which is then modified to define various environment variables that are used with CGI programs and scripts. The **SetVariable** method can be used to change existing environment variables or create new variables.

The standard CGI environment variables that are defined by the server are not created until the client request has been processed. This means that environment variables such as REMOTE_ADDR and SERVER_NAME will not be defined inside an **OnConnect** event handler.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.GetVariable Overload List

HttpServer.GetVariable Method (String, String)

Return the value of a CGI environment variable for the active client.

[Visual Basic]

```
Overloads Public Function GetVariable( _
   ByVal variableName As String, _
   ByRef variableValue As String _
) As Boolean
```

[C#]

```
public bool GetVariable(
   string variableName,
   ref string variableValue
);
```

Parameters

variableName

A string that that specifies the name of the environment variable. Variable names are not case-sensitive and should not include the equal sign which acts as a delimiter that separates the variable name from its value.

variableValue

A string variable that is passed by reference which will contain the value of the environment variable when the method returns.

Return Value

A boolean value which specifies if the header value was copied to the string buffer. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **GetVariable** method will return the value of an environment variable that has been defined for the client. Each client session inherits a copy of the process environment block, which is then modified to define various environment variables that are used with CGI programs and scripts. The **SetVariable** method can be used to change existing environment variables or create new variables.

The standard CGI environment variables that are defined by the server are not created until the client request has been processed. This means that environment variables such as REMOTE_ADDR and SERVER_NAME will not be defined inside an **OnConnect** event handler.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer.Initialize Method

Initialize an instance of the HttpServer class.

Overload List

Initialize an instance of the HttpServer class.

public bool Initialize();

Initialize an instance of the HttpServer class.

public bool Initialize(string);

See Also

HttpServer Class | SocketTools Namespace | Uninitialize Method

HttpServer.Initialize Method (String)

Initialize an instance of the HttpServer class.

[Visual Basic]
```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]
```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the HttpServer class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of HttpServer can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the HttpServer class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.HttpServer server = new SocketTools.HttpServer();

if (server.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(server.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim Server As New SocketTools.HttpServer

If Server.Initialize(strLicenseKey) = False Then
    MsgBox(Server.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

HttpServer Class | SocketTools Namespace | HttpServer.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

HttpServer.Initialize Method ()

Initialize an instance of the HttpServer class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the HttpServer class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

HttpServer Class | SocketTools Namespace | HttpServer.Initialize Overload List | Uninitialize Method

HttpServer.ReceiveRequest Method

Receive the request that was sent by the client to the server.

Overload List

Receive the request that was sent by the client to the server.

public bool ReceiveRequest(byte[],ref int);

Receive the request that was sent by the client to the server.

public bool ReceiveRequest(int,byte[],ref int);

Receive the request that was sent by the client to the server.

public bool ReceiveRequest(int,MemoryStream);

Receive the request that was sent by the client to the server.

public bool ReceiveRequest(int,ref string);

Receive the request that was sent by the client to the server.

public bool ReceiveRequest(MemoryStream);

Receive the request that was sent by the client to the server.

public bool ReceiveRequest(ref string);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.ReceiveRequest Method (Int32, Byte[], Int32)

Receive the request that was sent by the client to the server.

[Visual Basic]

```
Overloads Public Function ReceiveRequest( _
   ByVal clientId As Integer, _
   ByVal requestData As Byte(), _
   ByRef requestSize As Integer _
) As Boolean
```

[C#]

```
public bool ReceiveRequest(
   int clientId,
   byte[] requestData,
   ref int requestSize
);
```

Parameters

clientId
An integer that identifies the client session.

requestData
A byte array that will contain any data submitted by the client as part of the request.

requestSize
An integer value passed by reference that will contain the number of bytes copied into the byte array when the method returns.

Return Value

A boolean value which specifies if the client request was received. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **ReceiveRequest** method is called within an **OnCommand** event handler to process the command issued by the client and return information about the request to the server application. It is only necessary for the application to call this method if it wants to implement its own custom handling for a command.

It is recommended that you only use this method to process custom commands and not standard commands such as GET and POST. This ensures that the appropriate security checks are performed and the response conforms to the protocol standard. After the request data has been processed, the application should use the **SendResponse** or **SendError** method to send a response back to the client indicating success or failure.

This method may only be called once per command issued by the client.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.ReceiveRequest Overload List

HttpServer.ReceiveRequest Method (Byte[], Int32)

Receive the request that was sent by the client to the server.

[Visual Basic]
```
Overloads Public Function ReceiveRequest( _
   ByVal requestData As Byte(), _
   ByRef requestSize As Integer _
) As Boolean
```

[C#]
```
public bool ReceiveRequest(
   byte[] requestData,
   ref int requestSize
);
```

Parameters

requestData

A byte array that will contain any data submitted by the client as part of the request.

requestSize

An integer value passed by reference that will contain the number of bytes copied into the byte array when the method returns.

Return Value

A boolean value which specifies if the client request was received. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **ReceiveRequest** method is called within an **OnCommand** event handler to process the command issued by the client and return information about the request to the server application. It is only necessary for the application to call this method if it wants to implement its own custom handling for a command.

It is recommended that you only use this method to process custom commands and not standard commands such as GET and POST. This ensures that the appropriate security checks are performed and the response conforms to the protocol standard. After the request data has been processed, the application should use the **SendResponse** or **SendError** method to send a response back to the client indicating success or failure.

This method may only be called once per command issued by the client.

HttpServer.ReceiveRequest Method (Int32, MemoryStream)

Receive the request that was sent by the client to the server.

[Visual Basic]

```
Overloads Public Function ReceiveRequest( _
   ByVal clientId As Integer, _
   ByVal memStream As MemoryStream _
) As Boolean
```

[C#]

```
public bool ReceiveRequest(
   int clientId,
   MemoryStream memStream
);
```

Parameters

clientId

An integer that identifies the client session.

memStream

An instance of a MemoryStream object that will contain any data submitted by the client as part of the request.

Return Value

A boolean value which specifies if the client request was received. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **ReceiveRequest** method is called within an **OnCommand** event handler to process the command issued by the client and return information about the request to the server application. It is only necessary for the application to call this method if it wants to implement its own custom handling for a command.

It is recommended that you only use this method to process custom commands and not standard commands such as GET and POST. This ensures that the appropriate security checks are performed and the response conforms to the protocol standard. After the request data has been processed, the application should use the **SendResponse** or **SendError** method to send a response back to the client indicating success or failure.

This method may only be called once per command issued by the client.

HttpServer Class | SocketTools Namespace | HttpServer.ReceiveRequest Overload List

HttpServer.RedirectRequest Method

Redirect the request from the client to another URL.

Overload List

Redirect the request from the client to another URL.

public bool RedirectRequest(int,string);

Redirect the request from the client to another URL.

public bool RedirectRequest(int,string,bool);

Redirect the request from the client to another URL.

public bool RedirectRequest(string);

Redirect the request from the client to another URL.

public bool RedirectRequest(string,bool);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.RedirectRequest Method (Int32, String, Boolean)

Redirect the request from the client to another URL.

[Visual Basic]

```
Overloads Public Function RedirectRequest( _
   ByVal clientId As Integer, _
   ByVal locationUrl As String, _
   ByVal isPermanent As Boolean _
) As Boolean
```

[C#]

```
public bool RedirectRequest(
   int clientId,
   string locationUrl,
   bool isPermanent
);
```

Parameters

clientId

An integer that identifies the client session.

locationUrl

A string that specifies the new location for the requested resource. This value must be a complete URL, including the http:// or https:// scheme.

isPermanent

A boolean value that specifies if the redirection should be considered temporary or permanent. If this value is true, a brower will typically cache the response and use the new resource location for subsequent requests. If this value is false, the redirection is considered to be temporary and a browser will continue to use the original resource URI.

Return Value

A boolean value which specifies if the request has been redirected. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **RedirectRequest** method can be used within an **OnCommand** event handler to redirect the client to a new location for the resource that it has requested. This redirection can be permanent or temporary, depending on whether the server expects the client to continue to use the original URL when requesting the resource.

If the ***isPermanent*** parameter is false, the actual status code that is returned to the client depends on the version of the protocol that is being used. If the client has issued the request using HTTP 1.0 then the server will return a 302 code to the client. If the client used HTTP 1.1, the server will return a 307 code to the client that indicates it should use the same command verb (GET, POST, etc.) when requesting the resource at the new location.

This method provides a simplified interface for sending a redirection status code that also implicitly sets the Location response header to the value of the ***location*** parameter. If the server application needs to send alternate redirection codes such as 305 (Use Proxy) then it should use **SetHeader** method to set the value of the Location response header, followed by the **SendReponse** method to send the redirection status code.

HttpServer.RedirectRequest Method (Int32, String)

Redirect the request from the client to another URL.

[Visual Basic]

```
Overloads Public Function RedirectRequest( _
   ByVal clientId As Integer, _
   ByVal locationUrl As String _
) As Boolean
```

[C#]

```
public bool RedirectRequest(
   int clientId,
   string locationUrl
);
```

Parameters

clientId
An integer that identifies the client session.

locationUrl
A string that specifies the new location for the requested resource. This value must be a complete URL, including the http:// or https:// scheme.

Return Value

A boolean value which specifies if the request has been redirected. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **RedirectRequest** method can be used within an **OnCommand** event handler to redirect the client to a new location for the resource that it has requested. This redirection can be permanent or temporary, depending on whether the server expects the client to continue to use the original URL when requesting the resource.

If the ***isPermanent*** parameter is false, the actual status code that is returned to the client depends on the version of the protocol that is being used. If the client has issued the request using HTTP 1.0 then the server will return a 302 code to the client. If the client used HTTP 1.1, the server will return a 307 code to the client that indicates it should use the same command verb (GET, POST, etc.) when requesting the resource at the new location.

This method provides a simplified interface for sending a redirection status code that also implicitly sets the Location response header to the value of the ***location*** parameter. If the server application needs to send alternate redirection codes such as 305 (Use Proxy) then it should use **SetHeader** method to set the value of the Location response header, followed by the **SendReponse** method to send the redirection status code.

HttpServer Class | SocketTools Namespace | HttpServer.RedirectRequest Overload List

HttpServer.RedirectRequest Method (String, Boolean)

Redirect the request from the client to another URL.

```
[Visual Basic]
Overloads Public Function RedirectRequest( _
   ByVal locationUrl As String, _
   ByVal isPermanent As Boolean _
) As Boolean
```

```
[C#]
public bool RedirectRequest(
   string locationUrl,
   bool isPermanent
);
```

Parameters

locationUrl
A string that specifies the new location for the requested resource. This value must be a complete URL, including the http:// or https:// scheme.

isPermanent
A boolean value that specifies if the redirection should be considered temporary or permanent. If this value is true, a brower will typically cache the response and use the new resource location for subsequent requests. If this value is false, the redirection is considered to be temporary and a browser will continue to use the original resource URI.

Return Value

A boolean value which specifies if the request has been redirected. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **RedirectRequest** method can be used within an **OnCommand** event handler to redirect the client to a new location for the resource that it has requested. This redirection can be permanent or temporary, depending on whether the server expects the client to continue to use the original URL when requesting the resource.

If the *isPermanent* parameter is false, the actual status code that is returned to the client depends on the version of the protocol that is being used. If the client has issued the request using HTTP 1.0 then the server will return a 302 code to the client. If the client used HTTP 1.1, the server will return a 307 code to the client that indicates it should use the same command verb (GET, POST, etc.) when requesting the resource at the new location.

This method provides a simplified interface for sending a redirection status code that also implicitly sets the Location response header to the value of the *location* parameter. If the server application needs to send alternate redirection codes such as 305 (Use Proxy) then it should use **SetHeader** method to set the value of the Location response header, followed by the **SendReponse** method to send the redirection status code.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer Class | SocketTools Namespace | HttpServer.RedirectRequest Overload List

HttpServer.RedirectRequest Method (String)

Redirect the request from the client to another URL.

```
[Visual Basic]
Overloads Public Function RedirectRequest( _
   ByVal locationUrl As String _
) As Boolean
```

```
[C#]
public bool RedirectRequest(
   string locationUrl
);
```

Parameters

locationUrl

A string that specifies the new location for the requested resource. This value must be a complete URL, including the http:// or https:// scheme.

Return Value

A boolean value which specifies if the request has been redirected. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **RedirectRequest** method can be used within an **OnCommand** event handler to redirect the client to a new location for the resource that it has requested. This redirection can be permanent or temporary, depending on whether the server expects the client to continue to use the original URL when requesting the resource.

If the ***isPermanent*** parameter is false, the actual status code that is returned to the client depends on the version of the protocol that is being used. If the client has issued the request using HTTP 1.0 then the server will return a 302 code to the client. If the client used HTTP 1.1, the server will return a 307 code to the client that indicates it should use the same command verb (GET, POST, etc.) when requesting the resource at the new location.

This method provides a simplified interface for sending a redirection status code that also implicitly sets the Location response header to the value of the ***location*** parameter. If the server application needs to send alternate redirection codes such as 305 (Use Proxy) then it should use **SetHeader** method to set the value of the Location response header, followed by the **SendReponse** method to send the redirection status code.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a server has been started, it will be stopped and any active client connections will be terminated. All properties will be reset to their default values.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Restart Method

Restarts the server and terminates all active client connections.

[Visual Basic]

```
Public Function Restart() As Boolean
```

[C#]

```
public bool Restart();
```

Return Value

A boolean value which specifies if the server was restarted. A return value of **true** specifies that the server has been successfully restarted. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Restart** method terminates all active client connections, recreates a new listening socket bound to the same address and port number, and then resumes accepting new client connections.

HttpServer Class | SocketTools Namespace

HttpServer.RegisterHandler Method (Int32, String, String, String, String)

Register a CGI program for use and associate it with a file name extension.

[Visual Basic]

```
Overloads Public Function RegisterHandler( _
   ByVal hostId As Integer, _
   ByVal extension As String, _
   ByVal program As String, _
   ByVal parameters As String, _
   ByVal directory As String _
) As Boolean
```

[C#]

```
public bool RegisterHandler(
   int hostId,
   string extension,
   string program,
   string parameters,
   string directory
);
```

Parameters

hostId
An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

extension
A string which specifies the file name extension that is associated with the CGI program.

program
A string which specifies the full path to the CGI program on the local system.

parameters
A string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the CGI program does not require any command line parameters, this parameter may be an empty string.

directory
A string that specifies the current working directory for the program. If this parameter is an empty string, the program will use the root directory of the virtual host as the current working directory.

Return Value

A boolean value which specifies if the CGI handler was registered. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **RegisterHandler** method registers an executable CGI program and associates it with a file name extension. When the client issues a GET or POST command that specifies a file with that extension, the program will be executed and the output return to the client.

The ***program*** string specifies file name of the CGI program. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple file name extensions that reference the same program. The only requirement is that the extension be unique for the given host. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the C:\Program Files folder.

It is important to note that the program specified by ***ProgramFile*** must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The ***parameters*** string can specify additional command line parameters that should be passed to the CGI program as arguments. This string can also contain a placeholder named "%1" that will be replaced by the full path to the local script filename. If no parameters are specified, the script file name will be passed to the program as its only argument.

The executable program that is registered using this program must be a console application that conforms to the CGI/1.1 specification defined in RFC 3875. Request data submitted by the client as part of a POST will be provided to the program as standard input. The output from the program must be written to standard output. The first lines of output from the program should be any response headers, followed by an empty line. Each line should be terminated with a carriage-return and linefeed (CRLF) sequence. If the CGI program outputs additional data to be processed by the client, it should provide Content-Type and Content-Length response headers.

When developing a CGI program, it is important to take into consideration the environment that it will be executing in. The program will be started as a child process of the server application, and will inherit the same privileges. This means that it will typically have access to the boot drive, the Windows folders and the system registry. CGI programs must ensure that all query parameters and request data submitted by the client have been validated.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

HttpServer.RegisterProgram Method (Int32, String, String, String, String)

Register a CGI program for use and associate it with a virtual path on the server.

[Visual Basic]

```
Overloads Public Function RegisterProgram( _
   ByVal hostId As Integer, _
   ByVal command As String, _
   ByVal program As String, _
   ByVal parameters As String, _
   ByVal directory As String _
) As Boolean
```

[C#]

```
public bool RegisterProgram(
   int hostId,
   string command,
   string program,
   string parameters,
   string directory
);
```

Parameters

hostId
An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

command
A string which specifies the virtual path to the CGI program. This must be an absolute path, but does not have to specify a pre-existing virtual path or map to the directory structure of the root document directory for the server. The maximum length of the virtual path is 1024 characters.

program
A string which specifies the full path to the CGI program on the local system.

parameters
A string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the CGI program does not require any command line parameters, this parameter may be an empty string.

directory
An optional string that specifies the current working directory for the program. If this parameter is an empty string, the server will use the root document directory for the virtual host.

Return Value

A boolean value which specifies if the CGI program was registered with the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **RegisterProgram** method registers a CGI program and associates it with a virtual path. When the client issues a GET or POST command specifying the virtual path associated with the program, the program will be executed and the output return to the client.

The ***program*** string specifies file name of the CGI program. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple virtual paths that reference the same executable file. The only requirement is that the virtual path be unique for the given host. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the C:\Program Files folder.

It is important to note that the program specified by ***program*** must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The ***parameters*** string can specify additional command line parameters that should be passed to the CGI program as arguments. This string can also contain a placeholder named "%1" that will be replaced by the virtual path associated with the program. If this argument is omitted, no additional parameters are passed to the program.

The executable program that is registered using this program must be a console application that conforms to the CGI/1.1 specification defined in RFC 3875. Request data submitted by the client as part of a POST will be provided to the program as standard input. The output from the program must be written to standard output. The first lines of output from the program should be any response headers, followed by an empty line. Each line should be terminated with a carriage-return and linefeed (CRLF) sequence. If the CGI program outputs additional data to be processed by the client, it should provide Content-Type and Content-Length response headers.

When developing a CGI program, it is important to take into consideration the environment that it will be executing in. The program will be started as a child process of the server application, and will inherit the same privileges. This means that it will typically have access to the boot drive, the Windows folders and the system registry. CGI programs must ensure that all query parameters and request data submitted by the client have been validated.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

HttpServer.RegisterProgram Method (Int32, String, String, String)

Register a CGI program for use and associate it with a virtual path on the server.

[Visual Basic]

```
Overloads Public Function RegisterProgram( _
   ByVal hostId As Integer, _
   ByVal command As String, _
   ByVal program As String, _
   ByVal parameters As String _
) As Boolean
```

[C#]

```
public bool RegisterProgram(
   int hostId,
   string command,
   string program,
   string parameters
);
```

Parameters

hostId

An integer value which identifies the virtual host. A value of zero specifies that the default virtual host should be used.

command

A string which specifies the virtual path to the CGI program. This must be an absolute path, but does not have to specify a pre-existing virtual path or map to the directory structure of the root document directory for the server. The maximum length of the virtual path is 1024 characters.

program

A string which specifies the full path to the CGI program on the local system.

parameters

A string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the CGI program does not require any command line parameters, this parameter may be an empty string.

Return Value

A boolean value which specifies if the CGI program was registered with the server. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **RegisterProgram** method registers a CGI program and associates it with a virtual path. When the client issues a GET or POST command specifying the virtual path associated with the program, the program will be executed and the output return to the client.

The ***program*** string specifies file name of the CGI program. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple virtual paths that reference the same executable file. The only requirement is that the virtual path be unique for the given host. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the C:\Program Files folder.

It is important to note that the program specified by ***program*** must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The ***parameters*** string can specify additional command line parameters that should be passed to the CGI program as arguments. This string can also contain a placeholder named "%1" that will be replaced by the virtual path associated with the program. If this argument is omitted, no additional parameters are passed to the program.

The executable program that is registered using this program must be a console application that conforms to the CGI/1.1 specification defined in RFC 3875. Request data submitted by the client as part of a POST will be provided to the program as standard input. The output from the program must be written to standard output. The first lines of output from the program should be any response headers, followed by an empty line. Each line should be terminated with a carriage-return and linefeed (CRLF) sequence. If the CGI program outputs additional data to be processed by the client, it should provide Content-Type and Content-Length response headers.

When developing a CGI program, it is important to take into consideration the environment that it will be executing in. The program will be started as a child process of the server application, and will inherit the same privileges. This means that it will typically have access to the boot drive, the Windows folders and the system registry. HttpServer Class | SocketTools Namespace

HttpServer.RequireAuthentication Method (Int32, String)

Send a response to the client indicating that authentication is required.

[Visual Basic]

```
Overloads Public Function RequireAuthentication( _
   ByVal clientId As Integer, _
   ByVal realm As String _
) As Boolean
```

[C#]

```
public bool RequireAuthentication(
   int clientId,
   string realm
);
```

Parameters

clientId

An integer that identifies the client session.

realm

A string value that is displayed a web browser to indicate to the user which username and password they should use. If this parameter is omitted or is an empty string, the domain name the client used to establish the connection will be used.

Return Value

A boolean value which specifies if the response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **RequireAuthentication** method can be used within an **OnCommand** event handler to indicate to the client that it must provide a username and password to access the requested resource. The client should respond by issuing another request that includes the required credentials. To determine if a client has included valid credentials with its request, check the value of the **IsAuthenticated** property.

Some clients may require that the session be secure if authentication is requested or display warning messages to the user if the connection is not secure. If your application will require clients to authenticate before accessing specific resources, it is recommended that you enable security by setting the **Secure** property to **True** prior to starting the server.

Send a response to the client indicating that authentication is required.

[Visual Basic]
```
Overloads Public Function RequireAuthentication( _
   ByVal clientId As Integer _
) As Boolean
```

[C#]
```
public bool RequireAuthentication(
   int clientId
);
```

Parameters

clientId
An integer that identifies the client session.

Return Value

A boolean value which specifies if the response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **RequireAuthentication** method can be used within an **OnCommand** event handler to indicate to the client that it must provide a username and password to access the requested resource. The client should respond by issuing another request that includes the required credentials. To determine if a client has included valid credentials with its request, check the value of the **IsAuthenticated** property.

Some clients may require that the session be secure if authentication is requested or display warning messages to the user if the connection is not secure. If your application will require clients to authenticate before accessing specific resources, it is recommended that you enable security by setting the **Secure** property to **True** prior to starting the server.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.RequireAuthentication Overload List

HttpServer.RequireAuthentication Method (String)

Send a response to the client indicating that authentication is required.

```
[Visual Basic]
Overloads Public Function RequireAuthentication( _
   ByVal realm As String _
) As Boolean
```

```
[C#]
public bool RequireAuthentication(
   string realm
);
```

Parameters

realm

A string value that is displayed a web browser to indicate to the user which username and password they should use. If this parameter is omitted or is an empty string, the domain name the client used to establish the connection will be used.

Return Value

A boolean value which specifies if the response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **RequireAuthentication** method can be used within an **OnCommand** event handler to indicate to the client that it must provide a username and password to access the requested resource. The client should respond by issuing another request that includes the required credentials. To determine if a client has included valid credentials with its request, check the value of the **IsAuthenticated** property.

Some clients may require that the session be secure if authentication is requested or display warning messages to the user if the connection is not secure. If your application will require clients to authenticate before accessing specific resources, it is recommended that you enable security by setting the **Secure** property to **True** prior to starting the server.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer Class | SocketTools Namespace

HttpServer.ResolvePath Method (Int32, String, String, Boolean)

Resolve a path to its full virtual or local file name.

[Visual Basic]

```
Overloads Public Function ResolvePath( _
   ByVal clientId As Integer, _
   ByVal sourcePath As String, _
   ByRef resolvedPath As String, _
   ByVal isVirtual As Boolean _
) As Boolean
```

[C#]

```
public bool ResolvePath(
   int clientId,
   string sourcePath,
   ref string resolvedPath,
   bool isVirtual
);
```

Parameters

clientId
An integer that identifies the client session.

sourcePath
A string that specifies the name of the path to resolve. This may either be a virtual path, or a path to a local file name or directory.

resolvedPath
A string that will contain the resolved path when the method returns.

isVirtual
A Boolean parameter that specifies if the source path is a virtual path or local path.

Return Value

A boolean value which specifies if the source path could be resolved. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ResolvePath** method is used to resolve a local file name or directory to obtain its virtual path name, or obtain the full path name of a file or directory that is mapped to a virtual path. If the ***isVirtual*** parameter is **false**, the ***sourcePath*** parameter is considered to be a path to a local file or directory and the ***resolvedPath*** parameter will contain the virtual path. If the ***isVirtual*** parameter is **true**, then the s***ourcePath*** parameter is considered to be a virtual path and the ***resolvedPath*** parameter will contain the full path to the local file or directory that the virtual path is mapped to

A virtual path for the client is either relative to the server root directory, or the client home directory if the client was authenticated as a restricted user. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the ***SourcePath*** parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this method would return the virtual path to that directory as "/Documents/Research".

If the client session was authenticated as a restricted user, then the virtual path is always relative to the client home directory instead of the server root directory. This is because restricted users are isolated to their own home directory and any subdirectories. For example, if restricted user "John" has a home directory of "C:\ProgramData\MyServer\Users\John" and the ***SourcePath*** parameter was specified as "C:\ProgramData\MyServer\Users\John\Accounting\Projections.pdf" this method would return the virtual path as "/Accounting/Projections.pdf".

If the ***sourcePath*** parameter specifies a file or directory outside of the server root directory, this method will fail and the last error code will be set to **errorInvalidFileName**. This method can only be used with authenticated clients. If the ***clientId*** parameter specifies a client session that has not been authenticated, this method will fail and the last error code will be **errorAuthenticationRequired**.

HttpServer.ResolvePath Method (String, String, Boolean)

Resolve a path to its full virtual or local file name.

[Visual Basic]

```
Overloads Public Function ResolvePath( _
   ByVal sourcePath As String, _
   ByRef resolvedPath As String, _
   ByVal isVirtual As Boolean _
) As Boolean
```

[C#]

```
public bool ResolvePath(
   string sourcePath,
   ref string resolvedPath,
   bool isVirtual
);
```

Parameters

sourcePath
: A string that specifies the name of the path to resolve. This may either be a virtual path, or a path to a local file name or directory.

resolvedPath
: A string that will contain the resolved path when the method returns.

isVirtual
: A Boolean parameter that specifies if the source path is a virtual path or local path.

Return Value

A boolean value which specifies if the source path could be resolved. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **ResolvePath** method is used to resolve a local file name or directory to obtain its virtual path name, or obtain the full path name of a file or directory that is mapped to a virtual path. If the ***isVirtual*** parameter is **false**, the ***sourcePath*** parameter is considered to be a path to a local file or directory and the ***resolvedPath*** parameter will contain the virtual path. If the ***isVirtual*** parameter is **true**, then the s***ourcePath*** parameter is considered to be a virtual path and the ***resolvedPath*** parameter will contain the full path to the local file or directory that the virtual path is mapped to

A virtual path for the client is either relative to the server root directory, or the client home directory if the client was authenticated as a restricted user. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the ***SourcePath*** parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this method would return the virtual path to that directory as "/Documents/Research".

If the client session was authenticated as a restricted user, then the virtual path is always relative to the client home directory instead of the server root directory. This is because restricted users are isolated to their own home directory and any subdirectories. For example, if restricted user "John" has a home directory of "C:\ProgramData\MyServer\Users\John" and the ***SourcePath*** parameter was specified as "C:\ProgramData\MyServer\Users\John\Accounting\Projections.pdf" this method would return the virtual path as "/Accounting/Projections.pdf".

If the ***sourcePath*** parameter specifies a file or directory outside of the server root directory, this method will fail and the last error code will be set to **errorInvalidFileName**. This method can only be used with authenticated clients. If the ***clientId*** parameter specifies a client session that has not been authenticated, this method will fail and the last error code will be **errorAuthenticationRequired**.

HttpServer.Resume Method

Resume accepting new client connections.

[Visual Basic]

```
Public Function Resume() As Boolean
```

[C#]

```
public bool Resume();
```

Return Value

A boolean value which specifies if the server has resumed accepting client connections. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Resume** method instructs the server to resume accepting new client connections. Any pending client connections that were requested while the server was suspended will be accepted.

HttpServer Class | SocketTools Namespace

HttpServer.SendError Method (Int32, Int32, String)

Send an error result code and message to the client in response to a command.

[Visual Basic]

```
Overloads Public Function SendError( _
   ByVal clientId As Integer, _
   ByVal resultCode As Integer, _
   ByVal message As String _
) As Boolean
```

[C#]

```
public bool SendError(
   int clientId,
   int resultCode,
   string message
);
```

Parameters

clientId

An integer that identifies the client session.

resultCode

An integer value that specifies the error code that should be sent to the client. This value should correspond to the error result codes defined for HTTP in RFC 2616, which are three-digit values in the range of 400 through 599. The method will fail if an invalid error code is specified.

message

An string value that specifies a message to be sent to the client. If this parameter is an empty string, a default message associated with the result code will be used.

Return Value

A boolean value which specifies if the error response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SendError** method sends a response to the client indicating that an error has occurred, providing a numeric error code and HTML formatted text which may be displayed to the user. The ***Message*** parameter should provide a brief description of the error that will be included in the output sent to the client. Note that the message should not contain any special formatting control characters or HTML markup.

This method provides a simplified interface for sending an error response to the client. In some cases, a browser may choose to display its own error message to the user in place of the generic HTML document generated by this method. If you want your application to send a customized HTML document for a specific type of error, you should use the **SendResponse** method.

If you wish to redirect the client to use an alternate URL to access the requested resource, it is recommended that you use the **RedirectRequest** method rather than sending an error response.

HttpServer Class | SocketTools Namespace | HttpServer.SendError Overload List

HttpServer.SendError Method (Int32, Int32)

Send an error result code and message to the client in response to a command.

[Visual Basic]
```
Overloads Public Function SendError( _
   ByVal clientId As Integer, _
   ByVal resultCode As Integer _
) As Boolean
```

[C#]
```
public bool SendError(
   int clientId,
   int resultCode
);
```

Parameters

clientId

An integer that identifies the client session.

resultCode

An integer value that specifies the error code that should be sent to the client. This value should correspond to the error result codes defined for HTTP in RFC 2616, which are three-digit values in the range of 400 through 599. The method will fail if an invalid error code is specified.

Return Value

A boolean value which specifies if the error response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SendError** method sends a response to the client indicating that an error has occurred, providing a numeric error code and HTML formatted text which may be displayed to the user. The ***Message*** parameter should provide a brief description of the error that will be included in the output sent to the client. Note that the message should not contain any special formatting control characters or HTML markup.

This method provides a simplified interface for sending an error response to the client. In some cases, a browser may choose to display its own error message to the user in place of the generic HTML document generated by this method. If you want your application to send a customized HTML document for a specific type of error, you should use the **SendResponse** method.

If you wish to redirect the client to use an alternate URL to access the requested resource, it is recommended that you use the **RedirectRequest** method rather than sending an error response.

HttpServer Class | SocketTools Namespace | HttpServer.SendError Overload List

HttpServer.SendError Method (Int32, String)

Send an error result code and message to the client in response to a command.

[Visual Basic]

```
Overloads Public Function SendError( _
   ByVal resultCode As Integer, _
   ByVal message As String _
) As Boolean
```

[C#]

```
public bool SendError(
   int resultCode,
   string message
);
```

Parameters

resultCode

An integer value that specifies the error code that should be sent to the client. This value should correspond to the error result codes defined for HTTP in RFC 2616, which are three-digit values in the range of 400 through 599. The method will fail if an invalid error code is specified.

message

An string value that specifies a message to be sent to the client. If this parameter is an empty string, a default message associated with the result code will be used.

Return Value

A boolean value which specifies if the error response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SendError** method sends a response to the client indicating that an error has occurred, providing a numeric error code and HTML formatted text which may be displayed to the user. The ***Message*** parameter should provide a brief description of the error that will be included in the output sent to the client. Note that the message should not contain any special formatting control characters or HTML markup.

This method provides a simplified interface for sending an error response to the client. In some cases, a browser may choose to display its own error message to the user in place of the generic HTML document generated by this method. If you want your application to send a customized HTML document for a specific type of error, you should use the **SendResponse** method.

If you wish to redirect the client to use an alternate URL to access the requested resource, it is recommended that you use the **RedirectRequest** method rather than sending an error response.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer Class | SocketTools Namespace | HttpServer.SendError Overload List

HttpServer.SendError Method (Int32)

Send an error result code and message to the client in response to a command.

[Visual Basic]

```
Overloads Public Function SendError( _
   ByVal resultCode As Integer _
) As Boolean
```

[C#]

```
public bool SendError(
   int resultCode
);
```

Parameters

resultCode

An integer value that specifies the error code that should be sent to the client. This value should correspond to the error result codes defined for HTTP in RFC 2616, which are three-digit values in the range of 400 through 599. The method will fail if an invalid error code is specified.

Return Value

A boolean value which specifies if the error response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SendError** method sends a response to the client indicating that an error has occurred, providing a numeric error code and HTML formatted text which may be displayed to the user. The ***Message*** parameter should provide a brief description of the error that will be included in the output sent to the client. Note that the message should not contain any special formatting control characters or HTML markup.

This method provides a simplified interface for sending an error response to the client. In some cases, a browser may choose to display its own error message to the user in place of the generic HTML document generated by this method. If you want your application to send a customized HTML document for a specific type of error, you should use the **SendResponse** method.

If you wish to redirect the client to use an alternate URL to access the requested resource, it is recommended that you use the **RedirectRequest** method rather than sending an error response.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer Class | SocketTools Namespace

HttpServer.SendResponse Method (Int32, Int32, Byte[], Int32)

Send a result code and message to the client in response to a command.

[Visual Basic]

```
Overloads Public Function SendResponse( _
   ByVal clientId As Integer, _
   ByVal resultCode As Integer, _
   ByVal responseData As Byte(), _
   ByVal responseSize As Integer _
) As Boolean
```

[C#]

```
public bool SendResponse(
   int clientId,
   int resultCode,
   byte[] responseData,
   int responseSize
);
```

Parameters

clientId
An integer that identifies the client session.

resultCode
An integer value that specifies the command result code to be returned to the client.

responseData
A byte array that contains data that should be returned to the client in response to a request.

responseSize
An integer value that specifies the number of bytes of data that should be sent to the client.

Return Value

A boolean value which specifies if the response was sent to the client. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SendResponse** method is used to respond to a command issued by the client from within an **OnCommand** event handler. Command responses are normally handled by the server as a normal part of processing a command and this method is only used if the application has implemented custom commands or wishes to modify the standard responses sent by the server.

Result codes must be three digits (in the range of 100 through 999) and although this method will support the use of non-standard result codes, it is recommended that the client application use the standard codes defined in RFC 2616 whenever possible. The use of non-standard result codes may cause problems with HTTP clients that expect specific result codes in response to a particular command.

If you do not wish to return any data to the client in response to its request (for example, if you want the response to only consist of the headers set using the **SetHeader** method), then you can use the overloaded version of this method that omits the ***responseData*** parameter, and you should specify a result code of 204. This tells the client that the request was successful and there is no data included with the response.

This method should only be called once in response to a command sent by the client. If a result code has already been sent in response to a command and this method is called, it will fail and return an error. This is necessary because sending multiple result codes in response to a single command may cause unpredictable behavior by the client.

This version of the method would typically be used when returning binary data to the client. For textual data, such as an HTML or XML response, it is recommended that you use the overloaded version of this method that accepts a string.

The **SendResponse** method is used to respond to a command issued by the client from within an **OnCommand** event handler. Command responses are normally handled by the server as a normal part of processing a command and this method is only used if the application has implemented custom commands or wishes to modify the standard responses sent by the server.

Result codes must be three digits (in the range of 100 through 999) and although this method will support the use of non-standard result codes, it is recommended that the client application use the standard codes defined in RFC 2616 whenever possible. The use of non-standard result codes may cause problems with HTTP clients that expect specific result codes in response to a particular command.

This version of the method would be used when you do not need to provide any response data to the client. For successful responses, it is recommended that you specify a result code of 204 which tells the client that the response will not include any data.

To send an error response to the client, it is recommended that you use the **SendError** method. This will ensure that a valid error response will be sent to the client, including a default HTML page that can be displayed by a browser to notify a user of the error condition.

HttpServer Class | SocketTools Namespace

HttpServer.SetHeader Method (Int32, String, String)

Create or change the value of a response header for the client session.

[Visual Basic]

```
Overloads Public Function SetHeader( _
   ByVal clientId As Integer, _
   ByVal headerName As String, _
   ByVal headerValue As String _
) As Boolean
```

[C#]

```
public bool SetHeader(
   int clientId,
   string headerName,
   string headerValue
);
```

Parameters

clientId
An integer that identifies the client session.

headerName
A string that specifies the name of the header field. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value.

headerValue
A string variable that contains the new value of the response header.

Return Value

A boolean value which specifies if the response header was created or modified. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SetHeader** method will change the value of a response header for the specified client session, typically within an **OnCommand** event handler. If the ***headerName*** value matches an existing header field, its value will be replaced. If the header name is not defined, then a new header will be created with the given value. You should not change the value of most standard response header values unless you are certain of the impact that it would have on the normal operation of the client.

If you wish to define a custom header value that would be included in the response to a client request, you should prefix the header name with "X-" to avoid potential conflicts with the standard response headers. For example, if you wanted to identify a customer, you could create a header field with the name "X-Customer-ID" and set the value to the customer ID number. The client application would receive this custom header value as part of the response to its request for a document.

HttpServer Class | SocketTools Namespace | HttpServer.SetHeader Overload List

HttpServer.SetHeader Method (String, String)

Create or change the value of a response header for the client session.

[Visual Basic]

```
Overloads Public Function SetHeader( _
   ByVal headerName As String, _
   ByVal headerValue As String _
) As Boolean
```

[C#]

```
public bool SetHeader(
   string headerName,
   string headerValue
);
```

Parameters

headerName

A string that specifies the name of the header field. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value.

headerValue

A string variable that contains the new value of the response header.

Return Value

A boolean value which specifies if the response header was created or modified. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SetHeader** method will change the value of a response header for the specified client session, typically within an **OnCommand** event handler. If the ***headerName*** value matches an existing header field, its value will be replaced. If the header name is not defined, then a new header will be created with the given value. You should not change the value of most standard response header values unless you are certain of the impact that it would have on the normal operation of the client.

If you wish to define a custom header value that would be included in the response to a client request, you should prefix the header name with "X-" to avoid potential conflicts with the standard response headers. For example, if you wanted to identify a customer, you could create a header field with the name "X-Customer-ID" and set the value to the customer ID number. The client application would receive this custom header value as part of the response to its request for a document.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

HttpServer Class | SocketTools Namespace

HttpServer.SetVariable Method (Int32, String, String)

Create or change the value of a CGI environment variable for the specified client.

```
[Visual Basic]
Overloads Public Function SetVariable( _
   ByVal clientId As Integer, _
   ByVal variableName As String, _
   ByVal variableValue As String _
) As Boolean
```

```
[C#]
public bool SetVariable(
   int clientId,
   string variableName,
   string variableValue
);
```

Parameters

clientId
An integer that identifies the client session.

variableName
A string that specifies the name of the header field. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value.

variableValue
A string variable that contains the new value of the response header.

Return Value

A boolean value which specifies if the environment variable was created or modified. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SetVariable** method will change the value of a environment variable for the specified client session, typically within an **OnCommand** event handler. If the ***variableName*** value matches an existing variable, its value will be replaced. If the variable is not defined, then a new variable will be created with the given value. The value of an environment variable can be obtained using the **GetVariable** function.

The server will automatically create a number of different environment variables that will be passed to a program or script executed by the server. These variables are defined in RFC 3875 as part of the Common Gateway Interface (CGI) 1.1 specification. The following variables are defined by the server and should not be modified directly by the application:

AUTH_TYPE	The authorization scheme used by the server to authenticate the client session.
CONTENT_LENGTH	The length of the request data provided by the client.
CONTENT_TYPE	The MIME type that identifies the type of content provided by the client.
DOCUMENT_ROOT	The full path to the local document root directory on the server.
GATEWAY_INTERFACE	The version of the Common Gateway Interface that is being used by the server.

PATH_INFO	The resource or sub-resource that is to be returned by the program or script.
PATH_TRANSLATED	The path information mapped to the server root document directory structure.
QUERY_STRING	The URL encoded query parameters passed to the program or script.
REMOTE_ADDR	The network address of the client sending the request to the server.
REMOTE_HOST	The same value as the REMOTE_ADDR variable.
REMOTE_USER	The username specified as part of the authentication credentials provided by the client.
REQUEST_METHOD	The method used by the client to request the resource.
REQUEST_URI	The URI for the script provided by the client.
SCRIPT_FILENAME	The full path to the program or script on the server.
SCRIPT_NAME	The path to the program or script specified by the client.
SERVER_NAME	The hostname or IP address of the server that the client connected to.
SERVER_PORT	The port number that the client used to connect to the server.
SERVER_PORT_SECURE	This variable has a value of "1" if the client connection to the server is secure.
SERVER_PROTOCOL	The version of the server protocol used.
SERVER_SOFTWARE	The server identity string which specifies the application name and version.

In addition to the environment variables listed, the server will also create variables that are prefixed with "HTTP_" that are set to the value of request headers that are not otherwise defined. For example, the HTTP_USER_AGENT variable will be set to the value of the User-Agent header provided by the client as part of the request.

Note that calling the **SetVariable** method from within the **OnExecute** event handler will have no effect because it occurs after the CGI program or script has completed execution. To create or modify environment variables for the client session, it should be done within an **OnCommand** event handler.

This method will not change the environment block for the server process. Each client session is allocated its own private environment block which is inherited by the CGI program. When the client session terminates, the memory allocated for its environment is released.

HttpServer Class | SocketTools Namespace | HttpServer.SetVariable Overload List

HttpServer.SetVariable Method (String, String)

Create or change the value of a CGI environment variable for the specified client.

[Visual Basic]

```
Overloads Public Function SetVariable( _
   ByVal variableName As String, _
   ByVal variableValue As String _
) As Boolean
```

[C#]

```
public bool SetVariable(
   string variableName,
   string variableValue
);
```

Parameters

variableName

A string that specifies the name of the header field. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value.

variableValue

A string variable that contains the new value of the response header.

Return Value

A boolean value which specifies if the environment variable was created or modified. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **SetVariable** method will change the value of a environment variable for the specified client session, typically within an **OnCommand** event handler. If the ***variableName*** value matches an existing variable, its value will be replaced. If the variable is not defined, then a new variable will be created with the given value. The value of an environment variable can be obtained using the **GetVariable** method.

Note that calling the **SetVariable** method from within the **OnExecute** event handler will have no effect because it occurs after the CGI program or script has completed execution. To create or modify environment variables for the client session, it should be done within an **OnCommand** event handler.

This method will not change the environment block for the server process. Each client session is allocated its own private environment block which is inherited by the CGI program. When the client session terminates, the memory allocated for its environment is released.

This version of the method uses the active client session and should only be called from within a server event handler. To specify a client session outside of an event handler, use the version of this method that accepts a client ID parameter.

Start listening for client connections on the specified IP address and port number.

public bool Start(string,int,string);

Start listening for client connections on the specified IP address and port number.

public bool Start(string,int,string,int);

Start listening for client connections on the specified IP address and port number.

public bool Start(string,int,string,int,int);

Start listening for client connections on the specified IP address and port number.

public bool Start(string,int,string,int,int,ServerOptions);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Start Method (String, Int32, String, Int32, Int32, ServerOptions)

Start listening for client connections on the specified IP address and port number.

[Visual Basic]
```
Overloads Public Function Start( _
   ByVal localAddress As String, _
   ByVal localPort As Integer, _
   ByVal rootDirectory As String, _
   ByVal maxClients As Integer, _
   ByVal idleTime As Integer, _
   ByVal options As ServerOptions _
) As Boolean
```

[C#]
```
public bool Start(
   string localAddress,
   int localPort,
   string rootDirectory,
   int maxClients,
   int idleTime,
   ServerOptions options
);
```

Parameters

localAddress

A string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

localPort

An integer that specifies the port number the server should use to listen for client connections. If a value of zero is specified, the server will use the standard port number 80 to listen for connections, or port 443 if the server is configured to use implicit SSL. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

rootDirectory

A string that specifies the path to the root directory for the server. If this value is an empty string, the server will use the current working directory as the root directory.

maxClients

An integer value that specifies the maximum number of clients that may connect to the server.

idleTime

An integer value that specifies the number of seconds a client can be idle before the server terminates the session.

options

A ServerOptions enumeration that specifies one or more server options.

Return Value

A boolean value which specifies if the server was started. A return value of **true** specifies that the server has been successfully started. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 SP1 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

It is recommended that you always specify an absolute path for the server root directory, either by passing the full pathname as an argument to this method or by setting the **Directory** property. If the path includes environment variables surrounded by percent (%) symbols, they will be automatically expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. If the root directory does not exist at the time that the server is started, it will be created.

[C#]

```
public bool Start();
```

Return Value

A boolean value which specifies if the server was started. A return value of **true** specifies that the server has been successfully started. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 SP1 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

It is recommended that you always specify an absolute path for the server root directory, either by passing the full pathname as an argument to this method or by setting the **Directory** property. If the path includes environment variables surrounded by percent (%) symbols, they will be automatically expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. If the root directory does not exist at the time that the server is started, it will be created.

See Also

HttpServer Class | SocketTools Namespace | HttpServer.Start Overload List

HttpServer.Stop Method

Stop listening for new client connections and terminate all active clients already connected to the server.

[Visual Basic]

```
Public Function Stop() As Boolean
```

[C#]

```
public bool Stop();
```

Return Value

A boolean value which specifies if the server was stopped. A return value of **true** specifies that the server has been successfully stopped. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Stop** method instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. If this method is called when there is one or more clients connected to the server, it will signal each client thread to terminate and then wait for the server thread to terminate.

See Also

HttpServer Class | SocketTools Namespace | Restart Method | Resume Method | Start Method | Throttle Method

HttpServer.Suspend Method

Suspend accepting new client connections.

[Visual Basic]
```
Public Function Suspend() As Boolean
```

[C#]
```
public bool Suspend();
```

Return Value

A boolean value which specifies if the server has been suspended. A return value of **true** specifies that the server has been successfully stopped. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Suspend** method instructs the server to suspend accepting new client connections. All new clients that attempt to connect to the server will be will be immediately rejected by the server. To resume accepting new client connections, call the **Resume** method. This method will not affect those clients that have already established a connection with the server before the **Suspend** method was called.

HttpServer.Throttle Method

Limit the maximum number of client connections.

Overload List

Limit the maximum number of client connections.

public bool Throttle(int);

Limit the maximum number of client connections and connections per IP address.

public bool Throttle(int,int);

Limit the maximum number of client connections, connections per IP address and connection rate.

public bool Throttle(int,int,int);

See Also

HttpServer Class | SocketTools Namespace

HttpServer.Throttle Method (Int32, Int32, Int32)

Limit the maximum number of client connections, connections per IP address and connection rate.

[Visual Basic]

```
Overloads Public Function Throttle( _
   ByVal maxClients As Integer, _
   ByVal maxClientsPerAddress As Integer, _
   ByVal connectionRate As Integer _
) As Boolean
```

[C#]

```
public bool Throttle(
   int maxClients,
   int maxClientsPerAddress,
   int connectionRate
);
```

Parameters

maxClients

An integer value that specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

maxClientsPerAddress

An integer value that specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

connectionRate

An integer value that specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

A boolean value which specifies if the method was successful. A return value of **true** indicates success. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then the **Throttle** method is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

If the value of the ***maxGuests*** parameter is greater than zero, then anonymous logins will be enabled and clients can authenticate with the username "anonymous" and their email address as the password. If the parameter is set to zero, then anonymous logins will be disabled. Note that this will not affect any clients that are currently logged in, it only affects those clients that connect after the **Throttle** method has been called.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

HttpServer.Throttle Method (Int32, Int32)

Limit the maximum number of client connections and connections per IP address.

[Visual Basic]

```
Overloads Public Function Throttle( _
   ByVal maxClients As Integer, _
   ByVal maxClientsPerAddress As Integer _
) As Boolean
```

[C#]

```
public bool Throttle(
   int maxClients,
   int maxClientsPerAddress
);
```

Parameters

maxClients

An integer value that specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

maxClientsPerAddress

An integer value that specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

Return Value

A boolean value which specifies if the method was successful. A return value of **true** indicates success. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then the **Throttle** method is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

HttpServer.Uninitialize Method

Uninitialize the class library and release any resources allocated for the server.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the server and unloads the networking library. After this method has been called, no further network operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

HttpServer Class | SocketTools Namespace | Initialize Method

HttpServer Events

The events of the **HttpServer** class are listed below. For a complete list of **HttpServer** class members, see the HttpServer Members topic.

Public Instance Events

⚡ OnAuthenticate	Occurs when the client has requested authentication with the specified username and password.
⚡ OnCommand	Occurs when a client has issued a command to the server.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnDownload	Occurs when a connection is established with the remote host.
⚡ OnError	Occurs when an network operation fails.
⚡ OnExecute	Occurs when the client has executed an external script handler on the server.
⚡ OnIdle	Occurs when the there are no clients connected to the server.
⚡ OnResult	Occurs when the command issued by the client has been processed by the server.
⚡ OnStart	Occurs when the server starts accepting connections.
⚡ OnStop	Occurs when the server stops accepting connections.
⚡ OnTimeout	Occurs when the client has exceeded the maximum allowed idle time.
⚡ OnUpload	Occurs when the client has successfully uploaded a file to the server.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.OnAuthenticate Event

Occurs when the client has requested authentication with the specified username and password.

[Visual Basic]

```
Public Event OnAuthenticate As OnAuthenticateEventHandler
```

[C#]

```
public event OnAuthenticateEventHandler OnAuthenticate;
```

Event Data

The event handler receives an argument of type HttpServer.AuthenticateEventArgs containing data related to this event. The following **HttpServer.AuthenticateEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
HostName	Gets the host name used by the client to establish the connection to the server.
Password	Gets the password provided by the client for authentication.
UserName	Gets the password provided by the client for authentication.

Remarks

The **OnAuthenticate** event occurs when the client has requested authentication by sending the USER and PASS command to the server. The event handler can call the **Authenticate** method to authenticate the client session. If the client is not authenticated, the server will send an error message to the client and terminate the session.

If the application has created one or more virtual users using the **AddUser** method and/or the **LocalUser** property has been set to **True**, it is not necessary to implement an **OnAuthenticate** handler unless you also wish to perform custom authentication for specific users.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

Public Instance Constructors

HttpServer.AuthenticateEventArgs Constructor	Initializes a new instance of the HttpServer.AuthenticateEventArgs class.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
HostName	Gets the host name used by the client to establish the connection to the server.
Password	Gets the password provided by the client for authentication.
UserName	Gets the password provided by the client for authentication.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

HttpServer.AuthenticateEventArgs Class | SocketTools Namespace

HttpServer.AuthenticateEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

HttpServer.AuthenticateEventArgs Class | SocketTools Namespace

HttpServer.AuthenticateEventArgs.HostName Property

Gets the host name used by the client to establish the connection to the server.

[Visual Basic]

```
Public ReadOnly Property HostName As String
```

[C#]

```
public string HostName {get;}
```

Property Value

A string that specifies a host name.

See Also

HttpServer.AuthenticateEventArgs.Password Property

Gets the password provided by the client for authentication.

[Visual Basic]

```
Public ReadOnly Property Password As String
```

[C#]

```
public string Password {get;}
```

Property Value

A string that specifies the password provided by the client when it requests authentication.

See Also

HttpServer.AuthenticateEventArgs Class | SocketTools Namespace

HttpServer.AuthenticateEventArgs.UserName Property

Gets the password provided by the client for authentication.

[Visual Basic]

```
Public ReadOnly Property UserName As String
```

[C#]

```
public string UserName {get;}
```

Property Value

A string that specifies the username provided by the client when it requests authentication.

See Also

HttpServer.AuthenticateEventArgs Class | SocketTools Namespace

HttpServer.OnCommand Event

Occurs when a client has issued a command to the server.

[Visual Basic]

```
Public Event OnCommand As OnCommandEventHandler
```

[C#]

```
public event OnCommandEventHandler OnCommand;
```

Event Data

The event handler receives an argument of type HttpServer.CommandEventArgs containing data related to this event. The following **HttpServer.CommandEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
Command	Gets a value that specifies the command issued by the client.
Parameters	Gets a value that specifies the command parameters issued by the client.
Resource	Gets a value that specifies the resource requested by the client.

Remarks

The **OnCommand** event occurs after the client has sent a command to the server, but before the command has been processed. This event occurs for all commands issued by the client, including invalid or disabled commands. If the application wishes to handle the command itself, it must perform any processing and then call the **SendResponse** method to send the success or error code to the client. If the **SendResponse** method is not called, then the server will perform its default processing for the command.

After the command has been processed, the **OnResult** event handler will be invoked.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

HttpServer.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As OnConnectEventHandler
```

[C#]

```
public event OnConnectEventHandler OnConnect;
```

Event Data

The event handler receives an argument of type HttpServer.ConnectEventArgs containing data related to this event. The following **HttpServer.ConnectEventArgs** properties provide information specific to this event.

Property	Description
ClientAddress	Gets the address of the client establishing the connection.
ClientId	Gets a value that uniquely identifies the client session.

Remarks

The **OnConnect** event occurs after the client has established its initial connection to the server, after the server has checked the active client limits and the TLS handshake has been performed if required. If the server has been suspended, or the limit on the maximum number of client sessions has been exceeded, the server will terminate the client session prior to this event handler being invoked.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

HttpServer.OnDownload Event

Occurs when a connection is established with the remote host.

[Visual Basic]
```
Public Event OnDownload As OnDownloadEventHandler
```

[C#]
```
public event OnDownloadEventHandler OnDownload;
```

Event Data

The event handler receives an argument of type HttpServer.DownloadEventArgs containing data related to this event. The following **HttpServer.DownloadEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
FileName	Gets a value that specifies the file being downloaded.
FileSize	Gets a value that specifies the size of the file.

Remarks

The **OnDownload** event occurs after the client has successfully downloaded a file from the server using the GET command. If the file transfer fails or is aborted, this event will not occur.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

HttpServer.DownloadEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

HttpServer.DownloadEventArgs Class | SocketTools Namespace

HttpServer.DownloadEventArgs.FileName Property

Gets a value that specifies the file being downloaded.

[Visual Basic]

```
Public ReadOnly Property FileName As String
```

[C#]

```
public string FileName {get;}
```

Property Value

A string that specifies the full path to a file on the local system.

See Also

HttpServer.DownloadEventArgs Class | SocketTools Namespace

HttpServer.DownloadEventArgs.FileSize Property

Gets a value that specifies the size of the file.

[Visual Basic]

```
Public ReadOnly Property FileSize As Long
```

[C#]

```
public long FileSize {get;}
```

Property Value

A long integer value that specifies the size of the file in bytes.

HttpServer.DownloadEventArgs Class | SocketTools Namespace

HttpServer.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]
```
Public Event OnDisconnect As OnDisconnectEventHandler
```

[C#]
```
public event OnDisconnectEventHandler OnDisconnect;
```

Event Data

The event handler receives an argument of type HttpServer.DisconnectEventArgs containing data related to this event. The following **HttpServer.DisconnectEventArgs** property provides information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the client and there is no more data available to be read.

It is not necessary to call the **Disconnect** method inside the **OnDisconnect** event handler because the client session is already in the process of disconnecting from the server.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

HttpServer.DisconnectEventArgs overview

Public Instance Constructors

HttpServer.DisconnectEventArgs Constructor	Initializes a new instance of the HttpServer.DisconnectEventArgs class.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

HttpServer.OnError Event

Occurs when an network operation fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type HttpServer.ErrorEventArgs containing data related to this event. The following **HttpServer.ErrorEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a network operation fails.

This event handler may be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

HttpServer.OnExecute Event

Occurs when the client has executed an external script handler on the server.

[Visual Basic]

```
Public Event OnExecute As OnExecuteEventHandler
```

[C#]

```
public event OnExecuteEventHandler OnExecute;
```

Event Data

The event handler receives an argument of type HttpServer.ExecuteEventArgs containing data related to this event. The following **HttpServer.ExecuteEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
ExitCode	Gets a value that specifies the exit code for the script handler.
Output	Gets the output of the script handler executed by the client.
Parameters	Gets a value that specifies the parameters included in the request.
Resource	Gets a value that specifies the resource requested by the client.

Remarks

The **OnExecute** event occurs after the client has successfully executed an external script handler.

This event will only be generated if the client has the **httpAccessExecute** permission. Clients are not granted this permission by default, and must be explicitly permitted to execute external programs. If the client does have this permission, it can only execute specific programs that have been registered by the server application using the **RegisterProgram** method.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

HttpServer.ExecuteEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

HttpServer.ExecuteEventArgs Class | SocketTools Namespace

HttpServer.ExecuteEventArgs.ExitCode Property

Gets a value that specifies the exit code for the script handler.

[Visual Basic]

```
Public ReadOnly Property ExitCode As Integer
```

[C#]

```
public int ExitCode {get;}
```

Property Value

An integer value that specifies an exit code.

See Also

HttpServer.ExecuteEventArgs Class | SocketTools Namespace

HttpServer.ExecuteEventArgs.Output Property

Gets the output of the script handler executed by the client.

[Visual Basic]

```
Public ReadOnly Property Output As String
```

[C#]

```
public string Output {get;}
```

Property Value

A string that contains the output of the script handler executed on behalf of the client.

See Also

HttpServer.ExecuteEventArgs Class | SocketTools Namespace

HttpServer.ExecuteEventArgs.Resource Property

Gets a value that specifies the resource requested by the client.

[Visual Basic]

```
Public ReadOnly Property Resource As String
```

[C#]

```
public string Resource {get;}
```

Property Value

A string that specifies the virtual path to the script or executable that was requested by the client.

See Also

HttpServer.ExecuteEventArgs Class | SocketTools Namespace

HttpServer.OnIdle Event

Occurs when the there are no clients connected to the server.

[Visual Basic]

```
Public Event OnIdle As EventHandler
```

[C#]

```
public event EventHandler OnIdle;
```

Remarks

This event will only occur after at least one client has connected to the server and then closes its connection or is disconnected. This event will not occur immediately after the server has started using the **Start** method, and will not occur when the server is stopped using the **Stop** method. Your application should implement an **OnStart** event handler for when the server first starts, and an **OnStop** event handler for when the server is stopped.

If one or more new client connections are accepted after this event occurs, the event will be generated again when those clients disconnect and the active client count drops to zero. Therefore it is to be expected that this event will occur multiple times over the lifetime of the server as it continues to listen for connections

This event handler will be invoked in the context of the worker thread that is managing the server, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

See Also

HttpServer Class | SocketTools Namespace

HttpServer.OnResult Event

Occurs when the command issued by the client has been processed by the server.

[Visual Basic]
```
Public Event OnResult As OnResultEventHandler
```

[C#]
```
public event OnResultEventHandler OnResult;
```

Event Data

The event handler receives an argument of type HttpServer.ResultEventArgs containing data related to this event. The following **HttpServer.ResultEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
Command	Gets a value that specifies the command issued by the client.
Resource	Gets a value that specifies the resource requested by the client.
ResultCode	Gets the result code associated with the last command issued by the client.

Remarks

The **OnResult** event occurs after the server has processed a command issued by the client. This event will inform the application whether the command that was issued by the client was successful or not. If the command was successful, then other related events such as **OnDownload** may also fire after this event.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

HttpServer.ResultEventArgs Class | SocketTools Namespace

HttpServer.ResultEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

HttpServer.ResultEventArgs Class | SocketTools Namespace

HttpServer.ResultEventArgs.Command Property

Gets a value that specifies the command issued by the client.

[Visual Basic]

```
Public ReadOnly Property Command As String
```

[C#]

```
public string Command {get;}
```

Property Value

A string that specifies the command sent by the client.

See Also

HttpServer.ResultEventArgs Class | SocketTools Namespace

HttpServer.ResultEventArgs.ResultCode Property

Gets the result code associated with the last command issued by the client.

[Visual Basic]

```
Public ReadOnly Property ResultCode As Integer
```

[C#]

```
public int ResultCode {get;}
```

Property Value

An integer value that indicates if the command completed successfully.

Remarks

The **ResultCode** property is a three-digit numeric code that is used to indicate success or failure. These codes are defined as part of the Hypertext Transfer Protocol standard, with values in the range of 200-299 indicating success. Values in the range of 400-499 and 500-599 indicate failure due to various error conditions. Examples of such failures would be attempting to access a file that does not exist, issuing an unrecognized command or attempting to perform a privileged operation.

See Also

HttpServer.ResultEventArgs Class | SocketTools Namespace

HttpServer.OnStart Event

Occurs when the server starts accepting connections.

[Visual Basic]

```
Public Event OnStart As EventHandler
```

[C#]

```
public event EventHandler OnStart;
```

Remarks

The **OnStart** event occurs after the **Start** method has been called and the server and begins listening for connections from clients. An application can use this event to update the user interface and perform any additional initialization functions that are required by the application

See Also

HttpServer Class | SocketTools Namespace

HttpServer.OnStop Event

Occurs when the server stops accepting connections.

[Visual Basic]

```
Public Event OnStop As EventHandler
```

[C#]

```
public event EventHandler OnStop;
```

Remarks

The **OnStop** event occurs after the **Stop** method has been called and all active client sessions have terminated. An application can use this event to update the user interface and perform any additional cleanup functions that are required by the application. If the server has a large number of active clients, this event may not occur immediately. The **OnDisconnect** event will fire for each client as the server is in the process of shutting down. During the shutdown process, the server is still considered to be active, however it will not accept any further connections. When the **OnStop** event is fired, the server thread has terminated and the listening socket has been closed.

This event will not occur if the server is forcibly stopped using the **Reset** method, or when the **Uninitialize** method is called prior to disposing an instance of the control. Applications that depend on this event should ensure that the server is shutdown gracefully using the **Stop** method prior to terminating the application

HttpServer Class | SocketTools Namespace

HttpServer.OnTimeout Event

Occurs when the client has exceeded the maximum allowed idle time.

[Visual Basic]
```
Public Event OnTimeout As OnTimeoutEventHandler
```

[C#]
```
public event OnTimeoutEventHandler OnTimeout;
```

Event Data

The event handler receives an argument of type HttpServer.TimeoutEventArgs containing data related to this event. The following **HttpServer.TimeoutEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
Elapsed	Gets the amount of time that the client was idle.

Remarks

The **OnTimeout** event occurs after the client has has exceeded the maximum allowed idle time, and immediately before the client is disconnected from the server. This event will never occur during a file transfer or directory listing.

To change the default idle timeout period for all clients, set the **IdleTime** property prior to starting the server. To set the idle timeout period for a specific client, set the **ClientIdle** property in the **OnConnect** event handler.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

HttpServer.TimeoutEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

HttpServer.TimeoutEventArgs Class | SocketTools Namespace

HttpServer.OnUpload Event

Occurs when the client has successfully uploaded a file to the server.

[Visual Basic]

```
Public Event OnUpload As OnUploadEventHandler
```

[C#]

```
public event OnUploadEventHandler OnUpload;
```

Event Data

The event handler receives an argument of type HttpServer.UploadEventArgs containing data related to this event. The following **HttpServer.UploadEventArgs** properties provide information specific to this event.

Property	Description
ClientId	Gets a value that uniquely identifies the client session.
FileName	Gets a value that specifies the file being uploaded.
FileSize	Gets a value that specifies the size of the file.

Remarks

The **OnUpload** event occurs after the client has successfully uploaded a file to the server using the PUT command. If the file transfer fails or is aborted, this event will not occur.

This event handler will be invoked in the context of the worker thread that is managing the client session, not the thread that created an instance of the class. Because UI components should only be modified by the thread that created them, the event handler should never attempt to update the user interface directly.

ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

HttpServer.UploadEventArgs Properties

The properties of the **HttpServer.UploadEventArgs** class are listed below. For a complete list of **HttpServer.UploadEventArgs** class members, see the HttpServer.UploadEventArgs Members topic.

Public Instance Properties

ClientId	Gets a value that uniquely identifies the client session.
FileName	Gets a value that specifies the file being uploaded.
FileSize	Gets a value that specifies the size of the file.

See Also

HttpServer.UploadEventArgs Class | SocketTools Namespace

HttpServer.UploadEventArgs.ClientId Property

Gets a value that uniquely identifies the client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which identifies the client session.

Remarks

The **ClientId** property returns a unique integer value that identifies the client session that generated the event.

See Also

HttpServer.UploadEventArgs Class | SocketTools Namespace

HttpServer.UploadEventArgs.FileName Property

Gets a value that specifies the file being uploaded.

[Visual Basic]

```
Public ReadOnly Property FileName As String
```

[C#]

```
public string FileName {get;}
```

Property Value

A string that specifies the full path to a file on the local system.

See Also

HttpServer.UploadEventArgs Class | SocketTools Namespace

HttpServer.UploadEventArgs.FileSize Property

Gets a value that specifies the size of the file.

[Visual Basic]

```
Public ReadOnly Property FileSize As Long
```

[C#]

```
public long FileSize {get;}
```

Property Value

A long integer value that specifies the size of the file in bytes.

HttpServer.UploadEventArgs Class | SocketTools Namespace

HttpServer.OnAuthenticateEventHandler Delegate

Represents the method that will handle the OnAuthenticate event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnAuthenticateEventHandler( _
   ByVal sender As Object, _
   ByVal e As AuthenticateEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnAuthenticateEventHandler(
      object sender,
      AuthenticateEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An AuthenticateEventArgs that contains the event data.

Remarks

When you create an **OnAuthenticateEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnAuthenticateEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

See Also

SocketTools Namespace

HttpServer.OnCommandEventHandler Delegate

Represents the method that will handle the OnCommand event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnCommandEventHandler( _
   ByVal sender As Object, _
   ByVal e As CommandEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnCommandEventHandler(
      object sender,
      CommandEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An CommandEventArgs that contains the event data.

Remarks

When you create an **OnCommandEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnCommandEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

SocketTools Namespace

HttpServer.OnConnectEventHandler Delegate

Represents the method that will handle the OnConnect event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnConnectEventHandler( _
   ByVal sender As Object, _
   ByVal e As ConnectEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnConnectEventHandler(
      object sender,
      ConnectEventArgs e
   );
```

Parameters

sender
: The source of the event.

e
: An ConnectEventArgs that contains the event data.

Remarks

When you create an **OnConnectEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnConnectEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

SocketTools Namespace

HttpServer.OnDisconnectEventHandler Delegate

Represents the method that will handle the OnDisconnect event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnDisconnectEventHandler( _
   ByVal sender As Object, _
   ByVal e As DisconnectEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnDisconnectEventHandler(
      object sender,
      DisconnectEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An DisconnectEventArgs that contains the event data.

Remarks

When you create an **OnDisconnectEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnDisconnectEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

See Also

SocketTools Namespace

HttpServer.OnDownloadEventHandler Delegate

Represents the method that will handle the OnDownload event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnDownloadEventHandler( _
   ByVal sender As Object, _
   ByVal e As DownloadEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnDownloadEventHandler(
      object sender,
      DownloadEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An DownloadEventArgs that contains the event data.

Remarks

When you create an **OnDownloadEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnDownloadEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

See Also

SocketTools Namespace

HttpServer.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

See Also

SocketTools Namespace

HttpServer.OnExecuteEventHandler Delegate

Represents the method that will handle the OnExecute event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnExecuteEventHandler( _
   ByVal sender As Object, _
   ByVal e As ExecuteEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnExecuteEventHandler(
      object sender,
      ExecuteEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ExecuteEventArgs that contains the event data.

Remarks

When you create an **OnExecuteEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnExecuteEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

See Also

SocketTools Namespace

HttpServer.OnResultEventHandler Delegate

Represents the method that will handle the OnResult event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnResultEventHandler( _
   ByVal sender As Object, _
   ByVal e As ResultEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnResultEventHandler(
      object sender,
      ResultEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ResultEventArgs that contains the event data.

Remarks

When you create an **OnResultEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnResultEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

See Also

SocketTools Namespace

HttpServer.OnTimeoutEventHandler Delegate

Represents the method that will handle the OnTimeout event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnTimeoutEventHandler( _
   ByVal sender As Object, _
   ByVal e As TimeoutEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnTimeoutEventHandler(
      object sender,
      TimeoutEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An TimeoutEventArgs that contains the event data.

Remarks

When you create an **OnTimeoutEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnTimeoutEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

See Also

SocketTools Namespace

HttpServer.OnUploadEventHandler Delegate

Represents the method that will handle the OnUpload event.

[Visual Basic]

```
Public Delegate Sub HttpServer.OnUploadEventHandler( _
   ByVal sender As Object, _
   ByVal e As UploadEventArgs _
)
```

[C#]

```
public delegate void HttpServer.OnUploadEventHandler(
      object sender,
      UploadEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An UploadEventArgs that contains the event data.

Remarks

When you create an **OnUploadEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnUploadEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

See Also

SocketTools Namespace

HttpServer.FileAccess Enumeration

Specifies the file access permissions the HttpServer class supports.

[Visual Basic]

```
Public Enum HttpServer.FileAccess
```

[C#]

```
public enum HttpServer.FileAccess
```

Remarks

File access permissions can restrict the actions that any client can take, regardless of the user permissions assigned to the client session. For example, a client session may have permission to use the PUT command; however, unless the folder that they are attempting to create the file in also has **accessWrite** permission, the PUT command will fail.

For security reasons, when the server is started, regular files only have the **accessRead** permission and directories only have the **accessRead** and **accessList** permissions assigned to them. If you wish to allow clients to upload files to your server, or execute scripts stored in a directory, then you must create a virtual path to a physical directory and assign it the appropriate permissions. In both cases, best practices dictate that the physical directory should be located outside of the root directory of the server.

If you assign the **accessExecute** permission to a virtual directory to allow clients to execute scripts using the GET or POST commands, you should make sure that clients cannot list, create or modify files in that directory. The scripts in that directory must have a registered handler, created using the **RegisterHandler** method. It is not necessary to create a virtual path to a CGI program registered using the **RegisterProgram** method because execute permission for that program is granted by default.

Members

Member Name	Description
accessNone	The virtual path or file has not been assigned any permissions.
accessRead	If the virtual path specifies a file, the client can use the GET command to retrieve the contents of the file and the HEAD command will return information about the file. If the virtual path specifies a directory, the client can use the GET command to retrieve the index file for that directory. If the file or directory does not have this permission, the server will return an error to the client.
accessWrite	If the virtual path specifies a file, the client can modify the contents of the file using the PUT command. If the path specifies a directory, the client can use the PUT command to create a new file or replace an existing file in the directory.
accessExecute	If the virtual path specifies a script, the client can execute the script using either the GET or POST commands. If the path specifies a directory, then all scripts in that directory can be executed.

accessList	If the virtual path specifies a directory, and there is no default index file present, the server will return a list of files in that directory to the client. If this permission is not specified, the server will return an error if the directory does not have a default index file. It is recommended that you do not specify this permission when assigning the **accessExecute** permission to a directory
accessRestricted	Access to the file or directory should be restricted to using the GET command to retrieve documents. This is effectively the same as only specifying **accessRead** as the file access permissions. If this permission is combined with any permission other than **accessRead**, those permissions will be ignored.
accessProtected	Access to the file or directory is protected by a username and password. Clients should only be permitted to access the resource if they provide valid user credentials to the server. If this permission is assigned to a virtual path, the default command handlers will require the client to authenticate itself to permit access to the resource. The server application is responsible for authenticating the session.
accessDefault	This value specifies that the default access permissions should be granted to the file or directory. If the virtual path specifies a file, the client can use the GET command to return the contents. If the path specifies a directory, the client can use the GET command to return the index file or a list of files in the directory. If the server is in restricted mode, it will return an error if a directory does not have an index page.

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

SocketTools Namespace

HttpServer.ErrorCode Enumeration

Specifies the error codes returned by the HttpServer class.

[Visual Basic]

```
Public Enum HttpServer.ErrorCode
```

[C#]

```
public enum HttpServer.ErrorCode
```

Remarks

The HttpServer class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This method has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

HttpServer.FormatType Enumeration

Specifies the logfile formats that the HttpServer class supports.

[Visual Basic]
```
Public Enum HttpServer.FormatType
```

[C#]
```
public enum HttpServer.FormatType
```

Members

Member Name	Description
formatNone	This value specifies that the server should not create or update a log file. This is the default property value.
formatCommon	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
formatCombined	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
formatExtended	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

HttpServer.SecurityProtocols Enumeration

Specifies the security protocols that the HttpServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpServer.SecurityProtocols
```

[C#]

```
[Flags]
public enum HttpServer.SecurityProtocols
```

Remarks

The HttpServer class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when starting a secure server.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

HttpServer.ServerOptions Enumeration

Specifies the options that the HttpServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpServer.ServerOptions
```

[C#]

```
[Flags]
public enum HttpServer.ServerOptions
```

Remarks

The HttpServer class uses the **ServerOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionMultiUser	This option specifies the server should be started in multi-user mode, where users are assigned their own home directories and clients can access documents in those directories by including the username in the request URI. If this option is not specified, then all users will share the server root directory by default. This option does not have any effect on the maximum number of simultaneous client sessions that can be established with the server.	1
optionRestricted	This option specifies the server should be initialized in a restricted mode, limiting certain functionality. The only commands accepted by the server will be the GET and HEAD commands. The server will never return a list of files if the client provides a URL that maps to a local directory and there is no default index page. Clients will not be able to execute CGI programs or scripts, and cannot access files outside of the server root directory or its subdirectories.	2
optionLocalUser	This option specifies the server should perform user authentication using the Windows local account database. This option is useful if the server should accept local usernames, or if the	4

	application does not wish to implement an event handler for user authentication. If this option is not specified, the application is responsible for authenticating all users.	
optionNoIndex	This option specifies the server should not search for a default index page if the client provides a URL that maps to a local directory. By default, the server will search for a file named index.htm, index.html, default.htm, default.html or index.txt in the directory. If a file by one of those names is found, it will return the contents of that file rather than a list of files in the directory.	8
optionReadOnly	This option specifies the server should only allow read-only access to files by default. If this option is enabled, it will change the default permissions granted to authenticated users. Commands that are used to create, delete or modify files on the server will be disabled by default. It is recommended that this option be enabled if the server is publicly accessible over the Internet.	16
optionLockFiles	This option specifies that files should be exclusively locked when a client attempts to upload or download a file. If another client attempts to access the same file, the operation will fail. By default, the server will permit multiple clients to access the same file, although it will still write-lock files that are in the process of being uploaded.	64
optionHiddenFiles	This option specifies that when a client requests a resource, the server should permit access to hidden and system files or subdirectories. By default, the server will not allow access to a hidden or system file, even if the client session has been authenticated. This option is ignored if the server is started in restricted mode.	128
optionSecure	This option specifies that secure connections using SSL and/or TLS should be enabled. This option requires that a valid SSL certificate be installed on the local host. The default port number for secure HTTP connections is 443. If security is enabled, all client	4096

	connections to the server must be secure. Standard and secure connections cannot be shared by the same instance of the server. If your application must support both standard and secure connections, you must create two instances of the server listening on two different ports, one with **optionSecure** enabled and the other without.	
optionSecureFallback	This option specifies the server should permit the use of less secure cipher suites for compatibility with legacy clients. If this option is specified, the server will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768

HttpServer.ServerPriority Enumeration

Specifies the priorities that the HttpServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum HttpServer.ServerPriority
```

```
[C#]
[Flags]
public enum HttpServer.ServerPriority
```

Members

Member Name	Description	Value
priorityBackground	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. Each client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.	0
priorityLow	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. Each client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.	1
priorityNormal	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.	2
priorityHigh	This priority increases the overall resource utilization for each client session and their threads will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.	3
priorityCritical	This priority can significantly increase processor, memory and network utilization. Each client thread will be given higher scheduling priority and will be more responsive to network events. It is not recommended that this priority be used on a system with a single	4

	processor.	
priorityInvalid	An invalid transfer priority which indicates an error condition.	-1
priorityDefault	The default server priority. This is the same as specifying **priorityNormal**.	2
priorityLowest	The lowest valid server priority. This is the same as specifying **priorityBackground**.	0
priorityHighest	The highest valid server priority. This is the same as specifying **priorityCritical**.	4

HttpServer.TraceOptions Enumeration

Specifies the logging options that the HttpServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpServer.TraceOptions
```

[C#]

```
[Flags]
public enum HttpServer.TraceOptions
```

Remarks

The HttpServer class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.HttpServer (in SocketTools.HttpServer.dll)

HttpServer.UserAccess Enumeration

Specifies the user access permissions the HttpServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum HttpServer.UserAccess
```

[C#]

```
[Flags]
public enum HttpServer.UserAccess
```

Remarks

When a client establishes a connection to the server, it is granted a default set of user access permissions based on the initial configuration of the server. By default, the client is granted all permissions, which means the client may use any valid HTTP command. If the server is started in restricted mode, then the client is only granted permission to read files. This means that restricted mode clients cannot obtain directory listings of files, nor can they create files or execute CGI programs. The user access permissions define the types of HTTP commands that the client is permitted to use. However, server options and individual permissions on specific files and directories can further limit what actions the client can take.

If you assign the **accesRestricted** permission to a client, the server will impose significant limitations on the client. This permission provides a high level of security, ensuring that the client cannot access any other documents outside of the server root directory; however, it also prevents the client from executing scripts or submitting data. If the website depends on server-side scripts and the use of CGI programs, assigning this permission may effectively disable use of the site for that client session.

Members

Member Name	Description	Value
accessNone	The client has not been assigned any permissions.	0
accessAll	The client has been assigned all available permissions. This enables the client to issue all valid commands, including any external script handlers that have been registered for use with the server instance.	65535
accessRead	The client can download files and retrieve other resources using the GET command. This permission also allows the client to obtain information about a specific resource using the HEAD command. The resource that the client is attempting to retrieve must also have read permission, otherwise the command will fail.	1
accessWrite	The client can modify existing files or create new files using the PUT	2

	command. The directory where the client is attempting to create or modify the file must also have write permission, otherwise the command will fail. This permission is not granted by default to clients if the server is started in restricted mode. This permission is ignored if the server is started in read-only mode.	
accessExecute	The client can execute scripts and CGI programs. If this permission is not granted to the client, it will be unable to use the GET, HEAD or POST commands if the resource is a program or script registered with the server. This permission is not granted by default to clients if the server is started in restricted mode.	4
accessList	If the client issues a GET command and the resource specifies a directory, this permission allows the server to return a list of files to client if a default index file cannot be found. If this permission is not granted to the client, the directory must contain a default index file, otherwise the server will return an error. This permission is ignored if the server is started in restricted mode.	8
accessRestricted	The client is restricted to accessing documents using the GET and HEAD commands, and those documents must be located in the root directory for the virtual host or in a subdirectory. The client cannot execute scripts, submit data to the server using the POST command or upload files using the PUT command.	1048576
accessDefault	This value specifies that the default permissions should be granted to the client session. If the server is in restricted mode, the client will only be able to use the GET and HEAD commands to retrieve documents. If the server is not in restricted mode, the client can use all valid HTTP commands. This is the recommended access permissions for most clients.	8388608

IcmpClient Class

Implements the Internet Control Message Protocol.

For a list of all members of this type, see IcmpClient Members.

System.Object
  SocketTools.IcmpClient

[Visual Basic]
```
Public Class IcmpClient
    Implements IDisposable
```

[C#]
```
public class IcmpClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The Internet Control Message Protocol (ICMP) is commonly used to determine if a remote host is reachable and how packets of data are routed to that system. Users are most familiar with this protocol as it is implemented in the ping and tracert command line utilities. The ping command is used to check if a system is reachable and the amount of time that it takes for a packet of data to make a round trip from the local system, to the remote host and then back again. The tracert command is used to trace the route that a packet of data takes from the local system to the remote host, and can be used to identify potential problems with overall throughput and latency. The IcmpClient class can be used to build in this type of functionality in your own applications, giving you the ability to send and receive ICMP echo datagrams in order to perform your own analysis.

IcmpClient Members

IcmpClient overview

Public Static (Shared) Fields

icmpPacketSize	A constant value which specifies the default packet size.
icmpTimeout	A constant value which specifies the default timeout period in milliseconds.
icmpTimeToLive	A constant value which specifies the default time-to-live value.

Public Instance Constructors

IcmpClient Constructor	Initializes a new instance of the IcmpClient class.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
Handle	Gets a value that specifies the client handle allocated for the current session.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
Interval	Gets and sets the interval in milliseconds between echo packets.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets and sets the local Internet address that the client will be bound to.
LocalName	Gets a value which specifies the host name for the local system.
Options	Gets and sets a value which specifies one or more client options.
PacketSize	Gets and sets the size of an echo datagram.

RecvCount	Gets the number of echo reply datagrams received by the local host.
SendCount	Gets the number of echo datagrams sent by the local host.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in milliseconds.
TimeToLive	Gets and sets the default time-to-live value for echo datagrams.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TripAverage	Gets the average packet trip time in milliseconds.
TripMaximum	Gets the maximum packet trip time in milliseconds.
TripMinimum	Gets the minimum packet trip time in milliseconds.
Version	Gets a value which returns the current version of the IcmpClient class library.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
Dispose	Overloaded. Releases all resources used by IcmpClient.
Echo	Overloaded. Send an echo datagram to the specified host.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the IcmpClient

	class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
ToString (inherited from Object)	Returns a String that represents the current Object.
TraceRoute	Overloaded. Send a series of echo datagrams to trace the route taken from the local system to the remote host
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnEcho	Occurs when an echo datagram is sent to the remote host.
OnError	Occurs when an client operation fails.
OnReply	Occurs when an echo reply datagram is received by the local host.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnTrace	Occurs when an echo datagram is forwarded to an intermediate host.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the IcmpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

IcmpClient Properties

The properties of the **IcmpClient** class are listed below. For a complete list of **IcmpClient** class members, see the IcmpClient Members topic.

Public Instance Properties

AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
Handle	Gets a value that specifies the client handle allocated for the current session.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
Interval	Gets and sets the interval in milliseconds between echo packets.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets and sets the local Internet address that the client will be bound to.
LocalName	Gets a value which specifies the host name for the local system.
Options	Gets and sets a value which specifies one or more client options.
PacketSize	Gets and sets the size of an echo datagram.
RecvCount	Gets the number of echo reply datagrams received by the local host.
SendCount	Gets the number of echo datagrams sent by the local host.
Status	Gets a value which specifies the current status of the client.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method

	calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in milliseconds.
TimeToLive	Gets and sets the default time-to-live value for echo datagrams.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
TripAverage	Gets the average packet trip time in milliseconds.
TripMaximum	Gets the maximum packet trip time in milliseconds.
TripMinimum	Gets the minimum packet trip time in milliseconds.
Version	Gets a value which returns the current version of the IcmpClient class library.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnEcho** and **OnReply** are only fired if the client is in non-blocking mode.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]

```
Public Property HostAddress As String
```

[C#]

```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address using dotted notation.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Interval Property

Gets and sets the interval in milliseconds between echo packets.

[Visual Basic]

```
Public Property Interval As Integer
```

[C#]

```
public int Interval {get; set;}
```

Property Value

An integer value which specifies an interval in milliseconds.

Remarks

The **Interval** property determines the interval at which echo datagrams are automatically sent to the remote host. If the interval is set to zero, no datagrams are automatically sent.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]

```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]

```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public IcmpClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.LocalAddress Property

Gets and sets the local Internet address that the client will be bound to.

[Visual Basic]

```
Public Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get; set;}
```

Property Value

A string which specifies an Internet address in dotted notation.

Remarks

The **LocalAddress** property is used to specify the local Internet address that the client will be bound to when a connection is established with a remote host. By default this property is not assigned a value, which specifies that the client should be bound to any appropriate network interface on the local system.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

IcmpClient Class | SocketTools Namespace

IcmpClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]
```
Public Property Options As IcmpOptions
```

[C#]
```
public IcmpClient.IcmpOptions Options {get; set;}
```

Property Value

Returns one or more IcmpOptions enumeration flags which specify the options for the client. The default value for this property is **clientOptionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.PacketSize Property

Gets and sets the size of an echo datagram.

[Visual Basic]

```
Public Property PacketSize As Integer
```

[C#]

```
public int PacketSize {get; set;}
```

Property Value

An integer which specifies the size of an echo datagram in bytes.

Remarks

The **PacketSize** property determines the size of an ICMP echo datagram. The default packet size is 32 bytes. The minimum packet size is 1 byte and the maximum packet size is 65,535 bytes. Specifying a packet size outside of this range will result in an error. Note that packet sizes over 512 bytes may not be supported by your local networking hardware or intermediate routers.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.RecvCount Property

Gets the number of echo reply datagrams received by the local host.

[Visual Basic]

```
Public ReadOnly Property RecvCount As Integer
```

[C#]

```
public int RecvCount {get;}
```

Property Value

An integer value which specifies the number of echo reply datagrams.

Remarks

This value is automatically reset whenever a new remote host is specified.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.SendCount Property

Gets the number of echo datagrams sent by the local host.

[Visual Basic]

```
Public ReadOnly Property SendCount As Integer
```

[C#]

```
public int SendCount {get;}
```

Property Value

An integer value which specifies the number of echo datagrams sent.

Remarks

This value is automatically reset whenever a new remote host is specified.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As IcmpStatus
```

[C#]

```
public IcmpClient.IcmpStatus Status {get;}
```

Property Value

A IcmpStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]
```
Public Property ThreadModel As ThreadingModel
```

[C#]
```
public IcmpClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

See Also

IcmpClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

IcmpClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Timeout Property

Gets and sets a value which specifies a timeout period in milliseconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in milliseconds.

Remarks

Setting the **Timeout** property specifies the number of milliseconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set to 3000 milliseconds (3 seconds).

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.TimeToLive Property

Gets and sets the default time-to-live value for echo datagrams.

[Visual Basic]

```
Public Property TimeToLive As Integer
```

[C#]

```
public int TimeToLive {get; set;}
```

Remarks

The time-to-live (TTL) value is specified in the IP header of a datagram, and is used to control the number of routers that the datagram is passed through. Each router that handles the datagram decrements the TTL value by one. When it drops to zero, a datagram is returned to the sender, specifying that the TTL has been exceeded.

Setting this property changes the default TTL value for all subsequent ICMP datagrams sent by the local host, with the default value being 255. Reading this property returns the value of the TTL field in the IP header of the last echo reply datagram received.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]
```
Public Property TraceFile As String
```

[C#]
```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public IcmpClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

IcmpClient Class | SocketTools Namespace

IcmpClient.TripAverage Property

Gets the average packet trip time in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TripAverage As Integer
```

[C#]

```
public int TripAverage {get;}
```

Property Value

An integer value which specifies the average trip time in milliseconds.

Remarks

The **TripAverage** property returns the average number of milliseconds for an ICMP echo reply datagram to be returned from the remote host.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.TripMaximum Property

Gets the maximum packet trip time in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TripMaximum As Integer
```

[C#]

```
public int TripMaximum {get;}
```

Property Value

An integer value which specifies the maximum trip time in milliseconds.

Remarks

The **TripMaximum** property returns the maximum number of milliseconds for an ICMP echo reply datagram to be returned from the remote host.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.TripMinimum Property

Gets the minimum packet trip time in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TripMinimum As Integer
```

[C#]

```
public int TripMinimum {get;}
```

Property Value

An integer value which specifies the minimum trip time in milliseconds.

Remarks

The **TripMinimum** property returns the minimum number of milliseconds for an ICMP echo reply datagram to be returned from the remote host.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Version Property

Gets a value which returns the current version of the IcmpClient class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the IcmpClient class library. This value can be used by an application for validation and debugging purposes.

IcmpClient Class | SocketTools Namespace

IcmpClient Methods

The methods of the **IcmpClient** class are listed below. For a complete list of **IcmpClient** class members, see the IcmpClient Members topic.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
Dispose	Overloaded. Releases all resources used by IcmpClient.
Echo	Overloaded. Send an echo datagram to the specified host.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the IcmpClient class.
Reset	Reset the internal state of the object, resetting all properties to their default values.
ToString (inherited from Object)	Returns a String that represents the current Object.
TraceRoute	Overloaded. Send a series of echo datagrams to trace the route taken from the local system to the remote host
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the IcmpClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]
```
Public Function AttachThread() As Boolean
```

[C#]
```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

IcmpClient Class | SocketTools Namespace

IcmpClient.Echo Method

Send an echo datagram to the default host.

Overload List

Send an echo datagram to the default host.

public bool Echo();

Send an echo datagram to the specified host.

public bool Echo(string);

Send an echo datagram to the specified host.

public bool Echo(string,int);

Send an echo datagram to the specified host.

public bool Echo(string,int,int);

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Echo Method ()

Send an echo datagram to the default host.

[Visual Basic]

```
Overloads Public Function Echo() As Boolean
```

[C#]

```
public bool Echo();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Echo** method sends an ICMP echo datagram to the specified host, providing a simplified interface for pinging a remote system. If the method returns a value of **true**, then a reply was received for the echo datagram that was sent. This would typically indicate that the client can establish a reliable connection to the server. A return value of **false** indicates that there was no response to the echo datagrams. The remote host may not exist or may not be available.

The value returned by the **TripAverage** property provides information about the latency between the two hosts. Higher average time values would indicate greater latency and reduced throughput between the systems.

The failure for a host to respond to an ICMP echo datagram may not indicate a problem with the remote system. In some cases, a router between the local and remote host may be malfunctioning or discarding the datagrams. Systems can also be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of denial-of-service attacks.

The value of the **HostName** property specifies the remote host that the echo datagram will be sent to. The **Timeout** property specifies the timeout period in milliseconds. The **TimeToLive** property specifies the time-to-live value.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.Echo Overload List

IcmpClient.Echo Method (String)

Send an echo datagram to the specified host.

[Visual Basic]

```
Overloads Public Function Echo( _
   ByVal hostName As String _
) As Boolean
```

[C#]

```
public bool Echo(
   string hostName
);
```

Parameters

hostName

A string which specifies the host name or IP address which the echo datagram will be sent to.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Echo** method sends an ICMP echo datagram to the specified host, providing a simplified interface for pinging a remote system. If the method returns a value of **true**, then a reply was received for the echo datagram that was sent. This would typically indicate that the client can establish a reliable connection to the server. A return value of **false** indicates that there was no response to the echo datagrams. The remote host may not exist or may not be available.

The value returned by the **TripAverage** property provides information about the latency between the two hosts. Higher average time values would indicate greater latency and reduced throughput between the systems.

The failure for a host to respond to an ICMP echo datagram may not indicate a problem with the remote system. In some cases, a router between the local and remote host may be malfunctioning or discarding the datagrams. Systems can also be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of denial-of-service attacks.

The **Timeout** property specifies the timeout period in milliseconds. The **TimeToLive** property specifies the time-to-live value.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.Echo Overload List

IcmpClient.Echo Method (String, Int32)

Send an echo datagram to the specified host.

[Visual Basic]

```
Overloads Public Function Echo( _
   ByVal hostName As String, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Echo(
   string hostName,
   int timeout
);
```

Parameters

hostName
A string which specifies the host name or IP address which the echo datagram will be sent to.

timeout
An integer value which specifies the number of milliseconds until a blocking operation fails and the method returns to the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Echo** method sends an ICMP echo datagram to the specified host, providing a simplified interface for pinging a remote system. If the method returns a value of **true**, then a reply was received for the echo datagram that was sent. This would typically indicate that the client can establish a reliable connection to the server. A return value of **false** indicates that there was no response to the echo datagrams. The remote host may not exist or may not be available.

The value returned by the **TripAverage** property provides information about the latency between the two hosts. Higher average time values would indicate greater latency and reduced throughput between the systems.

The failure for a host to respond to an ICMP echo datagram may not indicate a problem with the remote system. In some cases, a router between the local and remote host may be malfunctioning or discarding the datagrams. Systems can also be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of denial-of-service attacks.

The **TimeToLive** property specifies the time-to-live value.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.Echo Overload List

IcmpClient.Echo Method (String, Int32, Int32)

Send an echo datagram to the specified host.

[Visual Basic]

```
Overloads Public Function Echo( _
   ByVal hostName As String, _
   ByVal timeout As Integer, _
   ByVal timeToLive As Integer _
) As Boolean
```

[C#]

```
public bool Echo(
   string hostName,
   int timeout,
   int timeToLive
);
```

Parameters

hostName
A string which specifies the host name or IP address which the echo datagram will be sent to.

timeout
An integer value which specifies the number of milliseconds until a blocking operation fails and the method returns to the caller.

timeToLive
An integer value which specifies the time-to-live (TTL) value for the echo datagram. This determines the maximum number of times that a packet will be forwarded from one system to another while enroute to its destination. The minimum time-to-live value is 1, the maximum is 255.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Echo** method sends an ICMP echo datagram to the specified host, providing a simplified interface for pinging a remote system. If the method returns a value of **true**, then a reply was received for the echo datagram that was sent. This would typically indicate that the client can establish a reliable connection to the server. A return value of **false** indicates that there was no response to the echo datagrams. The remote host may not exist or may not be available.

The value returned by the **TripAverage** property provides information about the latency between the two hosts. Higher average time values would indicate greater latency and reduced throughput between the systems.

The failure for a host to respond to an ICMP echo datagram may not indicate a problem with the remote system. In some cases, a router between the local and remote host may be malfunctioning or discarding the datagrams. Systems can also be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of denial-of-service attacks.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.Echo Overload List

IcmpClient.Dispose Method

Releases all resources used by IcmpClient.

Overload List

Releases all resources used by IcmpClient.

public void Dispose();

Releases the unmanaged resources allocated by the IcmpClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Dispose Method ()

Releases all resources used by IcmpClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.Dispose Overload List

IcmpClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the IcmpClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **IcmpClient** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.Dispose Overload List

IcmpClient.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.Initialize Method

Initialize an instance of the IcmpClient class.

Overload List

Initialize an instance of the IcmpClient class.

public bool Initialize();

Initialize an instance of the IcmpClient class.

public bool Initialize(string);

See Also

IcmpClient Class | SocketTools Namespace | Uninitialize Method

IcmpClient.Initialize Method ()

Initialize an instance of the IcmpClient class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the IcmpClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.Initialize Overload List | Uninitialize Method

IcmpClient.Initialize Method (String)

Initialize an instance of the IcmpClient class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the IcmpClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the IcmpClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.IcmpClient icmpClient = new SocketTools.IcmpClient();

if (icmpClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(icmpClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim icmpClient As New SocketTools.IcmpClient

If icmpClient.Initialize(strLicenseKey) = False Then
    MsgBox(icmpClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

IcmpClient.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

IcmpClient Class | SocketTools Namespace

IcmpClient.TraceRoute Method

Send a series of echo datagrams to trace the route taken from the local system to the remote host

Overload List

Send a series of echo datagrams to trace the route taken from the local system to the remote host

public int TraceRoute();

Send a series of echo datagrams to trace the route taken from the local system to the remote host

public int TraceRoute(string);

Send a series of echo datagrams to trace the route taken from the local system to the remote host

public int TraceRoute(string,int);

Send a series of echo datagrams to trace the route taken from the local system to the remote host

public int TraceRoute(string,int,int);

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.TraceRoute Method ()

Send a series of echo datagrams to trace the route taken from the local system to the remote host

[Visual Basic]

```
Overloads Public Function TraceRoute() As Integer
```

[C#]

```
public int TraceRoute();
```

Return Value

The method returns the total number of hops from the local system to the remote host. If the method fails, it will return a value of -1.

Remarks

The **TraceRoute** method sends a series of ICMP echo datagrams to the specified host, adjusting the time-to-live value to determine the intermediate hosts that route the packet. This method will always block the current thread until the trace completes.

The **OnTrace** event will fire for each intermediate host along the route.

The value of the **HostName** property specifies the remote host that the echo datagram will be sent to. The **Timeout** property specifies the timeout period in milliseconds.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.TraceRoute Overload List

IcmpClient.TraceRoute Method (String)

Send a series of echo datagrams to trace the route taken from the local system to the remote host

[Visual Basic]

```
Overloads Public Function TraceRoute( _
   ByVal hostName As String _
) As Integer
```

[C#]

```
public int TraceRoute(
   string hostName
);
```

Parameters

hostName

A string which specifies the host name or IP address which the echo datagram will be sent to.

Return Value

The method returns the total number of hops from the local system to the remote host. If the method fails, it will return a value of -1.

Remarks

The **TraceRoute** method sends a series of echo datagrams to the specified host, adjusting the time-to-live value to determine the intermediate hosts that route the packet. This method will always block the current thread until the trace completes.

The **OnTrace** event will fire for each intermediate host along the route.

The **Timeout** property specifies the timeout period in milliseconds.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.TraceRoute Overload List

IcmpClient.TraceRoute Method (String, Int32)

Send a series of echo datagrams to trace the route taken from the local system to the remote host

[Visual Basic]

```
Overloads Public Function TraceRoute( _
   ByVal hostName As String, _
   ByVal maxHops As Integer _
) As Integer
```

[C#]

```
public int TraceRoute(
   string hostName,
   int maxHops
);
```

Parameters

hostName

A string which specifies the host name or IP address which the echo datagram will be sent to.

maxHops

An integer value which specifies the maximum number of routers the echo datagram will be forwarded through (the number of hops) to the remote host. The minimum value is 1 and the maximum value is 255. It is recommended that most applications specify a value of at least 30.

Return Value

The method returns the total number of hops from the local system to the remote host. If the method fails, it will return a value of -1.

Remarks

The **TraceRoute** method sends a series of echo datagrams to the specified host, adjusting the time-to-live value to determine the intermediate hosts that route the packet. This method will always block the current thread until the trace completes.

The **OnTrace** event will fire for each intermediate host along the route.

The **Timeout** property specifies the timeout period in milliseconds.

IcmpClient.TraceRoute Method (String, Int32, Int32)

Send a series of echo datagrams to trace the route taken from the local system to the remote host

[Visual Basic]

```
Overloads Public Function TraceRoute( _
   ByVal hostName As String, _
   ByVal maxHops As Integer, _
   ByVal timeout As Integer _
) As Integer
```

[C#]

```
public int TraceRoute(
   string hostName,
   int maxHops,
   int timeout
);
```

Parameters

hostName

A string which specifies the host name or IP address which the echo datagram will be sent to.

maxHops

An integer value which specifies the maximum number of routers the echo datagram will be forwarded through (the number of hops) to the remote host. The minimum value is 1 and the maximum value is 255. It is recommended that most applications specify a value of at least 30.

timeout

An integer value which specifies the number of milliseconds until a blocking operation fails and the method returns to the caller.

Return Value

The method returns the total number of hops from the local system to the remote host. If the method fails, it will return a value of -1.

Remarks

The **TraceRoute** method sends a series of echo datagrams to the specified host, adjusting the time-to-live value to determine the intermediate hosts that route the packet. This method will always block the current thread until the trace completes.

The **OnTrace** event will fire for each intermediate host along the route.

See Also

IcmpClient Class | SocketTools Namespace | IcmpClient.TraceRoute Overload List

IcmpClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

IcmpClient Class | SocketTools Namespace | Initialize Method

IcmpClient Events

The events of the **IcmpClient** class are listed below. For a complete list of **IcmpClient** class members, see the IcmpClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnEcho	Occurs when an echo datagram is sent to the remote host.
⚡ OnError	Occurs when an client operation fails.
⚡ OnReply	Occurs when an echo reply datagram is received by the local host.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnTrace	Occurs when an echo datagram is forwarded to an intermediate host.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.OnEcho Event

Occurs when an echo datagram is sent to the remote host.

[Visual Basic]
```
Public Event OnEcho As OnEchoEventHandler
```

[C#]
```
public event OnEchoEventHandler OnEcho;
```

Event Data

The event handler receives an argument of type IcmpClient.EchoEventArgs containing data related to this event. The following **IcmpClient.EchoEventArgs** properties provide information specific to this event.

Property	Description
HostName	Gets the remote host name or IP address.
PacketSize	Gets the size of the echo datagram in bytes.
SequenceId	Gets the packet sequence number.

Remarks

The **OnEcho** event is generated for non-blocking sockets when an echo datagram is sent to the remote host. This event is only generated when the **Blocking** property is set to **false**.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.EchoEventArgs Class

Provides data for the OnEcho event.

For a list of all members of this type, see IcmpClient.EchoEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.IcmpClient.EchoEventArgs

[Visual Basic]

```
Public Class IcmpClient.EchoEventArgs
    Inherits EventArgs
```

[C#]

```
public class IcmpClient.EchoEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

EchoEventArgs provides information about the echo datagram sent to the remote host.

An OnEcho event occurs when an echo datagram is sent to a remote host.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

IcmpClient.EchoEventArgs overview

Public Instance Constructors

IcmpClient.EchoEventArgs Constructor	Initializes a new instance of the IcmpClient.EchoEventArgs class.

Public Instance Properties

HostName	Gets the remote host name or IP address.
PacketSize	Gets the size of the echo datagram in bytes.
SequenceId	Gets the packet sequence number.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

IcmpClient.EchoEventArgs Constructor

Initializes a new instance of the IcmpClient.EchoEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public IcmpClient.EchoEventArgs();
```

See Also

IcmpClient.EchoEventArgs Class | SocketTools Namespace

IcmpClient.EchoEventArgs Properties

The properties of the **IcmpClient.EchoEventArgs** class are listed below. For a complete list of **IcmpClient.EchoEventArgs** class members, see the IcmpClient.EchoEventArgs Members topic.

Public Instance Properties

HostName	Gets the remote host name or IP address.
PacketSize	Gets the size of the echo datagram in bytes.
SequenceId	Gets the packet sequence number.

See Also

IcmpClient.EchoEventArgs Class | SocketTools Namespace

IcmpClient.EchoEventArgs.HostName Property

Gets the remote host name or IP address.

[Visual Basic]

```
Public ReadOnly Property HostName As String
```

[C#]

```
public string HostName {get;}
```

Property Value

A string which specifies the remote host name or IP address.

See Also

IcmpClient.EchoEventArgs Class | SocketTools Namespace

IcmpClient.EchoEventArgs.PacketSize Property

Gets the size of the echo datagram in bytes.

[Visual Basic]

```
Public ReadOnly Property PacketSize As Integer
```

[C#]

```
public int PacketSize {get;}
```

Property Value

An integer value which specifies the size of the echo datagram in bytes.

See Also

IcmpClient.EchoEventArgs Class | SocketTools Namespace

IcmpClient.EchoEventArgs.SequenceId Property

Gets the packet sequence number.

[Visual Basic]
```
Public ReadOnly Property SequenceId As Integer
```

[C#]
```
public int SequenceId {get;}
```

Property Value

An integer which specifies the packet sequence number.

Remarks

The **SequenceId** value is used to uniquely identify each echo datagram that is sent to the remote host. This value will increase for each datagram that is sent until the remote host address is changed. Once a new remote host is specified, the sequence number is reset.

IcmpClient.EchoEventArgs Class | SocketTools Namespace

IcmpClient.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type IcmpClient.ErrorEventArgs containing data related to this event. The following **IcmpClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see IcmpClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.IcmpClient.ErrorEventArgs

[Visual Basic]
```
Public Class IcmpClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]
```
public class IcmpClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

IcmpClient.OnReply Event

Occurs when an echo reply datagram is received by the local host.

[Visual Basic]

```
Public Event OnReply As OnReplyEventHandler
```

[C#]

```
public event OnReplyEventHandler OnReply;
```

Event Data

The event handler receives an argument of type IcmpClient.ReplyEventArgs containing data related to this event. The following **IcmpClient.ReplyEventArgs** properties provide information specific to this event.

Property	Description
HostName	Gets the remote host name or IP address.
PacketSize	Gets the size of the echo datagram in bytes.
SequenceId	Gets the packet sequence number.
TripTime	Gets the time in milliseconds since the packet was sent to the remote host.

Remarks

This **OnReply** event is fired when a echo reply datagram is received from the remote system. Note that there is no guarantee that packets will be returned in the same sequence order they were sent or that they will be returned at all. This event is only generated when the **Blocking** property is set to **false**.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.ReplyEventArgs Class

Provides data for the OnReply event.

For a list of all members of this type, see IcmpClient.ReplyEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.IcmpClient.ReplyEventArgs

[Visual Basic]
```
Public Class IcmpClient.ReplyEventArgs
    Inherits EventArgs
```

[C#]
```
public class IcmpClient.ReplyEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ReplyEventArgs provides information about the echo reply datagram received from the remote host.

An OnReply event occurs when an echo reply datagram is received from a remote host.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

Gets the remote host name or IP address.

[Visual Basic]

```
Public ReadOnly Property HostName As String
```

[C#]

```
public string HostName {get;}
```

Property Value

A string which specifies the remote host name or IP address.

See Also

IcmpClient.ReplyEventArgs Class | SocketTools Namespace

IcmpClient.ReplyEventArgs.PacketSize Property

Gets the size of the echo datagram in bytes.

[Visual Basic]

```
Public ReadOnly Property PacketSize As Integer
```

[C#]

```
public int PacketSize {get;}
```

Property Value

An integer value which specifies the size of the echo datagram in bytes.

See Also

IcmpClient.ReplyEventArgs Class | SocketTools Namespace

IcmpClient.ReplyEventArgs.SequenceId Property

Gets the packet sequence number.

[Visual Basic]

```
Public ReadOnly Property SequenceId As Integer
```

[C#]

```
public int SequenceId {get;}
```

Property Value

An integer which specifies the packet sequence number.

Remarks

The **SequenceId** value is used to uniquely identify each echo datagram that is received from the remote host. This value will increase for each datagram that is received until the remote host address is changed. Once a new remote host is specified, the sequence number is reset.

IcmpClient.ReplyEventArgs Class | SocketTools Namespace

IcmpClient.ReplyEventArgs.TripTime Property

Gets the time in milliseconds since the packet was sent to the remote host.

[Visual Basic]

```
Public ReadOnly Property TripTime As Integer
```

[C#]

```
public int TripTime {get;}
```

Property Value

An integer which specifies the number of milliseconds that have elapsed since the packet was sent to the remote host.

Remarks

This value can be used to measure the latency between the local system and remote host.

See Also

IcmpClient.ReplyEventArgs Class | SocketTools Namespace

IcmpClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.OnTrace Event

Occurs when an echo datagram is forwarded to an intermediate host.

[Visual Basic]
```
Public Event OnTrace As OnTraceEventHandler
```

[C#]
```
public event OnTraceEventHandler OnTrace;
```

Event Data

The event handler receives an argument of type IcmpClient.TraceEventArgs containing data related to this event. The following **IcmpClient.TraceEventArgs** properties provide information specific to this event.

Property	Description
HostName	Gets the remote host name or IP address.
Replies	Gets the number of echo reply datagrams received from the remote host.
TraceHop	Gets a value which specifies the distance from the local system to the specified host.
TripAverage	Gets the average packet trip time in milliseconds.
TripMaximum	Gets the maximum packet trip time in milliseconds.
TripMinimum	Gets the minimum packet trip time in milliseconds.

Remarks

The **OnTrace** event is generated when the **TraceRoute** method is called. This event will fire for each intermediate host in the route from the local system and the remote host.

See Also

IcmpClient Class | SocketTools Namespace

IcmpClient.TraceEventArgs Class

Provides data for the OnTrace event.

For a list of all members of this type, see IcmpClient.TraceEventArgs Members.

System.Object

    SocketTools.IcmpClient.TraceEventArgs

[Visual Basic]
```
Public Class IcmpClient.TraceEventArgs
    Inherits EventArgs
```

[C#]
```
public class IcmpClient.TraceEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

TraceEventArgs provides information about an intermediate host as an echo datagram is forwarded from one system to another.

An OnTrace event occurs when the **TraceRoute** method is called.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

IcmpClient.TraceEventArgs Class | SocketTools Namespace

IcmpClient.TraceEventArgs.HostName Property

Gets the remote host name or IP address.

[Visual Basic]

```
Public ReadOnly Property HostName As String
```

[C#]

```
public string HostName {get;}
```

Property Value

A string which specifies the remote host name or IP address.

See Also

IcmpClient.TraceEventArgs Class | SocketTools Namespace

IcmpClient.TraceEventArgs.Replies Property

Gets the number of echo reply datagrams received from the remote host.

[Visual Basic]

```
Public ReadOnly Property Replies As Integer
```

[C#]

```
public int Replies {get;}
```

Property Value

An integer value which specifies the number of echo reply datagrams received from the remote host.

See Also

IcmpClient.TraceEventArgs Class | SocketTools Namespace

IcmpClient.TraceEventArgs.TraceHop Property

Gets a value which specifies the distance from the local system to the specified host.

[Visual Basic]

```
Public ReadOnly Property TraceHop As Integer
```

[C#]

```
public int TraceHop {get;}
```

Property Value

An integer which specifies distance from the local system to the specified host.

Remarks

This value represents the number of times that the packet was forwarded through a router, also known as the number of "hops" to the remote host. With a traceroute, this value will start at one and increment by one for each intermediate host until the destination is reached or the operation times out.

See Also

IcmpClient.TraceEventArgs Class | SocketTools Namespace

IcmpClient.TraceEventArgs.TripAverage Property

Gets the average packet trip time in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TripAverage As Integer
```

[C#]

```
public int TripAverage {get;}
```

Property Value

An integer value which specifies the average trip time in milliseconds.

See Also

IcmpClient.TraceEventArgs Class | SocketTools Namespace

IcmpClient.TraceEventArgs.TripMaximum Property

Gets the maximum packet trip time in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TripMaximum As Integer
```

[C#]

```
public int TripMaximum {get;}
```

Property Value

An integer value which specifies the maximum trip time in milliseconds.

See Also

IcmpClient.TraceEventArgs Class | SocketTools Namespace

IcmpClient.TraceEventArgs.TripMinimum Property

Gets the minimum packet trip time in milliseconds.

[Visual Basic]

```
Public ReadOnly Property TripMinimum As Integer
```

[C#]

```
public int TripMinimum {get;}
```

Property Value

An integer value which specifies the minimum trip time in milliseconds.

See Also

IcmpClient.TraceEventArgs Class | SocketTools Namespace

IcmpClient.ErrorCode Enumeration

Specifies the error codes returned by the IcmpClient class.

[Visual Basic]

```
Public Enum IcmpClient.ErrorCode
```

[C#]

```
public enum IcmpClient.ErrorCode
```

Remarks

The IcmpClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

See Also

SocketTools Namespace | LastError Property | LastErrorString Property | OnError Event

IcmpClient.IcmpOptions Enumeration

Specifies the options that the IcmpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum IcmpClient.IcmpOptions
```

```
[C#]
[Flags]
public enum IcmpClient.IcmpOptions
```

Remarks

The IcmpClient class uses the **IcmpOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

There are currently no additional options for IcmpClient class. This enumeration is provided for future expansion.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionNone**.	0
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	32768

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

See Also

SocketTools Namespace

IcmpClient.IcmpStatus Enumeration

Specifies the status values that may be returned by the IcmpClient class.

[Visual Basic]
```
Public Enum IcmpClient.IcmpStatus
```

[C#]
```
public enum IcmpClient.IcmpStatus
```

Remarks

The IcmpClient class uses the **IcmpStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusEcho	An ICMP datagram is being sent to the remote host.
statusReply	An ICMP datagram is being received from the remote host.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

SocketTools Namespace

IcmpClient.TraceOptions Enumeration

Specifies the logging options that the IcmpClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum IcmpClient.TraceOptions
```

[C#]

```
[Flags]
public enum IcmpClient.TraceOptions
```

Remarks

The IcmpClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

SocketTools Namespace

IcmpClient.OnEchoEventHandler Delegate

Represents the method that will handle the OnEcho event.

[Visual Basic]

```
Public Delegate Sub IcmpClient.OnEchoEventHandler( _
   ByVal sender As Object, _
   ByVal e As EchoEventArgs _
)
```

[C#]

```
public delegate void IcmpClient.OnEchoEventHandler(
      object sender,
      EchoEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An EchoEventArgs that contains the event data.

Remarks

When you create an **OnEchoEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnEchoEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

SocketTools Namespace

IcmpClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub IcmpClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void IcmpClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

SocketTools Namespace

IcmpClient.OnReplyEventHandler Delegate

Represents the method that will handle the OnReply event.

[Visual Basic]

```
Public Delegate Sub IcmpClient.OnReplyEventHandler( _
   ByVal sender As Object, _
   ByVal e As ReplyEventArgs _
)
```

[C#]

```
public delegate void IcmpClient.OnReplyEventHandler(
      object sender,
      ReplyEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ReplyEventArgs that contains the event data.

Remarks

When you create an **OnReplyEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnReplyEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

See Also

SocketTools Namespace

IcmpClient.OnTraceEventHandler Delegate

Represents the method that will handle the OnTrace event.

[Visual Basic]

```
Public Delegate Sub IcmpClient.OnTraceEventHandler( _
   ByVal sender As Object, _
   ByVal e As TraceEventArgs _
)
```

[C#]

```
public delegate void IcmpClient.OnTraceEventHandler(
      object sender,
      TraceEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An TraceEventArgs that contains the event data.

Remarks

When you create an **OnTraceEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnTraceEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

SocketTools Namespace

IcmpClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see IcmpClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.IcmpClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class IcmpClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class IcmpClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the IcmpClient class.

Example

```
<Assembly: SocketTools.IcmpClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.IcmpClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

See Also

IcmpClient.RuntimeLicenseAttribute Members | SocketTools Namespace

IcmpClient.RuntimeLicenseAttribute Members

IcmpClient.RuntimeLicenseAttribute overview

Public Instance Constructors

IcmpClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

IcmpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

IcmpClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public IcmpClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the IcmpClient class.

See Also

IcmpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

IcmpClient.RuntimeLicenseAttribute Properties

The properties of the **IcmpClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **IcmpClient.RuntimeLicenseAttribute** class members, see the IcmpClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

IcmpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

IcmpClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

IcmpClient.RuntimeLicenseAttribute Class | SocketTools Namespace

IcmpClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see IcmpClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.IcmpClientException

[Visual Basic]
```
Public Class IcmpClientException
    Inherits ApplicationException
```

[C#]
```
public class IcmpClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A IcmpClientException is thrown by the IcmpClient class when an error occurs.

The default constructor for the IcmpClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.IcmpClient (in SocketTools.IcmpClient.dll)

See Also

IcmpClientException Members | SocketTools Namespace

IcmpClientException Members

IcmpClientException overview

Public Instance Constructors

IcmpClientException	Overloaded. Initializes a new instance of the IcmpClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

IcmpClientException Class | SocketTools Namespace

IcmpClientException Constructor

Initializes a new instance of the IcmpClientException class with the last network error code.

Overload List

Initializes a new instance of the IcmpClientException class with the last network error code.

public IcmpClientException();

Initializes a new instance of the IcmpClientException class with a specified error number.

public IcmpClientException(int);

Initializes a new instance of the IcmpClientException class with a specified error message.

public IcmpClientException(string);

Initializes a new instance of the IcmpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public IcmpClientException(string,Exception);

See Also

IcmpClientException Class | SocketTools Namespace

IcmpClientException Constructor ()

Initializes a new instance of the IcmpClientException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public IcmpClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the IcmpClient.ErrorCode enumeration.

See Also

IcmpClientException Class | SocketTools Namespace | IcmpClientException Constructor Overload List

IcmpClientException Constructor (String)

Initializes a new instance of the IcmpClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public IcmpClientException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

IcmpClientException Class | SocketTools Namespace | IcmpClientException Constructor Overload List

IcmpClientException Constructor (String, Exception)

Initializes a new instance of the IcmpClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public IcmpClientException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

IcmpClientException Class | SocketTools Namespace | IcmpClientException Constructor Overload List

IcmpClientException Constructor (Int32)

Initializes a new instance of the IcmpClientException class with a specified error number.

```
[Visual Basic]
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

```
[C#]
public IcmpClientException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the IcmpClient.ErrorCode enumeration.

IcmpClientException Class | SocketTools Namespace | IcmpClientException Constructor Overload List

IcmpClientException Properties

The properties of the **IcmpClientException** class are listed below. For a complete list of **IcmpClientException** class members, see the IcmpClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

IcmpClientException Class | SocketTools Namespace

IcmpClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public IcmpClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a IcmpClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the IcmpClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the IcmpClient.ErrorCode enumeration.

See Also

IcmpClientException Class | SocketTools Namespace

IcmpClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

IcmpClientException Class | SocketTools Namespace

IcmpClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

IcmpClientException Class | SocketTools Namespace

IcmpClientException Methods

The methods of the **IcmpClientException** class are listed below. For a complete list of **IcmpClientException** class members, see the IcmpClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

IcmpClientException Class | SocketTools Namespace

IcmpClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

IcmpClientException Class | SocketTools Namespace

ImapClient Class

Implements the Internet Message Access Protocol.

For a list of all members of this type, see ImapClient Members.

System.Object
  SocketTools.ImapClient

[Visual Basic]
```
Public Class ImapClient
    Implements IDisposable
```

[C#]
```
public class ImapClient : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The Internet Message Access Protocol (IMAP) is an application protocol which is used to access a user's email messages which are stored on a mail server. However, unlike the Post Office Protocol (POP) where messages are downloaded and processed on the local system, the messages on an IMAP server are retained on the server and processed remotely. This is ideal for users who need access to a centralized store of messages or have limited bandwidth. For example, traveling salesmen who have notebook computers or mobile users on a wireless network would be ideal candidates for using IMAP.

The ImapClient class implements the current standard for this protocol, and provides functions to retrieve messages, or just certain parts of a message, create and manage mailboxes, search for specific messages based on certain criteria and so on.

This class supports secure connections using the standard TLS protocols.

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

ImapClient Members | SocketTools Namespace

ImapClient Members

ImapClient overview

Public Static (Shared) Fields

imapPortDefault	A constant value which specifies the default port number.
imapPortSecure	A constant value which specifies the default port number for a secure connection.
imapTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

ImapClient Constructor	Initializes a new instance of the ImapClient class.

Public Instance Fields

Mailbox	Gets the names of the available mailboxes for the current user.
MessagePart	Gets the contents of the specified message part.

Public Instance Properties

Authentication	Gets and sets the method used to authenticate the user.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
BearerToken	Gets and sets the bearer token used with OAuth 2.0 authentication.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.

CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Delimiter	Gets the hierarchical path delimiter used for the current mailbox.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
HeaderField	Gets and sets the current header field name.
HeaderValue	Gets the value of the current header field.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsIdle	Gets a value which indicates if the client is idle and the current mailbox is being monitored for status changes.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets a value that specifies if the date and time are localized.

LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Mailboxes	Gets the number of mailboxes available on the server.
MailboxFlags	Gets one or more flags which identify characteristics of the current mailbox.
MailboxMask	Gets and sets the current mailbox wildcard mask.
MailboxName	Gets and sets the name of the current mailbox.
MailboxPath	Gets and sets the current mailbox reference path.
MailboxSize	Gets the size of the current mailbox.
MailboxUID	Gets the unique identifier for the current mailbox.
Message	Gets and sets the current message number.
MessageCount	Gets the number of messages available in the current mailbox.
MessageFlags	Gets and sets one or more flags for the current message.
MessageParts	Gets the number of message parts in the current message.
MessageSize	Gets the size of the current message in bytes.
MessageUID	Gets the UID for the current message.
NewMessages	Gets the number of new messages available in the current mailbox.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client.
ReadOnly	Gets a value which specifies if the current mailbox can be modified.
RecentMessages	Gets the number of messages which have recently arrived in the mailbox.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.

SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
Subscribed	Gets a value that specifies if the user has subscribed to the currently selected mailbox.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client.
Version	Gets a value which returns the current version of the ImapClient class library.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
CheckMailbox	Create a checkpoint for the currently selected mailbox.
CloseMessage	Closes the current message.
Command	Overloaded. Send a custom command to the mail server.
Connect	Overloaded. Establish a connection with a remote host.

CopyMessage	Copy a message from the current mailbox to another mailbox.
CreateMailbox	Creates a new mailbox on the server.
CreateMessage	Overloaded. Create a new message.
DeleteMailbox	Overloaded. Deletes a mailbox from the server.
DeleteMessage	Overloaded. Flags a message for deletion from the current mailbox.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by ImapClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExamineMailbox	Selects the specified mailbox for read-only access.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Returns the value of a header field from the specified message part.
GetHeaders	Overloaded. Retrieves the headers for the specified message from the server.
GetMessage	Overloaded. Retrieve a message from the server and return the contents in a byte array.
GetType (inherited from Object)	Gets the Type of the current instance.
Idle	Overloaded. Enables mailbox status monitoring for the client session.
Initialize	Overloaded. Initialize an instance of the ImapClient class.
OpenMessage	Overloaded. Open the specified message for reading.
Read	Overloaded. Read data from the server and store it in a byte array.
Refresh	Updates the list of available mailboxes.
RenameMailbox	Change the name of a mailbox.
ReselectMailbox	Reselects the current mailbox.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SearchMailbox	Overloaded. Search the current mailbox for messages that match the specified criteria and character set.
SelectMailbox	Selects the specified mailbox for read-write access.

StoreMessage	Overloaded. Retrieve a message from the current mailbox and store it in a file on the local system.
SubscribeMailbox	Overloaded. Subscribes the user to the specified mailbox.
ToString (inherited from Object)	Returns a String that represents the current Object.
UndeleteMessage	Removes the deletion flag for the specified message.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
UnselectMailbox	Overloaded. Unselects the current mailbox.
UnsubscribeMailbox	Overloaded. Unsubscribes the user from the specified mailbox.
Write	Overloaded. Write one or more bytes of data to the server.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an client operation fails.
OnProgress	Occurs as a data stream is being read or written to the client.
OnRead	Occurs when data is available to be read from the client.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnUpdate	Occurs when the server sends a mailbox update notification to the client.
OnWrite	Occurs when data can be written to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the ImapClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

ImapClient Constructor

Initializes a new instance of the ImapClient class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public ImapClient();
```

See Also

ImapClient Class | SocketTools Namespace

ImapClient Fields

The fields of the **ImapClient** class are listed below. For a complete list of **ImapClient** class members, see the ImapClient Members topic.

Public Static (Shared) Fields

imapPortDefault	A constant value which specifies the default port number.
imapPortSecure	A constant value which specifies the default port number for a secure connection.
imapTimeout	A constant value which specifies the default timeout period.

Public Instance Fields

Mailbox	Gets the names of the available mailboxes for the current user.
MessagePart	Gets the contents of the specified message part.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Mailbox Field

Gets the names of the available mailboxes for the current user.

[Visual Basic]

```
Public ReadOnly Mailbox As MailboxArray
```

[C#]

```
public readonly MailboxArray Mailbox;
```

Remarks

The **Mailbox** array is used to enumerate the available mailboxes on the IMAP server. This is a zero-based array, which means that the index value for the first mailbox is zero. The total number of mailboxes that are available on the server is returned by the **Mailboxes** property.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MessagePart Field

Gets the contents of the specified message part.

[Visual Basic]
```
Public ReadOnly MessagePart As MessagePartArray
```

[C#]
```
public readonly MessagePartArray MessagePart;
```

Remarks

The **MessagePart** array returns the contents of the specified message part. All messages have at least one part, which consists of one or more header fields, followed by the body of the message. The default part, part 1, refers to the main message header and body. If the message contains multiple parts (as with a message that contains one or more attached files), the **MessagePart** array can be set to refer to that specific part of the message.

Messages with file attachments typically consist of a message part which describes the contents of the attachment, followed by the attachment itself. For a message with one attached file, there would be a total of three parts. Part 1 would refer to the main message part, which contains the headers such as From, To, Subject, Date and so on. For multipart messages, part 1 typically does not have a message body, since any text is usually created as a separate part (for those messages that do not contain multiple parts, the part 1 body contains the text message). Part 2 would contain the text describing the attachment, and part 3 would contain the attachment itself. If the attached file is binary, then the transfer encoding type would usually be base64.

It is important to note that an IMAP server considers the first part of a multipart message to be part 1, so the **MessagePart** array is one-based. This is different than the **SocketTools.MailMessage** class, which considers the first part of a mulitpart message to be zero

ImapClient Properties

The properties of the **ImapClient** class are listed below. For a complete list of **ImapClient** class members, see the ImapClient Members topic.

Public Instance Properties

Authentication	Gets and sets the method used to authenticate the user.
AutoResolve	Gets and sets a value that determines if host names and addresses are automatically resolved.
BearerToken	Gets and sets the bearer token used with OAuth 2.0 authentication.
Blocking	Gets and sets a value which indicates if the client is in blocking mode.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
Delimiter	Gets the hierarchical path delimiter used for the current mailbox.
Handle	Gets a value that specifies the client handle allocated for the current session.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.

HeaderField	Gets and sets the current header field name.
HeaderValue	Gets the value of the current header field.
HostAddress	Gets and sets a value which specifies the Internet address used to establish a connection.
HostName	Gets and sets a value which specifies the host name used to establish a connection.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking client operation.
IsConnected	Gets a value which indicates if a connection to the remote host has been established.
IsIdle	Gets a value which indicates if the client is idle and the current mailbox is being monitored for status changes.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsReadable	Gets a value which indicates if there is data available to be read from the socket connection to the server.
IsWritable	Gets a value which indicates if data can be written to the client without blocking.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LocalAddress	Gets the local Internet address that the client is bound to.
Localize	Gets a value that specifies if the date and time are localized.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Mailboxes	Gets the number of mailboxes available on the server.
MailboxFlags	Gets one or more flags which identify characteristics of the current mailbox.
MailboxMask	Gets and sets the current mailbox wildcard mask.
MailboxName	Gets and sets the name of the current mailbox.
MailboxPath	Gets and sets the current mailbox reference path.
MailboxSize	Gets the size of the current mailbox.
MailboxUID	Gets the unique identifier for the current mailbox.
Message	Gets and sets the current message number.

MessageCount	Gets the number of messages available in the current mailbox.
MessageFlags	Gets and sets one or more flags for the current message.
MessageParts	Gets the number of message parts in the current message.
MessageSize	Gets the size of the current message in bytes.
MessageUID	Gets the UID for the current message.
NewMessages	Gets the number of new messages available in the current mailbox.
Options	Gets and sets a value which specifies one or more client options.
Password	Gets and sets the password used to authenticate the client.
ReadOnly	Gets a value which specifies if the current mailbox can be modified.
RecentMessages	Gets the number of messages which have recently arrived in the mailbox.
RemotePort	Gets and sets a value which specifies the remote port number.
RemoteService	Gets and sets a value which specifies the remote service.
ResultCode	Gets a value which specifies the last result code returned by the server.
ResultString	Gets a string value which describes the result of the previous command.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Status	Gets a value which specifies the current status of the client.
Subscribed	Gets a value that specifies if the user has subscribed to the currently selected mailbox.
ThreadModel	Gets and sets a value which specifies the threading model for the class instance.

ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client.
Version	Gets a value which returns the current version of the ImapClient class library.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Authentication Property

Gets and sets the method used to authenticate the user.

[Visual Basic]

```
Public Property Authentication As ImapAuthentication
```

[C#]

```
public ImapClient.ImapAuthentication Authentication {get; set;}
```

Property Value

A ImapAuthentication enumeration value which specifies the authentication method.

Remarks

The **authXOAuth2** and **authBearer** authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

See Also

ImapClient Class | SocketTools Namespace | BearerToken Poperty | Password Property | UserName Property

ImapClient.AutoResolve Property

Gets and sets a value that determines if host names and addresses are automatically resolved.

[Visual Basic]

```
Public Property AutoResolve As Boolean
```

[C#]

```
public bool AutoResolve {get; set;}
```

Property Value

Returns **true** if host names are automatically resolved to Internet addresses. The default value is **false**.

Remarks

Setting the **AutoResolve** property determines if the class automatically resolves host names and addresses specified by the **HostName** and **HostAddress** properties. If set to **true**, setting the **HostName** property will cause the class to automatically determine the corresponding IP address and update the **HostAddress** property accordingly. Likewise, setting the **HostAddress** property will cause the class to determine the host name and update the **HostName** property. Setting this property to **false** prevents the class from resolving host names until a connection attempt is made.

It is important to note that setting the **HostName** or **HostAddress** property may cause the current thread to block, sometimes for several seconds, until the name or address is resolved. To prevent this behavior, set this property value to **false**.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.BearerToken Property

Gets and sets the bearer token used with OAuth 2.0 authentication.

[Visual Basic]
```
Public Property BearerToken As String
```

[C#]
```
public string BearerToken {get; set;}
```

Property Value

Returns a string which contains the bearer token. Assigning a value to this property sets the curent authentication type to use OAuth 2.0 authentication and updates the bearer token.

Remarks

Assigning a value to the **BearerToken** property will automatically change the current authentication method to use OAuth 2.0 if necessary.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining a bearer token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the bearer token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

Your application should not store the bearer token for later use. They usually have a relatively short lifespan, typically about an hour, and are designed to be used with the current client session. You should specify offline access as part of the OAuth 2.0 scope, and store the refresh token provided by the service. The refresh token has a much onger validity period and can be used to obtain a new access token when needed.

If the current authentication method does not use OAuth 2.0, this property will return an empty string and you should use the **Password** property to obtain the current user password.

See Also

ImapClient Class | SocketTools Namespace | Authentication Property | Password Property | UserName Property

ImapClient.Blocking Property

Gets and sets a value which indicates if the client is in blocking mode.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

Returns **true** if the client is in blocking mode; otherwise it returns **false**. The default value is **true**.

Remarks

Setting the **Blocking** property determines if client operations complete synchronously or asynchronously. If set to **true**, then each client operation (such as sending or receiving data) will return when the operation has completed or timed-out. If set to **false**, client operations will return immediately. If the operation would result in the client blocking (such as attempting to read data when no data has been sent by the remote host), an error is generated.

It is important to note that certain events, such as **OnDisconnect, OnRead** and **OnWrite** are only fired if the client is in non-blocking mode.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]

```
Public ReadOnly Property CertificateExpires As String
```

[C#]

```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]

```
Public ReadOnly Property CertificateIssued As String
```

[C#]

```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]

```
Public ReadOnly Property CertificateIssuer As String
```

[C#]

```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.CertificateName Property

Gets and sets a value that specifies the name of the client certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property is used to specify the name of a client certificate to use when establishing a secure connection. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

ImapClient Class | SocketTools Namespace | CertificateStore Property | Secure Property

ImapClient.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the remote host.

[Visual Basic]

```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]

```
public ImapClient.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the remote host when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]
```
Public Property CertificateStore As String
```

[C#]
```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

ImapClient Class | SocketTools Namespace | CertificatePassword Property | Secure Property

ImapClient.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]

```
Public ReadOnly Property CertificateSubject As String
```

[C#]

```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]
```
Public ReadOnly Property CipherStrength As Integer
```

[C#]
```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Delimiter Property

Gets the hierarchical path delimiter used for the current mailbox.

[Visual Basic]

```
Public ReadOnly Property Delimiter As String
```

[C#]

```
public string Delimiter {get;}
```

Property Value

A string which specifies the path delimiter used for the current mailbox.

Remarks

The **Delimiter** property returns a string which specifies the path delimiter used for the current mailbox. If the IMAP server supports multiple levels of mailboxes, then a special character or sequence of characters are used as delimiters between different levels of the mailbox hierarchy. On most systems, including most UNIX and Windows platforms, the delimiter is the forward slash "/" character.

It is possible that an IMAP server may only support a flat namespace, in which case this property will return an empty string.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Handle Property

Gets a value that specifies the client handle allocated for the current session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no active connection, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current client session.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.HeaderField Property

Gets and sets the current header field name.

[Visual Basic]

```
Public Property HeaderField As String
```

[C#]

```
public string HeaderField {get; set;}
```

Property Value

A string which specifies the current header field name.

Remarks

The **HeaderField** property returns the name of the current header field. Setting this property causes the control to determine if that header field exists, and if it does, to update the **HeaderValue** property with its value. This property can be used to obtain the value of any header in the current message.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.HeaderValue Property

Gets the value of the current header field.

[Visual Basic]

```
Public ReadOnly Property HeaderValue As String
```

[C#]

```
public string HeaderValue {get;}
```

Property Value

A string which specifies the value of the current header field.

Remarks

The **HeaderValue** property returns the value of the header field specified by the **HeaderField** property. This property can be used to obtain the value of any header in the current message.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.HostAddress Property

Gets and sets a value which specifies the Internet address used to establish a connection.

[Visual Basic]
```
Public Property HostAddress As String
```

[C#]
```
public string HostAddress {get; set;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **HostAddress** property can be used to set the Internet address for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the address is assigned to a valid host name, the **HostName** property will be updated with that value.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.HostName Property

Gets and sets a value which specifies the host name used to establish a connection.

[Visual Basic]

```
Public Property HostName As String
```

[C#]

```
public string HostName {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **HostName** property can be used to set the host name for a remote system that you wish to communicate with. If the **AutoResolve** property is set to **true** and the name can be resolved to a valid Internet address, the **HostAddress** property will be updated with that value.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking client operation.

[Visual Basic]
```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]
```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next client operation will not fail. An application should always check the return value from a client operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.IsConnected Property

Gets a value which indicates if a connection to the remote host has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the remote host. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.IsIdle Property

Gets a value which indicates if the client is idle and the current mailbox is being monitored for status changes.

[Visual Basic]

```
Public ReadOnly Property IsIdle As Boolean
```

[C#]

```
public bool IsIdle {get;}
```

Property Value

Returns **true** if the client is idle and the current mailbox is being monitored; otherwise returns **false**.

Remarks

The **IsIdle** property can be used to determine if the **Idle** method has been called to place the client session in an idle state, monitoring the connection for any status messages sent by the server. Typically this is done to allow the application to be notified asynchronously whenever a new message is stored in the mailbox, or when a message has been expunged.

The worker thread that monitors the client connection in the background can terminate if an IMAP command is sent to the server, if the **Cancel** method is called or if the client disconnects from the server. This property enables the application to determine if this background thread is still active or not.

See Also

ImapClient Class | SocketTools Namespace | Idle Method | OnUpdate Event

ImapClient.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.IsReadable Property

Gets a value which indicates if there is data available to be read from the socket connection to the server.

[Visual Basic]

```
Public ReadOnly Property IsReadable As Boolean
```

[C#]

```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to read the client. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.IsWritable Property

Gets a value which indicates if data can be written to the client without blocking.

[Visual Basic]

```
Public ReadOnly Property IsWritable As Boolean
```

[C#]

```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without blocking. For non-blocking sessions, this property can be checked before the application attempts to write data to the client. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public ImapClient.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.LocalAddress Property

Gets the local Internet address that the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address.

Remarks

The **LocalAddress** property returns the local Internet address that the client is bound to when a connection is established with a remote host. This property may return either an IPv4 or IPv6 formatted address, depending on the type of connection that was established.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Localize Property

Gets a value that specifies if the date and time are localized.

[Visual Basic]

```
Public Property Localize As Boolean
```

[C#]

```
public bool Localize {get; set;}
```

Property Value

A boolean value which specifies if the date and time is localized.

Remarks

Setting the **Localize** property controls how date and time values are localized. If the property is set to **true**, then the date and time will be adjusted to the current timezone. If the property is set to **false**, the date and time are returned as UTC (Coordinated Universal Time) values.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.LocalPort Property

Gets the local port number the client is bound to.

[Visual Basic]

```
Public ReadOnly Property LocalPort As Integer
```

[C#]

```
public int LocalPort {get;}
```

Property Value

An integer value which specifies a port number. The default value is 0.

Remarks

The **LocalPort** property is used to identify the local port number that the client is bound to to when a connection is established with a remote host.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Mailboxes Property

Gets the number of mailboxes available on the server.

[Visual Basic]

```
Public ReadOnly Property Mailboxes As Integer
```

[C#]

```
public int Mailboxes {get;}
```

Property Value

An integer value which specifies the number of available mailboxes.

Remarks

The **Mailboxes** property returns the total number of mailboxes available to the current account on the server. This property can be used in conjunction with the **Mailbox** array to enumerate the names of all of the mailboxes which can be selected by the client.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MailboxFlags Property

Gets one or more flags which identify characteristics of the current mailbox.

[Visual Basic]

```
Public ReadOnly Property MailboxFlags As ImapFlags
```

[C#]

```
public ImapClient.ImapFlags MailboxFlags {get;}
```

Property Value

An ImapFlags enumeration value which specifies one or more mailbox flags.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MailboxMask Property

Gets and sets the current mailbox wildcard mask.

[Visual Basic]

```
Public Property MailboxMask As String
```

[C#]

```
public string MailboxMask {get; set;}
```

Property Value

A string which specifies the current mailbox wildcard mask.

Remarks

The **MailboxMask** property returns the current mailbox wildcard mask. If no wildcard mask has been specified by the client, this property will return an empty string.

Setting the **MailboxMask** property will determine which mailboxes are returned by the **Mailbox** array. Wildcards may include the asterisk (which matches any mailbox as well as any child mailboxes) and the percent sign (which matches any mailbox, but does not match any child mailboxes). This property may be used in conjunction with the **MailboxPath** property to further qualify which mailboxes are returned.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MailboxName Property

Gets and sets the name of the current mailbox.

[Visual Basic]

```
Public Property MailboxName As String
```

[C#]

```
public string MailboxName {get; set;}
```

Property Value

A string that specifies the name of the current mailbox.

Remarks

The **MailboxName** property returns the name of the currently selected mailbox. If no mailbox has been selected by the client, this property will return an empty string.

Setting the **MailboxName** property will select a new mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, call the **UnselectMailbox** method prior to selecting the new mailbox. Setting the **MailboxName** property to an empty string will cause the current mailbox to be unselected, and a new mailbox will not be selected. Before the application can access any messages, it must select a new mailbox.

Selecting a new mailbox will automatically update those properties which provide information about the current mailbox, such as the **MailboxFlags** and **MailboxUID** properties. If an application wishes to update the information for the current mailbox, simply set the **MailboxName** property again with the same mailbox name. Note that this will not cause any messages marked for deletion to be expunged.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

If the mailbox name contains international characters then it is automatically encoded using a modified version of UTF-7 encoding. For example, if a mailbox is named "Håndskrift", the mailbox name created on the server will be the string "H&AOU-ndskrift". The control will automatically decode UTF-7 encoded mailbox names, making the conversion transparent to the application.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MailboxPath Property

Gets and sets the current mailbox reference path.

[Visual Basic]
```
Public Property MailboxPath As String
```

[C#]
```
public string MailboxPath {get; set;}
```

Property Value

A string which specifies the current mailbox reference path.

Remarks

The **MailboxPath** property returns the current mailbox reference path. If no path has been specified by the client, this property will return an empty string.

Setting the **MailboxPath** property will determine which mailboxes are returned by the **Mailbox** array. Typically this is used to specify a subdirectory where mail folders are stored for the current user. Note that some mail servers may not permit absolute reference paths, and in most cases the path should include a trailing slash. This property may be used in conjunction with the **MailboxMask** property to further qualify which mailboxes are returned.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MailboxSize Property

Gets the size of the current mailbox.

[Visual Basic]

```
Public ReadOnly Property MailboxSize As Integer
```

[C#]

```
public int MailboxSize {get;}
```

Property Value

An integer value which specifies the size of the mailbox in bytes.

Remarks

The **MailboxSize** property returns the combined size of all messages in the current mailbox. Referencing this property will cause the current thread to block and may require a significant amount of time to calculate the mailbox size if there are a large number of messages in the mailbox. Because it can potentially result in long delays, it is not recommended that an application calculate the mailbox size unless it is absolutely necessary.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MailboxUID Property

Gets the unique identifier for the current mailbox.

[Visual Basic]

```
Public ReadOnly Property MailboxUID As Integer
```

[C#]

```
public int MailboxUID {get;}
```

Property Value

An integer value which specifies the mailbox UID.

Remarks

The **MailboxUID** property returns an integer value which uniquely identifies the mailbox and corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

An application can use the **MailboxUID** property value in combination with the **MessageUID** property in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update it's local copy of that mailbox.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Message Property

Gets and sets the current message number.

[Visual Basic]

```
Public Property Message As Integer
```

[C#]

```
public int Message {get; set;}
```

Property Value

An integer value which specifies the current message number.

Remarks

The **Message** property sets or returns the message number for the currently selected mailbox. Message numbers range from 1 through the number of messages available on the server, as returned by the **MessageCount** property. Setting the **Message** property to an invalid message number will generate an exception.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MessageCount Property

Gets the number of messages available in the current mailbox.

[Visual Basic]

```
Public ReadOnly Property MessageCount As Integer
```

[C#]

```
public int MessageCount {get;}
```

Property Value

An integer value which specifies the number of messages.

Remarks

The **MessageCount** property returns the number of messages available to be retrieved from the currently selected mailbox.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MessageFlags Property

Gets and sets one or more flags for the current message.

[Visual Basic]
```
Public Property MessageFlags As ImapFlags
```

[C#]
```
public ImapClient.ImapFlags MessageFlags {get; set;}
```

Property Value

An ImapFlags enumeration value which specifies one or more message flags.

Remarks

The **MessageFlags** property returns information about the currently selected message specified by the **Message** property. Setting the **MessageFlags** property changes the flags for the currently selected message. Multiple bit flags can be combined using the bitwise Or operator. An application can test if a flag is set by using the bitwise And operator.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MessageParts Property

Gets the number of message parts in the current message.

[Visual Basic]
```
Public ReadOnly Property MessageParts As Integer
```

[C#]
```
public int MessageParts {get;}
```

Property Value

An integer value which specifies the number of message parts.

Remarks

The **MessageParts** property returns the number of message parts in the current message. All messages have at least one part, referenced as part 1. Multipart messages will consist of additional parts which may be accessed by reading the **MessagePart** array or calling the **GetMessage** method.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MessageSize Property

Gets the size of the current message in bytes.

[Visual Basic]

```
Public ReadOnly Property MessageSize As Integer
```

[C#]

```
public int MessageSize {get;}
```

Property Value

An integer value which specifies the size of the message.

Remarks

The **MessageSize** property returns the size of the current message in bytes. The size includes the header and body portion of the message.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.MessageUID Property

Gets the UID for the current message.

[Visual Basic]

```
Public ReadOnly Property MessageUID As Integer
```

[C#]

```
public int MessageUID {get;}
```

Property Value

An integer value which specifies the current message UID.

Remarks

The **MessageUID** property returns an integer value which specifies a unique identifier for this message. The actual value is determined by the server and should be considered opaque. If the client application stores the message UID on the local system, it should also store the UID for the mailbox that contains the message. If the mailbox UID changes, the message UID may no longer be valid.

An application can use the **MessageUID** property value in combination with the **MailboxUID** property in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update it's local copy of that mailbox.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.NewMessages Property

Gets the number of new messages available in the current mailbox.

[Visual Basic]

```
Public ReadOnly Property NewMessages As Integer
```

[C#]

```
public int NewMessages {get;}
```

Property Value

An integer value which specifies the number of new, unread messages in the current mailbox.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]

```
Public Property Options As ImapOptions
```

[C#]

```
public ImapClient.ImapOptions Options {get; set;}
```

Property Value

Returns one or more ImapOptions enumeration flags which specify the options for the client. The default value for this property is **imapOptionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Password Property

Gets and sets the password used to authenticate the client.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

The **Password** property specifies the password used to authenticate the client session. This property is used as the default value for the **Connect** method if no password is specified as an argument.

Refer to the **Authentication** property for more information on the available authentication methods. If you are using the OAuth 2.0 authentication method, this property should not be set to the user's password. Instead, you should set the **BearerToken** property to the OAuth 2.0 bearer token issued by the mail service provider. Note that these access tokens can be much larger than your typical password and are only valid for a limited period of time.

You can use the **Password** property to specify an OAuth 2.0 bearer token. However, it is recommended that you use the **BearerToken** property instead of assigning it to this property. It will ensure compatibility with future versions of the class and make it clear in your code you are using an OAuth 2.0 bearer token and not a password. If the **AuthType** property specifies one of the OAuth 2.0 authentication methods, this property will return the bearer token.

See Also

ImapClient Class | SocketTools Namespace | Authentication Property | BearerToken Property | UserName Property | Connect Method

ImapClient.ReadOnly Property

Gets a value which specifies if the current mailbox can be modified.

[Visual Basic]

```
Public ReadOnly Property ReadOnly As Boolean
```

[C#]

```
public bool ReadOnly {get;}
```

Property Value

A boolean value which specifies if the current mailbox can be modified. A value of **true** specifies that the mailbox cannot be modified by the client. A value of **false** specifies that the mailbox can be modified.

Remarks

The **ExamineMailbox** method can be used to select a mailbox in read-only mode. The **SelectMailbox** method can be used to select a mailbox in read-write mode, which allows the contents of the mailbox to be modified.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.RecentMessages Property

Gets the number of messages which have recently arrived in the mailbox.

[Visual Basic]

```
Public ReadOnly Property RecentMessages As Integer
```

[C#]

```
public int RecentMessages {get;}
```

Property Value

An integer value which specifies the number of recent messages.

Remarks

The **RecentMessages** property returns the number of messages which have been recently added to the currently selected mailbox. This property is particularly useful when the INBOX mailbox is selected because it enables the application to check if any new messages have arrived.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.RemotePort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]
```
Public Property RemotePort As Integer
```

[C#]
```
public int RemotePort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RemotePort** property is used to set the port number that will be used to establish a connection with a remote host. If the port number specifies a well-known port, the **RemoteService** property will be updated with that name.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.ResultCode Property

Gets a value which specifies the last result code returned by the server.

[Visual Basic]
```
Public ReadOnly Property ResultCode As ImapResult
```

[C#]
```
public ImapClient.ImapResult ResultCode {get;}
```

Property Value

An ImapResult enumeration value which specifies the last result code returned by the server.

Remarks

One of the following result codes may be returned after a command is executed on the server:

ResultCode	Description
resultUnknown	An unknown result code was returned by the server.
resultOk	The previous command completed successfully. The result string contains information about the results of the command.
resultNo	The previous command could not be completed. The result string contains information about why the command failed.
resultBad	The previous command could not be completed, the command may be invalid or not supported on the server. The result string contains information about why the command failed.
resultContinue	The command has executed and is waiting for additional data from the client.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.ResultString Property

Gets a string value which describes the result of the previous command.

[Visual Basic]
```
Public ReadOnly Property ResultString As String
```

[C#]
```
public string ResultString {get;}
```

Property Value

A string which describes the result of the previous command executed on the server.

Remarks

The **ResultString** property returns the result string from the last action taken by the client. This string is generated by the remote server, and typically is used to describe the result code. For example, if the previous result code indicates an error, the result string may describe the condition that caused the error.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established with the remote host. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Connect** method. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an exception may be generated when this property value is set.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public ImapClient.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]

```
public ImapClient.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]
```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]
```
public ImapClient.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]

```
Public Property SecureProtocol As SecurityProtocols
```

[C#]

```
public ImapClient.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the control is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Status Property

Gets a value which specifies the current status of the client.

[Visual Basic]

```
Public ReadOnly Property Status As ImapStatus
```

[C#]

```
public ImapClient.ImapStatus Status {get;}
```

Property Value

A ImapStatus enumeration value which specifies the current client status.

Remarks

The **Status** property returns the current status of the client. This property can be used to check on blocking connections to determine if the client is interacting with the remote host before taking some action.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Subscribed Property

Gets a value that specifies if the user has subscribed to the currently selected mailbox.

[Visual Basic]

```
Public Property Subscribed As Boolean
```

[C#]

```
public bool Subscribed {get; set;}
```

Property Value

A boolean value that specifies if the user has subscribed to the current mailbox.

Remarks

The **Subscribed** property is used to determine if the current mailbox has been subscribed to by the user. If the property returns **false**, the server has indicated that the user has not subscribed to the mailbox. If the property returns **true**, the current mailbox is in the user's subscription list.

Setting the **Subscribed** property changes the subscription status of the current mailbox. Setting the property to **true** adds the mailbox to the user's list of subscribed mailboxes, while setting it to **false** removes the mailbox from the subscription list.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.ThreadModel Property

Gets and sets a value which specifies the threading model for the class instance.

[Visual Basic]

```
Public Property ThreadModel As ThreadingModel
```

[C#]

```
public ImapClient.ThreadingModel ThreadModel {get; set;}
```

Property Value

Returns one or more ThreadingModel enumeration value which specifies the threading model for the client. The default value for this property is **modelSingleThread**.

Remarks

The **ThreadModel** property specifies the threading model that is used by the class instance when a connection is established. The default value for this property is **modelSingleThread**, which specifies that only the thread that established the connection should be permitted to invoke methods. It is important to note that this threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this property to **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this property will not affect an active client session. The threading model must be specified prior to invoking the **Connect** method.

See Also

ImapClient Class | SocketTools Namespace | AttachThread Method | ThreadingModel Enumeration | ThreadModel Attribute

ImapClient.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.TimeZone Property

Gets and sets the current timezone offset in seconds.

[Visual Basic]

```
Public Property TimeZone As Integer
```

[C#]

```
public int TimeZone {get; set;}
```

Property Value

An integer value which specifies the current timezone offset in seconds.

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

This property value is used in conjunction with the **Localize** property to control how date and time localization is handled.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]

```
Public Property Trace As Boolean
```

[C#]

```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.TraceFile Property

Gets and sets a value which specifies the name of the logfile.

[Visual Basic]
```
Public Property TraceFile As String
```

[C#]
```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]
```
Public Property TraceFlags As TraceOptions
```

[C#]
```
public ImapClient.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.UserName Property

Gets and sets the username used to authenticate the client.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

The **UserName** property specifies the username used to authenticate the client session. This property is used as the default value for the **Connect** method if no username is specified as an argument.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Version Property

Gets a value which returns the current version of the ImapClient class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the ImapClient class library. This value can be used by an application for validation and debugging purposes.

See Also

ImapClient Class | SocketTools Namespace

ImapClient Methods

The methods of the **ImapClient** class are listed below. For a complete list of **ImapClient** class members, see the ImapClient Members topic.

Public Instance Methods

AttachThread	Attach an instance of the class to the current thread
Cancel	Cancel the current blocking client operation.
CheckMailbox	Create a checkpoint for the currently selected mailbox.
CloseMessage	Closes the current message.
Command	Overloaded. Send a custom command to the mail server.
Connect	Overloaded. Establish a connection with a remote host.
CopyMessage	Copy a message from the current mailbox to another mailbox.
CreateMailbox	Creates a new mailbox on the server.
CreateMessage	Overloaded. Create a new message.
DeleteMailbox	Overloaded. Deletes a mailbox from the server.
DeleteMessage	Overloaded. Flags a message for deletion from the current mailbox.
Disconnect	Terminate the connection with a remote host.
Dispose	Overloaded. Releases all resources used by ImapClient.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExamineMailbox	Selects the specified mailbox for read-only access.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Returns the value of a header field from the specified message part.
GetHeaders	Overloaded. Retrieves the headers for the specified message from the server.
GetMessage	Overloaded. Retrieve a message from the server and return the contents in a byte array.
GetType (inherited from Object)	Gets the Type of the current instance.
Idle	Overloaded. Enables mailbox status monitoring for the client session.

Initialize	Overloaded. Initialize an instance of the ImapClient class.
OpenMessage	Overloaded. Open the specified message for reading.
Read	Overloaded. Read data from the server and store it in a byte array.
Refresh	Updates the list of available mailboxes.
RenameMailbox	Change the name of a mailbox.
ReselectMailbox	Reselects the current mailbox.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SearchMailbox	Overloaded. Search the current mailbox for messages that match the specified criteria and character set.
SelectMailbox	Selects the specified mailbox for read-write access.
StoreMessage	Overloaded. Retrieve a message from the current mailbox and store it in a file on the local system.
SubscribeMailbox	Overloaded. Subscribes the user to the specified mailbox.
ToString (inherited from Object)	Returns a String that represents the current Object.
UndeleteMessage	Removes the deletion flag for the specified message.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
UnselectMailbox	Overloaded. Unselects the current mailbox.
UnsubscribeMailbox	Overloaded. Unsubscribes the user from the specified mailbox.
Write	Overloaded. Write one or more bytes of data to the server.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the ImapClient class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.AttachThread Method

Attach an instance of the class to the current thread

[Visual Basic]

```
Public Function AttachThread() As Boolean
```

[C#]

```
public bool AttachThread();
```

Return Value

A boolean value which specifies if the client could be attached to the current thread. If this method returns **false**, the client could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

When an instance of the class is created it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that instance, an error is returned. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create an instance of the class, establish a connection and then pass that instance to another worker thread. The **AttachThread** method can be used to change the ownership of the class instance to the new worker thread.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored by the original thread. Under no circumstances should **AttachThread** be used to forcibly destroy an instance of a class allocated by another thread while a blocking operation is in progress. To cancel a blocking operation, use the **Cancel** method and then delete the class instance after the blocking function exits and control is returned to the current thread.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.CheckMailbox Method

Create a checkpoint for the currently selected mailbox.

[Visual Basic]
```
Public Function CheckMailbox() As Boolean
```

[C#]
```
public bool CheckMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CheckMailbox** method requests that the server create a checkpoint of the currently selected mailbox, and updates the current number of new, unread messages available to the client.

When the client requests a checkpoint, the server may perform implementation-dependent housekeeping for that mailbox, such updating the mailbox on disk with the current state of the mailbox in memory. On some systems this command has no effect other than to update the client with the current number of messages in the mailbox.

This function actually sends two IMAP commands. The first is the CHECK command, followed by the NOOP command to poll for any new messages that have arrived. In addition to polling the server for new messages, this command can also be used to ensure the idle timer on the server does not expire and force a disconnect from the client.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.CloseMessage Method

Closes the current message.

[Visual Basic]
```
Public Function CloseMessage() As Boolean
```

[C#]
```
public bool CloseMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CloseMessage** method closes the current message. If there is any remaining data left to be read from the message, it will be read and discarded.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Command Method

Send a custom command to the mail server.

Overload List

Send a custom command to the mail server.

ImapClient.Command Method (String)

Send a custom command to the mail server.

[Visual Basic]

```
Overloads Public Function Command( _
   ByVal command As String _
) As Boolean
```

[C#]

```
public bool Command(
   string command
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine if the command was successful, check the value of the **ResultCode** property. To obtain additional information returned by the server in response to the command, check the value of the **ResultString** property.

ImapClient.Command Method (String, String)

Send a custom command to the mail server.

```
[Visual Basic]
Overloads Public Function Command( _
   ByVal command As String, _
   ByVal parameter As String _
) As Boolean
```

```
[C#]
public bool Command(
   string command,
   string parameter
);
```

Parameters

command

A string which specifies the command to send. Valid commands vary based on the Internet protocol and the type of server that the client is connected to. Consult the protocol standard and/or the technical reference documentation for the server to determine what commands may be issued by a client application.

parameter

A string which specifies one or more parameters to be sent along with the command. If more than one parameter is required, they should be separated by a single space character. Consult the protocol standard and/or technical reference documentation for the server to determine what parameters should be provided when issuing a specific command. If no parameters are required for the command, this argument may be omitted.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Command** method sends a command to the remote host and processes the result code sent back in response to that command. This method can be used to send custom commands to a server to take advantage of features or capabilities that may not be supported internally by the class library.

To determine if the command was successful, check the value of the **ResultCode** property. To obtain additional information returned by the server in response to the command, check the value of the **ResultString** property.

ImapClient Class | SocketTools Namespace

ImapClient.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect() As Boolean
```

[C#]

```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **HostName** or **HostAddress** property will be used to determine the host name or address to connect to.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

ImapClient.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

ImapClient.Connect Method (String, Int32, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout,
   ImapOptions options
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout
An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller. This value is only meaningful for blocking connections.

options
One or more of the ImapOptions enumeration flags.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

ImapClient.Connect Method (String, Int32, String, String)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   string userName,
   string userPassword
);
```

Parameters

hostName
A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort
An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

userName
A string which specifies a username used to authenticate the client session.

userPassword
A string which specifies the password used to authenticate the client session.

Return Value

A boolean value which specifies if the connection has been established. If the client is in blocking mode, a return value of **true** indicates that the connection has completed and the application may send and receive data from the remote host. If the client is in non-blocking mode, a return value of **true** indicates that the client has successfully created a socket and the connection is in progress.

When a non-blocking connection has completed, the OnConnect event will be fired. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

ImapClient.CopyMessage Method

Copy a message from the current mailbox to another mailbox.

[Visual Basic]

```
Public Function CopyMessage( _
   ByVal messageId As Integer, _
   ByVal mailboxName As String _
) As Boolean
```

[C#]

```
public bool CopyMessage(
   int messageId,
   string mailboxName
);
```

Parameters

messageId

The message identifier which specifies which message will be copied to the mailbox. This value must be greater than zero and specify a valid message number.

mailboxName

A string which specifies the name of the mailbox that the message will be copied to. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CopyMessage** method copies a message from the current mailbox to the specified mailbox. The message is appended to the mailbox, and the message flags and internal date are preserved. If the mailbox does not exist, the method will fail. To create a new mailbox, use the **CreateMailbox** method. A message can be copied within the same mailbox, in which case the server may flag it as a new message.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.CreateMailbox Method

Creates a new mailbox on the server.

[Visual Basic]

```
Public Function CreateMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

[C#]

```
public bool CreateMailbox(
   string mailboxName
);
```

Parameters

mailboxName

A string which specifies the name of the new mailbox to be created.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMailbox** method creates a new mailbox on the server. If the mailbox name is suffixed with the server's hierarchy delimiter, this indicates to the server that the client intends to create mailbox names under the specified name in the hierarchy. If superior hierarchical names are specified in the mailbox name, then the server may automatically create them as needed. For example, if the mailbox name "Mail/Office/Projects" is specified and "Mail/Office" does not exist, it may be automatically created by the server.

The special mailbox name INBOX is reserved, and cannot be created. It is recommended that mailbox names only consist of printable ASCII characters, and the special characters "*" and "%" should be avoided.

ImapClient.CreateMessage Method (Byte[], Int32)

Create a new message.

[Visual Basic]

```
Overloads Public Function CreateMessage( _
   ByVal message As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool CreateMessage(
   byte[] message,
   int length
);
```

Parameters

message

A byte array that contains the message data.

length

An integer value which specifies the size of the message in bytes. This value cannot be larger than the size of the message buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMessage** method creates a new message, appending it to the contents of the specified mailbox. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The message will be created in the mailbox specified by the **MailboxName** property.

) As Boolean
```

[C#]

```
public bool CreateMessage(
   byte[] message,
   int length,
   ImapFlags messageFlags
);
```

Parameters

message

A byte array that contains the message data.

length

An integer value which specifies the size of the message in bytes. This value cannot be larger than the size of the message buffer specified by the caller.

messageFlags

An ImapFlags enumeration value which specifies one or more message flags. One or more of the following flags may be used:

Flag	Description
imapFlagNone	The message will be created with no flags set.
imapFlagAnswered	The message has been answered.
imapFlagDraft	The message is a draft copy.
imapFlagUrgent	The message is urgent.
imapFlagSeen	The message has already been read.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMessage** method creates a new message, appending it to the contents of the specified mailbox. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

ImapClient.DeleteMailbox Method

Deletes the currently selected mailbox from the server.

Overload List

Deletes the currently selected mailbox from the server.

public bool DeleteMailbox();

Deletes a mailbox from the server.

public bool DeleteMailbox(string);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.DeleteMailbox Method ()

Deletes the currently selected mailbox from the server.

[Visual Basic]

```
Overloads Public Function DeleteMailbox() As Boolean
```

[C#]

```
public bool DeleteMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteMailbox** method deletes the currently selected mailbox from the server. The current mailbox will be automatically unselected and any messages marked for deletion will be expunged before the mailbox is removed. If the delete operation fails, the client will remain in an unselected state until either the **ExamineMailbox** or **SelectMailbox** method is called

A mailbox cannot be deleted if it contains inferior hierarchical names and has the **imapFlagNoSelect** attribute. On most systems this is the case when the mailbox name references a directory on the server, and that directory contains other subdirectories or mailboxes. To remove the current mailbox, you must first delete any child mailboxes that exist.

The special mailbox named INBOX cannot be deleted.

```
public bool DeleteMailbox(
   string mailboxName
);
```

Parameters

mailboxName

A string which specifies the name of the new mailbox to be deleted.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteMailbox** method deletes a mailbox from the server. A mailbox cannot be deleted if it contains inferior hierarchical names and has the **imapFlagNoSelect** attribute. On most systems this is the case when the mailbox name references a directory on the server, and that directory contains other subdirectories or mailboxes. To remove the mailbox, you must first delete any child mailboxes that exist.

If the mailbox that is deleted is the currently selected mailbox, it will be automatically unselected and any messages marked for deletion will be expunged before the mailbox is removed. If the delete operation fails, the client will remain in an unselected state until either the **ExamineMailbox** or **SelectMailbox** method is called.

The special mailbox named INBOX cannot be deleted.

ImapClient.DeleteMessage Method

Flags the current message for deletion from the mailbox.

Overload List

Flags the current message for deletion from the mailbox.

public bool DeleteMessage();

Flags a message for deletion from the current mailbox.

public bool DeleteMessage(int);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.DeleteMessage Method ()

Flags the current message for deletion from the mailbox.

[Visual Basic]

```
Overloads Public Function DeleteMessage() As Boolean
```

[C#]

```
public bool DeleteMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method only flags the current message for deletion, it is not actually deleted until the mailbox is expunged or another mailbox is selected. This function will return an error if the current mailbox is in read-only mode, such as if it was selected using the **ExamineMailbox** method.

It is important to note that unlike the POP3 protocol, a message that is flagged for deletion is still accessible on the IMAP server until the mailbox is expunged. This means, for example, that a deleted message can still be retrieved using the **GetMessage** method.

To determine if a message has been flagged for deletion, set the **Message** property to the message number and then check the value of the **MessageFlags** property to determine if the **ImapFlags.flagDeleted** flag has been set.

To remove the deletion flag from the message, use the **UndeleteMessage** method. To prevent all messages in the current mailbox from being expunged, use the **ReselectMailbox** function to reset the current mailbox state. Calling the **Reset** method will also unselect the current mailbox without expunging deleted messages.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.DeleteMessage Overload List

ImapClient.DeleteMessage Method (Int32)

Flags a message for deletion from the current mailbox.

[Visual Basic]

```
Overloads Public Function DeleteMessage( _
   ByVal messageId As Integer _
) As Boolean
```

[C#]

```
public bool DeleteMessage(
   int messageId
);
```

Parameters

messageId

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method only flags the message for deletion, it is not actually deleted until the mailbox is expunged or another mailbox is selected. This function will return an error if the current mailbox is in read-only mode, such as if it was selected using the **ExamineMailbox** method.

It is important to note that unlike the POP3 protocol, a message that is flagged for deletion is still accessible on the IMAP server until the mailbox is expunged. This means, for example, that a deleted message can still be retrieved using the **GetMessage** method.

To determine if a message has been flagged for deletion, set the **Message** property to the message number and then check the value of the **MessageFlags** property to determine if the **ImapFlags.flagDeleted** flag has been set.

To remove the deletion flag from the message, use the **UndeleteMessage** method. To prevent all messages in the current mailbox from being expunged, use the **ReselectMailbox** function to reset the current mailbox state. Calling the **Reset** method will also unselect the current mailbox without expunging deleted messages.

ImapClient Class | SocketTools Namespace | ImapClient.DeleteMessage Overload List

ImapClient.Disconnect Method

Terminate the connection with a remote host.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and releases the client handle allocated by the class. Note that the socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the client will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

ImapClient Class | SocketTools Namespace

ImapClient.Dispose Method

Releases all resources used by ImapClient.

Overload List

Releases all resources used by ImapClient.

public void Dispose();

Releases the unmanaged resources allocated by the ImapClient class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Dispose Method ()

Releases all resources used by ImapClient.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.Dispose Overload List

ImapClient.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the ImapClient class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **ImapClient** class so the memory they were occupying can be reclaimed by garbage collection.

ImapClient Class | SocketTools Namespace | ImapClient.Dispose Overload List

ImapClient.ExamineMailbox Method

Selects the specified mailbox for read-only access.

[Visual Basic]

```
Public Function ExamineMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

[C#]

```
public bool ExamineMailbox(
   string mailboxName
);
```

Parameters

mailboxName
A string that specifies the name of the mailbox to be examined.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ExamineMailbox** method is used to select a mailbox in read-only mode. Messages can be read, but they cannot be modified or deleted from the mailbox and new messages will not lose their status as new messages if they are accessed.

If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **UnselectMailbox** method prior to examining the new mailbox.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-write mode, use the **SelectMailbox** method.

ImapClient.GetHeader Method

Returns the value of a header field from the specified message part.

Overload List

Returns the value of a header field from the specified message part.

public bool GetHeader(int,int,string,ref string);

Returns the value of a header field from the specified message.

public bool GetHeader(int,string,ref string);

Returns the value of a header field from the current message.

public bool GetHeader(string,ref string);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.GetHeader Method (Int32, Int32, String, String)

Returns the value of a header field from the specified message part.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal messageId As Integer, _
   ByVal messagePart As Integer, _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   int messageId,
   int messagePart,
   string headerName,
   ref string headerValue
);
```

Parameters

messageId
An integer value that specifies the message to retrieve the header value from. This value must be greater than zero. The first message in the mailbox is message number one.

messagePart
An integer value that specifies the message part that the header value is to be be retrieved from. Message parts start with a value of one. A value of zero specifies that the RFC822 header field for the message will be used.

headerName
A string which specifies the message header to retrieve.

headerValue
A string passed by reference which will contain the value of the specified message header if the method is successful.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method returns the value of a header field from the specified message part. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this method.

   ByVal messageId As Integer, _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   int messageId,
   string headerName,
   ref string headerValue
);
```

Parameters

messageId
An integer value that specifies the message to retrieve the header value from. This value must be greater than zero. The first message in the mailbox is message number one.

headerName
A string which specifies the message header to retrieve.

headerValue
A string passed by reference which will contain the value of the specified message header if the method is successful.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method returns the value of a header field from the specified message. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this method.

Returns the value of a header field from the current message.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   string headerName,
   ref string headerValue
);
```

Parameters

headerName
A string which specifies the message header to retrieve.

headerValue
A string passed by reference which will contain the value of the specified message header if the method is successful.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method returns the value of a header field from the current message. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this method.

The current message number is specified by the value of the **Message** property.

ImapClient Class | SocketTools Namespace

ImapClient.GetHeaders Method (Byte[], Int32)

Retrieves the headers for the current message from the server.

[Visual Basic]

```
Overloads Public Function GetHeaders( _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetHeaders(
   byte[] buffer,
   ref int length
);
```

Parameters

buffer
A byte array that will contain the message data when the method returns.

length
An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeaders** method is used to retrieve the message headers from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Note that the header data will be from the first part of the message, not from any additional sections of a multipart message. In other words, the headers such as From, To, Subject and Date will be returned in the buffer. To retrieve the headers from a specific section of a multipart message, you can use the **GetMessage** method and specify the **ImapSections.sectionHeader** option.

The current message number is specified by the value of the **Message** property.

ImapClient.GetMessage Method (Byte[], Int32)

Retrieve the current message from the server and return the contents in a byte array.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetMessage(
   byte[] buffer,
   ref int length
);
```

Parameters

buffer

A byte array that the message data will be stored in.

length

An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this parameter will be updated with the actual number of bytes copied into the array.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve the current message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The current message number is specified by the value of the **Message** property.

ImapClient Class | SocketTools Namespace | ImapClient.GetMessage Overload List

ImapClient.GetMessage Method (Int32, Int32, Byte[], Int32)

Retrieve a message from the server and return the contents in a byte array.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByVal messageId As Integer, _
   ByVal messagePart As Integer, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetMessage(
   int messageId,
   int messagePart,
   byte[] buffer,
   ref int length
);
```

Parameters

messageId

Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

messagePart

An integer value that specifies the message part that should be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

buffer

A byte array that the message data will be stored in.

length

An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this parameter will be updated with the actual number of bytes copied into the array.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

ImapClient Class | SocketTools Namespace | ImapClient.GetMessage Overload List

ImapClient.GetMessage Method (Int32, Int32, Byte[], Int32, ImapSections)

Retrieve a message from the server and return the contents in a byte array.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByVal messageId As Integer, _
   ByVal messagePart As Integer, _
   ByVal buffer As Byte(), _
   ByRef length As Integer, _
   ByVal options As ImapSections _
) As Boolean
```

[C#]

```
public bool GetMessage(
   int messageId,
   int messagePart,
   byte[] buffer,
   ref int length,
   ImapSections options
);
```

Parameters

messageId
Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

messagePart
An integer value that specifies the message part that should be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

buffer
A byte array that the message data will be stored in.

length
An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this parameter will be updated with the actual number of bytes copied into the array.

options
An ImapSections enumeration value which specifies which section of the message to return.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

ImapClient Class | SocketTools Namespace | ImapClient.GetMessage Overload List

ImapClient.GetMessage Method (Int32, Int32, String)

Retrieve a message from the server and return the contents in a string.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByVal messageId As Integer, _
   ByVal messagePart As Integer, _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool GetMessage(
   int messageId,
   int messagePart,
   ref string buffer
);
```

Parameters

messageId

Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

messagePart

An integer value that specifies the message part that should be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

buffer

A string passed by reference that will contain the message data when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

ImapClient Class | SocketTools Namespace | ImapClient.GetMessage Overload List

ImapClient.Idle Method

Enables mailbox status monitoring for the client session.

Overload List

Enables mailbox status monitoring for the client session.

public bool Idle();

Enables mailbox status monitoring for the client session.

public bool Idle(IdleOptions,int);

See Also

ImapClient Class | SocketTools Namespace | OnUpdate

ImapClient.Idle Method ()

Enables mailbox status monitoring for the client session.

[Visual Basic]

```
Overloads Public Function Idle() As Boolean
```

[C#]

```
public bool Idle();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Many IMAP servers support the ability to asynchronously send status updates to the client, rather than have the client periodically poll the server. The client enables this feature by calling the **Idle** method and providing an event handler for the **OnUpdate** event. Typically these events inform the client that a new message has arrived or that a message has been expunged from the mailbox.

The **Idle** method begins monitoring the client session asynchronously and returns control immediately to the caller. If the server sends a update notification to the client, the **OnUpdate** event will fire with information about the status change. Sending an IMAP command to the server will cause the client to stop monitoring the session for status changes. To explicitly stop monitoring the session, use the **Cancel** method.

This method works by sending the IDLE command to the server and starting a worker thread which monitors the connection and looks for untagged responses issued by the server. Events will be generated for EXISTS, EXPUNGE and RECENT messages. Note that some servers may periodically send untagged OK messages to the client, indicating that the connection is still active; these messages are explicitly ignored.

The **OnUpdate** event is invoked within the context of the worker thread that is monitoring the client session. Because of this, applications should not directly update the user interface from within the event handler. For example, if the server sends a notification that a new email message has arrived, the application should not attempt to read the new message and update the user interface directly from within the event handler. Instead, it should create a delegate and use the **Control.Invoke** method to marshal the call to the thread that owns the control's window handle. Failure to do this can cause the application to become unstable. For more information, refer to the **Control.Invoke** method in the .NET Framework documentation.

An application should never make an assumption about how a particular server may send update notifications to the client. Servers can be configured to use different intervals at which notifications are sent. For example, a server may send new message notifications immediately, but may periodically notify the client when a message has been expunged. Alternatively, a server may only send notifications at fixed intervals, in which case the client would not be notified of any new messages until the interval period is reached. It is not possible for a client to know what a particular server's update interval is. Applications that require that degree of control should not use the **Idle** method and should poll the server instead.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.Idle Overload List | OnUpdate

ImapClient.Idle Method (IdleOptions, Int32)

Enables mailbox status monitoring for the client session.

[Visual Basic]

```
Overloads Public Function Idle( _
   ByVal options As IdleOptions, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Idle(
   IdleOptions options,
   int timeout
);
```

Parameters

options

One or more of the IdleOptions enumeration flags.

timeout

Specifies the timeout period in seconds to wait for a notification from the server. This parameter is only used when the **ImapIdle.idleWait** option has been specified.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Many IMAP servers support the ability to asynchronously send status updates to the client, rather than have the client periodically poll the server. The client enables this feature by calling the **Idle** method and providing an event handler for the **OnUpdate** event. Typically these events inform the client that a new message has arrived or that a message has been expunged from the mailbox.

The **Idle** method can operate in one of two modes, based on the options specified by the caller. If the option **idleNoWait** is specified, the method begins monitoring the client session asynchronously and returns control immediately to the caller. If the server sends a update notification to the client, the **OnUpdate** event will fire with information about the status change. If the option **idleWait** is specified, the method will block waiting for the server to send a notification message to the client. The method will return when either a message is received or the timeout period is exceeded. Sending an IMAP command to the server will cause the client to stop monitoring the session for status changes. To explicitly stop monitoring the session, use the **Cancel** method.

This method works by sending the IDLE command to the server and starting a worker thread which monitors the connection and looks for untagged responses issued by the server. Events will be generated for EXISTS, EXPUNGE and RECENT messages. Note that some servers may periodically send untagged OK messages to the client, indicating that the connection is still active; these messages are explicitly ignored.

The **OnUpdate** event is invoked within the context of the worker thread that is monitoring the client session. Because of this, applications should not directly update the user interface from within the event handler. For example, if the server sends a notification that a new email message has arrived, the application should not attempt to read the new message and update the user interface directly from within the event handler. Instead, it should create a delegate and use the **Control.Invoke** method to marshal the call to the thread that owns the control's window handle. Failure to do this can cause the application to become unstable. For more information, refer to the **Control.Invoke** method in the .NET Framework documentation.

An application should never make an assumption about how a particular server may send update notifications to the client. Servers can be configured to use different intervals at which notifications are sent. For example, a server may send new message notifications immediately, but may periodically notify the client when a message has been expunged. Alternatively, a server may only send notifications at fixed intervals, in which case the client would not be notified of any new messages until the interval period is reached. It is not possible for a client to know what a particular server's update interval is. Applications that require that degree of control should not use the **Idle** method and should poll the server instead.

ImapClient.Initialize Method

Initialize an instance of the ImapClient class.

Overload List

Initialize an instance of the ImapClient class.

public bool Initialize();

Initialize an instance of the ImapClient class.

public bool Initialize(string);

See Also

ImapClient Class | SocketTools Namespace | Uninitialize Method

ImapClient.Initialize Method ()

Initialize an instance of the ImapClient class.

[Visual Basic]
```
Overloads Public Function Initialize() As Boolean
```

[C#]
```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the ImapClient class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.Initialize Overload List | Uninitialize Method

ImapClient.Initialize Method (String)

Initialize an instance of the ImapClient class.

[Visual Basic]
```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]
```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the ImapClient class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the ImapClient class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.ImapClient imapClient = new SocketTools.ImapClient();

if (imapClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(imapClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim imapClient As New SocketTools.ImapClient

If imapClient.Initialize(strLicenseKey) = False Then
    MsgBox(imapClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

ImapClient Class | SocketTools Namespace

ImapClient.OpenMessage Method ()

Open the current message for reading.

[Visual Basic]

```
Overloads Public Function OpenMessage() As Boolean
```

[C#]

```
public bool OpenMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenMessage** method opens the current message in the mailbox. The client can then read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

The current message number is specified by the value of the **Message** property.

ImapClient Class | SocketTools Namespace | ImapClient.OpenMessage Overload List

ImapClient.OpenMessage Method (Int32)

Open the specified message for reading.

[Visual Basic]

```
Overloads Public Function OpenMessage( _
   ByVal messageId As Integer _
) As Boolean
```

[C#]

```
public bool OpenMessage(
   int messageId
);
```

Parameters

messageId

Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenMessage** method opens a message in the current mailbox. The client can then read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

ImapClient.OpenMessage Method (Int32, Int32)

Open the specified message for reading.

[Visual Basic]

```
Overloads Public Function OpenMessage( _
   ByVal messageId As Integer, _
   ByVal messagePart As Integer _
) As Boolean
```

[C#]

```
public bool OpenMessage(
   int messageId,
   int messagePart
);
```

Parameters

messageId

Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

messagePart

An integer value that specifies the message part that should be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenMessage** method opens a message or a specific part of a multipart message in the current mailbox. The client can then read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.OpenMessage Overload List

ImapClient.OpenMessage Method (Int32, Int32, ImapSections)

Open the specified message for reading.

[Visual Basic]

```
Overloads Public Function OpenMessage( _
   ByVal messageId As Integer, _
   ByVal messagePart As Integer, _
   ByVal options As ImapSections _
) As Boolean
```

[C#]

```
public bool OpenMessage(
   int messageId,
   int messagePart,
   ImapSections options
);
```

Parameters

messageId
Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

messagePart
An integer value that specifies the message part that should be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

options
An ImapSections enumeration value which specifies which section of the message to return.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenMessage** method opens a message in the current mailbox. The client can then read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.OpenMessage Overload List

ImapClient.OpenMessage Method (Int32, Int32, Int32, Int32, ImapSections)

Open the specified message for reading.

[Visual Basic]

```
Overloads Public Function OpenMessage( _
   ByVal messageId As Integer, _
   ByVal messagePart As Integer, _
   ByVal offset As Integer, _
   ByRef length As Integer, _
   ByVal options As ImapSections _
) As Boolean
```

[C#]

```
public bool OpenMessage(
   int messageId,
   int messagePart,
   int offset,
   ref int length,
   ImapSections options
);
```

Parameters

messageId
Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

messagePart
An integer value that specifies the message part that should be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

offset
The byte offset into the message. This parameter can be used in conjunction with the ***length*** argument to return a specific part of a message. If this argument is omitted or a value of zero is specified, the server will return data from the beginning of the message.

length
An integer passed by reference which should be initialized to the maximum number of bytes to be read, and will contain the size of the message when the function returns. To specify the entire message, from the offset specified by the ***offset*** parameter to the end of the message, initialize the ***length*** parameter to a value of -1.

options
An ImapSections enumeration value which specifies which section of the message to return.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenMessage** method opens a message or a specific part of a multipart message in the current mailbox. The message data may also be limited a specific byte offset and length, which can be useful for previewing the contents. The client can then read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

See Also

Open the specified message for reading.

[Visual Basic]

```
Overloads Public Function OpenMessage( _
   ByVal messageId As Integer, _
   ByVal messagePart As Integer, _
   ByRef length As Integer, _
   ByVal options As ImapSections _
) As Boolean
```

[C#]

```
public bool OpenMessage(
   int messageId,
   int messagePart,
   ref int length,
   ImapSections options
);
```

Parameters

messageId
: Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

messagePart
: An integer value that specifies the message part that should be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

length
: An integer passed by reference which should be initialized to the maximum number of bytes to be read, and will contain the size of the message when the function returns. To specify the entire message, initialize the ***length*** parameter to a value of -1.

options
: An ImapSections enumeration value which specifies which section of the message to return.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **OpenMessage** method opens a message or a specific part of a multipart message in the current mailbox. The message data may also be limited a specific byte offset and length, which can be useful for previewing the contents. The client can then read the contents of the message using the **Read** method, and once all of the data has been read, the message should be closed by calling the **CloseMessage** method.

Read data from the server and store it in a byte array.

Overload List

Read data from the server and store it in a byte array.

public int Read(byte[]);

Read data from the server and store it in a byte array.

public int Read(byte[],int);

Read data from the server and store it in a string.

public int Read(ref string);

Read data from the server and store it in a string.

public int Read(ref string,int);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Read Method (Byte[])

Read data from the server and store it in a byte array.

[Visual Basic]
```
Overloads Public Function Read( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]
```
public int Read(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the size of the byte array passed to the method. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

Overloads Public Function Read( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.Read Overload List

ImapClient.Read Method (String)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer
);
```

Parameters

buffer

A string that will contain the data read from the client.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to a maximum of 4096 bytes. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.Read Overload List

ImapClient.Read Method (String, Int32)

Read data from the server and store it in a string.

[Visual Basic]

```
Overloads Public Function Read( _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Read(
   ref string buffer,
   int length
);
```

Parameters

buffer

A string that will contain the data read from the client.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

An integer value which specifies the number of bytes actually read from the server. A return value of zero specifies that the remote host has closed the connection and there is no more data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Read** method returns data that has been read from the server, up to the number of bytes specified. If no data is available to be read, an error will be generated if the client is in non-blocking mode. If the client is in blocking mode, the program will stop until data is received from the server or the connection is closed.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

ImapClient Class | SocketTools Namespace | ImapClient.Read Overload List

ImapClient.Refresh Method

Updates the list of available mailboxes.

[Visual Basic]
```
Public Function Refresh() As Boolean
```

[C#]
```
public bool Refresh();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Refresh** method updates the list of mailboxes that may be selected by the client. The available mailboxes may be enumerated using the **Mailbox** property array, with the **Mailboxes** property returning the total number of mailboxes.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.RenameMailbox Method

Change the name of a mailbox.

[Visual Basic]
```
Public Function RenameMailbox( _
   ByVal oldMailbox As String, _
   ByVal newMailbox As String _
) As Boolean
```

[C#]
```
public bool RenameMailbox(
   string oldMailbox,
   string newMailbox
);
```

Parameters

oldMailbox
A string that specifies the name of the mailbox to be renamed on the server. The mailbox must exist on the server, otherwise an error will be returned.

newMailbox
A string that specifies the new name for the mailbox. An error will be returned if a mailbox with that name already exists.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

If the existing mailbox name contains inferior hierarchical names (mailboxes under the specified mailbox) then those mailboxes will also be renamed. For example, if the mailbox "Mail/Pictures" contains two mailboxes, "Personal" and "Work" and it is renamed to "Mail/Images" then the two mailboxes under it would be automatically renamed to "Mail/Images/Personal" and "Mail/Images/Work".

If the mailbox being renamed is the currently selected mailbox, the current mailbox will be unselected and any messages marked for deletion will be expunged. The new mailbox name will then automatically be re-selected. To prevent deleted messages from being removed from the mailbox prior to being renamed, use the **UnselectMailbox** method to unselect the current mailbox before calling **RenameMailbox**. Note that if the rename operation fails, the client may be left in an unselected state.

It is permitted to rename the special mailbox INBOX. In this case, the messages will be moved from the INBOX mailbox to the new mailbox. If the INBOX mailbox is currently selected, the new mailbox will not automatically be selected. INBOX will remain the selected mailbox.

ImapClient Class | SocketTools Namespace

ImapClient.ReselectMailbox Method

Reselects the current mailbox.

[Visual Basic]

```
Public Function ReselectMailbox() As Boolean
```

[C#]

```
public bool ReselectMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ReselectMailbox** method forces the current mailbox to be reselected and updates those properties which return information about the mailbox, such as the **MailboxFlags** property. Deleted messages are not expunged from the mailbox and remain marked for deletion.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

ImapClient.SearchMailbox Method

Search the current mailbox for messages that match the specified criteria.

Overload List

Search the current mailbox for messages that match the specified criteria.

public int SearchMailbox(string,int[],int);

Search the current mailbox for messages that match the specified criteria and character set.

public int SearchMailbox(string,string,int[],int);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.SearchMailbox Method (String, Int32[], Int32)

Search the current mailbox for messages that match the specified criteria.

[Visual Basic]

```
Overloads Public Function SearchMailbox( _
   ByVal criteria As String, _
   ByVal messageList As Integer(), _
   ByVal maxMessages As Integer _
) As Integer
```

[C#]

```
public int SearchMailbox(
   string criteria,
   int[] messageList,
   int maxMessages
);
```

Parameters

criteria

A string which consists of one or more keywords which are used to define the search criteria. The following keywords are recognized:

Keyword	Description
ANSWERED	Match those messages which have the **ImapFlags.flagAnswered** flag set.
BCC *address*	Match those messages which contain the specified address in the BCC header field.
BEFORE *date*	Match those messages which were added to the mailbox prior to the specified date.
BODY *string*	Match those messages where the body contains the specified string.
CC *address*	Match those messages which contain the specified address in the CC header field.
DELETED	Match those messages which have the **ImapFlags.flagDeleted** flag set.
DRAFT	Match those messages which have the **ImapFlags.flagDraft** flag set.
FLAGGED	Match those messages which have the **ImapFlags.flagUrgent** flag set.
FROM *address*	Match those messages which contain the specified address in the FROM header field.
HEADER *field string*	Match those messages which contain the string in the specified header field. If no string is specified, then all messages which contain the header will be matched.
LARGER *size*	Match those messages which are larger than the

	specified size in bytes.
NEW	Match those messages which have the **ImapFlags.flagRecent** flag set, but not the **ImapFlags.flagSeen** flag.
OLD	Match those messages which do not have the **ImapFlags.flagRecent** flag set.
ON *date*	Match those messages which were added on the specified date.
RECENT	Match those messages which have the **ImapFlags.flagRecent** flag set.
SEEN	Match those messages which have the **ImapFlags.flagSeen** flag set.
SENTBEFORE *date*	Match those messages whose Date header value is earlier than the specified date.
SENTON *date*	Match those messages whose Date header value is the same as the specified date.
SENTSINCE *date*	Match those messages whose Date header value is later than the specified date.
SINCE *date*	Match those messages added to the mailbox after the specified date.
SMALLER *size*	Match those messages which are smaller than the specified size in bytes.
SUBJECT *string*	Match those messages whose Subject header contains the specified string.
TEXT *string*	Match those messages whose headers or body contains the specified string.
TO *address*	Match those messages which contain the specified address in the TO header field.
UID *sequence*	Match those messages with unique identifiers in the sequence set.
UNANSWERED	Match those messages which do not have the **ImapFlags.flagAnswered** flag set.
UNDELETED	Match those messages which do not have the **ImapFlags.flagDeleted** flag set.
UNDRAFT	Match those messages which do not have the **ImapFlags.flagDraft** flag set.
UNFLAGGED	Match those messages which do not have the **ImapFlags.flagUrgent** flag set.
UNSEEN	Match those messages which do not have the **ImapFlags.flagUnseen** flag set.

messageList

An array of integers which will contain the message numbers of those messages which match the search criteria.

maxMessages

An integer value which specifies the maximum number of message numbers which can be returned in the ***messageList*** array. This value cannot be larger than the size of the array.

Return Value

The number of messages which were found to match the search criteria. If no messages match the criteria, then the return value will be zero. A return value of -1 indicates an error, and the specific error code can be determined by checking the value of the **LastError** property.

Remarks

The **SearchMailbox** method is used to search a mailbox for messages which match a given criteria and return a list of the matching message numbers. The search criteria is composed of one or more search keywords and and optional value to match against. String searches are not case sensitive and partial matches in the message are returned. The message numbers returned by this method are only valid until the mailbox is expunged or another mailbox is selected.

In addition to the listed keywords, the keyword NOT may prefix a keyword to return those messages which do not match the search criteria. For example, "NOT TO user@domain.com" would return those messages which were not addressed to user@domain.com.

If multiple search keywords are specified, the result is the intersection of all those messages which meet the search criteria. For example, a search criteria of "DELETED SINCE 1-Jan-2010" would return all those messages which are marked for deletion and were added to the mailbox after 1 January 2010.

Those search keywords which expect dates must be specified in format ***dd-mmm-yyyy*** where the month is the three letter abbreviation for the month name. Note that the internal date the message was added to the mailbox is not the same as the value of the Date header field in the message.

If the search keyword requires a string value and the string contains one or more spaces, you must enclose the search string in quotes as part of the criteria string. The quotes around the search string prevents the server from interpreting it as a multiple search criteria to be evaluated. If you are using a search string provided by a user, it is recommended that you always enclose it in quotes to prevent any potential ambiguity in the search. Even if the search string does not contain any spaces, it is always safe to enclose it in quotes.

The UID keyword expects a one or more unique message identifiers. These values may provided as comma separated list, or a range delimited by a colon. For example, "UID 23000:24000" would return all those messages who have UIDs ranging from 23000 through to 24000.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.SearchMailbox Overload List

ImapClient.SearchMailbox Method (String, String, Int32[], Int32)

Search the current mailbox for messages that match the specified criteria and character set.

[Visual Basic]

```
Overloads Public Function SearchMailbox( _
   ByVal criteria As String, _
   ByVal charset As String, _
   ByVal messageList As Integer(), _
   ByVal maxMessages As Integer _
) As Integer
```

[C#]

```
public int SearchMailbox(
   string criteria,
   string charset,
   int[] messageList,
   int maxMessages
);
```

Parameters

criteria

A string which consists of one or more keywords which are used to define the search criteria. The following keywords are recognized:

Keyword	Description
ANSWERED	Match those messages which have the **ImapFlags.flagAnswered** flag set.
BCC *address*	Match those messages which contain the specified address in the BCC header field.
BEFORE *date*	Match those messages which were added to the mailbox prior to the specified date.
BODY *string*	Match those messages where the body contains the specified string.
CC *address*	Match those messages which contain the specified address in the CC header field.
DELETED	Match those messages which have the **ImapFlags.flagDeleted** flag set.
DRAFT	Match those messages which have the **ImapFlags.flagDraft** flag set.
FLAGGED	Match those messages which have the **ImapFlags.flagUrgent** flag set.
FROM *address*	Match those messages which contain the specified address in the FROM header field.
HEADER *field string*	Match those messages which contain the string in the specified header field. If no string is specified, then all messages which contain the header will be matched.

LARGER *size*	Match those messages which are larger than the specified size in bytes.
NEW	Match those messages which have the **ImapFlags.flagRecent** flag set, but not the **ImapFlags.flagSeen** flag.
OLD	Match those messages which do not have the **ImapFlags.flagRecent** flag set.
ON *date*	Match those messages which were added on the specified date.
RECENT	Match those messages which have the **ImapFlags.flagRecent** flag set.
SEEN	Match those messages which have the **ImapFlags.flagSeen** flag set.
SENTBEFORE *date*	Match those messages whose Date header value is earlier than the specified date.
SENTON *date*	Match those messages whose Date header value is the same as the specified date.
SENTSINCE *date*	Match those messages whose Date header value is later than the specified date.
SINCE *date*	Match those messages added to the mailbox after the specified date.
SMALLER *size*	Match those messages which are smaller than the specified size in bytes.
SUBJECT *string*	Match those messages whose Subject header contains the specified string.
TEXT *string*	Match those messages whose headers or body contains the specified string.
TO *address*	Match those messages which contain the specified address in the TO header field.
UID *sequence*	Match those messages with unique identifiers in the sequence set.
UNANSWERED	Match those messages which do not have the **ImapFlags.flagAnswered** flag set.
UNDELETED	Match those messages which do not have the **ImapFlags.flagDeleted** flag set.
UNDRAFT	Match those messages which do not have the **ImapFlags.flagDraft** flag set.
UNFLAGGED	Match those messages which do not have the **ImapFlags.flagUrgent** flag set.
UNSEEN	Match those messages which do not have the **ImapFlags.flagUnseen** flag set.

charset

An string which specifies the character set to use when searching the mailbox. If this argument is omitted, the default US-ASCII character set will be used. Note that not all servers support searches using anything but the default character set.

messageList

An array of integers which will contain the message numbers of those messages which match the search criteria.

maxMessages

An integer value which specifies the maximum number of message numbers which can be returned in the ***messageList*** array. This value cannot be larger than the size of the array.

Return Value

The number of messages which were found to match the search criteria. If no messages match the criteria, then the return value will be zero. A return value of -1 indicates an error, and the specific error code can be determined by checking the value of the **LastError** property.

Remarks

The **SearchMailbox** method is used to search a mailbox for messages which match a given criteria and return a list of the matching message numbers. The search criteria is composed of one or more search keywords and and optional value to match against. String searches are not case sensitive and partial matches in the message are returned. The message numbers returned by this method are only valid until the mailbox is expunged or another mailbox is selected.

In addition to the listed keywords, the keyword NOT may prefix a keyword to return those messages which do not match the search criteria. For example, "NOT TO user@domain.com" would return those messages which were not addressed to user@domain.com.

If multiple search keywords are specified, the result is the intersection of all those messages which meet the search criteria. For example, a search criteria of "DELETED SINCE 1-Jan-2010" would return all those messages which are marked for deletion and were added to the mailbox after 1 January 2010.

Those search keywords which expect dates must be specified in format ***dd-mmm-yyyy*** where the month is the three letter abbreviation for the month name. Note that the internal date the message was added to the mailbox is not the same as the value of the Date header field in the message.

If the search keyword requires a string value and the string contains one or more spaces, you must enclose the search string in quotes as part of the criteria string. The quotes around the search string prevents the server from interpreting it as a multiple search criteria to be evaluated. If you are using a search string provided by a user, it is recommended that you always enclose it in quotes to prevent any potential ambiguity in the search. Even if the search string does not contain any spaces, it is always safe to enclose it in quotes.

The UID keyword expects a one or more unique message identifiers. These values may provided as comma separated list, or a range delimited by a colon. For example, "UID 23000:24000" would return all those messages who have UIDs ranging from 23000 through to 24000.

ImapClient.SelectMailbox Method

Selects the specified mailbox for read-write access.

```
[Visual Basic]
Public Function SelectMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

```
[C#]
public bool SelectMailbox(
   string mailboxName
);
```

Parameters

mailboxName

A string argument which specifies the name of the mailbox to be selected.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SelectMailbox** method is used to select a mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **UnselectMailbox** method prior to selecting the new mailbox.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-only mode, use the **ExamineMailbox** method.

ImapClient.StoreMessage Method

Retrieve a message from the current mailbox and store it in a file on the local system.

Overload List

Retrieve a message from the current mailbox and store it in a file on the local system.

public bool StoreMessage(int,string);

Retrieve the current message and store it in a file on the local system.

public bool StoreMessage(string);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.StoreMessage Method (Int32, String)

Retrieve a message from the current mailbox and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function StoreMessage( _
   ByVal messageId As Integer, _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool StoreMessage(
   int messageId,
   string fileName
);
```

Parameters

messageId

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

fileName

A string which specifies the file that the message will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **StoreMessage** method retrieves a message from the server and stores it in a file on the local system. The contents of the message is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.StoreMessage Overload List

ImapClient.StoreMessage Method (String)

Retrieve the current message and store it in a file on the local system.

```
[Visual Basic]
Overloads Public Function StoreMessage( _
   ByVal fileName As String _
) As Boolean
```

```
[C#]
public bool StoreMessage(
   string fileName
);
```

Parameters

fileName

A string which specifies the file that the message will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **StoreMessage** method retrieves the current message from the server and stores it in a file on the local system. The contents of the message is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The current message number is specified by the value of the **Message** property.

ImapClient.SubscribeMailbox Method

Subscribes the user to the current mailbox.

Overload List

Subscribes the user to the current mailbox.

public bool SubscribeMailbox();

Subscribes the user to the specified mailbox.

public bool SubscribeMailbox(string);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.SubscribeMailbox Method ()

Subscribes the user to the current mailbox.

[Visual Basic]

```
Overloads Public Function SubscribeMailbox() As Boolean
```

[C#]

```
public bool SubscribeMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SubscribeMailbox** method adds the current mailbox to the current user's list of active or subscribed mailboxes. The user will remain subscribed to the mailbox across multiple sessions, until the **UnsubscribeMailbox** method is called to remove the mailbox from the subscription list.

Note that if a user subscribes to a mailbox and that mailbox is later renamed or deleted, the mailbox will not be automatically removed from the user's subscription list. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

The current mailbox is specified by the value of the **MailboxName** property.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.SubscribeMailbox Overload List

ImapClient.SubscribeMailbox Method (String)

Subscribes the user to the specified mailbox.

[Visual Basic]

```
Overloads Public Function SubscribeMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

[C#]

```
public bool SubscribeMailbox(
   string mailboxName
);
```

Parameters

mailboxName

A string which specifies the name of the mailbox to subscribe to.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SubscribeMailbox** method adds the specified mailbox to the current user's list of active or subscribed mailboxes. The user will remain subscribed to the mailbox across multiple sessions, until the **UnsubscribeMailbox** method is called to remove the mailbox from the subscription list.

Note that if a user subscribes to a mailbox and that mailbox is later renamed or deleted, the mailbox will not be automatically removed from the user's subscription list. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.SubscribeMailbox Overload List

ImapClient.UndeleteMessage Method

Removes the deletion flag for the specified message.

[Visual Basic]

```
Public Function UndeleteMessage( _
   ByVal messageId As Integer _
) As Boolean
```

[C#]

```
public bool UndeleteMessage(
   int messageId
);
```

Parameters

messageId

Number of message to undelete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UndeleteMessage** method removes the deletion flag for the specified message in the current mailbox. To determine if a message has been marked for deletion, set the **Message** property to the message number and then check the value of the **MessageFlags** property to determine if the **imapFlagDeleted** bit flag has been set.

ImapClient Class | SocketTools Namespace

ImapClient.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

ImapClient Class | SocketTools Namespace | Initialize Method

ImapClient.UnselectMailbox Method

Unselects the current mailbox and expunges deleted messages.

Overload List

Unselects the current mailbox and expunges deleted messages.

public bool UnselectMailbox();

Unselects the current mailbox.

public bool UnselectMailbox(bool);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.UnselectMailbox Method ()

Unselects the current mailbox and expunges deleted messages.

[Visual Basic]

```
Overloads Public Function UnselectMailbox() As Boolean
```

[C#]

```
public bool UnselectMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UnselectMailbox** method unselects the current mailbox. Once the mailbox has been unselected, no messages in that mailbox can be accessed, and any messages which have been flagged for deletion are removed.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.UnselectMailbox Overload List

ImapClient.UnselectMailbox Method (Boolean)

Unselects the current mailbox.

[Visual Basic]
```
Overloads Public Function UnselectMailbox( _
   ByVal expunge As Boolean _
) As Boolean
```

[C#]
```
public bool UnselectMailbox(
   bool expunge
);
```

Parameters

expunge

An boolean value which determines if deleted messages will be expunged from the mailbox. A value of **true** specifies that messages that have been marked for deletion will be removed from the mailbox. A value of **false** specifies that no messages will be removed from the mailbox.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UnselectMailbox** method unselects the current mailbox. Once the mailbox has been unselected, no messages in that mailbox can be accessed.

```
public bool UnsubscribeMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UnsubscribeMailbox** method removes the current mailbox from the current user's list of active or subscribed mailboxes. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

The current mailbox is specified by the value of the **MailboxName** property.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.UnsubscribeMailbox Overload List

ImapClient.UnsubscribeMailbox Method (String)

Unsubscribes the user from the specified mailbox.

[Visual Basic]

```
Overloads Public Function UnsubscribeMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

[C#]

```
public bool UnsubscribeMailbox(
   string mailboxName
);
```

Parameters

mailboxName

A string which specifies the name of the mailbox to unsubscribe from.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UnsubscribeMailbox** method removes the specified mailbox from the current user's list of active or subscribed mailboxes. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

ImapClient Class | SocketTools Namespace | ImapClient.UnsubscribeMailbox Overload List

ImapClient.Write Method

Write one or more bytes of data to the server.

Overload List

Write one or more bytes of data to the server.

public int Write(byte[]);

Write one or more bytes of data to the server.

public int Write(byte[],int);

Write a string of characters to the server.

public int Write(string);

Write a string of characters to the server.

public int Write(string,int);

See Also

ImapClient Class | SocketTools Namespace

ImapClient.Write Method (Byte[])

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.Write Overload List

ImapClient.Write Method (Byte[], Int32)

Write one or more bytes of data to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that contains the data to be written to the server.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.Write Overload List

ImapClient.Write Method (String)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer
A string which contains the data to be written to the server.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

See Also

ImapClient Class | SocketTools Namespace | ImapClient.Write Overload List

ImapClient.Write Method (String, Int32)

Write a string of characters to the server.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer

A string which contains the data to be written to the server.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the server. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to the server. If there is enough room in the client's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space and the client is in blocking mode, then the method will block until the data can be sent. If the client is in non-blocking mode and the send buffer is full, an error will occur.

ImapClient Class | SocketTools Namespace | ImapClient.Write Overload List

ImapClient Events

The events of the **ImapClient** class are listed below. For a complete list of **ImapClient** class members, see the ImapClient Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an client operation fails.
⚡ OnProgress	Occurs as a data stream is being read or written to the client.
⚡ OnRead	Occurs when data is available to be read from the client.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnUpdate	Occurs when the server sends a mailbox update notification to the client.
⚡ OnWrite	Occurs when data can be written to the client.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a remote host as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a socket is created but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed on the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the remote host closes its connection, terminating the client session with the application. Because there may still be data in the client receive buffers, you should continue to read data from the client until the **Read** method returns a value of 0. Once all of the data has been read, you should call the **Disconnect** method to close the local socket and release the resources allocated for the client.

This event is only generated if the client is in non-blocking mode.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.OnError Event

Occurs when an client operation fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type ImapClient.ErrorEventArgs containing data related to this event. The following **ImapClient.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

ImapClient Class | SocketTools Namespace | OnErrorEventHandler Delegate

ImapClient.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see ImapClient.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.ImapClient.ErrorEventArgs

[Visual Basic]
```
Public Class ImapClient.ErrorEventArgs
    Inherits EventArgs
```

[C#]
```
public class ImapClient.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

See Also

ImapClient.ErrorEventArgs Members | SocketTools Namespace

ImapClient.ErrorEventArgs Members

ImapClient.ErrorEventArgs overview

Public Instance Constructors

ImapClient.ErrorEventArgs Constructor	Initializes a new instance of the ImapClient.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

ImapClient.ErrorEventArgs Class | SocketTools Namespace

ImapClient.ErrorEventArgs Constructor

Initializes a new instance of the ImapClient.ErrorEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public ImapClient.ErrorEventArgs();
```

See Also

ImapClient.ErrorEventArgs Class | SocketTools Namespace

ImapClient.ErrorEventArgs Properties

The properties of the **ImapClient.ErrorEventArgs** class are listed below. For a complete list of **ImapClient.ErrorEventArgs** class members, see the ImapClient.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

ImapClient.ErrorEventArgs Class | SocketTools Namespace

ImapClient.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

ImapClient.ErrorEventArgs Class | SocketTools Namespace | Error Property

ImapClient.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public ImapClient.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

ImapClient.ErrorEventArgs Class | SocketTools Namespace | Description Property

ImapClient.OnProgress Event

Occurs as a data stream is being read or written to the client.

[Visual Basic]

```
Public Event OnProgress As OnProgressEventHandler
```

[C#]

```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type ImapClient.ProgressEventArgs containing data related to this event. The following **ImapClient.ProgressEventArgs** properties provide information specific to this event.

Property	Description
BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Message	Gets the message number.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the client. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

See Also

ImapClient Class | SocketTools Namespace | OnProgressEventHandler Delegate

ImapClient.ProgressEventArgs Class

Provides data for the OnProgress event.

For a list of all members of this type, see ImapClient.ProgressEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.ImapClient.ProgressEventArgs

[Visual Basic]

```
Public Class ImapClient.ProgressEventArgs
    Inherits EventArgs
```

[C#]

```
public class ImapClient.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes copied from the data stream, the total number of bytes in the data stream and a completion percentage.

The OnProgress event occurs as a data stream is being read or written to the client. This event only occurs when the **GetHeaders**, **GetMessage** or **StoreMessage** methods are called.

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

ImapClient.ProgressEventArgs Class | SocketTools Namespace

ImapClient.ProgressEventArgs Properties

The properties of the **ImapClient.ProgressEventArgs** class are listed below. For a complete list of **ImapClient.ProgressEventArgs** class members, see the ImapClient.ProgressEventArgs Members topic.

Public Instance Properties

BytesCopied	Gets a value which specifies the number of bytes of data that has been read or written.
BytesTotal	Gets a value which specifies the total number of bytes in the data stream.
Message	Gets the message number.
Percent	Gets a value which specifies the percentage of data that has been read or written.

See Also

ImapClient.ProgressEventArgs Class | SocketTools Namespace

ImapClient.ProgressEventArgs.BytesCopied Property

Gets a value which specifies the number of bytes of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property BytesCopied As Integer
```

[C#]

```
public int BytesCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesCopied** property specifies the number of bytes that have been read from the client and stored in the local stream buffer, or written from the stream buffer to the client.

See Also

ImapClient.ProgressEventArgs Class | SocketTools Namespace | BytesTotal Property | Percent Property

ImapClient.ProgressEventArgs.BytesTotal Property

Gets a value which specifies the total number of bytes in the data stream.

[Visual Basic]

```
Public ReadOnly Property BytesTotal As Integer
```

[C#]

```
public int BytesTotal {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **BytesTotal** property specifies the total amount of data being read from the client and stored in the data stream, or written from the data stream to the client. If the amount of data was unknown or unspecified at the time the method call was made, then this value will always be the same as the **BytesCopied** property.

See Also

ImapClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | Percent Property

ImapClient.ProgressEventArgs.Message Property

Gets the message number.

[Visual Basic]

```
Public ReadOnly Property Message As Integer
```

[C#]

```
public int Message {get;}
```

Property Value

An integer value which specifies the message number.

Remarks

The **Message** property specifies the message number for the current message that is being downloaded from the mail server to the local host. If the **OnProgress** event occurs while message data is being uploaded to the server, this property will return a value of zero.

See Also

ImapClient.ProgressEventArgs Class | SocketTools Namespace

ImapClient.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

See Also

ImapClient.ProgressEventArgs Class | SocketTools Namespace | BytesCopied Property | BytesTotal Property

ImapClient.OnRead Event

Occurs when data is available to be read from the client.

[Visual Basic]

```
Public Event OnRead As EventHandler
```

[C#]

```
public event EventHandler OnRead;
```

Remarks

The **OnRead** event occurs when data is available to be read from the client. This event is level-triggered, which means that once this event fires, it will not occur again until some data has been read from the client. This design prevents an application from being flooded with event notifications. It is recommended that your application read all of the available data from the server and store it in a local buffer for processing. See the example below.

This event is only generated if the client is in non-blocking mode.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]
```
Public Event OnTimeout As EventHandler
```

[C#]
```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.OnUpdate Event

Occurs when the server sends a mailbox update notification to the client.

[Visual Basic]

```
Public Event OnUpdate As OnUpdateEventHandler
```

[C#]

```
public event OnUpdateEventHandler OnUpdate;
```

Event Data

The event handler receives an argument of type ImapClient.UpdateEventArgs containing data related to this event. The following **ImapClient.UpdateEventArgs** properties provide information specific to this event.

Property	Description
Message	Gets the message number.
UpdateType	Gets the type of update notification that has been sent by the server.

Remarks

This event is only generated when the **Idle** method has been used to enable mailbox status monitoring.

See Also

ImapClient Class | SocketTools Namespace | Idle Method | OnUpdateEventHandler Delegate

ImapClient.UpdateEventArgs Class

Provides data for the OnUpdate event.

For a list of all members of this type, see ImapClient.UpdateEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.ImapClient.UpdateEventArgs

[Visual Basic]
```
Public Class ImapClient.UpdateEventArgs
    Inherits EventArgs
```

[C#]
```
public class ImapClient.UpdateEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

ImapClient.UpdateEventArgs Constructor

Initializes a new instance of the ImapClient.UpdateEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public ImapClient.UpdateEventArgs();
```

See Also

ImapClient.UpdateEventArgs Class | SocketTools Namespace

ImapClient.UpdateEventArgs Properties

The properties of the **ImapClient.UpdateEventArgs** class are listed below. For a complete list of **ImapClient.UpdateEventArgs** class members, see the ImapClient.UpdateEventArgs Members topic.

Public Instance Properties

Message	Gets the message number.
UpdateType	Gets the type of update notification that has been sent by the server.

See Also

ImapClient.UpdateEventArgs Class | SocketTools Namespace

ImapClient.UpdateEventArgs.Message Property

Gets the message number.

[Visual Basic]
```
Public ReadOnly Property Message As Integer
```

[C#]
```
public int Message {get;}
```

Property Value

An integer value which specifies the message number.

Remarks

The **Message** property specifies the message number for the message that has been added to or expunged from the current mailbox. A value of zero indicates that the update notification does not reference a specific message in the mailbox.

See Also

ImapClient.UpdateEventArgs Class | SocketTools Namespace

ImapClient.UpdateEventArgs.UpdateType Property

Gets the type of update notification that has been sent by the server.

[Visual Basic]

```
Public ReadOnly Property UpdateType As IdleUpdate
```

[C#]

```
public ImapClient.IdleUpdate UpdateType {get;}
```

Property Value

One or more of the IdleUpdate enumeration flags.

See Also

ImapClient.UpdateEventArgs Class | SocketTools Namespace

ImapClient.OnWrite Event

Occurs when data can be written to the client.

[Visual Basic]
```
Public Event OnWrite As EventHandler
```

[C#]
```
public event EventHandler OnWrite;
```

Remarks

The **OnWrite** event occurs when the application can write data to the client. This event will typically occur when a connection is first established with the remote host, and after the **Write** method has failed because there was insufficient memory available in the client send buffers. In the second case, when some of the buffered data has been successfully sent to the remote host and there is space available in the send buffers, this event is used to signal the application that it may attempt to send more data.

This event is only generated if the client is in non-blocking mode.

See Also

ImapClient Class | SocketTools Namespace

ImapClient.ErrorCode Enumeration

Specifies the error codes returned by the ImapClient class.

[Visual Basic]

```
Public Enum ImapClient.ErrorCode
```

[C#]

```
public enum ImapClient.ErrorCode
```

Remarks

The ImapClient class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

ImapClient.ImapFlags Enumeration

Specifies the mailbox and message flags that the ImapClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum ImapClient.ImapFlags
```

[C#]
```
[Flags]
public enum ImapClient.ImapFlags
```

Members

Member Name	Description	Value
flagNone	No flags have been set for the current message or mailbox.	0
flagAnswered	The message has been answered.	1
flagDraft	The message is a draft copy and has not been delivered.	2
flagUrgent	The message has been flagged for urgent or special attention.	4
flagSeen	The message has been read.	8
flagRecent	The message has been added to the mailbox recent.	256
flagDeleted	The message has been marked for deletion.	512
flagNoInferiors	The mailbox does not contain any child mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.	65536
flagNoSelect	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not an actual mailbox.	131072
flagMarked	The mailbox is marked as being of interest to a client. If this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.	262144
flagUnmarked	The mailbox is marked as not being of interest to a client. If this flag is used, it	524288

	typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

ImapClient.IdleOptions Enumeration

Specifies the idle monitoring options that the ImapClient class supports.

[Visual Basic]

```
Public Enum ImapClient.IdleOptions
```

[C#]

```
public enum ImapClient.IdleOptions
```

Remarks

The **Idle** method can operate in two modes, based on the options specified by the caller. If the option **imapIdleNoWait** is specified, the method begins monitoring the client session asynchronously and returns control immediately to the caller. If the server sends a update notification to the client, the **OnUpdate** event will fire with information about the status change. If the option **imapIdleWait** is specified, the method will block waiting for the server to send a notification message to the client. The method will return when either a message is received or the timeout period is exceeded.

Members

Member Name	Description
idleNoWait	The **Idle** method should return immediately after idle processing has been enabled. When this option is used, the application may continue to perform other functions while the client session is monitored for status updates sent by the server. The client will continue to monitor status changes until an IMAP command issued or the client disconnects from the server. This is the default option.
idleWait	The **Idle** method should wait until the server sends a status update, or until the timeout period is reached. The client will stop monitoring status changes when the function returns. If this option is used in a single-threaded application, normal message processing can be impeded, causing the application to appear non-responsive until the timeout period is reached. It is strongly recommended that single-threaded applications with a user interface specify the **imapIdleNoWait** option instead.

Requirements

SocketTools Namespace | Idle Method (SocketTools.ImapClient) | OnUpdate Event (SocketTools.ImapClient)

ImapClient.IdleUpdate Enumeration

Specifies the types of update notification messages that the ImapClient class supports.

[Visual Basic]
```
Public Enum ImapClient.IdleUpdate
```

[C#]
```
public enum ImapClient.IdleUpdate
```

Members

Member Name	Description
updateUnknown	The server has sent an unrecognized notification message. This does not necessarily reflect an error condition, as some servers may send additional notification messages beyond the standard EXISTS, EXPUNGE and RECENT messages. Most applications should ignore this type of notification.
updateMessage	The server has sent notification message to the client indicating that a new message has arrived. Typically this update notification occurs shortly after the new message has been stored in the current mailbox.
updateExpunge	The server has sent a notification message to the client indicating that a message has been removed from the current mailbox. It is recommended that the application re-examine the mailbox when this notification is received. Typically this notification is only sent periodically by the server, and may not be sent immediately after a message has been expunged from the mailbox.
updateMailbox	The server has sent notification message to the client indicating that the state of the mailbox has changed. This message is sent periodically by the server and may not be sent immediately after a new message arrives or a message is flagged as unread. It is recommended that the application re-examine the mailbox when this notification is received.

ImapClient.ImapOptions Enumeration

Specifies the options that the ImapClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum ImapClient.ImapOptions
```

[C#]
```
[Flags]
public enum ImapClient.ImapOptions
```

Remarks

The ImapClient class uses the **ImapOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDefault	The default connection option. This is the same as specifying **optionNone**.	0
optionIdentify	This option specifies the client should identify itself to the server. If enabled, the client will send the ID command to the server as defined in RFC 2971. This option has no effect if the server does not support the ID command.	1
optionTunnel	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.	1024
optionTrustedSite	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the SSL or TLS protocols.	2048
optionSecure	This option specifies the client should attempt to establish a secure	4096

	connection with the server. The server must support secure connections using either the SSL or TLS protocol.	
optionExplicitSSL	This option specifies the client should attempt to establish a secure explicit SSL session. The initial connection to the server is not encrypted, and the client will attempt to negotiate a secure connection by sending the STARTTLS command to the server. Some servers may require this option when connecting to the server on ports other than the default secure port of 993.	4096
optionImplicitSSL	This option specifies the client should attempt to establish a secure implicit SSL session. The SSL handshake is initiated immediately after the connection to the server has been established.	8192
optionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768
optionPreferIPv6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.	262144
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288

ImapClient.ImapResult Enumeration

Specifies the result codes that the ImapClient class supports.

[Visual Basic]

```
Public Enum ImapClient.ImapResult
```

[C#]

```
public enum ImapClient.ImapResult
```

Members

Member Name	Description
resultUnknown	An unknown result code was returned by the server.
resultOk	The previous command completed successfully. The result string contains information about the results of the command.
resultNo	The previous command could not be completed. The result string contains information about why the command failed.
resultBad	The previous command could not be completed, the command may be invalid or not supported on the server. The result string contains information about why the command failed.
resultContinue	The command has executed and is waiting for additional data from the client.

ImapClient.ImapSections Enumeration

Specifies the message sections that the ImapClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum ImapClient.ImapSections
```

[C#]

```
[Flags]
public enum ImapClient.ImapSections
```

Members

Member Name	Description	Value
sectionDefault	All headers and the complete body of the specified message or message part are to be retrieved. The client application is responsible for parsing the header block. If the message is a MIME multipart message and the complete message is returned, the application is responsible for parsing the individual message parts if necessary.	0
sectionHeader	All headers for the specified message or message part are to be retrieved. The client application is responsible for parsing the header block.	1
sectionMimeHeader	The MIME headers for the specified message or message are to be retrieved. Only those header fields which are used in MIME messages, such as Content-Type will be returned to the client. This is typically useful when processing the header for a multipart message which contains file attachments. The client application is responsible for parsing the header block.	2
sectionBody	The body of the specified message or message part will be retrieved. For a MIME formatted message, this may include data that is uuencoded or base64 encoded. The application is responsible for decoding this data.	4
sectionPreview	The message header or body is being previewed and should not be marked as read by the server. This prevents the message from having the	4096

	IMAP_FLAG_SEEN flag from being automatically set when the message data is retrieved.	

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

SocketTools Namespace

ImapClient.ImapStatus Enumeration

Specifies the status values that may be returned by the ImapClient class.

[Visual Basic]
```
Public Enum ImapClient.ImapStatus
```

[C#]
```
public enum ImapClient.ImapStatus
```

Remarks

The ImapClient class uses the **ImapStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	A client session has not been created. Attempts to perform any network operations, such as sending or receiving data, will generate an error.
statusIdle	A client session has been created, but is not currently in use. A blocking socket operation can be executed at this point.
statusConnect	The client is in the process of establishing a connection with a remote host.
statusRead	The client is in the process of receiving data from a remote host.
statusWrite	The client is in the process of sending data to a remote host.
statusDisconnect	The client session is being closed and subsequent attempts to access the client will result in an error.

ImapClient.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the ImapClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum ImapClient.SecureCipherAlgorithm
```

[C#]
```
[Flags]
public enum ImapClient.SecureCipherAlgorithm
```

Remarks

The ImapClient class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128

ImapClient.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the ImapClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum ImapClient.SecureHashAlgorithm
```

[C#]

```
[Flags]
public enum ImapClient.SecureHashAlgorithm
```

Remarks

The ImapClient class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

SocketTools Namespace

ImapClient.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the ImapClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum ImapClient.SecureKeyAlgorithm
```

[C#]
```
[Flags]
public enum ImapClient.SecureKeyAlgorithm
```

Remarks

The ImapClient class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

SocketTools Namespace

ImapClient.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the ImapClient class.

[Visual Basic]

```
Public Enum ImapClient.SecurityCertificate
```

[C#]

```
public enum ImapClient.SecurityCertificate
```

Remarks

The ImapClient class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the remote host when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the remote host. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

See Also

SocketTools Namespace

ImapClient.SecurityProtocols Enumeration

Specifies the security protocols that the ImapClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum ImapClient.SecurityProtocols
```

[C#]
```
[Flags]
public enum ImapClient.SecurityProtocols
```

Remarks

The ImapClient class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

See Also

SocketTools Namespace

ImapClient.TraceOptions Enumeration

Specifies the logging options that the ImapClient class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum ImapClient.TraceOptions
```

[C#]
```
[Flags]
public enum ImapClient.TraceOptions
```

Remarks

The ImapClient class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

SocketTools Namespace

ImapClient.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub ImapClient.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void ImapClient.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

See Also

SocketTools Namespace

ImapClient.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

[Visual Basic]

```
Public Delegate Sub ImapClient.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

[C#]

```
public delegate void ImapClient.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender
The source of the event.

e
A ProgressEventArgs that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

See Also

SocketTools Namespace

ImapClient.OnUpdateEventHandler Delegate

Represents the method that will handle the OnUpdate event.

[Visual Basic]

```
Public Delegate Sub ImapClient.OnUpdateEventHandler( _
   ByVal sender As Object, _
   ByVal e As UpdateEventArgs _
)
```

[C#]

```
public delegate void ImapClient.OnUpdateEventHandler(
      object sender,
      UpdateEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An UpdateEventArgs that contains the event data.

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

See Also

SocketTools Namespace | UpdateEventArgs Class

ImapClient.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see ImapClient.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.ImapClient.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class ImapClient.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class ImapClient.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the ImapClient class.

Example

```
<Assembly: SocketTools.ImapClient.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.ImapClient.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

See Also

ImapClient.RuntimeLicenseAttribute Members | SocketTools Namespace

ImapClient.RuntimeLicenseAttribute Members

ImapClient.RuntimeLicenseAttribute overview

Public Instance Constructors

ImapClient.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

ImapClient.RuntimeLicenseAttribute Class | SocketTools Namespace

ImapClient.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public ImapClient.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the ImapClient class.

See Also

ImapClient.RuntimeLicenseAttribute Class | SocketTools Namespace

ImapClient.RuntimeLicenseAttribute Properties

The properties of the **ImapClient.RuntimeLicenseAttribute** class are listed below. For a complete list of **ImapClient.RuntimeLicenseAttribute** class members, see the ImapClient.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

ImapClient.RuntimeLicenseAttribute Class | SocketTools Namespace

ImapClient.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

ImapClient.RuntimeLicenseAttribute Class | SocketTools Namespace

ImapClientException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see ImapClientException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.ImapClientException

[Visual Basic]
```
Public Class ImapClientException
    Inherits ApplicationException
```

[C#]
```
public class ImapClientException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A ImapClientException is thrown by the ImapClient class when an error occurs.

The default constructor for the ImapClientException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.ImapClient (in SocketTools.ImapClient.dll)

See Also

ImapClientException Members | SocketTools Namespace

ImapClientException Members

ImapClientException overview

Public Instance Constructors

ImapClientException	Overloaded. Initializes a new instance of the ImapClientException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

ImapClientException Class | SocketTools Namespace

ImapClientException Constructor

Initializes a new instance of the ImapClientException class with the last network error code.

Overload List

Initializes a new instance of the ImapClientException class with the last network error code.

public ImapClientException();

Initializes a new instance of the ImapClientException class with a specified error number.

public ImapClientException(int);

Initializes a new instance of the ImapClientException class with a specified error message.

public ImapClientException(string);

Initializes a new instance of the ImapClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public ImapClientException(string,Exception);

See Also

ImapClientException Class | SocketTools Namespace

ImapClientException Constructor ()

Initializes a new instance of the ImapClientException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public ImapClientException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the ImapClient.ErrorCode enumeration.

See Also

ImapClientException Class | SocketTools Namespace | ImapClientException Constructor Overload List

ImapClientException Constructor (String)

Initializes a new instance of the ImapClientException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public ImapClientException(
   string message
);
```

Parameters

message
: The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

ImapClientException Class | SocketTools Namespace | ImapClientException Constructor Overload List

ImapClientException Constructor (String, Exception)

Initializes a new instance of the ImapClientException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]
```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]
```
public ImapClientException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

ImapClientException Class | SocketTools Namespace | ImapClientException Constructor Overload List

ImapClientException Constructor (Int32)

Initializes a new instance of the ImapClientException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public ImapClientException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the ImapClient.ErrorCode enumeration.

See Also

ImapClientException Class | SocketTools Namespace | ImapClientException Constructor Overload List

ImapClientException Properties

The properties of the **ImapClientException** class are listed below. For a complete list of **ImapClientException** class members, see the ImapClientException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

ImapClientException Class | SocketTools Namespace

ImapClientException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public ImapClient.ErrorCode ErrorCode {get;}
```

Property Value

Returns a ImapClient.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the ImapClientException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the ImapClient.ErrorCode enumeration.

See Also

ImapClientException Class | SocketTools Namespace

ImapClientException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

ImapClientException Class | SocketTools Namespace

ImapClientException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

ImapClientException Class | SocketTools Namespace

ImapClientException Methods

The methods of the **ImapClientException** class are listed below. For a complete list of **ImapClientException** class members, see the ImapClientException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

ImapClientException Class | SocketTools Namespace

ImapClientException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

ImapClientException Class | SocketTools Namespace

InternetDialer Class

Implements an interface to the Remote Access Services API.

For a list of all members of this type, see InternetDialer Members.

System.Object
  SocketTools.InternetDialer

[Visual Basic]
```
Public Class InternetDialer
    Implements IDisposable
```

[C#]
```
public class InternetDialer : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The InternetDialer class provides a way for client applications to connect to a remote server using Microsoft Windows Remote Access Services (RAS). To use this class, the dial-up networking software must be installed on the local system. For access to the Internet, the TCP/IP protocol must be installed and configured. The class may configured to use either the SLIP or PPP protocols, depending on the requirements of the service provider. Refer to your system documentation for information about installing and configuring dial-up networking on your system.

For those applications which may be used in a mobile environment, or otherwise require remote network access, the InternetDialer class provides a convenient interface to this service. Connections can be established and discontinued under the direct control of the program, rather than requiring that the user execute another program before starting your application.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

InternetDialer overview

Public Static (Shared) Fields

rasDeviceATM	A constant value which specifies an ATM device type.
rasDeviceFrameRelay	A constant value which specifies a frame relay device type.
rasDeviceGeneric	A constant value which specifies a generic device type.
rasDeviceIRDA	A constant value which specifies an infrared device type.
rasDeviceISDN	A constant value which specifies an ISDN device type.
rasDeviceModem	A constant value which specifies a modem device type.
rasDevicePad	A constant value which specifies a packet assembler/disassembler device type.
rasDeviceParallel	A constant value which specifies an parallel port device type.
rasDevicePPPoE	A constant value which specifies a PPP over Ethernet device type.
rasDeviceSerial	A constant value which specifies a serial port device type.
rasDeviceSonet	A constant value which specifies a SONET device type.
rasDeviceSW56	A constant value which specifies a SW56 device type.
rasDeviceVPN	A constant value which specifies a VPN device type.
rasDeviceX25	A constant value which specifies an X25 device type.

Public Instance Constructors

InternetDialer Constructor	Initializes a new instance of the InternetDialer class.

Public Instance Fields

Connection	Gets the handle for a dial-up networking session.
DeviceEntry	Gets the name of the specified device entry.
NameServer	Gets and sets the IP addresses of the nameservers assigned to the current phonebook entry.

PhoneBookEntry	Gets the name for the specified phone book entry.

Public Instance Properties

AreaCode	Gets and sets the area code for the current phonebook entry.
AutoConnect	Automatically inherit connections established by another process.
AutoDial	Enable and disable autodialing on the local system.
AutoDisconnect	Automatically disconnect from the remote server.
Blocking	Gets and sets the blocking state of the class.
BytesIn	Gets the number of bytes that have been received by the dial-up networking device.
BytesOut	Gets the number of bytes that have been transmitted by the dial-up networking device.
Callback	Specifies that the remote server should call the system back.
CallbackNumber	Gets and sets the telephone number for the remote server to call back on.
Connections	Gets the number of active dial-up networking sessions.
ConnectSpeed	Gets the line speed for the current dial-up networking connection.
CountryCode	Gets and sets the country code for the current phonebook entry.
CountryName	Gets and sets the country name for the current phonebook entry.
DefaultGateway	Enable and disable the default gateway for IP packets through the dial-up adapter.
DeviceCount	Gets the number of dial-up networking devices available.
DeviceName	Gets and sets the device name for the current dial-up networking connection.
DeviceType	Gets and sets the device type for the current dial-up networking connection.
DynamicAddress	Enables and disables the use of dynamically allocated IP addresses.
DynamicNameServers	Enables and disables the use of dynamically assigned nameserver addresses.
EntryName	Gets and sets the current phone book entry name.
FramingProtocol	Gets and sets the framing protocol for the current phonebook entry.

Handle	Gets and sets the handle for the current dial-up networking connection.
InternetAddress	Gets the address assigned to the current dial-up networking session.
Interval	Gets and sets the interval at which the connection is monitored.
IpHeaderCompression	Enables and disables IP header compression for the current phonebook entry.
IsConnected	Gets a value which indicates if a connection has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LcpExtensions	Enables and disables the use of PPP LCP extensions for the current phonebook entry.
LocalNumber	Gets and sets the local telephone number specified in the phonebook entry.
ModemLights	Enables and disables the dial-up networking system tray icon.
ModemSpeaker	Enables and disables the modem speaker.
NetworkLogon	Enables and disables a network login for the current phonebook entry.
NetworkProtocol	Gets and sets the network protocol for the current phonebook entry.
Password	Gets the password required to establish a connection with the service provider.
PhoneBook	Sets the file name of the Remote Access phonebook to use.
PhoneBookEntries	Gets the number of entries in the current phonebook.
PhoneNumber	Gets and sets the telephone number of the service provider.
RequireEncryption	Enables and disables secure authentication for the current phonebook entry.
ScriptFile	Gets and sets the name of the script file for the current phonebook entry.
ServerAddress	Gets the address of the dial-up networking server.
SoftwareCompression	Enables and disables software compression for the current phonebook entry.

Status	Gets a value which specifies the current status of the dial-up networking connection.
Terminal	Gets and sets the interactive terminal window mode for the current phonebook entry.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
UserDomain	Gets and sets the NT domain on which user authentication is to occur.
UserName	Gets the username required to establish a connection with the service provider.
UserPhoneBook	Gets the name of the default user phonebook.
Version	Gets a value which returns the current version of the InternetDialer class library.

Public Instance Methods

Connect	Overloaded. Establish a connection with a dial-up networking services provider.
CreateEntry	Create a new entry in the current phonebook.
DeleteEntry	Overloaded. Delete a phonebook entry from the current phonebook.
Disconnect	Terminate the connection with the dial-up networking service provider.
Dispose	Overloaded. Releases all resources used by InternetDialer.
EditEntry	Edit an existing phonebook entry in the current phonebook.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the InternetDialer class.
LoadEntry	Overloaded. Load the specified entry from the current phonebook.
RenameEntry	Rename an existing phonebook entry.
Reset	Reset the internal state of the object, resetting all properties to their default values.

SaveEntry	Overloaded. Save the current settings to the specified phonebook entry in the current phonebook.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnConnect	Occurs when a connection is established with the service provider.
OnDisconnect	Occurs when the dial-up networking connection is terminated.
OnError	Occurs when an client operation fails.
OnStatus	Occurs when the when the connection state changes.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the InternetDialer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

rasDeviceSW56	A constant value which specifies a SW56 device type.
rasDeviceVPN	A constant value which specifies a VPN device type.
rasDeviceX25	A constant value which specifies an X25 device type.

Public Instance Fields

Connection	Gets the handle for a dial-up networking session.
DeviceEntry	Gets the name of the specified device entry.
NameServer	Gets and sets the IP addresses of the nameservers assigned to the current phonebook entry.
PhoneBookEntry	Gets the name for the specified phone book entry.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Connection Field

Gets the handle for a dial-up networking session.

[Visual Basic]

```
Public ReadOnly Connection As ConnectionArray
```

[C#]

```
public readonly ConnectionArray Connection;
```

Remarks

The **Connection** array can be used to enumerate the active dial-up networking sessions on the local system. The index is zero-based, and the number of connections is returned by the **Connections** property. The property returns an integer value which represents the handle to the session. Setting the **Handle** property to this value will cause the control to inherit the session and the control's properties will be updated with information about the connection.

Specifying an index greater than the number of available connections will generate an exception.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.DeviceEntry Field

Gets the name of the specified device entry.

[Visual Basic]

```
Public ReadOnly DeviceEntry As DeviceEntryArray
```

[C#]

```
public readonly DeviceEntryArray DeviceEntry;
```

Remarks

The **DeviceEntry** array can be used in conjunction with the **DeviceCount** property to enumerate the available dial-up networking devices. Typically this is used to provide a user with a selection of dial-up devices. The device used by the current phonebook entry can be changed by setting the **DeviceName** property to one of the device entry values.

Note that you should first set the **DeviceType** property to the type of device which you wish to enumerate. The default device type is **rasDeviceModem**, for serial analog modems or other devices which recognize the AT command set.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.NameServer Field

Gets and sets the IP addresses of the nameservers assigned to the current phonebook entry.

[Visual Basic]
```
Public ReadOnly NameServer As NameServerArray
```

[C#]
```
public readonly NameServerArray NameServer;
```

Remarks

The **NameServer** array is used to set or return the nameserver IP addresses assigned to the current phonebook entry. Setting the array to an IP address changes the corresponding address assigned to the phonebook entry. Note that assigned nameserver addresses are only used if the **DynamicNameServers** property has been set to **false**. If dynamic nameservers are assigned to the session this array will not return those addresses, it will return empty strings.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.PhoneBookEntry Field

Gets the name for the specified phone book entry.

[Visual Basic]

```
Public ReadOnly PhoneBookEntry As PhoneBookEntryArray
```

[C#]

```
public readonly PhoneBookEntryArray PhoneBookEntry;
```

Remarks

The **PhoneBookEntry** array contains a list of the entries in the current phone book, and may be used to establish a connection with a remote server. Specifying an index greater than the number of available entries in the phone book will generate an exception.

InternetDialer Class | SocketTools Namespace

InternetDialer Properties

The properties of the **InternetDialer** class are listed below. For a complete list of **InternetDialer** class members, see the InternetDialer Members topic.

Public Instance Properties

AreaCode	Gets and sets the area code for the current phonebook entry.
AutoConnect	Automatically inherit connections established by another process.
AutoDial	Enable and disable autodialing on the local system.
AutoDisconnect	Automatically disconnect from the remote server.
Blocking	Gets and sets the blocking state of the class.
BytesIn	Gets the number of bytes that have been received by the dial-up networking device.
BytesOut	Gets the number of bytes that have been transmitted by the dial-up networking device.
Callback	Specifies that the remote server should call the system back.
CallbackNumber	Gets and sets the telephone number for the remote server to call back on.
Connections	Gets the number of active dial-up networking sessions.
ConnectSpeed	Gets the line speed for the current dial-up networking connection.
CountryCode	Gets and sets the country code for the current phonebook entry.
CountryName	Gets and sets the country name for the current phonebook entry.
DefaultGateway	Enable and disable the default gateway for IP packets through the dial-up adapter.
DeviceCount	Gets the number of dial-up networking devices available.
DeviceName	Gets and sets the device name for the current dial-up networking connection.
DeviceType	Gets and sets the device type for the current dial-up networking connection.
DynamicAddress	Enables and disables the use of dynamically allocated IP addresses.
DynamicNameServers	Enables and disables the use of dynamically assigned nameserver addresses.

EntryName	Gets and sets the current phone book entry name.
FramingProtocol	Gets and sets the framing protocol for the current phonebook entry.
Handle	Gets and sets the handle for the current dial-up networking connection.
InternetAddress	Gets the address assigned to the current dial-up networking session.
Interval	Gets and sets the interval at which the connection is monitored.
IpHeaderCompression	Enables and disables IP header compression for the current phonebook entry.
IsConnected	Gets a value which indicates if a connection has been established.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LcpExtensions	Enables and disables the use of PPP LCP extensions for the current phonebook entry.
LocalNumber	Gets and sets the local telephone number specified in the phonebook entry.
ModemLights	Enables and disables the dial-up networking system tray icon.
ModemSpeaker	Enables and disables the modem speaker.
NetworkLogon	Enables and disables a network login for the current phonebook entry.
NetworkProtocol	Gets and sets the network protocol for the current phonebook entry.
Password	Gets the password required to establish a connection with the service provider.
PhoneBook	Sets the file name of the Remote Access phonebook to use.
PhoneBookEntries	Gets the number of entries in the current phonebook.
PhoneNumber	Gets and sets the telephone number of the service provider.
RequireEncryption	Enables and disables secure authentication for the current phonebook entry.
ScriptFile	Gets and sets the name of the script file for the current phonebook entry.

ServerAddress	Gets the address of the dial-up networking server.
SoftwareCompression	Enables and disables software compression for the current phonebook entry.
Status	Gets a value which specifies the current status of the dial-up networking connection.
Terminal	Gets and sets the interactive terminal window mode for the current phonebook entry.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
UserDomain	Gets and sets the NT domain on which user authentication is to occur.
UserName	Gets the username required to establish a connection with the service provider.
UserPhoneBook	Gets the name of the default user phonebook.
Version	Gets a value which returns the current version of the InternetDialer class library.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.AreaCode Property

Gets and sets the area code for the current phonebook entry.

[Visual Basic]
```
Public Property AreaCode As String
```

[C#]
```
public string AreaCode {get; set;}
```

Property Value

A string which specifies the area code.

Remarks

The **AreaCode** property is used to set or return the current phonebook entry's area code. If no area code has been specified, then this property will return an empty string. The value of this property is ignored unless the **CountryCode** property is also set to a valid country code.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.AutoConnect Property

Automatically inherit connections established by another process.

[Visual Basic]

```
Public Property AutoConnect As Boolean
```

[C#]

```
public bool AutoConnect {get; set;}
```

Property Value

A boolean value which specifies if connections are automatically inherited by the class.

Remarks

The **AutoConnect** property determines if the class automatically detects if a connection has been established by another process. When enabled, the class will periodically check for any connections that have been established. The **Interval** property controls the frequency in which the control performs this check.

If the class detects that a connection has been made, it will immediately fire the **OnConnect** event, followed by the **OnStatus** event, to indicate that a connection has been established. The class then begins to monitor that connection as usual, until that connection is dropped or the control is unloaded.

To periodically check to see if a connection has been established by another process without using the **AutoConnect** property, read the value of the **Connections** property, which returns the number of active dial-up networking connections. A value greater than zero indicates that a dial-up networking connection has been established.

If there are multiple dial-up networking devices on the system, it may be possible for more than one connection to be active at a time. If this is the case, setting the **AutoConnect** property to **true** will cause the class to inherit the first active connection. To manage multiple dial-up connections, use the **Connection** array to enumerate the available connections and set the **Handle** property to take control of a specific session.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.AutoDial Property

Enable and disable autodialing on the local system.

[Visual Basic]

```
Public Property AutoDial As Boolean
```

[C#]

```
public bool AutoDial {get; set;}
```

Property Value

A boolean value which specifies if autodialing has been enabled.

Remarks

The **AutoDial** property can be used to determine if autodialing is enabled or disabled on the current system. When autodialing is enabled and an application attempts to establish a connection over the Internet, a dialog box will be displayed asking the user if they want to connect to their default service provider. This property will return **true** if autodialing is currently enabled, or **false** if it has been disabled.

Setting the **AutoDial** property allows an application to change the autodial settings for the current user. Setting the property value to **true** specifies that you wish to enable autodialing, and the system will prompt the user to establish a dial-up connection when necessary. Setting the property to **false** disables autodialing, and prevents the system from prompting the user. This can be beneficial if your application needs to run in an unattended mode. If you change the autodial settings for the user, it is recommended that you restore them to their original value before the application terminates.

If the autodial settings cannot be changed by the current user, an exception will be generated.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.AutoDisconnect Property

Automatically disconnect from the remote server.

[Visual Basic]

```
Public Property AutoDisconnect As Boolean
```

[C#]

```
public bool AutoDisconnect {get; set;}
```

Property Value

A boolean value that specifies if connections are automatically terminated.

Remarks

The **AutoDisconnect** property determines if this instance of the class should automatically disconnect from a remote host when the destructor is called, typically when the application terminates. The default value for this property is **true**.

If a dial-up connection was already established at the time an instance of the class is created, this property will be reset to **false**, preventing it from automatically disconnecting from the host when it is unloaded. Therefore, to always force the control to automatically terminate a connection when it is unloaded, you must explicitly set the property value to **true** in your application.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Blocking Property

Gets and sets the blocking state of the class.

[Visual Basic]

```
Public Property Blocking As Boolean
```

[C#]

```
public bool Blocking {get; set;}
```

Property Value

A boolean value which specifies the blocking state of the class.

Remarks

The **Blocking** property determines how the class establishes a dial-up connection. If set to **true**, the class will wait until a connection has been established or the connection attempt fails before returning control to the application. If set to **false**, the class will begin the connection process and return control immediately to the application. For a non-blocking connection, the application should monitor the **OnStatus** event to determine the progress of the connection attempt. The default value for this property is **false**.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.BytesIn Property

Gets the number of bytes that have been received by the dial-up networking device.

[Visual Basic]

```
Public ReadOnly Property BytesIn As Integer
```

[C#]

```
public int BytesIn {get;}
```

Property Value

An integer which specifies the number of bytes received.

Remarks

The **BytesIn** property returns the number of bytes that have been received by the dial-up networking device. If the control is unable to determine the number of bytes received, it will return a value of zero.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.BytesOut Property

Gets the number of bytes that have been transmitted by the dial-up networking device.

[Visual Basic]

```
Public ReadOnly Property BytesOut As Integer
```

[C#]

```
public int BytesOut {get;}
```

Property Value

An integer which specifies the number of bytes transmitted.

Remarks

The **BytesOut** property returns the number of bytes that have been transmitted by the dial-up networking device. If the control is unable to determine the number of bytes transmitted, it will return a value of zero.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Callback Property

Specifies that the remote server should call the system back.

[Visual Basic]

```
Public Property Callback As Boolean
```

[C#]

```
public bool Callback {get; set;}
```

Property Value

A boolean value which specifies if the server should call the local system back.

Remarks

Setting the **Callback** property specifies that the server should call the user back at the telephone number specified by the **CallbackNumber** property. This property is ignored unless the user has "Set By Caller" callback permission on the server.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.CallbackNumber Property

Gets and sets the telephone number for the remote server to call back on.

[Visual Basic]

```
Public Property CallbackNumber As String
```

[C#]

```
public string CallbackNumber {get; set;}
```

Property Value

A string which specifies the callback telephone number.

Remarks

Setting the **CallbackNumber** property specifies that the server should call the user back at the given telephone number. This property is ignored unless the user has "Set By Caller" callback permission on the server. Assigning an asterisk to this property causes the number stored in the phone book entry to be used for callback.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Connections Property

Gets the number of active dial-up networking sessions.

[Visual Basic]

```
Public ReadOnly Property Connections As Integer
```

[C#]

```
public int Connections {get;}
```

Property Value

An integer value which specifies the number of active dial-up networking sessions.

Remarks

The **Connections** property returns the number of active dial-up networking connections on the local system. A value of zero indicates that there is no dial-up networking connection. This property is used in conjunction with the **Connection** array to enumerate the connections on the current system.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.ConnectSpeed Property

Gets the line speed for the current dial-up networking connection.

[Visual Basic]
```
Public ReadOnly Property ConnectSpeed As Integer
```

[C#]
```
public int ConnectSpeed {get;}
```

Property Value

An integer value which specifies the connection speed.

Remarks

The **ConnectSpeed** property returns the speed, in bytes per second, at which the current dial-up networking device has established a connection. If the class is unable to determine the connection speed, it will return a value of zero.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.CountryCode Property

Gets and sets the country code for the current phonebook entry.

[Visual Basic]

```
Public Property CountryCode As Integer
```

[C#]

```
public int CountryCode {get; set;}
```

Property Value

An integer value which specifies the country code.

Remarks

The **CountryCode** property specifies the numeric country code for the current phonebook entry. If this value is zero, then the country and area code information is not used when dialing the phone number. The country code for the United States is 1.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.CountryName Property

Gets and sets the country name for the current phonebook entry.

[Visual Basic]

```
Public Property CountryName As String
```

[C#]

```
public string CountryName {get; set;}
```

Property Value

A string which specifies the country name.

Remarks

The **CountryName** property returns the name of the country associated with the country code used when dialing the current phonebook entry. If no country code has been specified, this property will return an empty string. Setting this property to the name of a country will change the current country code. If no area code has been defined, and the country code specifies the current dialing location, the **AreaCode** property will be updated to the current area code.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.DefaultGateway Property

Enable and disable the default gateway for IP packets through the dial-up adapter.

[Visual Basic]

```
Public Property DefaultGateway As Boolean
```

[C#]

```
public bool DefaultGateway {get; set;}
```

Property Value

A boolean value which specifies if the default gateway should be used.

Remarks

The **DefaultGateway** property is used to determine the default gateway for IP packets. If set to **true**, then packets are routed through the dial-up networking adapter when the connection is active. The value of this property corresponds to the Use Default Gateway checkbox on the TCP/IP configuration dialog.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.DeviceCount Property

Gets the number of dial-up networking devices available.

[Visual Basic]

```
Public ReadOnly Property DeviceCount As Integer
```

[C#]

```
public int DeviceCount {get;}
```

Property Value

An integer value which specifies the number of devices.

Remarks

The **DeviceCount** property returns the number of dial-up networking devices available. This property can be used in conjunction with the **DeviceEntry** array to enumerate the devices.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.DeviceName Property

Gets and sets the device name for the current dial-up networking connection.

[Visual Basic]

```
Public Property DeviceName As String
```

[C#]

```
public string DeviceName {get; set;}
```

Property Value

A string which specifies the device name.

Remarks

The **DeviceName** property returns a description of the device that the connection was established on. For example, the string "US Robotics Sportster 56000" may be returned for a modem. Note that this property value may change if the **DeviceType** property is modified. Setting this property will change the device used to establish the dial-up networking connection. Changes to this property value should be made after changes to the **DeviceType** property.

To enumerate a list of available devices for a given device type, use the **DeviceCount** property and **DeviceEntry** array.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.DeviceType Property

Gets and sets the device type for the current dial-up networking connection.

[Visual Basic]

```
Public Property DeviceType As String
```

[C#]

```
public string DeviceType {get; set;}
```

Property Value

A string which specifies the device type.

Remarks

The **DeviceType** property returns the type of device that the connection was established with. Setting this property will change the type of device that will be used to establish the connection. Examples of valid device types are:

DeviceType	Description
modem	An internal or external serial analog modem device, or other serial communications device which supports the AT command set.
isdn	An ISDN terminal adapter. Note that some ISDN devices, such as the 3Com ImpactIQ are considered modem devices.
vpn	A virtual private network connection.

Because changing the device type can change the current device name, it is recommended that applications change this property value before changing the value of the **DeviceName** property.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.DynamicAddress Property

Enables and disables the use of dynamically allocated IP addresses.

[Visual Basic]

```
Public Property DynamicAddress As Boolean
```

[C#]

```
public bool DynamicAddress {get; set;}
```

Property Value

A boolean value which specifies if a dynamically allocated IP address should be used.

Remarks

The **DynamicAddress** property determines if the current phonebook entry should use a dynamically assigned IP address. If this property is set to **true**, then an IP address is assigned to the dial-up adapter when the connection is established. If set to **false**, then the dial-up adapter IP address is set to the value of the **InternetAddress** property.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.DynamicNameServers Property

Enables and disables the use of dynamically assigned nameserver addresses.

[Visual Basic]

```
Public Property DynamicNameServers As Boolean
```

[C#]

```
public bool DynamicNameServers {get; set;}
```

Property Value

A boolean value which specifies if dynamically allocated nameservers should be used.

Remarks

The **DynamicNameServers** property determines if the current phonebook entry should use dynamically assigned nameservers. If this property is set to **true**, then one or more nameservers are assigned to the dial-up adapter when the connection is established. If set to **false**, then the dial-up adapter nameservers are set to the values specified by the **NameServer** property array.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.EntryName Property

Gets and sets the current phone book entry name.

[Visual Basic]

```
Public Property EntryName As String
```

[C#]

```
public string EntryName {get; set;}
```

Property Value

A string which specifies the current phonebook entry name.

Remarks

The **EntryName** property can be used to specify a phone book entry to use to connect with a remote server. The entry name identifies a communications profile which includes the telephone number, callback number and domain name of the remote host. Setting the **EntryName** property to an empty string indicates that a telephone number will be provided to establish the connection.

In Windows documentation, the phonebook entry name is also referred to as a ***connectoid***.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.FramingProtocol Property

Gets and sets the framing protocol for the current phonebook entry.

[Visual Basic]

```
Public Property FramingProtocol As RasFramingProtocol
```

[C#]

```
public InternetDialer.RasFramingProtocol FramingProtocol {get; set;}
```

Property Value

A RasFramingProtocol enumeration which specifies the framing protocol.

Remarks

The **FramingProtocol** property is used to set or return the framing protocol used for the current phonebook entry.

Note that unless there is a specific need for the application to use SLIP or the Microsoft RAS protocol, it is recommended that PPP always be selected as the framing protocol.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Handle Property

Gets and sets the handle for the current dial-up networking connection.

[Visual Basic]

```
Public Property Handle As Integer
```

[C#]

```
public int Handle {get; set;}
```

Property Value

An integer value which specifies a dial-up networking connection.

Remarks

The **Handle** property returns the handle to the current dial-up networking connection, or a value of zero if the class has not been used to establish a connection. Setting the value of this property to a valid handle causes the class to inherit the specified connection, and its properties will be updated with information about that connection. This enables an application to monitor and control a connection that was established by another program.

Setting the **Handle** property to a value of zero causes the class to release the current connection, however it will not cause the dial-up networking session to terminate. To disconnect from the remote server, the **Disconnect** method must be called by the application. Setting the property to a non-zero value which does not specify a valid handle will generate an exception.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.InternetAddress Property

Gets the address assigned to the current dial-up networking session.

[Visual Basic]
```
Public Property InternetAddress As String
```

[C#]
```
public string InternetAddress {get; set;}
```

Property Value

A string which specifies an Internet Protocol (IP) address.

Remarks

The **InternetAddress** property returns the address assigned to the current dial-up networking session. If no connection has been established, or the connection has not been made with a PPP server, then this property will return an empty string. If the **DynamicAddress** property is set to **false**, changing this property value will update the address assigned to the current phonebook entry.

The address may only be changed before a connection is established.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Interval Property

Gets and sets the interval at which the connection is monitored.

[Visual Basic]

```
Public Property Interval As Integer
```

[C#]

```
public int Interval {get; set;}
```

Property Value

An integer value which specifies the interval in milliseconds.

Remarks

The **Interval** property specifies the interval, in milliseconds, at which the connection is monitored by the class. The minimum value of 0 indicates that the class should not monitor the connection. The maximum interval value is 65536 milliseconds, which is slightly more than one minute. The default value is 1000, which causes the control to check the connection status every second.

Note that setting the property value to zero will prevent the class from detecting certain conditions, such as a disconnected telephone line or a modem that is turned off.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.IpHeaderCompression Property

Enables and disables IP header compression for the current phonebook entry.

[Visual Basic]

```
Public Property IpHeaderCompression As Boolean
```

[C#]

```
public bool IpHeaderCompression {get; set;}
```

Property Value

A boolean value which specifies if IP header compression is enabled.

Remarks

The **IpHeaderCompression** property is used to enable or disable IP header compression. If set to **true**, when a connection is established, RAS will negotiate with the dial-up server to use header compression. If set to **false**, header compression will not be negotiated. This property corresponds to the Use IP Header Compression checkbox on the TCP/IP configuration dialog.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.IsConnected Property

Gets a value which indicates if a connection has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

A boolean value which specifies if a connection has been established with a service provider.

Remarks

The **IsConnected** property is used to determine if the class has connected to the remote host. A value of **true** indicates that a connection has been established.

Note that the **IsConnected** property should not be used to determine if an active dial-up networking connection has been established by another application. The property will only return **true** if the class has been used to establish the connection itself, or if a connection is inherited by setting either the **AutoConnect** or **Handle** properties. To determine if there are any active dial-up networking connections, check the value of the **Connections** property.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public InternetDialer.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.LcpExtensions Property

Enables and disables the use of PPP LCP extensions for the current phonebook entry.

[Visual Basic]

```
Public Property LcpExtensions As Boolean
```

[C#]

```
public bool LcpExtensions {get; set;}
```

Property Value

A boolean value which specifies if PPP LCP extensions are enabled.

Remarks

The **LcpExtensions** property determines if the PPP LCP extensions defined in RFC 1570 will be used. If the PPP framing protocol is being used for the dial-up connection, it is recommended that this property be set to **true**. However, some older implementations of PPP may require that this property be set to **false** in order to establish a connection.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.LocalNumber Property

Gets and sets the local telephone number specified in the phonebook entry.

[Visual Basic]

```
Public Property LocalNumber As String
```

[C#]

```
public string LocalNumber {get; set;}
```

Property Value

A string which specifies the local telephone number.

Remarks

The **LocalNumber** property sets or returns the local phone number that is specified in the current phonebook entry. If the **CountryCode** property has a value of zero, then the local number is dialed to connect to the server. If the **CountryCode** property is set to a valid country code, then RAS will also use the country and area code values when dialing the phone number.

Note that this property only determines the local phone number for the phonebook entry, and can be overridden by setting the **PhoneNumber** property to a specific value.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.ModemLights Property

Enables and disables the dial-up networking system tray icon.

[Visual Basic]

```
Public Property ModemLights As Boolean
```

[C#]

```
public bool ModemLights {get; set;}
```

Property Value

A boolean value which specifies if the system tray icon is displayed.

Remarks

The **ModemLights** property determines if the dial-up networking icon in the system tray is displayed when a connection is established.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.ModemSpeaker Property

Enables and disables the modem speaker.

[Visual Basic]

```
Public Property ModemSpeaker As Boolean
```

[C#]

```
public bool ModemSpeaker {get; set;}
```

Property Value

A boolean value which specifies if the modem speaker is enabled.

Remarks

The **ModemSpeaker** property determines if the modem speaker is enabled when dialing the remote server. If the property is set to **false**, the modem will be silent when dialing the telephone number and establishing the connection. Note that setting this property to **true** will not force the speaker on if the modem hardware has been configured to explicitly disable the speaker.

To disable the speaker, the modem must support changes to the speaker volume. Disabling the speaker is typically done by instructing the modem to set the speaker volume to zero.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.NetworkLogon Property

Enables and disables a network login for the current phonebook entry.

[Visual Basic]

```
Public Property NetworkLogon As Boolean
```

[C#]

```
public bool NetworkLogon {get; set;}
```

Property Value

A boolean value which specifies if a network login is enabled.

Remarks

The **NetworkLogon** property determines if the client automatically logs on to the network after a connection has been established.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.NetworkProtocol Property

Gets and sets the network protocol for the current phonebook entry.

[Visual Basic]

```
Public Property NetworkProtocol As RasNetworkProtocol
```

[C#]

```
public InternetDialer.RasNetworkProtocol NetworkProtocol {get; set;}
```

Property Value

A RasNetworkProtocol enumeration value which specifies the network protocol.

Remarks

The **NetworkProtocol** property is used to set or return the network protocol used for the current phonebook entry.

Note that unless there is a specific need for the application to use the NetBEUI or IPX protocols, it is recommended that only the TCP/IP protocol be specified.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Password Property

Gets the password required to establish a connection with the service provider.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password for the current phonebook entry.

Remarks

The **Password** property specifies the password required to establish a connection with the service provider.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.PhoneBook Property

Sets the file name of the Remote Access phonebook to use.

[Visual Basic]

```
Public Property PhoneBook As String
```

[C#]

```
public string PhoneBook {get; set;}
```

Property Value

A string which specifies the current phonebook.

Remarks

The **PhoneBook** property specifies the file name of the Remote Access phone book. Setting this property to an empty string causes the default phonebook to be used.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.PhoneBookEntries Property

Gets the number of entries in the current phonebook.

[Visual Basic]
```
Public ReadOnly Property PhoneBookEntries As Integer
```

[C#]
```
public int PhoneBookEntries {get;}
```

Property Value

An integer value which specifies the number of phonebook entries.

Remarks

The **PhoneBookEntries** property returns the number of entries in the current phonebook. A value of zero indicates that no phonebook entries are available.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.PhoneNumber Property

Gets and sets the telephone number of the service provider.

[Visual Basic]

```
Public Property PhoneNumber As String
```

[C#]

```
public string PhoneNumber {get; set;}
```

Property Value

A string which specifies a telephone number.

Remarks

The **PhoneNumber** property specifies the telephone number of the service provider. If this property is not set, then the **PhoneEntry** property must be set to a valid phone book entry. If both the **PhoneNumber** and **PhoneEntry** properties are defined, the **PhoneNumber** property will override the value specified in the phonebook.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.RequireEncryption Property

Enables and disables secure authentication for the current phonebook entry.

[Visual Basic]
```
Public Property RequireEncryption As Boolean
```

[C#]
```
public bool RequireEncryption {get; set;}
```

Property Value

A boolean value which specifies if secure authentication is enabled.

Remarks

The **RequireEncryption** property determines if encryption is required during PPP authentication. If the property is set to **true**, then only secure password schemes can be used to authenticate the client. If the property is set to **false**, the client can use the PAP plain-text authentication protocol to authenticate the client. Some older PPP implementations may require that this property be set to **false** in order to establish a connection.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.ScriptFile Property

Gets and sets the name of the script file for the current phonebook entry.

[Visual Basic]

```
Public Property ScriptFile As String
```

[C#]

```
public string ScriptFile {get; set;}
```

Property Value

A string which specifies the name of the script file.

Remarks

The **ScriptFile** property specifies the name of the login script used to establish a connection with the remote host. This property must be set to the full pathname of the script file. If a script file is not required, then this property should be set to an empty string.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.ServerAddress Property

Gets the address of the dial-up networking server.

[Visual Basic]

```
Public ReadOnly Property ServerAddress As String
```

[C#]

```
public string ServerAddress {get;}
```

Property Value

A string which specifies an Internet Protocol (IP) address.

Remarks

The **ServerAddress** property returns the address of the dial-up networking server that the local host has connected to. If no connection has been established, or the connection has not been made with a PPP server, then this property will return an empty string. This property may also return an empty string if the remote server did not provide this information during the connection process.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.SoftwareCompression Property

Enables and disables software compression for the current phonebook entry.

[Visual Basic]

```
Public Property SoftwareCompression As Boolean
```

[C#]

```
public bool SoftwareCompression {get; set;}
```

Property Value

A boolean value which specifies if software compression is enabled.

Remarks

The **SoftwareCompression** property determines if data compression is negotiated during the connection. If the property is set to **true**, then the client will negotiate a compatible compression protocol. Software compression should only be disabled if the client is unable to establish a connection with the server.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Status Property

Gets a value which specifies the current status of the dial-up networking connection.

[Visual Basic]

```
Public ReadOnly Property Status As DialerStatus
```

[C#]

```
public InternetDialer.DialerStatus Status {get;}
```

Property Value

A DialerStatus enumeration value which specifies the current status.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Terminal Property

Gets and sets the interactive terminal window mode for the current phonebook entry.

[Visual Basic]
```
Public Property Terminal As RasTerminalMode
```

[C#]
```
public InternetDialer.RasTerminalMode Terminal {get; set;}
```

Property Value

A RasTerminalMode enumeration which specifies the terminal window mode.

Remarks

The **Terminal** array is used to control if a terminal window is displayed during the dial-up networking connection process. The terminal window can be used to allow user input before and/or after the dial-up networking connection has been established. If scripting has been enabled by setting the **ScriptFile** property, no terminal window should be displayed after the connection. This is because scripting has it's own terminal implementation.

Displaying a terminal window also imposes several restrictions on the behavior of the class. Because of how the Remote Access Services API is implemented by Microsoft, a connection dialog will be displayed after the **Connect** method is called if the **Terminal** property is non-zero. Setting this property to a non-zero value will also disable any asynchronous event notifications. It is not recommended that you set this property unless it is absolutely necessary.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]
```
Public Property ThrowError As Boolean
```

[C#]
```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error. The timeout period is only used when the client is in blocking mode. Although this property can be changed when the client is in non-blocking mode, the value will be ignored until the client is returned to blocking mode.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.UserDomain Property

Gets and sets the NT domain on which user authentication is to occur.

[Visual Basic]
```
Public Property UserDomain As String
```

[C#]
```
public string UserDomain {get; set;}
```

Property Value

A string which specifies the NT domain name.

Remarks

The **UserDomain** property is used to specify the NT domain on which the user name and password will be authenticated. An empty string specifies the domain in which the Remote Access server is a member. An asterisk specifies the domain stored in the phone book entry.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.UserName Property

Gets the username required to establish a connection with the service provider.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username for the current phonebook entry.

Remarks

The **UserName** property specifies the username required to establish a connection with the service provider.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.UserPhoneBook Property

Gets the name of the default user phonebook.

[Visual Basic]

```
Public ReadOnly Property UserPhoneBook As String
```

[C#]

```
public string UserPhoneBook {get;}
```

Property Value

A string which specifies a phonebook name.

Remarks

The **UserPhoneBook** property returns the name of the default user phonebook. The value returned depends on how the user has configured dial-up networking, specifically whether the system, user or alternate phonebook has been selected. The current phonebook can be changed by setting the **PhoneBook** property.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Version Property

Gets a value which returns the current version of the InternetDialer class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the InternetDialer class library. This value can be used by an application for validation and debugging purposes.

InternetDialer Class | SocketTools Namespace

InternetDialer Methods

The methods of the **InternetDialer** class are listed below. For a complete list of **InternetDialer** class members, see the InternetDialer Members topic.

Public Instance Methods

Connect	Overloaded. Establish a connection with a dial-up networking services provider.
CreateEntry	Create a new entry in the current phonebook.
DeleteEntry	Overloaded. Delete a phonebook entry from the current phonebook.
Disconnect	Terminate the connection with the dial-up networking service provider.
Dispose	Overloaded. Releases all resources used by InternetDialer.
EditEntry	Edit an existing phonebook entry in the current phonebook.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the InternetDialer class.
LoadEntry	Overloaded. Load the specified entry from the current phonebook.
RenameEntry	Rename an existing phonebook entry.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SaveEntry	Overloaded. Save the current settings to the specified phonebook entry in the current phonebook.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the InternetDialer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading

	the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Connect Method

Establish a connection with a dial-up networking services provider.

Overload List

Establish a connection with a dial-up networking services provider.

public bool Connect();

Establish a connection with a dial-up networking services provider.

public bool Connect(string);

Establish a connection with a dial-up networking services provider.

public bool Connect(string,string,string);

Establish a connection with a dial-up networking services provider.

public bool Connect(string,string,string,string);

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Connect Method ()

Establish a connection with a dial-up networking services provider.

[Visual Basic]

```
Overloads Public Function Connect() As Boolean
```

[C#]

```
public bool Connect();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Connect** method establishes a dial-up networking connection with a service provider using the current phonebook entry.

The current phonebook entry name is specified by the **EntryName** property.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.Connect Overload List

InternetDialer.Connect Method (String)

Establish a connection with a dial-up networking services provider.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal entryName As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string entryName
);
```

Parameters

entryName

A string which specifies the phonebook entry that should be used when establishing the connection.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Connect** method establishes a dial-up networking connection with a service provider using the specified phonebook entry. The entry name is the same name as the connectoid that is displayed when you list the available dial-up networking connections on the local system.

For a list of all of the available phonebook entries, reference the **PhoneBookEntry** array.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.Connect Overload List

InternetDialer.Connect Method (String, String, String)

Establish a connection with a dial-up networking services provider.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal phoneNumber As String, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string phoneNumber,
   string userName,
   string userPassword
);
```

Parameters

phoneNumber
A string which specifies the phone number to dial.

userName
A string which specifies the username which will be used to authenticate the session.

userPassword
A string which specifies the password which will be used to authenticate the session.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Connect** method establishes a dial-up networking connection with a service provider. A temporary phonebook entry will be created for the dial-up networking session, and this entry will be removed when the local host disconnects from the service provider.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.Connect Overload List

InternetDialer.Connect Method (String, String, String, String)

Establish a connection with a dial-up networking services provider.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal phoneNumber As String, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal userDomain As String _
) As Boolean
```

[C#]

```
public bool Connect(
   string phoneNumber,
   string userName,
   string userPassword,
   string userDomain
);
```

Parameters

phoneNumber
A string which specifies the phone number to dial.

userName
A string which specifies the username which will be used to authenticate the session.

userPassword
A string which specifies the password which will be used to authenticate the session.

userDomain
A string which specifies the domain on which the username and password will be authenticated. An empty string specifies the domain in which the Remote Access Server is a member.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Connect** method establishes a dial-up networking connection with a service provider. A temporary phonebook entry will be created for the dial-up networking session, and this entry will be removed when the local host disconnects from the service provider.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.Connect Overload List

InternetDialer.CreateEntry Method

Create a new entry in the current phonebook.

[Visual Basic]
```
Public Function CreateEntry() As Boolean
```

[C#]
```
public bool CreateEntry();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateEntry** method displays a dialog box which allows the user to create a new phonebook entry on the system. If you do not wish to display a dialog box, use the **SaveEntry** method instead.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.DeleteEntry Method

Delete the current phonebook entry from the phonebook.

Overload List

Delete the current phonebook entry from the phonebook.

public bool DeleteEntry();

Delete a phonebook entry from the current phonebook.

public bool DeleteEntry(string);

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.DeleteEntry Method ()

Delete the current phonebook entry from the phonebook.

[Visual Basic]

```
Overloads Public Function DeleteEntry() As Boolean
```

[C#]

```
public bool DeleteEntry();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The current phonebook entry name is specified by the **EntryName** property.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.DeleteEntry Overload List

InternetDialer.DeleteEntry Method (String)

Delete a phonebook entry from the current phonebook.

[Visual Basic]

```
Overloads Public Function DeleteEntry( _
   ByVal entryName As String _
) As Boolean
```

[C#]

```
public bool DeleteEntry(
   string entryName
);
```

Parameters

entryName

A string which specifies the phonebook entry name to delete.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.DeleteEntry Overload List

InternetDialer.Disconnect Method

Terminate the connection with the dial-up networking service provider.

[Visual Basic]
```
Public Function Disconnect() As Boolean
```

[C#]
```
public bool Disconnect();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method may cause the current thread to block as the connection is terminated and the dial-up network device is being reset to its default state. Any active network connections using this dial-up networking connection will be terminated.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Dispose Method

Releases all resources used by InternetDialer.

Overload List

Releases all resources used by InternetDialer.

public void Dispose();

Releases the unmanaged resources allocated by the InternetDialer class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Dispose Method ()

Releases all resources used by InternetDialer.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.Dispose Overload List

InternetDialer.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the InternetDialer class and optionally releases the managed resources.

[Visual Basic]
```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]
```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **InternetDialer** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.Dispose Overload List

InternetDialer.EditEntry Method

Edit an existing phonebook entry in the current phonebook.

[Visual Basic]

```
Public Function EditEntry( _
   ByVal entryName As String _
) As Boolean
```

[C#]

```
public bool EditEntry(
   string entryName
);
```

Parameters

entryName
A string which specifies the name of the phonebook entry to be edited.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **EditEntry** method edits the specified entry from the local phonebook. This will cause a dialog box to be displayed from which the user can change the connection information. If you do not want to display a dialog, then use the **SaveEntry** method instead.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]
```
Overrides Protected Sub Finalize()
```

[C#]
```
protected override void Finalize();
```

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Initialize Method

Initialize an instance of the InternetDialer class.

Overload List

Initialize an instance of the InternetDialer class.

public bool Initialize();

Initialize an instance of the InternetDialer class.

public bool Initialize(string);

See Also

InternetDialer Class | SocketTools Namespace | Uninitialize Method

InternetDialer.Initialize Method ()

Initialize an instance of the InternetDialer class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the InternetDialer class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.Initialize Overload List | Uninitialize Method

InternetDialer.Initialize Method (String)

Initialize an instance of the InternetDialer class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the InternetDialer class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the InternetDialer class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.InternetDialer xxxClient = new SocketTools.InternetDialer();

if (xxxClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(xxxClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim xxxClient As New SocketTools.InternetDialer

If xxxClient.Initialize(strLicenseKey) = False Then
    MsgBox(xxxClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

InternetDialer.LoadEntry Method

Reload the current phonebook entry from the phonebook.

Overload List

Reload the current phonebook entry from the phonebook.

public bool LoadEntry();

Load the specified entry from the current phonebook.

public bool LoadEntry(string);

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.LoadEntry Method ()

Reload the current phonebook entry from the phonebook.

[Visual Basic]
```
Overloads Public Function LoadEntry() As Boolean
```

[C#]
```
public bool LoadEntry();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The current entry from the phonebook will be reloaded and any changes made to the current entry will be abandoned.

The current phonebook entry name is specified by the **EntryName** property.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.LoadEntry Overload List

InternetDialer.LoadEntry Method (String)

Load the specified entry from the current phonebook.

[Visual Basic]

```
Overloads Public Function LoadEntry( _
   ByVal entryName As String _
) As Boolean
```

[C#]

```
public bool LoadEntry(
   string entryName
);
```

Parameters

entryName

A string which specifies the name of a phonebook entry.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **LoadEntry** method loads the specified entry from the current phonebook and sets the class properties to match the configuration.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.LoadEntry Overload List

InternetDialer.RenameEntry Method

Rename an existing phonebook entry.

[Visual Basic]

```
Public Function RenameEntry( _
   ByVal oldEntryName As String, _
   ByVal newEntryName As String _
) As Boolean
```

[C#]

```
public bool RenameEntry(
   string oldEntryName,
   string newEntryName
);
```

Parameters

oldEntryName
A string which specifies the phonebook entry which will be renamed.

newEntryName
A string which specifies the new name for the phonebook entry.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **RenameEntry** method renames the specified entry in the local phonebook. The new entry name must not already exist in the phonebook.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a socket has been allocated, it will be released and any active connections will be terminated. All properties will be reset to their default values.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.SaveEntry Method

Save the current phonebook entry settings.

Overload List

Save the current phonebook entry settings.

public bool SaveEntry();

Save the current settings to the specified phonebook entry in the current phonebook.

public bool SaveEntry(string);

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.SaveEntry Method ()

Save the current phonebook entry settings.

[Visual Basic]
```
Overloads Public Function SaveEntry() As Boolean
```

[C#]
```
public bool SaveEntry();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SaveEntry** method saves the current phonebook entry settings, based on the class property values. If the entry does not exist, it will be created. If the entry does exist, it will be overwritten. Note that unlike the **CreateEntry** method, this method does not display any user-interface dialogs.

The current phonebook entry name is specified by the **EntryName** property.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.SaveEntry Overload List

InternetDialer.SaveEntry Method (String)

Save the current settings to the specified phonebook entry in the current phonebook.

[Visual Basic]

```
Overloads Public Function SaveEntry( _
   ByVal entryName As String _
) As Boolean
```

[C#]

```
public bool SaveEntry(
   string entryName
);
```

Parameters

entryName

A string which specifies the name of the phonebook entry.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SaveEntry** method saves the specified entry to the current phonebook, based on the class property values. If the entry does not exist, it will be created. If the entry does exist, it will be overwritten. Note that unlike the **CreateEntry** method, this method does not display any user-interface dialogs.

See Also

InternetDialer Class | SocketTools Namespace | InternetDialer.SaveEntry Overload List

InternetDialer.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the current thread and unloads the networking library. After this method has been called, no further client operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

InternetDialer Class | SocketTools Namespace | Initialize Method

InternetDialer Events

The events of the **InternetDialer** class are listed below. For a complete list of **InternetDialer** class members, see the InternetDialer Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnConnect	Occurs when a connection is established with the service provider.
⚡ OnDisconnect	Occurs when the dial-up networking connection is terminated.
⚡ OnError	Occurs when an client operation fails.
⚡ OnStatus	Occurs when the when the connection state changes.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking client operation, such as sending or receiving data, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.OnConnect Event

Occurs when a connection is established with the service provider.

[Visual Basic]

```
Public Event OnConnect As EventHandler
```

[C#]

```
public event EventHandler OnConnect;
```

Remarks

The **OnConnect** event occurs when a connection is made with a service provider as a result of a **Connect** method call. When the **Connect** method is called and the **Blocking** property is set to **false**, a dial-up networking connection is initiated, but the connection is not actually established until after this event occurs. Between the time connection process is started and this event fires, no operation may be performed by the client other than calling the **Disconnect** method.

This event is only generated if the client is in non-blocking mode.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.OnDisconnect Event

Occurs when the dial-up networking connection is terminated.

[Visual Basic]

```
Public Event OnDisconnect As EventHandler
```

[C#]

```
public event EventHandler OnDisconnect;
```

Remarks

The **OnDisconnect** event occurs when the dial-up networking connection has been terminated. This event is only generated if the client is in non-blocking mode.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.OnError Event

Occurs when an client operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type InternetDialer.ErrorEventArgs containing data related to this event. The following **InternetDialer.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see InternetDialer.ErrorEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.InternetDialer.ErrorEventArgs

[Visual Basic]
```
Public Class InternetDialer.ErrorEventArgs
    Inherits EventArgs
```

[C#]
```
public class InternetDialer.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

See Also

InternetDialer.ErrorEventArgs Members | SocketTools Namespace

InternetDialer.ErrorEventArgs Members

InternetDialer.ErrorEventArgs overview

Public Instance Constructors

InternetDialer.ErrorEventArgs Constructor	Initializes a new instance of the InternetDialer.ErrorEventArgs class.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetDialer.ErrorEventArgs Class | SocketTools Namespace

InternetDialer.ErrorEventArgs Constructor

Initializes a new instance of the InternetDialer.ErrorEventArgs class.

[Visual Basic]
```
Public Sub New()
```

[C#]
```
public InternetDialer.ErrorEventArgs();
```

See Also

InternetDialer.ErrorEventArgs Class | SocketTools Namespace

InternetDialer.ErrorEventArgs Properties

The properties of the **InternetDialer.ErrorEventArgs** class are listed below. For a complete list of **InternetDialer.ErrorEventArgs** class members, see the InternetDialer.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

InternetDialer.ErrorEventArgs Class | SocketTools Namespace

InternetDialer.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

InternetDialer.ErrorEventArgs Class | SocketTools Namespace | Error Property

InternetDialer.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public InternetDialer.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

InternetDialer.ErrorEventArgs Class | SocketTools Namespace | Description Property

InternetDialer.OnStatus Event

Occurs when the when the connection state changes.

[Visual Basic]

```
Public Event OnStatus As OnStatusEventHandler
```

[C#]

```
public event OnStatusEventHandler OnStatus;
```

Event Data

The event handler receives an argument of type InternetDialer.StatusEventArgs containing data related to this event. The following **InternetDialer.StatusEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a description of the current dial-up networking connection status.
Status	Gets a value which specifies the current status of the dial-up networking connection.

Remarks

The **OnStatus** event is generated when the status of the connection changes. Typically this occurs when a connection is being established with a dial-up networking server.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.StatusEventArgs Class

Provides data for the OnStatus event.

For a list of all members of this type, see InternetDialer.StatusEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.InternetDialer.StatusEventArgs

[Visual Basic]

```
Public Class InternetDialer.StatusEventArgs
    Inherits EventArgs
```

[C#]

```
public class InternetDialer.StatusEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

StatusEventArgs specifies the status code and a description of the status for the last status change that has occurred.

The OnStatus event occurs whenever the status of the dial-up networking connection changes.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

See Also

InternetDialer.StatusEventArgs Members | SocketTools Namespace

InternetDialer.StatusEventArgs Class | SocketTools Namespace

InternetDialer.StatusEventArgs Constructor

Initializes a new instance of the InternetDialer.StatusEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public InternetDialer.StatusEventArgs();
```

See Also

InternetDialer.StatusEventArgs Class | SocketTools Namespace

InternetDialer.StatusEventArgs Properties

The properties of the **InternetDialer.StatusEventArgs** class are listed below. For a complete list of **InternetDialer.StatusEventArgs** class members, see the InternetDialer.StatusEventArgs Members topic.

Public Instance Properties

Description	Gets a description of the current dial-up networking connection status.
Status	Gets a value which specifies the current status of the dial-up networking connection.

See Also

InternetDialer.StatusEventArgs Class | SocketTools Namespace

InternetDialer.StatusEventArgs.Description Property

Gets a description of the current dial-up networking connection status.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the connection status.

See Also

InternetDialer.StatusEventArgs Class | SocketTools Namespace | Error Property

InternetDialer.StatusEventArgs.Status Property

Gets a value which specifies the current status of the dial-up networking connection.

[Visual Basic]

```
Public ReadOnly Property Status As DialerStatus
```

[C#]

```
public InternetDialer.DialerStatus Status {get;}
```

Property Value

A DialerStatus enumeration value which specifies the current status.

See Also

InternetDialer.StatusEventArgs Class | SocketTools Namespace

InternetDialer.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

This event is only generated if the client is in blocking mode.

See Also

InternetDialer Class | SocketTools Namespace

InternetDialer.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub InternetDialer.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void InternetDialer.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender
The source of the event.

e
An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

See Also

SocketTools Namespace

InternetDialer.OnStatusEventHandler Delegate

Represents the method that will handle the OnStatus event.

[Visual Basic]

```
Public Delegate Sub InternetDialer.OnStatusEventHandler( _
   ByVal sender As Object, _
   ByVal e As StatusEventArgs _
)
```

[C#]

```
public delegate void InternetDialer.OnStatusEventHandler(
      object sender,
      StatusEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A StatusEventArgs object that contains the event data.

Remarks

When you create an **OnStatusEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnStatusEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

See Also

SocketTools Namespace

InternetDialer.DialerStatus Enumeration

Specifies the status values that may be returned by the InternetDialer class.

[Visual Basic]
```
Public Enum InternetDialer.DialerStatus
```

[C#]
```
public enum InternetDialer.DialerStatus
```

Remarks

The InternetDialer class uses the **DialerStatus** enumeration to identify the current status of the client.

Members

Member Name	Description
statusUnused	No connection has been established.
statusOpenPort	The communications port is about to be opened.
statusPortOpened	The communications port has been opened.
statusConnectDevice	A device is about to be connected.
statusDeviceConnected	A device has been connected successfully.
statusAllDevicesConnected	All devices have been connected.
statusAuthenticate	Authenticating username and password.
statusAuthNotify	An authentication event has occurred.
statusAuthRetry	Requesting authentication with new credentials.
statusAuthCallback	The remote server has requested a callback number.
statusAuthChangePassword	The user has requested to change the password.
statusAuthProject	Registering computer on the network.
statusAuthLinkSpeed	The link speed calculation phase is starting.
statusAuthAck	An authentication request is being acknowledged.
statusReAuthenticate	Authenticating username and password.
statusAuthenticated	The user has been authenticated.
statusPrepareForCallback	The line is about to be disconnected in preparation for callback.
statusWaitForModemReset	The modem is resetting itself in preparation for callback.
statusWaitForCallback	Waiting for callback from remote server.
statusProjected	Protocol specific information has been negotiated.
statusStartAuthentication	User authentication is being initiated.
statusCallbackComplete	Callback completed and resuming authentication.

statusLogonNetwork	Logging on to the network.
statusSubEntryConnected	A subentry has been connected.
statusSubEntryDisconnected	A subentry has been disconnected.
statusInteractive	Initiating interactive login session.
statusRetryAuthentication	Retrying user authentication.
statusCallbackSetByCaller	Callback has been set by caller.
statusPasswordExpired	Password has expired.
statusConnected	Connected to remote server.
statusDisconnected	Disconnected from remote server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

See Also

SocketTools Namespace

InternetDialer.ErrorCode Enumeration

Specifies the error codes returned by the InternetDialer class.

[Visual Basic]

```
Public Enum InternetDialer.ErrorCode
```

[C#]

```
public enum InternetDialer.ErrorCode
```

Remarks

The InternetDialer class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorDeviceNotFound	The specified device could not be found.
errorOperationTimeout	The specified operation has timed out.
errorPending	An operation is pending.
errorInvalidPortHandle	An invalid port handle was detected.
errorPortAlreadyOpen	The specified port is already open.
errorBufferTooSmall	The caller's buffer is too small.
errorWrongInfoSpecified	Incorrect information was specified.
errorCannotSetPortInfo	The port information cannot be set.
errorPortNotConnected	The specified port is not connected.
errorEventInvalid	An invalid event was detected.
errorDeviceDoesNotExist	A device was specified that does not exist.
errorDevicetypeDoesNotExist	A device type was specified that does not exist.
errorBufferInvalid	An invalid buffer was specified.
errorRouteNotAvailable	A route was specified that is not available.
errorRouteNotAllocated	A route was specified that is not allocated.
errorInvalidCompressionSpecified	An invalid compression was specified.
errorOutOfBuffers	There were insufficient buffers available.

errorPortNotFound	The specified port was not found.
errorAsyncRequestPending	An asynchronous request is pending.
errorAlreadyDisconnecting	The modem or other connecting device is already disconnecting.
errorPortNotOpen	The specified port is not open.
errorPortDisconnected	A connection to the remote computer could not be established.
errorNoEndpoints	No endpoints could be determined.
errorCannotOpenPhonebook	The system could not open the phone book file.
errorCannotLoadPhonebook	The system could not load the phone book file.
errorCannotFindPhonebookEntry	The system could not find the phone book entry for this connection.
errorCannotWritePhonebook	The system could not update the phone book file.
errorCorruptPhonebook	The system found invalid information in the phone book file.
errorCannotLoadString	A string could not be loaded.
errorKeyNotFound	A key could not be found.
errorDisconnection	The connection was terminated by the remote computer before it could be completed.
errorRemoteDisconnection	The connection was closed by the remote computer.
errorHardwareFailure	The modem or other connecting device was disconnected due to hardware failure.
errorUserDisconnection	The user disconnected the modem or other connecting device.
errorInvalidSize	An incorrect structure size was detected.
errorPortNotAvailable	The modem or other connecting device is already in use or is not configured properly.
errorCannotProjectClient	Your computer could not be registered on the remote network.
errorUnknown	There was an unknown error.
errorWrongDeviceAttached	The device attached to the port is not the one expected.
errorBadString	A string was detected that could not be converted.
errorRequestTimeout	The request has timed out.
errorCannotGetLana	No asynchronous net is available.
errorNetBIOSError	An error has occurred involving NetBIOS.
errorServerOutOfResources	The server cannot allocate NetBIOS resources needed to support the client.
errorNameExistsOnNet	One of your computer's NetBIOS names is already

	registered on the remote network.
errorServerGeneralNetFailure	A network adapter at the server failed.
errorMsgAliasNotAdded	You will not receive network message popups.
errorAuthInternal	There was an internal authentication error.
errorRestrictedLogonHours	The account is not permitted to log on at this time of day.
errorAcctDisabled	The account is disabled.
errorPasswdExpired	The password for this account has expired.
errorNoDialInPermission	The account does not have permission to dial in.
errorServerNotResponding	The remote access server is not responding.
errorFromDevice	The modem or other connecting device has reported an error.
errorUnrecognizedResponse	There was an unrecognized response from the modem or other connecting device.
errorMacroNotFound	A macro required by the modem or other connecting device was not found in the configuration file.
errorMacroNotDefined	A command or response in the configuration file refers to an undefined macro.
errorMessageMacroNotFound	The message macro was not found in the configuration file.
errorDefaultOffMacroNotFound	The configuration file contains an undefined macro.
errorFileCouldNotBeOpened	The configuration file could not be opened.
errorDevicenameTooLong	The device name in the configuration file is too long.
errorDevicenameNotFound	The configuration file refers to an unknown device name.
errorNoResponses	The configuration file contains no responses for the command.
errorNoCommandFound	The configuration file is missing a command.
errorWrongKeySpecified	There was an attempt to set a macro not listed in configuration file.
errorUnknownDeviceType	The configuration file refers to an unknown device type.
errorAllocatingMemory	The system has run out of memory.
errorPortNotConfigured	The modem or other connecting device is not properly configured.
errorDeviceNotReady	The modem or other connecting device is not functioning.

errorReadingIniFile	The system was unable to read the configuration file.
errorNoConnection	The connection was terminated.
errorBadUsageInIniFile	The usage parameter in the configuration file is invalid.
errorReadingSectionname	The system was unable to read the section name from the configuration file.
errorReadingDeviceType	The system was unable to read the device type from the configuration file.
errorReadingDeviceName	The system was unable to read the device name from the configuration file.
errorReadingUsage	The system was unable to read the usage from the configuration file.
errorReadingMaxConnectBps	The system was unable to read the maximum connection BPS rate from the configuration file.
errorReadingMaxCarrierBps	The system was unable to read the maximum carrier connection speed from the configuration file.
errorLineBusy	The phone line is busy.
errorVoiceAnswer	A person answered instead of a modem or other connecting device.
errorNoAnswer	The remote computer did not respond.
errorNoCarrier	The system could not detect the carrier.
errorNoDialtone	There was no dial tone.
errorInCommand	The modem or other connecting device reported a general error.
errorWritingSectionname	There was an error in writing the section name.
errorWritingDeviceType	There was an error in writing the device type.
errorWritingDeviceName	There was an error in writing the device name.
errorWritingMaxConnectBps	There was an error in writing the maximum connection speed..
errorWritingMaxCarrierBps	There was an error in writing the maximum carrier speed.
errorWritingUsage	There was an error in writing the usage.
errorWritingDefaultOff	There was an error in writing the default-off.
errorReadingDefaultOff	There was an error in reading the default-off.
errorEmptyIniFile	The configuration file is empty.
errorAuthenticationFailure	Access was denied because the username and/or password was invalid on the domain.
errorPortOrDevice	There was a hardware failure in the modem or other connecting device.

errorNotBinaryMacro	An internal error has occurred.
errorDcbNotFound	An internal error has occurred.
errorStateMachinesNotStarted	The state machines are not started.
errorStateMachinesAlreadyStarted	The state machines are already started.
errorPartialResponseLooping	The response looping did not complete.
errorUnknownResponseKey	A response keyname in the configuration file is not in the expected format.
errorRecvBufFull	The modem or other connecting device response caused a buffer overflow.
errorCmdTooLong	The expanded command in the configuration file is too long.
errorUnsupportedBps	The modem moved to a connection speed not supported by the COM driver.
errorUnexpectedResponse	Device response received when none expected.
errorInteractiveMode	The connection needs information from you, but the application does not allow user interaction.
errorBadCallbackNumber	The callback number is invalid.
errorInvalidAuthState	The authorization state is invalid.
errorWritingInitBps	An internal error has occurred.
errorX25Diagnostic	There was an error related to the X.25 protocol.
errorAcctExpired	The account has expired.
errorChangingPassword	There was an error changing the password on the domain.
errorOverrun	Serial overrun errors were detected while communicating with the modem.
errorRasmanCannotInitialize	A configuration error on this computer is preventing this connection.
errorBiplexPortNotAvailable	The two-way port is initializing, wait a few seconds and redial.
errorNoActiveIsdnLines	No active ISDN lines are available.
errorNoIsdnChannelsAvailable	No ISDN channels are available to make the call.
errorTooManyLineErrors	Too many errors occurred because of poor phone line quality.
errorIpConfiguration	The Remote Access Service IP configuration is unusable.
errorNoIpAddresses	No IP addresses are available in the static pool of Remote Access Service IP addresses.
errorPppTimeout	The connection was terminated because the remote computer did not respond in a timely manner.

errorPppRemoteTerminated	The connection was terminated by the remote computer.
errorPppNoProtocolsConfigured	A connection to the remote computer could not be established.
errorPppNoResponse	The remote computer did not respond.
errorPppInvalidPacket	Invalid data was received from the remote computer.
errorPhoneNumberTooLong	The phone number, including prefix and suffix, is too long.
errorIpxcpNoDialoutConfigured	The IPX protocol cannot dial out on the modem because this computer is not configured for dialing out.
errorIpxcpNoDialinConfigured	The IPX protocol cannot dial in on the modem because this computer is not configured for dialing in.
errorIpxcpDialoutAlreadyActive	The IPX protocol cannot be used for dialing out on more than one modem.
errorAccessingTcpcfgDll	Cannot access TCPCFG.DLL.
errorNoIpRasAdapter	The system cannot find an IP adapter.
errorSlipRequiresIp	SLIP cannot be used unless the IP protocol is installed.
errorProjectionNotComplete	Computer registration is not complete.
errorProtocolNotConfigured	The protocol is not configured.
errorPppNotConverging	Your computer and the remote computer could not agree on PPP control protocols.
errorPppCpRejected	A connection to the remote computer could not be completed.
errorPppLcpTerminated	The PPP link control protocol was terminated.
errorPppRequiredAddressRejected	The requested address was rejected by the server.
errorPppNcpTerminated	The remote computer terminated the control protocol.
errorPppLoopbackDetected	Loopback was detected.
errorPppNoAddressAssigned	The server did not assign an address.
errorCannotUseLogonCredentials	The authentication protocol required by the remote server cannot use the stored password.
errorTapiConfiguration	An invalid dialing rule was detected.
errorNoLocalEncryption	The local computer does not support the required data encryption type.
errorNoRemoteEncryption	The remote computer does not support the required data encryption type.
errorRemoteRequiresEncryption	The remote computer requires data encryption.

errorIpxcpNetNumberConflict	The system cannot use the IPX network number assigned by the remote computer.
errorInvalidSMM	An internal error has occurred.
errorSMMUninitialized	An internal error has occurred.
errorNoMacForPort	An internal error has occurred.
errorSmmTimeout	An internal error has occurred.
errorBadPhoneNumber	An invalid telephone number has been specified.
errorWrongModule	An internal error has occurred.
errorInvalidCallbackNumber	The callback number contains an invalid character.
errorScriptSyntax	A syntax error was encountered while processing a script.
errorHangupFailed	The connection could not be disconnected because it was created by the multi-protocol router.
errorBundleNotFound	The system could not find the multi-link bundle.
errorCannotDoCustomdial	The system cannot perform automated dial because this connection has a custom dialer specified.
errorDialAlreadyInProgress	This connection is already being dialed.
errorRasautoCannotInitialize	Remote Access Services could not be started automatically.
errorConnectionAlreadyShared	Internet Connection Sharing is already enabled on the connection.
errorSharingChangeFailed	An error occurred while the existing Internet Connection Sharing settings were being changed.
errorSharingRouterInstall	An error occurred while routing capabilities were being enabled.
errorShareConnectionFailed	An error occurred while Internet Connection Sharing was being enabled for the connection.
errorSharingPrivateInstall	An error occurred while the local network was being configured for sharing.
errorCannotShareConnection	Internet Connection Sharing cannot be enabled.
errorNoSmartCardReader	No smart card reader is installed.
errorSharingAddressExists	Internet Connection Sharing cannot be enabled.
errorNoCertificate	A certificate could not be found.
errorSharingMultipleAddresses	Internet Connection Sharing cannot be enabled.
errorFailedToEncrypt	The connection attempt failed because of failure to encrypt data.
errorBadAddressSpecified	The specified destination is not reachable.
errorConnectionReject	The remote computer rejected the connection

	attempt.
errorCongestion	The connection attempt failed because the network is busy.
errorIncompatible	The remote computer's network hardware is incompatible with the type of call requested.
errorNumberchanged	The connection attempt failed because the destination number has changed.
errorTempfailure	The connection attempt failed because of a temporary failure.
errorBlocked	The call was blocked by the remote computer.
errorDonotdisturb	The call could not be connected because the remote computer has invoked the Do Not Disturb feature.
errorOutoforder	The connection attempt failed because the modem on the remote computer is out of order.
errorUnableToAuthenticateServer	It was not possible to verify the identity of the server.
errorSmartCardRequired	To dial out using this connection you must use a smart card.
errorInvalidFunctionForEntry	An attempted function is not valid for this connection.
errorCertForEncryptionNotFound	The connection requires a certificate, and no valid certificate was found.
errorSharingRrasConflict	Network Address Translation must be removed before enabling Internet Connection Sharing.
errorSharingNoPrivateLan	Internet Connection Sharing cannot be enabled.
errorNoDiffUserAtLogon	You cannot dial using this connection at logon time.
errorNoRegCertAtLogon	You cannot dial using this connection at logon time.
errorOakleyNoCert	The L2TP connection attempt failed because there is no valid machine certificate on your computer for security authentication.
errorOakleyAuthFail	The L2TP connection attempt failed because the security layer could not authenticate the remote computer.
errorOakleyAttribFail	The L2TP connection attempt failed because the security layer could not negotiate compatible parameters with the remote computer.
errorOakleyGeneralProcessing	The L2TP connection attempt failed because the security layer encountered a processing error during initial negotiations with the remote computer.

errorOakleyNoPeerCert	The L2TP connection attempt failed because certificate validation on the remote computer failed.
errorOakleyNoPolicy	The L2TP connection attempt failed because security policy for the connection was not found.
errorOakleyTimedOut	The L2TP connection attempt failed because security negotiation timed out.
errorOakleyError	The L2TP connection attempt failed because an error occurred while negotiating security.
errorUnknownFramedProtocol	The Framed Protocol RADIUS attribute for this user is not PPP.
errorWrongTunnelType	The Tunnel Type RADIUS attribute for this user is not correct.
errorUnknownServiceType	The Service Type RADIUS attribute for this user is neither Framed nor Callback Framed.
errorConnectingDeviceNotFound	A connection to the remote computer could not be established because the modem was not found or was busy.
errorNoEaptlsCertificate	A certificate could not be found that can be used with this Extensible Authentication Protocol.
errorSharingHostAddressConflict	Internet Connection Sharing cannot be enabled.
errorAutomaticVpnFailed	Unable to establish the VPN connection.
errorValidatingServerCert	Unable to verify the digital certificate sent by the server.
errorReadSCard	The card supplied was not recognized, please check that the card is inserted correctly, and fits tightly
errorInvalidPEAPCookieConfig	The PEAP configuration stored in the session cookie does not match the current session configuration
errorInvalidPEAPCookieUser	The PEAP identity stored in the session cookie does not match the current identity
errorInvalidMSCHAPV2Config	You cannot dial using this connection at logon time, because it is configured to use logged on user's credentials
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorOperationNotSupported	The specified operation is not supported.

Requirements

InternetDialer.RasFramingProtocol Enumeration

Specifies the framing protocols supported by the InternetDialer class.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum InternetDialer.RasFramingProtocol
```

[C#]
```
[Flags]
public enum InternetDialer.RasFramingProtocol
```

Members

Member Name	Description	Value
framingProtocolPPP	Point-to-Point Protocol (PPP). This is the most common protocol used by Internet Service Providers (ISPs).	1
framingProtocolSLIP	Serial Line Internet Protocol (SLIP). This is a protocol commonly used when connecting to older UNIX systems.	2
framingProtocolRAS	A proprietary Microsoft protocol implemented in Windows for Workgroups 3.11 and Windows NT.	4

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

See Also

SocketTools Namespace

InternetDialer.RasNetworkProtocol Enumeration

Specifies the networking protocols supported by the InternetDialer class.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum InternetDialer.RasNetworkProtocol
```

```
[C#]
[Flags]
public enum InternetDialer.RasNetworkProtocol
```

Remarks

These values may be combined if multiple protocols should be negotiated when the connection is established. Note that unless there is a specific need for the application to use the NetBEUI or IPX protocols, it is recommended that only the TCP/IP protocol be specified.

Members

Member Name	Description	Value
networkProtocolNetBEUI	Negotiate the NetBEUI protocol.	1
networkProtocolIPX	Negotiate the IPX protocol.	2
networkProtocolIP	Negotiate the TCP/IP protocol.	4

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

SocketTools Namespace

InternetDialer.RasTerminalMode Enumeration

Specifies the interactive terminal modes supported by the InternetDialer class.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetDialer.RasTerminalMode
```

[C#]

```
[Flags]
public enum InternetDialer.RasTerminalMode
```

Remarks

These values may be combined if multiple terminal modes should be used when the connection is established. If scripting has been enabled by setting the **ScriptFile** property, no terminal window should be displayed after the connection. This is because scripting has it's own terminal implementation.

Members

Member Name	Description	Value
terminalNone	No terminal window is displayed	0
terminalBeforeDial	Terminal window is displayed before dialing.	1
terminalAfterDial	Terminal window is displayed after dialing. Do not use if scripting has been enabled.	2

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

InternetDialer.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see InternetDialer.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.InternetDialer.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class InternetDialer.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class InternetDialer.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the InternetDialer class.

Example

```
<Assembly: SocketTools.InternetDialer.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.InternetDialer.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

InternetDialer.RuntimeLicenseAttribute overview

Public Instance Constructors

InternetDialer.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetDialer.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetDialer.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public InternetDialer.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the InternetDialer class.

InternetDialer.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetDialer.RuntimeLicenseAttribute Properties

The properties of the **InternetDialer.RuntimeLicenseAttribute** class are listed below. For a complete list of **InternetDialer.RuntimeLicenseAttribute** class members, see the InternetDialer.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

InternetDialer.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetDialer.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

InternetDialer.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetDialerException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see InternetDialerException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.InternetDialerException

[Visual Basic]

```
Public Class InternetDialerException
    Inherits ApplicationException
```

[C#]

```
public class InternetDialerException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A InternetDialerException is thrown by the InternetDialer class when an error occurs.

The default constructor for the InternetDialerException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetDialer (in SocketTools.InternetDialer.dll)

InternetDialerException Members

InternetDialerException overview

Public Instance Constructors

InternetDialerException	Overloaded. Initializes a new instance of the InternetDialerException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetDialerException Class | SocketTools Namespace

InternetDialerException Constructor

Initializes a new instance of the InternetDialerException class with the last network error code.

Overload List

Initializes a new instance of the InternetDialerException class with the last network error code.

public InternetDialerException();

Initializes a new instance of the InternetDialerException class with a specified error number.

public InternetDialerException(int);

Initializes a new instance of the InternetDialerException class with a specified error message.

public InternetDialerException(string);

Initializes a new instance of the InternetDialerException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public InternetDialerException(string,Exception);

See Also

InternetDialerException Class | SocketTools Namespace

InternetDialerException Constructor ()

Initializes a new instance of the InternetDialerException class with the last network error code.

[Visual Basic]
```
Overloads Public Sub New()
```

[C#]
```
public InternetDialerException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the InternetDialer.ErrorCode enumeration.

See Also

InternetDialerException Class | SocketTools Namespace | InternetDialerException Constructor Overload List

InternetDialerException Constructor (String)

Initializes a new instance of the InternetDialerException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String _
)
```

[C#]

```
public InternetDialerException(
   string message
);
```

Parameters

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

InternetDialerException Class | SocketTools Namespace | InternetDialerException Constructor Overload List

InternetDialerException Constructor (String, Exception)

Initializes a new instance of the InternetDialerException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public InternetDialerException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the *innerException* parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

See Also

InternetDialerException Class | SocketTools Namespace | InternetDialerException Constructor Overload List

InternetDialerException Constructor (Int32)

Initializes a new instance of the InternetDialerException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public InternetDialerException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the InternetDialer.ErrorCode enumeration.

See Also

InternetDialerException Class | SocketTools Namespace | InternetDialerException Constructor Overload List

InternetDialerException Properties

The properties of the **InternetDialerException** class are listed below. For a complete list of **InternetDialerException** class members, see the InternetDialerException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

InternetDialerException Class | SocketTools Namespace

InternetDialerException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public InternetDialer.ErrorCode ErrorCode {get;}
```

Property Value

Returns a InternetDialer.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the InternetDialerException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the InternetDialer.ErrorCode enumeration.

See Also

InternetDialerException Class | SocketTools Namespace

InternetDialerException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]
```
Overrides Public ReadOnly Property Message As String
```

[C#]
```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

InternetDialerException Class | SocketTools Namespace

InternetDialerException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

InternetDialerException Class | SocketTools Namespace

InternetDialerException Methods

The methods of the **InternetDialerException** class are listed below. For a complete list of **InternetDialerException** class members, see the InternetDialerException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetDialerException Class | SocketTools Namespace

InternetDialerException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

InternetDialerException Class | SocketTools Namespace

InternetMail Class

The InternetMail class enables a developer to create, send and retrieve email messages. The class implements the Simple Mail Transfer Protocol (SMTP) for sending messages, the Post Office Protocol (POP3) for retrieving messages from a mail server and the Multipurpose Internet Mail Extensions (MIME) standard for composing messages.

For a list of all members of this type, see InternetMail Members.

System.Object
  SocketTools.InternetMail

[Visual Basic]

```
Public Class InternetMail
    Implements IDisposable
```

[C#]

```
public class InternetMail : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The InternetMail class provides a simplified interface for composing, sending and retrieving email messages. The class was designed for ease-of-use and flexibility, without the inherent learning curve and additional coding required when using multiple components. In many cases, email functionality is simply one feature in an already complex project. Instead of setting dozens of properties and writing many lines of code to connect the output of one control to the input of another, the InternetMail class requires just two method calls to compose and deliver a message. The simple elegance of the component's interface translates directly into fewer lines of source code to write, debug and maintain. In turn, this allows the developer to focus his efforts on the core application without sacrificing features that add value to the end-user.

The class offers a comprehensive interface, providing the developer with everything that he needs to incorporate email functionality in an application. Many of the class' properties control the contents of a message, such as the list of recipients, the subject of the message and the message body. Methods are used to compose new messages, retrieve messages from a mail server and deliver messages to one or more recipients. Messages can also be managed on the mail server, or downloaded to the local system and stored in a file or a database record. The developer has complete access to all of the headers in the message, and can create custom application-specific header fields if needed. Event notifications enable the developer to provide the user with feedback, such as the progress of sending or retrieving a message. Advanced features such as delivery status notification, support for relay servers and secure encrypted connections are easily implemented by simply setting a few properties.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

InternetMail Members

InternetMail overview

Public Static (Shared) Fields

mailPortImap4	A constant value which specifies the default port number for a connection to a mail server.
mailPortImap4s	A constant value which specifies the default port number for a secure connection to a mail server.
mailPortPop3	A constant value which specifies the default port number for a connection to a mail server.
mailPortPop3s	A constant value which specifies the default port number for a secure connection to a mail server.
mailPortSmtp	A constant value which specifies the default port number for submitting messages to a mail server.
mailTimeout	A constant value which specifies the default timeout period.

Public Instance Constructors

InternetMail Constructor	Initializes a new instance of the InternetMail class.

Public Instance Fields

Mailbox	Gets the names of the available mailboxes for the current user.
NameServer	Change or return the Internet address for a nameserver
Recipient	Gets the recipients specified in the current message.

Public Instance Properties

AllHeaders	Gets a value which returns a list of all message recipients.
AllRecipients	Gets a value which returns a list of all message recipients.
Attachment	Gets and sets the name of the current file attachment.
Bcc	Gets and sets the blind carbon-copy header field value.
Cc	Gets and sets the carbon-copy header field value.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.

CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
ContentId	Gets the content identifier for the current message part.
ContentLength	Gets the size of the data stored in the current message part.
ContentType	Gets and sets the content type of the selected message part.
Date	Gets and sets the date for the current message.
Delivered	Gets the number of recipients the message has been delivered to.
Domain	Gets and sets the local domain name.
Encoding	Gets and sets the content encoding method used for the current message part.
From	Gets and sets the address of the user who sent the message.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
IsConnected	Gets a value which indicates if a connection to the mail server has been established.
IsIdle	Gets a value which indicates if the client is idle and the current mailbox is being monitored for status changes.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error

	that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LastMessage	Gets the number of the last message available in the current mailbox.
LocalAddress	Gets and sets the local Internet address that the client will be bound to.
Localize	Gets and sets a value which specifies if date and time values should be localized.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Mailboxes	Gets the number of mailboxes available on the server.
MailboxFlags	Gets one or more flags which identify characteristics of the current mailbox.
MailboxMask	Gets and sets the current mailbox wildcard mask.
MailboxName	Gets and sets the name of the current mailbox.
MailboxPath	Gets and sets the current mailbox reference path.
MailboxSize	Gets the size of the current mailbox.
MailboxUID	Gets the unique identifier for the current mailbox.
Mailer	Gets and sets the name of the mailer application.
Message	Gets and sets the current message headers and body.
MessageCount	Gets the number of messages available in the current mailbox.
MessageFlags	Gets and sets one or more flags for the current message.
MessageID	Gets the current message identifier.
MessageIndex	Gets and sets the current message number.
MessagePart	Gets and sets the current section index in a multipart message.
MessageParts	Gets the number of sections in a multipart message.
MessageSize	Gets the size of the current message in bytes.
MessageText	Gets and sets the text body of the current message part.
MessageUID	Gets the UID for the current message.
MimeVersion	Gets and sets the MIME version number for the current message.

NewMessages	Gets the number of new messages available in the current mailbox.
Options	Gets and sets a value which specifies one or more client options.
Organization	Gets and sets the name of the organization that originated the message.
Password	Gets and sets the password used to authenticate the client.
Priority	Gets and sets the current message priority.
RecentMessages	Gets the number of messages which have recently arrived in the mailbox.
Recipients	Gets the number of recipients specified in the current message.
RelayPort	Gets and sets a value which specifies the relay server port number.
RelayServer	Gets and sets a value which specifies the relay server name or address.
ReplyTo	Gets and sets the address of the user who should receive replies to this message.
ReturnReceipt	Gets and sets the address of the person who should receive a message indicating that the message has been read.
Secure	Gets and sets a value which specifies if a secure connection is established.
SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Sender	Gets and sets the address of the user who originated the message.
ServerName	Gets and sets a value which specifies the host name or address of the mail server.
ServerPort	Gets and sets a value which specifies the remote port number.
ServerType	Gets and sets a value which specifies the type of mail server the client is connecting to.
Subject	Gets and sets the subject of the current message.
Subscribed	Gets a value that specifies if the user has

	subscribed to the currently selected mailbox.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
To	Gets and sets the address of the message recipient.
Trace	Gets and sets a value which indicates if network function tracing is enabled.
TraceFile	Gets and sets a value which specifies the name of the client function tracing logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the InternetMail class library.

Public Instance Methods

AppendMessage	Append text to the body of the current message part.
AttachData	Overloaded. Attach the contents of a byte array to the current message.
AttachFile	Overloaded. Attach the specified file to the current message.
AttachImage	Overloaded. Attach an inline image to the current message.
AttachThread	Obsolete. Attach an instance of the class to the current thread.
Cancel	Cancel the current blocking client operation.
ChangePassword	Change the mailbox password for the current user.
CheckMailbox	Create a checkpoint for the currently selected mailbox.
ClearMessage	Clear the header and body of the current message.
ComposeMessage	Overloaded. Compose a new mail message.
Connect	Overloaded. Establish a connection with a mail server.
CopyMessage	Copy a message from the current mailbox to

	another mailbox.
CreateMailbox	Creates a new mailbox on the server.
CreateMessage	Overloaded. Create a new message.
CreatePart	Overloaded. Create a new message part in a multipart message.
DeleteHeader	Overloaded. Delete a header field from the specified message part.
DeleteMailbox	Overloaded. Deletes a mailbox from the server.
DeleteMessage	Flags a message for deletion from the current mailbox.
DeletePart	Delete the specified message part from the current message.
Disconnect	Terminate the connection with the remote server.
Dispose	Overloaded. Releases all resources used by InternetMail.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExportMessage	Overloaded. Export the current message to a file on the local system.
ExtractAllFiles	Overloaded. Extract all file attachments from the current message.
ExtractFile	Overloaded. Extract the contents of a file attachment and store it on the local system.
FindAttachment	Search for a specific file attachment in the current message.
GetFirstHeader	Return the first header in the current message part.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Return the value of a header field in the specified message part.
GetHeaders	Overloaded. Retrieves the headers for the specified message from the server.
GetMessage	Overloaded. Retrieve a message from the server and return the contents in a byte array.
GetNextHeader	Return the next header in the current message part.
GetType (inherited from Object)	Gets the Type of the current instance.
Idle	Overloaded. Enables mailbox status monitoring for the client session.

ImportMessage	Replace the current message with the contents of a file.
Initialize	Overloaded. Initialize an instance of the InternetMail class.
ParseAddress	Overloaded. Parse an Internet email address.
ParseMessage	Parse the specified string, adding the contents to the current message.
RenameMailbox	Change the name of a mailbox.
ReselectMailbox	Reselects the current mailbox.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SearchMailbox	Overloaded. Search the current mailbox for messages that match the specified criteria and character set.
SelectMailbox	Selects the specified mailbox for read-write access.
SendMessage	Overloaded. Submit the specified message to a mail server for delivery.
SetHeader	Overloaded. Set the value for a header in the specified message part.
StoreMessage	Overloaded. Retrieve a message from the current mailbox and store it in a file on the local system.
SubscribeMailbox	Overloaded. Subscribes the user to the specified mailbox.
ToString (inherited from Object)	Returns a String that represents the current Object.
UndeleteMessage	Removes the deletion flag for the specified message.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
UnselectMailbox	Overloaded. Unselects the current mailbox.
UnsubscribeMailbox	Overloaded. Unsubscribes the user from the specified mailbox.

Public Instance Events

OnCancel	Occurs when a blocking client operation is canceled.
OnDelivered	Occurs when a message has been submitted for delivery.
OnError	Occurs when an client operation fails.
OnProgress	Occurs as a data stream is being read or written to the client.
OnRecipient	Occurs when a message is about to be submitted for delivery.

OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnUpdate	Occurs when the server sends a mailbox update notification to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the InternetMail class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the current message.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetMail Fields

The fields of the **InternetMail** class are listed below. For a complete list of **InternetMail** class members, see the InternetMail Members topic.

Public Static (Shared) Fields

mailPortImap4	A constant value which specifies the default port number for a connection to a mail server.
mailPortImap4s	A constant value which specifies the default port number for a secure connection to a mail server.
mailPortPop3	A constant value which specifies the default port number for a connection to a mail server.
mailPortPop3s	A constant value which specifies the default port number for a secure connection to a mail server.
mailPortSmtp	A constant value which specifies the default port number for submitting messages to a mail server.
mailTimeout	A constant value which specifies the default timeout period.

Public Instance Fields

Mailbox	Gets the names of the available mailboxes for the current user.
NameServer	Change or return the Internet address for a nameserver
Recipient	Gets the recipients specified in the current message.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.mailPortImap4 Field

A constant value which specifies the default port number for a connection to a mail server.

[Visual Basic]

```
Public Const mailPortImap4 As Integer = 143
```

[C#]

```
public const int mailPortImap4 = 143;
```

Remarks

The default port number for the Internet Message Access Protocol is 143.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.mailPortImap4s Field

A constant value which specifies the default port number for a secure connection to a mail server.

[Visual Basic]

```
Public Const mailPortImap4s As Integer = 993
```

[C#]

```
public const int mailPortImap4s = 993;
```

Remarks

The default port number for a secure connection using IMAP4 over SSL/TLS is 993.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.mailPortPop3 Field

A constant value which specifies the default port number for a connection to a mail server.

[Visual Basic]

```
Public Const mailPortPop3 As Integer = 110
```

[C#]

```
public const int mailPortPop3 = 110;
```

Remarks

The default port number for the Post Office Protocol is 110.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.mailPortPop3s Field

A constant value which specifies the default port number for a secure connection to a mail server.

[Visual Basic]

```
Public Const mailPortPop3s As Integer = 995
```

[C#]

```
public const int mailPortPop3s = 995;
```

Remarks

The default port number for a secure connection using POP3 over SSL/TLS is 995.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.mailPortSmtp Field

A constant value which specifies the default port number for submitting messages to a mail server.

[Visual Basic]

```
Public Const mailPortSmtp As Integer = 25
```

[C#]

```
public const int mailPortSmtp = 25;
```

Remarks

The default port number for the Simple Mail Transfer Protocol is 25.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.mailTimeout Field

A constant value which specifies the default timeout period.

[Visual Basic]

```
Public Const mailTimeout As Integer = 20
```

[C#]

```
public const int mailTimeout = 20;
```

Remarks

The default timeout period is 20 seconds for each blocking network operation. An error will occur if the operation does not complete within the specified time period.

InternetMail Class | SocketTools Namespace

InternetMail Properties

The properties of the **InternetMail** class are listed below. For a complete list of **InternetMail** class members, see the InternetMail Members topic.

Public Instance Properties

AllHeaders	Gets a value which returns a list of all message recipients.
AllRecipients	Gets a value which returns a list of all message recipients.
Attachment	Gets and sets the name of the current file attachment.
Bcc	Gets and sets the blind carbon-copy header field value.
Cc	Gets and sets the carbon-copy header field value.
CertificateExpires	Get a value that specifies the date that the security certificate expires.
CertificateIssued	Get a value that specifies the date that the security certificate was issued.
CertificateIssuer	Get a value that provides information about the organization that issued the certificate.
CertificateName	Gets and sets a value that specifies the name of the client certificate.
CertificatePassword	Gets and sets the password associated with the client certificate.
CertificateStatus	Gets a value which indicates the status of the security certificate returned by the remote host.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateSubject	Gets a value that provides information about the organization that the server certificate was issued to.
CertificateUser	Gets and sets the user that owns the client certificate.
CipherStrength	Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.
ContentId	Gets the content identifier for the current message part.
ContentLength	Gets the size of the data stored in the current message part.
ContentType	Gets and sets the content type of the selected message part.

Date	Gets and sets the date for the current message.
Delivered	Gets the number of recipients the message has been delivered to.
Domain	Gets and sets the local domain name.
Encoding	Gets and sets the content encoding method used for the current message part.
From	Gets and sets the address of the user who sent the message.
HashStrength	Gets a value which specifies the length of the message digest that was selected for a secure connection.
IsConnected	Gets a value which indicates if a connection to the mail server has been established.
IsIdle	Gets a value which indicates if the client is idle and the current mailbox is being monitored for status changes.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
LastMessage	Gets the number of the last message available in the current mailbox.
LocalAddress	Gets and sets the local Internet address that the client will be bound to.
Localize	Gets and sets a value which specifies if date and time values should be localized.
LocalName	Gets a value which specifies the host name for the local system.
LocalPort	Gets the local port number the client is bound to.
Mailboxes	Gets the number of mailboxes available on the server.
MailboxFlags	Gets one or more flags which identify characteristics of the current mailbox.
MailboxMask	Gets and sets the current mailbox wildcard mask.
MailboxName	Gets and sets the name of the current mailbox.
MailboxPath	Gets and sets the current mailbox reference path.
MailboxSize	Gets the size of the current mailbox.
MailboxUID	Gets the unique identifier for the current mailbox.
Mailer	Gets and sets the name of the mailer application.

Message	Gets and sets the current message headers and body.
MessageCount	Gets the number of messages available in the current mailbox.
MessageFlags	Gets and sets one or more flags for the current message.
MessageID	Gets the current message identifier.
MessageIndex	Gets and sets the current message number.
MessagePart	Gets and sets the current section index in a multipart message.
MessageParts	Gets the number of sections in a multipart message.
MessageSize	Gets the size of the current message in bytes.
MessageText	Gets and sets the text body of the current message part.
MessageUID	Gets the UID for the current message.
MimeVersion	Gets and sets the MIME version number for the current message.
NewMessages	Gets the number of new messages available in the current mailbox.
Options	Gets and sets a value which specifies one or more client options.
Organization	Gets and sets the name of the organization that originated the message.
Password	Gets and sets the password used to authenticate the client.
Priority	Gets and sets the current message priority.
RecentMessages	Gets the number of messages which have recently arrived in the mailbox.
Recipients	Gets the number of recipients specified in the current message.
RelayPort	Gets and sets a value which specifies the relay server port number.
RelayServer	Gets and sets a value which specifies the relay server name or address.
ReplyTo	Gets and sets the address of the user who should receive replies to this message.
ReturnReceipt	Gets and sets the address of the person who should receive a message indicating that the message has been read.
Secure	Gets and sets a value which specifies if a secure connection is established.

SecureCipher	Gets a value that specifies the encryption algorithm used for a secure connection.
SecureHash	Gets a value that specifies the message digest algorithm used for a secure connection.
SecureKeyExchange	Gets a value that specifies the key exchange algorithm used for a secure connection.
SecureProtocol	Gets and sets a value which specifies the protocol used for a secure connection.
Sender	Gets and sets the address of the user who originated the message.
ServerName	Gets and sets a value which specifies the host name or address of the mail server.
ServerPort	Gets and sets a value which specifies the remote port number.
ServerType	Gets and sets a value which specifies the type of mail server the client is connecting to.
Subject	Gets and sets the subject of the current message.
Subscribed	Gets a value that specifies if the user has subscribed to the currently selected mailbox.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
TimeZone	Gets and sets the current timezone offset in seconds.
To	Gets and sets the address of the message recipient.
Trace	Gets and sets a value which indicates if network function tracing is enabled.
TraceFile	Gets and sets a value which specifies the name of the client function tracing logfile.
TraceFlags	Gets and sets a value which specifies the client function tracing flags.
UserName	Gets and sets the username used to authenticate the client session.
Version	Gets a value which returns the current version of the InternetMail class library.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.AllHeaders Property

Gets a value which returns a list of all message recipients.

[Visual Basic]

```
Public ReadOnly Property AllHeaders As String
```

[C#]

```
public string AllHeaders {get;}
```

Property Value

A string which contains the complete RFC822 headers for the message.

Remarks

The **AllHeaders** property will return all of the RFC 822 header values in a string. This includes the message headers that are most commonly referred to, such as the To, From and Subject headers. Each header and its value are separated by a colon, and terminated with a carriage return and linefeed (CRLF) pair.

The headers and their values returned by this property will not be identical to the header block in the original message. If a header value is split across multiple lines, the text returned by this property will be folded, with the complete header value on a single line of text and removing any extraneous whitespace. If the header value has been encoded by the mail client, this property will return the decoded value, not the original encoded value.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.AllRecipients Property

Gets a value which returns a list of all message recipients.

[Visual Basic]
```
Public ReadOnly Property AllRecipients As String
```

[C#]
```
public string AllRecipients {get;}
```

Property Value

A string which contains a comma-separated list of all message recipients.

Remarks

The **AllRecipients** property returns a string value that contains a comma-separated list of all message recipients. To individually enumerate through each of the recipient addresses, you can use the **Recipient** property array and **Recipients** property.

Note that this property value will include those addresses specified by the **Bcc** property, even though they are not included in the message header.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Attachment Property

Gets and sets the name of the current file attachment.

[Visual Basic]

```
Public ReadOnly Property Attachment As String
```

[C#]

```
public string Attachment {get;}
```

Property Value

A string which specifies the name of an attached file.

Remarks

The **Attachment** property specifies the name of the file attachment in a multipart message. When a new part is selected that contains an attached file, the **Attachment** property is updated to reflect the attached file's name.

This property is used by the attach and extract actions to specify the local file name that will be used. Changing its value does not change the attached file name in the multipart message itself.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Bcc Property

Gets and sets the blind carbon-copy header field value.

[Visual Basic]

```
Public Property Bcc As String
```

[C#]

```
public string Bcc {get; set;}
```

Property Value

A string which specifies one or more blind carbon-copy recipients.

Remarks

The **Bcc** property returns the list of addresses that are to receive blind carbon copies of the message. Setting the property creates or modifies the Bcc header field. Multiple addresses can be specified by separating them with commas.

A blind carbon copy is when a copy of a message is delivered to a recipient, but that recipient is not listed in the message headers. Because the other recipients of that same message will not see the address in the headers, they will not know it was delivered to that person. As a result, the Bcc header field is not normally exported when the **ExportMessage** method is called, or when the contents of the message are referenced using the **Message** property. To include the Bcc header in the message, use the **exportAllHeaders** option. Of course, if this option is specified, the addresses in the Bcc list will no longer be blind to the other recipients.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.BearerToken Property

Gets and sets the bearer token used with OAuth 2.0 authentication.

[Visual Basic]

```
Public Property BearerToken As String
```

[C#]

```
public string BearerToken {get; set;}
```

Property Value

Returns a string which contains the bearer token. Assigning a value to this property sets the curent authentication type to use OAuth 2.0 authentication and updates the bearer token.

Remarks

Assigning a value to the **BearerToken** property will automatically change the current authentication method to use OAuth 2.0 and will clear the current **Password** property value.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining a bearer token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the bearer token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

Your application should not store the bearer token for later use. They usually have a relatively short lifespan, typically about an hour, and are designed to be used with the current client session. You should specify offline access as part of the OAuth 2.0 scope, and store the refresh token provided by the service. The refresh token has a much onger validity period and can be used to obtain a new access token when needed.

If the current authentication method does not use OAuth 2.0, this property will return an empty string and you should use the **Password** property to obtain the current user password.

See Also

InternetMail Class | SocketTools Namespace | Password Property | UserName Property | Connect Method

InternetMail.Cc Property

Gets and sets the carbon-copy header field value.

[Visual Basic]

```
Public Property Cc As String
```

[C#]

```
public string Cc {get; set;}
```

Property Value

A string which specifies one or more carbon-copy recipients.

Remarks

The **Cc** property returns the list of addresses that were delivered carbon copies of the message. Setting the property creates or modifies the Cc header field. Multiple addresses can be specified by separating them with commas.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.CertificateExpires Property

Get a value that specifies the date that the security certificate expires.

[Visual Basic]

```
Public ReadOnly Property CertificateExpires As String
```

[C#]

```
public string CertificateExpires {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateExpires** property returns a string that specifies the date and time that the security certificate expires. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.CertificateIssued Property

Get a value that specifies the date that the security certificate was issued.

[Visual Basic]

```
Public ReadOnly Property CertificateIssued As String
```

[C#]

```
public string CertificateIssued {get;}
```

Property Value

A string which specifies a date using the local date and time format.

Remarks

The **CertificateIssued** property returns a string that specifies the date and time that the security certificate was issued. This property will return an empty string if a secure connection has not been established with the remote host.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.CertificateIssuer Property

Get a value that provides information about the organization that issued the certificate.

[Visual Basic]

```
Public ReadOnly Property CertificateIssuer As String
```

[C#]

```
public string CertificateIssuer {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateIssuer** property returns a string that contains information about the organization that issued the server certificate. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.CertificateName Property

Gets and sets a value that specifies the name of the client certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the certificate name.

Remarks

The **CertificateName** property is used to specify the name of a client certificate to use when establishing a secure connection. It is only required that you set this property value if the server requires a client certificate for authentication. If this property is not set, a client certificate will not be provided to the server. If a certificate name is specified, the certificate must have a private key associated with it, otherwise the connection attempt will fail because the control will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

InternetMail Class | SocketTools Namespace | CertificateStore Property | Secure Property

InternetMail.CertificateStatus Property

Gets a value which indicates the status of the security certificate returned by the remote host.

[Visual Basic]

```
Public ReadOnly Property CertificateStatus As SecurityCertificate
```

[C#]

```
public InternetMail.SecurityCertificate CertificateStatus {get;}
```

Property Value

A SecurityCertificate enumeration value which specifies the status of the certificate.

Remarks

The **CertificateStatus** property is used to determine the status of the security certificate returned by the remote host when a secure connection has been established. This property value should be checked after the connection to the server has completed, but prior to beginning a transaction.

Note that if the certificate cannot be validated, the secure connection will not be automatically terminated. It is the responsibility of your application to determine the best course of action to take if the certificate is invalid. Even if the security certificate cannot be validated, the data exchanged with the remote host will still be encrypted.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]

```
Public Property CertificateStore As String
```

[C#]

```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when establishing a secure connection. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the client certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the client certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in PKCS12

format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

InternetMail Class | SocketTools Namespace | CertificatePassword Property | Secure Property

InternetMail.CertificateSubject Property

Gets a value that provides information about the organization that the server certificate was issued to.

[Visual Basic]

```
Public ReadOnly Property CertificateSubject As String
```

[C#]

```
public string CertificateSubject {get;}
```

Property Value

A string that contains a comma separated list of name value pairs.

Remarks

The **CertificateSubject** property returns a string that contains information about the organization that the server certificate was issued to. The string value is a comma separated list of tagged name and value pairs. In the nomenclature of the X.500 standard, each of these pairs are called a relative distinguished name (RDN), and when concatenated together, forms the issuer's distinguished name (DN). For example:

```
C=US, O="RSA Data Security, Inc.", OU=Secure Server Certification Authority
```

To obtain a specific value, such as the name of the issuer or the issuer's country, the application must parse the string returned by this property. Some of the common tokens used in the distinguished name are:

Token	Description
C	The ISO standard two character country code.
S	The name of the state or province.
L	The name of the city or locality.
O	The name of the company or organization.
OU	The name of the department or organizational unit
CN	The common name; with X.509 certificates, this is the domain name of the site the certificate was issued for.

This property will return an empty string if a secure connection has not been established with the remote host.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.CipherStrength Property

Gets a value that indicates the length of the key used by the encryption algorithm for a secure connection.

[Visual Basic]

```
Public ReadOnly Property CipherStrength As Integer
```

[C#]

```
public int CipherStrength {get;}
```

Property Value

An integer value which specifies the encryption key length if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **CipherStrength** property returns the number of bits in the key used to encrypt the secure data stream. Common values returned by this property are 128 and 256. A key length of 40 or 56 bits is considered insecure and subject to brute force attacks. 128-bit and 256-bit keys are considered secure. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ContentId Property

Gets the content identifier for the current message part.

[Visual Basic]
```
Public ReadOnly Property ContentId As String
```

[C#]
```
public string ContentId {get;}
```

Property Value

A string which specifies the content identifier.

Remarks

The **ContentId** property returns the unique content identifier string for the current message part. This multipart header field is not commonly used, and if undefined, will return an empty string.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ContentLength Property

Gets the size of the data stored in the current message part.

[Visual Basic]

```
Public ReadOnly Property ContentLength As Integer
```

[C#]

```
public int ContentLength {get;}
```

Property Value

An integer which specifies the size of the current message part in bytes.

Remarks

The **ContentLength** property returns the size of the data stored in the selected message part. This property is read-only, and is updated when the current message part changes.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ContentType Property

Gets and sets the content type of the selected message part.

[Visual Basic]
```
Public Property ContentType As String
```

[C#]
```
public string ContentType {get; set;}
```

Property Value

A string which specifies the content type.

Remarks

The **ContentType** property returns the MIME type for the currently selected message part. The type string consists of a primary type and secondary sub-type separated by a slash, followed by one or more optional parameters delimited by semi-colons. For example, this is a common content type for text messages:

```
text/plain; charset=utf-8
```

The **text** designation indicates that this message part contains readable text, and the **plain** sub-type indicates that the text does not contain any special encoding. The optional parameter which follows the content type provides additional information about the content. In this example, it specifies which character set should be used to display the text. The two common character sets used are UTF-8 and US-ASCII.

There are seven predefined, standard content types, each with their own sub-types. The following table lists these types, along with some common sub-types that are found in messages:

Type	Description
text	Indicates that the message part contains text. This is the most common type found in mail messages; if no content type is explicitly defined, then it is assumed to be plain text. Examples are text/plain, text/richtext and text/html.
image	Indicates that the message part contains a graphics image. Examples are image/gif and image/jpeg.
audio	Indicates that the message part contains audio data; the basic sub-type is 8-bit PCM encoded audio (commonly found with the .au filename extension). Examples are audio/basic, audio/aiff and audio/wav.
video	Indicates that the message part contains a video clip in the specified format. Examples are video/mpeg and video/avi.
application	Indicates that the message part contains application specific data, typically used with the octet-stream sub-type to indicate binary file attachments for executable programs, compressed

	file archives, etc. Examples are application/octet-stream and application/postscript.
message	Indicates that the message part contains a complete RFC 822 compliant message, complete with headers. An example is message/rfc822.
multipart	Indicates that this is part of a mixed message (a message that contains multiple parts of different content types). Examples are multipart/alternative and multipart/mixed.

The three most common content types that are used in applications are text/plain for the mail message body, application/octet-stream for binary file attachments and multipart/mixed for messages that contain both text and attached files. For more information about the different content types, refer to the Multipurpose Internet Mail Extensions (MIME) standards document RFC 1521.

InternetMail Class | SocketTools Namespace

InternetMail.Date Property

Gets and sets the date for the current message.

[Visual Basic]
```
Public Property Date As String
```

[C#]
```
public string Date {get; set;}
```

Property Value

A string which specifies the date in RFC 822 format.

Remarks

The **Date** property returns the value of the date field in the current message header. Setting this property causes the date field to be updated with the specified value. When setting the date, any one of the following formats may be used:

Format	Example
mm/dd/yy[yy] hh:mm[:ss]	03/01/2006 12:00:00
yy[yy]/mm/dd hh:mm[:ss]	2006/03/01 12:00:00
dd mmm yy[yy] hh:mm[:ss]	01 Mar 2006 12:00:00
mmm dd yy[yy] hh:mm[:ss]	Mar 01 2006 12:00:00

Any extraneous information that may be included in the date string, such as the day of the week, is ignored. In addition to the date and time, the string may also include a time zone specification at the end. If no time zone is specified, the current time zone is used.

When specifying a time zone, the value should either be prefixed by a plus sign (+) to indicate that the time zone is to the east of GMT, or a minus sign (-) to indicates that it's to the west. Four digits follow, with the first two indicating the number of hours east or west of GMT, and the last two digits indicating the number of minutes. Therefore, a value of -0800 means that the time zone is eight hours to the west of GMT, or in other words, the Pacific time zone.

Regardless of the format of the string assigned to the property, it always returns the date in the same format (which conforms to the RFC 822 specification). Using the above examples, the date would be returned as "Wed, 01 Mar 2006 12:00:00 -0800" if you are located in the Pacific timezone.

The **Localize** property affects how dates are processed by the control. If enabled, dates are automatically adjusted for the local time zone. By default, localization is disabled.

InternetMail Class | SocketTools Namespace

InternetMail.Delivered Property

Gets the number of recipients the message has been delivered to.

[Visual Basic]

```
Public ReadOnly Property Delivered As Integer
```

[C#]

```
public int Delivered {get;}
```

Property Value

An integer value which specifies the number of recipients the message was successfully delivered to.

Remarks

The **Delivered** property returns the number of recipients that the message was successfully delivered to using the **SendMessage** method. This property is updated after the method returns, and can be compared against the value of the **Recipients** property to check that the message was submitted to all recipients.

It is important to note that there is no guarantee that the recipient has retrieved and read the message, only that it has been submitted successfully to the mail server for delivery.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Domain Property

Gets and sets the local domain name.

[Visual Basic]

```
Public Property Domain As String
```

[C#]

```
public string Domain {get; set;}
```

Property Value

A string value which specifies the local domain name.

Remarks

The **Domain** property specifies the domain name of the local host, and is used to identify the current system when sending messages. If this property is not defined, then the local host name will be used.

Note that explicitly setting the **Domain** property to a value that does not match your local host name may cause some mail servers to reject any messages that you attempt to send.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Encoding Property

Gets and sets the content encoding method used for the current message part.

[Visual Basic]

```
Public Property Encoding As String
```

[C#]

```
public string Encoding {get; set;}
```

Property Value

A string which specifies the encoding type.

Remarks

The **Encoding** property returns the method used for encoding the current message part. Setting this property causes the Content-Transfer-Encoding header value to be updated. The following values are commonly used:

Type	Description
7bit	The default transfer encoding type, which consists of printable ASCII characters.
8bit	Printable ASCII characters, including those characters with the high-bit set as is common with the ISO Latin-1 character set.
binary	All characters; binary transfer encoding is rarely used.
quoted-printable	Printable ASCII characters, with non-printable or extended characters represented using their hexadecimal equivalents.
base64	The transfer encoding type commonly used to convert binary data into 7-bit ASCII characters so that it may be transported safely through the mail system.
x-uuencode	A transfer encoding type similar in function to the base64 encoding method.

Note that setting this property only updates the Content-Transfer-Encoding header value. To control the actual encoding method used for attachments, specify the encoding method when calling the **AttachFile** method.

InternetMail Class | SocketTools Namespace

InternetMail.From Property

Gets and sets the address of the user who sent the message.

[Visual Basic]
```
Public Property From As String
```

[C#]
```
public string From {get; set;}
```

Property Value

A string which specifies the sender of the message.

Remarks

The **From** property returns the address of the user who sent the message. Setting the property causes the From header field to be updated with the new value.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.HashStrength Property

Gets a value which specifies the length of the message digest that was selected for a secure connection.

[Visual Basic]

```
Public ReadOnly Property HashStrength As Integer
```

[C#]

```
public int HashStrength {get;}
```

Property Value

An integer value which specifies the length of the message digest if a secure connection has been established; otherwise a value of 0 is returned.

Remarks

The **HashStrength** property returns the number of bits used in the message digest (hash) that was selected. Common values returned by this property are 128 and 160. If this property returns a value of 0, this means that a secure connection has not been established with the remote host.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.IsConnected Property

Gets a value which indicates if a connection to the mail server has been established.

[Visual Basic]

```
Public ReadOnly Property IsConnected As Boolean
```

[C#]

```
public bool IsConnected {get;}
```

Property Value

Returns **true** if the connection has been established; otherwise returns **false**.

Remarks

The **IsConnected** property can only be used to indicate if there is still a logical connection to the mail server. It cannot be used to detect abnormal conditions such as the remote host aborting the connection, the physical network connection being lost or other critical errors.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.IsIdle Property

Gets a value which indicates if the client is idle and the current mailbox is being monitored for status changes.

[Visual Basic]
```
Public ReadOnly Property IsIdle As Boolean
```

[C#]
```
public bool IsIdle {get;}
```

Property Value

Returns **true** if the client is idle and the current mailbox is being monitored; otherwise returns **false**.

Remarks

The **IsIdle** property can be used to determine if the **Idle** method has been called to place the client session in an idle state, monitoring the connection for any status messages sent by the server. Typically this is done to allow the application to be notified asynchronously whenever a new message is stored in the mailbox, or when a message has been expunged.

The worker thread that monitors the client connection in the background can terminate if an IMAP command is sent to the server, if the **Cancel** method is called or if the client disconnects from the server. This property enables the application to determine if this background thread is still active or not.

See Also

InternetMail Class | SocketTools Namespace | Idle Method | OnUpdate Event

InternetMail.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required libraries or not being able to access the system registry.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public InternetMail.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.LastMessage Property

Gets the number of the last message available in the current mailbox.

[Visual Basic]

```
Public ReadOnly Property LastMessage As Integer
```

[C#]

```
public int LastMessage {get;}
```

Property Value

An integer value which specifies the number of messages.

Remarks

The **LastMessage** property returns the number of the last message available in the currently selected mailbox. This value may be different than the value returned by the **MessageCount** property if one or more messages have been deleted. This is because the **MessageCount** property returns the number of available messages, and this value will decrement whenever a message is flagged for deletion. The **LastMessage** property value is constant and will always return the last message number in the mailbox, regardless if any messages have been deleted.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.LocalAddress Property

Gets and sets the local Internet address that the client will be bound to.

[Visual Basic]

```
Public ReadOnly Property LocalAddress As String
```

[C#]

```
public string LocalAddress {get;}
```

Property Value

A string which specifies an Internet address in dotted notation.

Remarks

The **LocalAddress** property is used to specify the local Internet address that the client will be bound to when a connection is established with a remote host. By default this property is not assigned a value, which specifies that the client should be bound to any appropriate network interface on the local system.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Localize Property

Gets and sets a value which specifies if date and time values should be localized.

[Visual Basic]

```
Public Property Localize As Boolean
```

[C#]

```
public bool Localize {get; set;}
```

Property Value

A boolean value which specifies if date and time values should be localized.

Remarks

The **Localize** property is used to enable or disable localization features of the class. Currently this only affects the way in which dates are processed by the class. If set to **true**, the control will adjust for the local time zone when setting and reading the **Date** property. The default value for this property is **false**.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.LocalName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property LocalName As String
```

[C#]

```
public string LocalName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **LocalName** property returns the fully-qualified host name assigned to the local system. If the system has not been configured with an Internet domain name, then this property will return the NetBIOS name assigned to the local system.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MailboxArray Class

The class used to return the available mailboxes for the current user.

For a list of all members of this type, see InternetMail.MailboxArray Members.

System.Object
  SocketTools.InternetMail.MailboxArray

[Visual Basic]

```
<DefaultMember(MemberName:="Item")>
Public Class InternetMail.MailboxArray
```

[C#]

```
[DefaultMember(MemberName="Item")]
public class InternetMail.MailboxArray
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **MailboxArray** class returns the available mailboxes for the current user. A read-only instance of this class is created by the class constructor and accessed using the **Mailbox** array.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

InternetMail.MailboxArray Members | SocketTools Namespace

InternetMail.MailboxArray Members

InternetMail.MailboxArray overview

Public Instance Properties

Count	Returns the maximum number of elements in the array.
Item	Gets the name of a mailbox.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetMail.MailboxArray Class | SocketTools Namespace

InternetMail.MailboxArray Properties

The properties of the **InternetMail.MailboxArray** class are listed below. For a complete list of **InternetMail.MailboxArray** class members, see the InternetMail.MailboxArray Members topic.

Public Instance Properties

Count	Returns the maximum number of elements in the array.
Item	Gets the name of a mailbox.

See Also

InternetMail.MailboxArray Class | SocketTools Namespace

InternetMail.MailboxArray.Count Property

Returns the maximum number of elements in the array.

[Visual Basic]
```
Public ReadOnly Property Count As Integer
```

[C#]
```
public int Count {get;}
```

Property Value

An integer value.

Remarks

This property will return the same value as the **Mailboxes** property and is used to determine the maximum index value for the **Mailbox** array.

See Also

InternetMail.MailboxArray Class | SocketTools Namespace

InternetMail.MailboxArray.Item Property

Gets the name of a mailbox.

[Visual Basic]

```
Public Default ReadOnly Property Item( _
   ByVal index As Integer _
) As String
```

[C#]

```
public string this[
   int index
] {get;}
```

Parameters

index

An integer value which specifies the index into the array.

Property Value

A string which specifies the name of a mailbox.

See Also

InternetMail.MailboxArray Class | SocketTools Namespace

InternetMail.Mailboxes Property

Gets the number of mailboxes available on the server.

[Visual Basic]

```
Public ReadOnly Property Mailboxes As Integer
```

[C#]

```
public int Mailboxes {get;}
```

Property Value

An integer value which specifies the number of available mailboxes.

Remarks

The **Mailboxes** property returns the total number of mailboxes available to the current account on the server. This property can be used in conjunction with the **Mailbox** array to enumerate the names of all of the mailboxes which can be selected by the client.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MailboxFlags Property

Gets one or more flags which identify characteristics of the current mailbox.

[Visual Basic]

```
Public ReadOnly Property MailboxFlags As ImapFlags
```

[C#]

```
public InternetMail.ImapFlags MailboxFlags {get;}
```

Property Value

An ImapFlags enumeration value which specifies one or more mailbox flags.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MailboxMask Property

Gets and sets the current mailbox wildcard mask.

[Visual Basic]

```
Public Property MailboxMask As String
```

[C#]

```
public string MailboxMask {get; set;}
```

Property Value

A string which specifies the current mailbox wildcard mask.

Remarks

The **MailboxMask** property returns the current mailbox wildcard mask. If no wildcard mask has been specified by the client, this property will return an empty string.

Setting the **MailboxMask** property will determine which mailboxes are returned by the **Mailbox** array. Wildcards may include the asterisk (which matches any mailbox as well as any child mailboxes) and the percent sign (which matches any mailbox, but does not match any child mailboxes). This property may be used in conjunction with the **MailboxPath** property to further qualify which mailboxes are returned.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MailboxName Property

Gets and sets the name of the current mailbox.

[Visual Basic]
```
Public Property MailboxName As String
```

[C#]
```
public string MailboxName {get; set;}
```

Property Value

A string that specifies the name of the current mailbox.

Remarks

The **MailboxName** property returns the name of the currently selected mailbox. If no mailbox has been selected by the client, this property will return an empty string.

Setting the **MailboxName** property will select a new mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, call the **UnselectMailbox** method prior to selecting the new mailbox. Setting the **MailboxName** property to an empty string will cause the current mailbox to be unselected, and a new mailbox will not be selected. Before the application can access any messages, it must select a new mailbox.

Selecting a new mailbox will automatically update those properties which provide information about the current mailbox, such as the **MailboxFlags** and **MailboxUID** properties. If an application wishes to update the information for the current mailbox, simply set the **MailboxName** property again with the same mailbox name. Note that this will not cause any messages marked for deletion to be expunged.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

If the mailbox name contains international characters then it is automatically encoded using a modified version of UTF-7 encoding. For example, if a mailbox is named "Håndskrift", the mailbox name created on the server will be the string "H&AOU-ndskrift". The control will automatically decode UTF-7 encoded mailbox names, making the conversion transparent to the application.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MailboxPath Property

Gets and sets the current mailbox reference path.

[Visual Basic]

```
Public Property MailboxPath As String
```

[C#]

```
public string MailboxPath {get; set;}
```

Property Value

A string which specifies the current mailbox reference path.

Remarks

The **MailboxPath** property returns the current mailbox reference path. If no path has been specified by the client, this property will return an empty string.

Setting the **MailboxPath** property will determine which mailboxes are returned by the **Mailbox** array. Typically this is used to specify a subdirectory where mail folders are stored for the current user. Note that some mail servers may not permit absolute reference paths, and in most cases the path should include a trailing slash. This property may be used in conjunction with the **MailboxMask** property to further qualify which mailboxes are returned.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MailboxSize Property

Gets the size of the current mailbox.

[Visual Basic]
```
Public ReadOnly Property MailboxSize As Integer
```

[C#]
```
public int MailboxSize {get;}
```

Property Value

An integer value which specifies the size of the mailbox in bytes.

Remarks

The **MailboxSize** property returns the combined size of all messages in the current mailbox. Referencing this property will cause the current thread to block and may require a significant amount of time to calculate the mailbox size if there are a large number of messages in the mailbox. Because it can potentially result in long delays, it is not recommended that an application calculate the mailbox size unless it is absolutely necessary.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MailboxUID Property

Gets the unique identifier for the current mailbox.

[Visual Basic]
```
Public ReadOnly Property MailboxUID As Integer
```

[C#]
```
public int MailboxUID {get;}
```

Property Value

An integer value which specifies the mailbox UID.

Remarks

The **MailboxUID** property returns an integer value which uniquely identifies the mailbox and corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

An application can use the **MailboxUID** property value in combination with the **MessageUID** property in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update it's local copy of that mailbox.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Mailer Property

Gets and sets the name of the mailer application.

[Visual Basic]

```
Public Property Mailer As String
```

[C#]

```
public string Mailer {get; set;}
```

Property Value

A string which specifies the name of the mailer application.

Remarks

The **Mailer** property returns the value of the X-Mailer field in the current message header. Setting this property causes the field to be updated with the specified value. This is typically used to identify the program which generated the message.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Message Property

Gets and sets the current message headers and body.

[Visual Basic]

```
Public Property Message As String
```

[C#]

```
public string Message {get; set;}
```

Property Value

A string which contains the complete message.

Remarks

The **Message** property returns the current message, including the headers and all message parts, as a string. Setting this property will cause the current message to be cleared and replaced by the new value. The contents must follow the standard specifications for a message. If the property is set to an empty string, the current message is cleared.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MessageCount Property

Gets the number of messages available in the current mailbox.

[Visual Basic]

```
Public ReadOnly Property MessageCount As Integer
```

[C#]

```
public int MessageCount {get;}
```

Property Value

An integer value which specifies the number of messages.

Remarks

The **MessageCount** property returns the number of messages available to be retrieved from the currently selected mailbox.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MessageFlags Property

Gets and sets one or more flags for the current message.

[Visual Basic]

```
Public Property MessageFlags As ImapFlags
```

[C#]

```
public InternetMail.ImapFlags MessageFlags {get; set;}
```

Property Value

An ImapFlags enumeration value which specifies one or more message flags.

Remarks

The **MessageFlags** property returns information about the currently selected message specified by the **Message** property. Setting the **MessageFlags** property changes the flags for the currently selected message. Multiple bit flags can be combined using the bitwise Or operator. An application can test if a flag is set by using the bitwise And operator.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MessageID Property

Gets the current message identifier.

[Visual Basic]

```
Public Property MessageID As String
```

[C#]

```
public string MessageID {get; set;}
```

Property Value

A string which specifies the message identifier.

Remarks

The **MessageID** property returns a unique string that can be used to identify the message.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MessageIndex Property

Gets and sets the current message number.

[Visual Basic]

```
Public Property MessageIndex As Integer
```

[C#]

```
public int MessageIndex {get; set;}
```

Property Value

An integer value which specifies the current message number.

Remarks

The **Message** property sets or returns the message number for the currently selected mailbox. Message numbers range from 1 through the number of messages available on the server, as returned by the **MessageCount** property. Setting the **Message** property to an invalid message number will generate an exception.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MessagePart Property

Gets and sets the current section index in a multipart message.

[Visual Basic]

```
Public Property MessagePart As Integer
```

[C#]

```
public int MessagePart {get; set;}
```

Property Value

An integer which specifies the current message part.

Remarks

The **MessagePart** property returns the current message part index. All messages have at least one part, which consists of one or more header fields, followed by the body of the message. The default part, part 0, refers to the main message header and body. If the message contains multiple parts (as with a message that contains one or more attached files), the **Part** property can be set to refer to that specific part of the message.

For example, messages with file attachments typically consist of a message part which describes the contents of the attachment, followed by the attachment itself. For a message with one attached file, there would be a total of three parts. Part 0 would refer to the main message part, which contains the headers such as From, To, Subject, Date and so on. For multipart messages, part 0 typically does not have a message body, since any text is usually created as a separate part (for those messages that do not contain multiple parts, the part 0 body contains the text message). Part 1 would contain the text describing the attachment, and part 2 would contain the attachment itself. If the attached file is binary, then the transfer encoding type would usually be base64.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MessageParts Property

Gets the number of sections in a multipart message.

[Visual Basic]

```
Public ReadOnly Property MessageParts As Integer
```

[C#]

```
public int MessageParts {get;}
```

Property Value

An integer value which specifies the number of message parts.

Remarks

The **MessageParts** property returns the number of parts in the current message. All messages have at least one part, referenced as part 0. Multipart messages will consist of additional parts which may be accessed by setting the **MessagePart** property.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MessageSize Property

Gets the size of the current message in bytes.

[Visual Basic]
```
Public ReadOnly Property MessageSize As Integer
```

[C#]
```
public int MessageSize {get;}
```

Property Value

An integer value which specifies the size of the message.

Remarks

The **MessageSize** property returns the size of the current message in bytes. The size includes the header and body portion of the message.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MessageText Property

Gets and sets the text body of the current message part.

[Visual Basic]

```
Public Property MessageText As String
```

[C#]

```
public string MessageText {get; set;}
```

Property Value

A string which contains the body of the current message part.

Remarks

The **MessageText** property returns the body of the current message part. Setting this property replaces the body of the current message part with the new text.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.MessageUID Property

Gets the UID for the current message.

[Visual Basic]

```
Public ReadOnly Property MessageUID As String
```

[C#]

```
public string MessageUID {get;}
```

Property Value

An string value which specifies the current message UID.

Remarks

The **MessageID** property returns a string which uniquely identifies the message on the server. The identifier is assigned by the mail server, and retains the same value across multiple client sessions. This value is typically used when the client wants to leave a message on the mail server, but does not wish to retrieve the message contents multiple times. For example, the client can store the unique ID for each message that it retrieves, but does not delete from the server. The next time that it connects to the mail server, it compares the unique ID of a message against the stored values. If there is a match, the client knows that the message has already been retrieved, and does not need to do so again.

This property requires that the server support the optional UIDL command. If the command is not supported, this property will always return an empty string. Note that the unique ID for the message is not the same as the Message-ID header field in the message itself.

InternetMail Class | SocketTools Namespace

InternetMail.MimeVersion Property

Gets and sets the MIME version number for the current message.

[Visual Basic]

```
Public Property MimeVersion As String
```

[C#]

```
public string MimeVersion {get; set;}
```

Property Value

A string that specifies the version number.

Remarks

The **MimeVersion** property returns the version number for the current message. Setting this property causes the MIME-Version header value to be changed to the specified value. An empty string causes the MIME version number to be set to the default value of "1.0". It is recommended that you do not change the value of this property.

InternetMail Class | SocketTools Namespace

InternetMail.NameServerArray Class

The class used to return the nameservers configured for the local host.

For a list of all members of this type, see InternetMail.NameServerArray Members.

System.Object
  SocketTools.InternetMail.NameServerArray

[Visual Basic]
```
<DefaultMember(MemberName:="Item")>
Public Class InternetMail.NameServerArray
```

[C#]
```
[DefaultMember(MemberName="Item")]
public class InternetMail.NameServerArray
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **NameServerArray** class returns the nameservers configured for the local host. A read-only instance of this class is created by the InternetMail class constructor and accessed using the **NameServer** array.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

InternetMail.NameServerArray Members | SocketTools Namespace | NameServer Field

InternetMail.NameServerArray Members

InternetMail.NameServerArray overview

Public Instance Properties

Count	Returns the maximum number of elements in the array.
Item	Returns the Internet address for the specified nameserver.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetMail.NameServerArray Properties

The properties of the **InternetMail.NameServerArray** class are listed below. For a complete list of **InternetMail.NameServerArray** class members, see the InternetMail.NameServerArray Members topic.

Public Instance Properties

Count	Returns the maximum number of elements in the array.
Item	Returns the Internet address for the specified nameserver.

See Also

InternetMail.NameServerArray Class | SocketTools Namespace | NameServer Field

InternetMail.NameServerArray.Count Property

Returns the maximum number of elements in the array.

[Visual Basic]

```
Public ReadOnly Property Count As Integer
```

[C#]

```
public int Count {get;}
```

Property Value

An integer value.

Remarks

This property will return the maximum number of nameservers that may be configured.

See Also

InternetMail.NameServerArray Class | SocketTools Namespace

InternetMail.NameServerArray.Item Property

Returns the Internet address for the specified nameserver.

[Visual Basic]

```
Public Default Property Item( _
   ByVal index As Integer _
) As String
```

[C#]

```
public string this[
   int index
] {get; set;}
```

Parameters

index

An integer value which specifies the index into the array.

Property Value

A string which specifies an Internet address using dot notation.

See Also

InternetMail.NameServerArray Class | SocketTools Namespace

InternetMail.NewMessages Property

Gets the number of new messages available in the current mailbox.

[Visual Basic]

```
Public ReadOnly Property NewMessages As Integer
```

[C#]

```
public int NewMessages {get;}
```

Property Value

An integer value which specifies the number of new, unread messages in the current mailbox.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Options Property

Gets and sets a value which specifies one or more client options.

[Visual Basic]
```
Public Property Options As InternetMailOptions
```

[C#]
```
public InternetMail.InternetMailOptions Options {get; set;}
```

Property Value

Returns one or more InternetMailOptions enumeration flags which specify the options for the client. The default value for this property is **optionNone**.

Remarks

The **Options** property specifies one or more default options options which are used when establishing a connection using the **Connect** method.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Organization Property

Gets and sets the name of the organization that originated the message.

[Visual Basic]

```
Public Property Organization As String
```

[C#]

```
public string Organization {get; set;}
```

Property Value

A string which specifies the organization name.

Remarks

The **Organization** property returns the name of the organization that originated the current message. Setting this property updates the specified header value. Note that many mail clients do not generate an Organization header field, in which case the property value will be an empty string.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Password Property

Gets and sets the password used to authenticate the client.

[Visual Basic]

```
Public Property Password As String
```

[C#]

```
public string Password {get; set;}
```

Property Value

A string which specifies the password.

Remarks

The **Password** property specifies the password used to authenticate the client session. This property is used as the default value for the **Connect** method if no password is specified as an argument.

Assigning a value to his property will clear any OAuth 2.0 bearer token which may have been previously assigned to the **BearerToken** property and default authentication methods will be used with the mail service.

If the **BearerToken** property has been set, the client will use OAuth 2.0 for authentication and this property will return an empty string.

See Also

InternetMail Class | SocketTools Namespace | BearerToken Property | UserName Property | Connect Method

InternetMail.Priority Property

Gets and sets the current message priority.

[Visual Basic]

```
Public Property Priority As String
```

[C#]

```
public string Priority {get; set;}
```

Property Value

A string which specifies the message priority.

Remarks

The **Priority** property returns the current priority for the message. Setting this property value causes the X-Priority header to be updated with the specified value.

There is no standard for specifying message priority. The convention is to use a number from 1-5, with 1 indicating the highest priority, 3 as normal priority and 5 as the lowest priority. Some mailers follow the number with a space and then text that describes the priority level.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.RecentMessages Property

Gets the number of messages which have recently arrived in the mailbox.

[Visual Basic]

```
Public ReadOnly Property RecentMessages As Integer
```

[C#]

```
public int RecentMessages {get;}
```

Property Value

An integer value which specifies the number of recent messages.

Remarks

The **RecentMessages** property returns the number of messages which have been recently added to the currently selected mailbox. This property is particularly useful when the INBOX mailbox is selected because it enables the application to check if any new messages have arrived.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.RecipientArray Class

The class used to return the recipient addresses for the current message.

For a list of all members of this type, see InternetMail.RecipientArray Members.

System.Object
 SocketTools.InternetMail.RecipientArray

[Visual Basic]
```
<DefaultMember(MemberName:="Item")>
Public Class InternetMail.RecipientArray
```

[C#]
```
[DefaultMember(MemberName="Item")]
public class InternetMail.RecipientArray
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **RecipientArray** class returns the recipient addresses for the current message. A read-only instance of this class is created by the InternetMail class constructor and accessed using the **Recipient** array.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

InternetMail.RecipientArray Members | SocketTools Namespace

InternetMail.RecipientArray Members

InternetMail.RecipientArray overview

Public Instance Properties

Count	Returns the maximum number of elements in the array.
Item	Gets the email address of a recipient specified in the current message.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Gets the recipient addresses for the current message.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetMail.RecipientArray.Count Property

Returns the maximum number of elements in the array.

[Visual Basic]
```
Public ReadOnly Property Count As Integer
```

[C#]
```
public int Count {get;}
```

Property Value

An integer value.

Remarks

This property will return the same value as the **Recipients** property and is used to determine the maximum index value for the **Recipient** array.

See Also

InternetMail.RecipientArray Class | SocketTools Namespace

InternetMail.RecipientArray.Item Property

Gets the email address of a recipient specified in the current message.

[Visual Basic]

```
Public Default ReadOnly Property Item( _
   ByVal index As Integer _
) As String
```

[C#]

```
public string this[
   int index
] {get;}
```

Parameters

index

An integer value which specifies the index into the array.

Property Value

A string which contains an email address.

See Also

InternetMail.RecipientArray Class | SocketTools Namespace

InternetMail.RecipientArray Methods

The methods of the **InternetMail.RecipientArray** class are listed below. For a complete list of **InternetMail.RecipientArray** class members, see the InternetMail.RecipientArray Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Gets the recipient addresses for the current message.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetMail.RecipientArray Class | SocketTools Namespace

InternetMail.RecipientArray.ToString Method

Gets the recipient addresses for the current message.

[Visual Basic]

```
Overrides Public Function ToString() As String
```

[C#]

```
public override string ToString();
```

Return Value

A string which specifies the email addresses for the recipients of the current message.

Remarks

The **ToString** method returns a comma separated list of email addresses for all recipients specified in the current message.

See Also

InternetMail.RecipientArray Class | SocketTools Namespace

InternetMail.Recipients Property

Gets the number of recipients specified in the current message.

[Visual Basic]

```
Public ReadOnly Property Recipients As Integer
```

[C#]

```
public int Recipients {get;}
```

Property Value

An integer which specifies the number of recipients.

Remarks

The **Recipients** property returns the number of recipient addresses that have been specified in the current message. This includes all of the addresses listed in the To, Cc and Bcc header fields. This property can be used in conjunction with the **Recipient** array to enumerate all of the recipient addresses in the message.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.RelayPort Property

Gets and sets a value which specifies the relay server port number.

[Visual Basic]

```
Public Property RelayPort As Integer
```

[C#]

```
public int RelayPort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **RelayPort** property is used to set the port number that will be used to establish a connection with a relay server when sending a message.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.RelayServer Property

Gets and sets a value which specifies the relay server name or address.

[Visual Basic]

```
Public Property RelayServer As String
```

[C#]

```
public string RelayServer {get; set;}
```

Property Value

A string which specifies a host name.

Remarks

The **RelayServer** property can be used to set the host name for the relay mail server that will be responsible for delivering the message.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ReplyTo Property

Gets and sets the address of the user who should receive replies to this message.

[Visual Basic]

```
Public Property ReplyTo As String
```

[C#]

```
public string ReplyTo {get; set;}
```

Property Value

A string that specifies an email address.

Remarks

The **ReplyTo** property returns the address of the user who should receive replies to the current message. Setting this property updates the Reply-To header with the specified value.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ReturnReceipt Property

Gets and sets the address of the person who should receive a message indicating that the message has been read.

[Visual Basic]

```
Public Property ReturnReceipt As String
```

[C#]

```
public string ReturnReceipt {get; set;}
```

Property Value

A string value which specifies an email address.

Remarks

The **ReturnReceipt** property returns the address of the person who should receive a message indicating that the current message has been read. Setting this property updates the Disposition-Notification-To header field with the specified value.

Setting the **ReturnReceipt** property does not automatically cause an acknowledgement to be returned to the sender. An application is responsible for checking to make sure the header field contains a valid address and then generating the return receipt message.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Secure Property

Gets and sets a value which specifies if a secure connection is established.

[Visual Basic]

```
Public Property Secure As Boolean
```

[C#]

```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connection is established; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if a secure connection is established with the remote host. The default value for this property is **false**, which specifies that a standard connection to the server is used. To establish a secure connection, the application should set this property value to **true** prior to calling the **Connect** method. Once the connection has been established, the client may exchange data with the server as with standard connections.

It is strongly recommended that any application that sets this property **true** use error handling to trap an errors that may occur. If the control is unable to initialize the security libraries, or otherwise cannot create a secure session for the client, an exception may be generated when this property value is set.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.SecureCipher Property

Gets a value that specifies the encryption algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureCipher As SecureCipherAlgorithm
```

[C#]

```
public InternetMail.SecureCipherAlgorithm SecureCipher {get;}
```

Property Value

A SecureCipherAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureCipher** property returns a value which identifies the algorithm used to encrypt the data stream. If a secure connection has not been established, this property will return a value of **cipherNone**.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.SecureHash Property

Gets a value that specifies the message digest algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureHash As SecureHashAlgorithm
```

[C#]

```
public InternetMail.SecureHashAlgorithm SecureHash {get;}
```

Property Value

A SecureHashAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureHash** property returns a value which identifies the message digest (hash) algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **hashNone**.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.SecureKeyExchange Property

Gets a value that specifies the key exchange algorithm used for a secure connection.

[Visual Basic]

```
Public ReadOnly Property SecureKeyExchange As SecureKeyAlgorithm
```

[C#]

```
public InternetMail.SecureKeyAlgorithm SecureKeyExchange {get;}
```

Property Value

A SecureKeyAlgorithm enumeration value which identifies the algorithm.

Remarks

The **SecureKeyExchange** property returns a value which identifies the key exchange algorithm that was selected when a secure connection was established. If a secure connection has not been established, this property will return a value of **keyExchangeNone**.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.SecureProtocol Property

Gets and sets a value which specifies the protocol used for a secure connection.

[Visual Basic]

```
Public Property SecureProtocol As SecurityProtocols
```

[C#]

```
public InternetMail.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when establishing a secure connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when establishing a secure connection with a server or accepting a secure connection from a client. By default, the class will attempt to use either SSL v3 or TLS v1 to establish the connection, with the appropriate protocol automatically selected based on the capabilities of the remote host. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Multiple security protocols may be specified by combining them using a bitwise **or** operator. After a connection has been established, this property will identify the protocol that was selected. Attempting to set this property after a connection has been established will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Accept** or **Connect** methods.

In some cases, a server may only accept a secure connection if the TLS v1 protocol is specified. If the security protocol is not compatible with the server, then the connection will fail with an error indicating that the control is unable to establish a security context for the session. In this case, try assigning the property to **protocolTLS1** and attempt the connection again.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Sender Property

Gets and sets the address of the user who originated the message.

[Visual Basic]

```
Public Property Sender As String
```

[C#]

```
public string Sender {get; set;}
```

Property Value

A string which specifies the sender's email address.

Remarks

The **Sender** property returns the address of the user who originated the message. Setting this property updates the X-Sender header with the specified value.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ServerName Property

Gets and sets a value which specifies the host name or address of the mail server.

[Visual Basic]

```
Public Property ServerName As String
```

[C#]

```
public string ServerName {get; set;}
```

Property Value

A string which specifies a server host name or address.

Remarks

The **ServerName** property can be used to set the host name for the mail server that you want to establish a connection to.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ServerPort Property

Gets and sets a value which specifies the remote port number.

[Visual Basic]

```
Public Property ServerPort As Integer
```

[C#]

```
public int ServerPort {get; set;}
```

Property Value

An integer value which specifies a port number.

Remarks

The **ServerPort** property is used to set the port number that will be used to establish a connection with a mail server.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ServerType Property

Gets and sets a value which specifies the type of mail server the client is connecting to.

[Visual Basic]
```
Public Property ServerType As MailServerType
```

[C#]
```
public InternetMail.MailServerType ServerType {get; set;}
```

Property Value

Returns a MailServerType enumeration value which specifies the type of mail server, either using the Post Office Protocol or the Internet Message Access Protocol.

Remarks

If this property value is specified as **serverUnknown**, the actual server type will be determined by the value of the **ServerPort** property, if the port number is recognized as a standard service port. If the server type cannot be automatically identified, an error will be returned when the **Connect** method is called.

If you are connecting using a non-standard port number, you should always initialize this property value to the correct server type before attempting to establish a connection.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Subject Property

Gets and sets the subject of the current message.

[Visual Basic]

```
Public Property Subject As String
```

[C#]

```
public string Subject {get; set;}
```

Property Value

A string which specifies the subject of the message.

Remarks

The **Subject** property returns the subject of the current message. Setting this property updates the Subject header with the specified value. Note that not all messages have subjects, in which case this property will be set to an empty string.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Subscribed Property

Gets a value that specifies if the user has subscribed to the currently selected mailbox.

[Visual Basic]

```
Public Property Subscribed As Boolean
```

[C#]

```
public bool Subscribed {get; set;}
```

Property Value

A boolean value that specifies if the user has subscribed to the current mailbox.

Remarks

The **Subscribed** property is used to determine if the current mailbox has been subscribed to by the user. If the property returns **false**, the server has indicated that the user has not subscribed to the mailbox. If the property returns **true**, the current mailbox is in the user's subscription list.

Setting the **Subscribed** property changes the subscription status of the current mailbox. Setting the property to **true** adds the mailbox to the user's list of subscribed mailboxes, while setting it to **false** removes the mailbox from the subscription list.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a blocking operation fails and returns an error.

For most applications it is recommended the timeout period be set between 10 and 20 seconds.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.TimeZone Property

Gets and sets the current timezone offset in seconds.

[Visual Basic]

```
Public Property TimeZone As Integer
```

[C#]

```
public int TimeZone {get; set;}
```

Property Value

An integer value which specifies the current timezone offset.

Remarks

The **TimeZone** property returns the current offset from UTC in seconds. Setting the property changes the current timezone offset to the specified value. The value of this property is initially determined by the date and time settings on the local system.

The **TimeZone** property value is used in conjunction with the **Localize** property to control how message date and time localization is handled.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.To Property

Gets and sets the address of the message recipient.

[Visual Basic]

```
Public Property To As String
```

[C#]

```
public string To {get; set;}
```

Property Value

A string which specifies the recipient of the message.

Remarks

The **To** property returns the address of the message recipient. Setting this property causes the To header to be updated with the specified value. Multiple addresses can be specified by separating them with commas.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Trace Property

Gets and sets a value which indicates if network function tracing is enabled.

[Visual Basic]
```
Public Property Trace As Boolean
```

[C#]
```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.TraceFile Property

Gets and sets a value which specifies the name of the client function tracing logfile.

[Visual Basic]

```
Public Property TraceFile As String
```

[C#]

```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.TraceFlags Property

Gets and sets a value which specifies the client function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public InternetMail.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

InternetMail.UserName Property

Gets and sets the username used to authenticate the client session.

[Visual Basic]

```
Public Property UserName As String
```

[C#]

```
public string UserName {get; set;}
```

Property Value

A string which specifies the username.

Remarks

If a username is not specified when the **Connect** method is called, the value of this property will be used as the default username when establishing a connection with the server.

See Also

InternetMail Class | SocketTools Namespace | BearerToken Property | Password Property | Connect Method

InternetMail.Version Property

Gets a value which returns the current version of the InternetMail class library.

[Visual Basic]

```
Public ReadOnly Property Version As String
```

[C#]

```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the InternetMail class library. This value can be used by an application for validation and debugging purposes.

InternetMail Class | SocketTools Namespace

InternetMail Methods

The methods of the **InternetMail** class are listed below. For a complete list of **InternetMail** class members, see the InternetMail Members topic.

Public Instance Methods

AppendMessage	Append text to the body of the current message part.
AttachData	Overloaded. Attach the contents of a byte array to the current message.
AttachFile	Overloaded. Attach the specified file to the current message.
AttachImage	Overloaded. Attach an inline image to the current message.
AttachThread	Obsolete. Attach an instance of the class to the current thread.
Cancel	Cancel the current blocking client operation.
ChangePassword	Change the mailbox password for the current user.
CheckMailbox	Create a checkpoint for the currently selected mailbox.
ClearMessage	Clear the header and body of the current message.
ComposeMessage	Overloaded. Compose a new mail message.
Connect	Overloaded. Establish a connection with a mail server.
CopyMessage	Copy a message from the current mailbox to another mailbox.
CreateMailbox	Creates a new mailbox on the server.
CreateMessage	Overloaded. Create a new message.
CreatePart	Overloaded. Create a new message part in a multipart message.
DeleteHeader	Overloaded. Delete a header field from the specified message part.
DeleteMailbox	Overloaded. Deletes a mailbox from the server.
DeleteMessage	Flags a message for deletion from the current mailbox.
DeletePart	Delete the specified message part from the current message.
Disconnect	Terminate the connection with the remote server.
Dispose	Overloaded. Releases all resources used by InternetMail.

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExportMessage	Overloaded. Export the current message to a file on the local system.
ExtractAllFiles	Overloaded. Extract all file attachments from the current message.
ExtractFile	Overloaded. Extract the contents of a file attachment and store it on the local system.
FindAttachment	Search for a specific file attachment in the current message.
GetFirstHeader	Return the first header in the current message part.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Return the value of a header field in the specified message part.
GetHeaders	Overloaded. Retrieves the headers for the specified message from the server.
GetMessage	Overloaded. Retrieve a message from the server and return the contents in a byte array.
GetNextHeader	Return the next header in the current message part.
GetType (inherited from Object)	Gets the Type of the current instance.
Idle	Overloaded. Enables mailbox status monitoring for the client session.
ImportMessage	Replace the current message with the contents of a file.
Initialize	Overloaded. Initialize an instance of the InternetMail class.
ParseAddress	Overloaded. Parse an Internet email address.
ParseMessage	Parse the specified string, adding the contents to the current message.
RenameMailbox	Change the name of a mailbox.
ReselectMailbox	Reselects the current mailbox.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SearchMailbox	Overloaded. Search the current mailbox for messages that match the specified criteria and character set.
SelectMailbox	Selects the specified mailbox for read-write access.
SendMessage	Overloaded. Submit the specified message to a

	mail server for delivery.
SetHeader	Overloaded. Set the value for a header in the specified message part.
StoreMessage	Overloaded. Retrieve a message from the current mailbox and store it in a file on the local system.
SubscribeMailbox	Overloaded. Subscribes the user to the specified mailbox.
ToString (inherited from Object)	Returns a String that represents the current Object.
UndeleteMessage	Removes the deletion flag for the specified message.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
UnselectMailbox	Overloaded. Unselects the current mailbox.
UnsubscribeMailbox	Overloaded. Unsubscribes the user from the specified mailbox.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the InternetMail class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the current message.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetMail Class | SocketTools Namespace

InternetMail.AppendMessage Method

Append text to the body of the current message part.

[Visual Basic]

```
Public Function AppendMessage( _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool AppendMessage(
   string messageText
);
```

Parameters

messageText

A string which specifies the message text to be appended to the current message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.AttachData Method

Attach the contents of a byte array to the current message.

Overload List

Attach the contents of a byte array to the current message.

public bool AttachData(byte[],int);

Attach the contents of a byte array to the current message.

public bool AttachData(byte[],int,string);

Attach the contents of a byte array to the current message.

public bool AttachData(byte[],int,string,string);

Attach the contents of a byte array to the current message.

public bool AttachData(byte[],int,string,string,MimeAttachment);

Attach the contents of a string to the current message.

public bool AttachData(string);

Attach the contents of a string to the current message.

public bool AttachData(string,string);

Attach the contents of a string to the current message.

public bool AttachData(string,string,string);

Attach the contents of a string to the current message.

public bool AttachData(string,string,string,MimeAttachment);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.AttachData Method (Byte[], Int32)

Attach the contents of a byte array to the current message.

```
[Visual Basic]
Overloads Public Function AttachData( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Boolean
```

```
[C#]
public bool AttachData(
   byte[] buffer,
   int length
);
```

Parameters

buffer
A byte array that contains the data to be attached to the message.

length
An integer value which specifies the maximum number of bytes top copy from the buffer. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The contents of the buffer will be attached to the message as inline content.

The buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachData Overload List

InternetMail.AttachData Method (Byte[], Int32, String)

Attach the contents of a byte array to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As Byte(), _
   ByVal length As Integer, _
   ByVal contentName As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   byte[] buffer,
   int length,
   string contentName
);
```

Parameters

buffer

A byte array that contains the data to be attached to the message.

length

An integer value which specifies the maximum number of bytes top copy from the buffer. This value cannot be larger than the size of the buffer specified by the caller.

contentName

An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. If this parameter is omitted or passed as an empty string then no name is defined and the data is attached as inline content. Note that if a file name is specified with a path, only the base file name will be used.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachData Overload List

InternetMail.AttachData Method (Byte[], Int32, String, String)

Attach the contents of a byte array to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As Byte(), _
   ByVal length As Integer, _
   ByVal contentName As String, _
   ByVal contentType As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   byte[] buffer,
   int length,
   string contentName,
   string contentType
);
```

Parameters

buffer
A byte array that contains the data to be attached to the message.

length
An integer value which specifies the maximum number of bytes top copy from the buffer. This value cannot be larger than the size of the buffer specified by the caller.

contentName
An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. Note that if a file name is specified with a path, only the base file name will be used.

contentType
An string argument which specifies the type of data being attached. The value must be a valid MIME content type. If the buffer contains only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachData Overload List

InternetMail.AttachData Method (Byte[], Int32, String, String, MimeAttachment)

Attach the contents of a byte array to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As Byte(), _
   ByVal length As Integer, _
   ByVal contentName As String, _
   ByVal contentType As String, _
   ByVal options As MimeAttachment _
) As Boolean
```

[C#]

```
public bool AttachData(
   byte[] buffer,
   int length,
   string contentName,
   string contentType,
   MimeAttachment options
);
```

Parameters

buffer

A byte array that contains the data to be attached to the message.

length

An integer value which specifies the maximum number of bytes top copy from the buffer. This value cannot be larger than the size of the buffer specified by the caller.

contentName

An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. Note that if a file name is specified with a path, only the base file name will be used.

contentType

An string argument which specifies the type of data being attached. The value must be a valid MIME content type. If the buffer contains only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

options

A MimeAttachment enumeration which specifies how the data should be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachData Overload List

InternetMail.AttachData Method (String)

Attach the contents of a string to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   string buffer
);
```

Parameters

buffer

A string that contains the data to be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The contents of the buffer will be attached to the message as inline content with a content type of text/plain.

This implementation of the method should never be used to attach binary data to a message. If you need to attach binary data, use the implementation of that accepts a byte array as the ***buffer*** parameter.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachData Overload List

InternetMail.AttachData Method (String, String)

Attach the contents of a string to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As String, _
   ByVal contentName As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   string buffer,
   string contentName
);
```

Parameters

buffer

A string that contains the data to be attached to the message.

contentName

An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. Note that if a file name is specified with a path, only the base file name will be used.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The content will be attached using the content type of text/plain.

This implementation of the method should never be used to attach binary data to a message. If you need to attach binary data, use the implementation of that accepts a byte array as the ***buffer*** parameter.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachData Overload List

InternetMail.AttachData Method (String, String, String)

Attach the contents of a string to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As String, _
   ByVal contentName As String, _
   ByVal contentType As String _
) As Boolean
```

[C#]

```
public bool AttachData(
   string buffer,
   string contentName,
   string contentType
);
```

Parameters

buffer

A string that contains the data to be attached to the message.

contentName

An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in.Note that if a file name is specified with a path, only the base file name will be used.

contentType

An string argument which specifies the type of data being attached. The value must be a valid MIME content type. If the buffer contains only text characters, then the content type will be specified as "text/plain". If the buffer contains binary data, then the content type will be specified as "application/octet-stream", which is appropriate for any type of data.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This implementation of the method should never be used to attach binary data to a message. If you need to attach binary data, use the implementation of that accepts a byte array as the ***buffer*** parameter.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachData Overload List

InternetMail.AttachData Method (String, String, String, MimeAttachment)

Attach the contents of a string to the current message.

[Visual Basic]

```
Overloads Public Function AttachData( _
   ByVal buffer As String, _
   ByVal contentName As String, _
   ByVal contentType As String, _
   ByVal options As MimeAttachment _
) As Boolean
```

[C#]

```
public bool AttachData(
   string buffer,
   string contentName,
   string contentType,
   MimeAttachment options
);
```

Parameters

buffer
A string that contains the data to be attached to the message.

contentName
An string argument which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in.Note that if a file name is specified with a path, only the base file name will be used.

contentType
An string argument which specifies the type of data being attached. The value must be a valid MIME content type. If the buffer contains only text characters, then the content type will be specified as text/plain. If the buffer contains binary data, then the content type will be specified as application/octet-stream, which is appropriate for any type of data.

options
A MimeAttachment enumeration which specifies how the data should be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This implementation of the method should never be used to attach binary data to a message. If you need to attach binary data, use the implementation of that accepts a byte array as the *buffer* parameter.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachData Overload List

InternetMail.AttachFile Method

Attach the specified file to the current message.

Overload List

Attach the specified file to the current message.

public bool AttachFile(string);

Attach the specified file to the current message.

public bool AttachFile(string,MimeAttachment);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.AttachFile Method (String)

Attach the specified file to the current message.

[Visual Basic]

```
Overloads Public Function AttachFile( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool AttachFile(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the file to be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AttachFile** method attaches the specified file to the current message. If the message already contains one or more file attachments, then it is added to the end of the message. If the message does not contain any attached files, then it is converted to a multipart message and the file is appended to the message.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachFile Overload List

InternetMail.AttachFile Method (String, MimeAttachment)

Attach the specified file to the current message.

[Visual Basic]

```
Overloads Public Function AttachFile( _
   ByVal fileName As String, _
   ByVal options As MimeAttachment _
) As Boolean
```

[C#]

```
public bool AttachFile(
   string fileName,
   MimeAttachment options
);
```

Parameters

fileName
A string which specifies the name of the file to be attached to the message.

options
A MimeAttachment enumeration which specifies how the data should be attached to the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **AttachFile** method attaches the specified file to the current message. If the message already contains one or more file attachments, then it is added to the end of the message. If the message does not contain any attached files, then it is converted to a multipart message and the file is appended to the message.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.AttachFile Overload List

InternetMail.AttachThread Method

NOTE: This method is now obsolete.

The AttachThread method has been deprecated

Attach an instance of the class to the current thread.

[Visual Basic]

```
<Obsolete(Message:="The AttachThread method has been deprecated", IsError:=False)>
Public Function AttachThread() As Boolean
```

[C#]

```
[Obsolete(Message="The AttachThread method has been deprecated", IsError=False)]
public bool AttachThread();
```

Return Value

A boolean value which specifies if the message could be attached to the current thread. If this method returns **false**, the message could not be attached to the thread and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method has been deprecated and should no longer be used. The current version of the InternetMail class uses a free threading model which permits any thread to access methods and properties. However, applications must take care to synchronize access to the class instance across multiple threads if they are modifying the message contents.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Cancel Method

Cancel the current blocking client operation.

[Visual Basic]

```
Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking client operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ChangePassword Method

Change the mailbox password for the current user.

[Visual Basic]

```
Public Function ChangePassword( _
   ByVal userName As String, _
   ByVal oldPassword As String, _
   ByVal newPassword As String _
) As Boolean
```

[C#]

```
public bool ChangePassword(
   string userName,
   string oldPassword,
   string newPassword
);
```

Parameters

userName
A string which specifies the username for which the password will be changed.

oldPassword
A string which specifies the current password.

newPassword
A string which specifies the new password.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ChangePassword** method changes the current password that will be used to authenticate the user. Once the password has been changed, the **Password** property will be updated with the new password.

Note that in order to change the user's mailbox password, the server must be running the poppass service on port 106, on the same server. Because passwords are transmitted as clear text (unencrypted), this service is not considered secure and may not be available.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.CheckMailbox Method

Create a checkpoint for the currently selected mailbox.

[Visual Basic]
```
Public Function CheckMailbox() As Boolean
```

[C#]
```
public bool CheckMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CheckMailbox** method requests that the server create a checkpoint of the currently selected mailbox, and updates the current number of new, unread messages available to the client.

When the client requests a checkpoint, the server may perform implementation-dependent housekeeping for that mailbox, such updating the mailbox on disk with the current state of the mailbox in memory. On some systems this command has no effect other than to update the client with the current number of messages in the mailbox.

This function actually sends two IMAP commands. The first is the CHECK command, followed by the NOOP command to poll for any new messages that have arrived. In addition to polling the server for new messages, this command can also be used to ensure the idle timer on the server does not expire and force a disconnect from the client.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ClearMessage Method

Clear the header and body of the current message.

[Visual Basic]

```
Public Function ClearMessage() As Boolean
```

[C#]

```
public bool ClearMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ClearMessage** method clears the current message, releasing the memory allocated for the message and any attachments.

InternetMail Class | SocketTools Namespace

InternetMail.ComposeMessage Method

Compose a new mail message.

Overload List

Compose a new mail message.

public bool ComposeMessage(string,string,string,string);

Compose a new mail message.

public bool ComposeMessage(string,string,string,string,string);

Compose a new mail message.

public bool ComposeMessage(string,string,string,string,string,string);

Compose a new mail message.

public bool ComposeMessage(string,string,string,string,string,string,string);

Compose a new mail message.

public bool ComposeMessage(string,string,string,string,string,string,string,MimeCharacterSet,MimeEncoding);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ComposeMessage Method (String, String, String, String)

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageSubject,
   string messageText
);
```

Parameters

messageFrom

A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo

A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageSubject

A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value

messageText

An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.ComposeMessage Overload List

InternetMail.ComposeMessage Method (String, String, String, String, String)

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageCc As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageCc,
   string messageSubject,
   string messageText
);
```

Parameters

messageFrom
A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo
A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageCc
A string argument which specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

messageSubject
A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value

messageText
An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageCc As String, _
   ByVal messageBcc As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageCc,
   string messageBcc,
   string messageSubject,
   string messageText
);
```

Parameters

messageFrom
: A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo
: A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageCc
: A string argument which specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

messageBcc
: A string argument which specifies one or more additional recipient addresses that will receive a "blind" copy of the message. If this argument is not specified, then no Bcc header field will be created for this message. After the message has been composed, the **Bcc** property will be updated with this value. Note that the Bcc header field is not normally included in the header when the message is exported.

messageSubject
: A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value

messageText
: An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

InternetMail.ComposeMessage Method (String, String, String, String, String, String, String)

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageCc As String, _
   ByVal messageBcc As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String, _
   ByVal messageHTML As String _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageCc,
   string messageBcc,
   string messageSubject,
   string messageText,
   string messageHTML
);
```

Parameters

messageFrom

A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo

A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageCc

A string argument which specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

messageBcc

A string argument which specifies one or more additional recipient addresses that will receive a "blind" copy of the message. If this argument is not specified, then no Bcc header field will be created for this message. After the message has been composed, the **Bcc** property will be updated with this value. Note that the Bcc header field is not normally included in the header when the message is exported.

messageSubject

A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value

messageText

An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

messageHTML

A string argument which specifies an alternate HTML formatted message. If the ***messageText*** argument has been specified, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the ***messageText*** argument is an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

InternetMail.ComposeMessage Method (String, String, String, String, String, String, String, MimeCharacterSet, MimeEncoding)

Compose a new mail message.

[Visual Basic]

```
Overloads Public Function ComposeMessage( _
   ByVal messageFrom As String, _
   ByVal messageTo As String, _
   ByVal messageCc As String, _
   ByVal messageBcc As String, _
   ByVal messageSubject As String, _
   ByVal messageText As String, _
   ByVal messageHTML As String, _
   ByVal characterSet As MimeCharacterSet, _
   ByVal encodingType As MimeEncoding _
) As Boolean
```

[C#]

```
public bool ComposeMessage(
   string messageFrom,
   string messageTo,
   string messageCc,
   string messageBcc,
   string messageSubject,
   string messageText,
   string messageHTML,
   MimeCharacterSet characterSet,
   MimeEncoding encodingType
);
```

Parameters

messageFrom

A string argument which specifies the sender's email address. Only a single address should be specified. After the message has been composed, the **From** property will be updated with this value.

messageTo

A string argument which specifies one or more recipient email addresses. Multiple email addresses may be specified by separating them with commas. After the message has been composed, the **To** property will be updated with this value.

messageCc

A string argument which specifies one or more additional recipient addresses that will receive a copy of the message. If this argument is not specified, then no Cc header field will be created for this message. After the message has been composed, the **Cc** property will be updated with this value.

messageBcc

A string argument which specifies one or more additional recipient addresses that will receive a "blind" copy of the message. If this argument is not specified, then no Bcc header field will be created for this message. After the message has been composed, the **Bcc** property will be updated with this value. Note that the Bcc header field is not normally included in the header when the message is exported.

messageSubject

A string argument which specifies the subject for the message. If the argument is not specified, then no Subject header field will be created for this message. After the message has been composed, the **Subject** property will be updated with this value

messageText
An string argument which specifies the body of the message. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

messageHTML
A string argument which specifies an alternate HTML formatted message. If the ***messageText*** argument has been specified, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the ***messageText*** argument is an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

characterSet
A MimeCharacterSet enumeration value which specifies the character set to use when composing the message.

encodingType
A MimeEncoding enumeration value which specifies the encoding type to use when composing the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ComposeMessage** method creates a new mail message, or replaces the current message if one already exists.

See Also

InternetMail Class | SocketTools Namespace | BearerToken Property | Options Property | Password Property | ServerName Property | ServerPort Property | Timeout Property | UserName Property

InternetMail.Connect Method ()

Establish a connection with a remote host.

[Visual Basic]
```
Overloads Public Function Connect() As Boolean
```

[C#]
```
public bool Connect();
```

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may exchange data with the mail server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

Remarks

This method establishes a connection using assigned property values.

The value of the **ServerName** will be used to determine the host name or address to connect to.

The value of the **RemotePort** property will be used to determine the port number to connect to.

The value of the **Timeout** property will be used to specify the timeout period.

The value of the **Options** property will be used to specify the default options for the connection.

InternetMail.Connect Method (String, Int32)

Establish a connection with a remote host.

[Visual Basic]

```
Overloads Public Function Connect( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may exchange data with the mail server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Connect(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string which specifies the remote host to establish a connection with. This may specify a host name or an Internet address in dot-notation.

hostPort

An integer which specifies the port number for the connection. This value must be greater than zero and the maximum valid port number is 65535.

timeout

An integer value that specifies the number of seconds that the method will wait for the connection to complete before failing the operation and returning to the caller.

Return Value

A boolean value which specifies if the connection has been established. A return value of **true** indicates that the connection has completed and the application may exchange data with the mail server. If this method returns **false**, the connection could not be established and the application should check the value of the LastError property to determine the cause of the failure.

InternetMail.CopyMessage Method

Copy a message from the current mailbox to another mailbox.

[Visual Basic]

```
Public Function CopyMessage( _
   ByVal messageId As Integer, _
   ByVal mailboxName As String _
) As Boolean
```

[C#]

```
public bool CopyMessage(
   int messageId,
   string mailboxName
);
```

Parameters

messageId

The message identifier which specifies which message will be copied to the mailbox. This value must be greater than zero and specify a valid message number.

mailboxName

A string which specifies the name of the mailbox that the message will be copied to. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CopyMessage** method copies a message from the current mailbox to the specified mailbox. The message is appended to the mailbox, and the message flags and internal date are preserved. If the mailbox does not exist, the method will fail. To create a new mailbox, use the **CreateMailbox** method. A message can be copied within the same mailbox, in which case the server may flag it as a new message.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.CreateMailbox Method

Creates a new mailbox on the server.

```
[Visual Basic]
Public Function CreateMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

```
[C#]
public bool CreateMailbox(
   string mailboxName
);
```

Parameters

mailboxName

A string which specifies the name of the new mailbox to be created.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMailbox** method creates a new mailbox on the server. If the mailbox name is suffixed with the server's hierarchy delimiter, this indicates to the server that the client intends to create mailbox names under the specified name in the hierarchy. If superior hierarchical names are specified in the mailbox name, then the server may automatically create them as needed. For example, if the mailbox name "Mail/Office/Projects" is specified and "Mail/Office" does not exist, it may be automatically created by the server.

The special mailbox name INBOX is reserved, and cannot be created. It is recommended that mailbox names only consist of printable ASCII characters, and the special characters "*" and "%" should be avoided.

InternetMail Class | SocketTools Namespace

InternetMail.CreateMessage Method (Byte[], Int32)

Create a new message.

[Visual Basic]

```
Overloads Public Function CreateMessage( _
   ByVal message As Byte(), _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool CreateMessage(
   byte[] message,
   int length
);
```

Parameters

message
A byte array that contains the message data.

length
An integer value which specifies the size of the message in bytes. This value cannot be larger than the size of the message buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMessage** method creates a new message, appending it to the contents of the specified mailbox. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The message will be created in the mailbox specified by the **MailboxName** property.

) As Boolean
```

[C#]

```
public bool CreateMessage(
   byte[] message,
   int length,
   ImapFlags messageFlags
);
```

Parameters

message

A byte array that contains the message data.

length

An integer value which specifies the size of the message in bytes. This value cannot be larger than the size of the message buffer specified by the caller.

messageFlags

An ImapFlags enumeration value which specifies one or more message flags. One or more of the following flags may be used:

Flag	Description
imapFlagNone	The message will be created with no flags set.
imapFlagAnswered	The message has been answered.
imapFlagDraft	The message is a draft copy.
imapFlagUrgent	The message is urgent.
imapFlagSeen	The message has already been read.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMessage** method creates a new message, appending it to the contents of the specified mailbox. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The message will be created in the mailbox specified by the **MailboxName** property.

Flag	Description
imapFlagNone	The message will be created with no flags set.
imapFlagAnswered	The message has been answered.
imapFlagDraft	The message is a draft copy.
imapFlagUrgent	The message is urgent.
imapFlagSeen	The message has already been read.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMessage** method creates a new message, appending it to the contents of the specified mailbox. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

InternetMail Class | SocketTools Namespace | InternetMail.CreateMessage Overload List

InternetMail.CreateMessage Method (String, String, ImapFlags)

Create a new message.

```
[Visual Basic]
Overloads Public Function CreateMessage( _
   ByVal mailboxName As String, _
   ByVal message As String, _
   ByVal messageFlags As ImapFlags _
) As Boolean
```

```
[C#]
public bool CreateMessage(
   string mailboxName,
   string message,
   ImapFlags messageFlags
);
```

Parameters

mailboxName

A string which specifies the name of the mailbox the message will be created in.

message

A string that contains the message data.

messageFlags

An ImapFlags enumeration value which specifies one or more message flags. One or more of the following flags may be used:

Flag	Description
imapFlagNone	The message will be created with no flags set.
imapFlagAnswered	The message has been answered.
imapFlagDraft	The message is a draft copy.
imapFlagUrgent	The message is urgent.
imapFlagSeen	The message has already been read.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreateMessage** method creates a new message, appending it to the contents of the specified mailbox. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

InternetMail.CreatePart Method

Create an empty message part in a multipart message.

Overload List

Create an empty message part in a multipart message.

public bool CreatePart();

Create a new message part in a multipart message.

public bool CreatePart(string);

Create a new message part in a multipart message.

public bool CreatePart(string,MimeCharacterSet,MimeEncoding);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.CreatePart Method ()

Create an empty message part in a multipart message.

[Visual Basic]

```
Overloads Public Function CreatePart() As Boolean
```

[C#]

```
public bool CreatePart();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreatePart** method creates a new empty message part. If the current message is a simple RFC822 formatted message, then this method converts it to a MIME multipart message. The current message part will be set to the new part that was just created.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.CreatePart Overload List

InternetMail.CreatePart Method (String)

Create a new message part in a multipart message.

[Visual Basic]

```
Overloads Public Function CreatePart( _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool CreatePart(
   string messageText
);
```

Parameters

messageText

A string argument which specifies the body of the new message part. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreatePart** method creates a new message part. If the current message is a simple RFC822 formatted message, then this method converts it to a MIME multipart message. The current message part will be set to the new part that was just created.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.CreatePart Overload List

InternetMail.CreatePart Method (String, MimeCharacterSet, MimeEncoding)

Create a new message part in a multipart message.

[Visual Basic]

```
Overloads Public Function CreatePart( _
   ByVal messageText As String, _
   ByVal characterSet As MimeCharacterSet, _
   ByVal encodingType As MimeEncoding _
) As Boolean
```

[C#]

```
public bool CreatePart(
   string messageText,
   MimeCharacterSet characterSet,
   MimeEncoding encodingType
);
```

Parameters

messageText
: A string argument which specifies the body of the new message part. Each line of text contained in the string should be terminated with a carriage-return/linefeed (CRLF) pair, which is recognized as the end-of-line.

characterSet
: A MimeCharacterSet enumeration value which specifies the character set to use when composing the message.

encodingType
: A MimeEncoding enumeration value which specifies the encoding type to use when composing the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **CreatePart** method creates a new message part. If the current message is a simple RFC822 formatted message, then this method converts it to a MIME multipart message. The current message part will be set to the new part that was just created.

InternetMail Class | SocketTools Namespace | InternetMail.CreatePart Overload List

InternetMail.DeleteHeader Method

Delete a header field from the specified message part.

Overload List

Delete a header field from the specified message part.

public bool DeleteHeader(int,string);

Delete a header field from the current message part.

public bool DeleteHeader(string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.DeleteHeader Method (Int32, String)

Delete a header field from the specified message part.

[Visual Basic]

```
Overloads Public Function DeleteHeader( _
   ByVal messagePart As Integer, _
   ByVal headerName As String _
) As Boolean
```

[C#]

```
public bool DeleteHeader(
   int messagePart,
   string headerName
);
```

Parameters

messagePart
An integer which specifies the message part.

headerName
A string which specifies the header field to delete from the specified message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

A message part of zero specifies the main message part which contains the standard headers such as To, From and Subject. The number of message parts in the current message is returned by the **PartCount** property.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.DeleteHeader Overload List

InternetMail.DeleteHeader Method (String)

Delete a header field from the current message part.

[Visual Basic]

```
Overloads Public Function DeleteHeader( _
   ByVal headerName As String _
) As Boolean
```

[C#]

```
public bool DeleteHeader(
   string headerName
);
```

Parameters

headerName

A string which specifies the header field to delete from the current message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The current message part is returned by the **Part** property.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.DeleteHeader Overload List

InternetMail.DeleteMailbox Method

Deletes the currently selected mailbox from the server.

Overload List

Deletes the currently selected mailbox from the server.

public bool DeleteMailbox();

Deletes a mailbox from the server.

public bool DeleteMailbox(string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.DeleteMailbox Method ()

Deletes the currently selected mailbox from the server.

[Visual Basic]
```
Overloads Public Function DeleteMailbox() As Boolean
```

[C#]
```
public bool DeleteMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteMailbox** method deletes the currently selected mailbox from the server. The current mailbox will be automatically unselected and any messages marked for deletion will be expunged before the mailbox is removed. If the delete operation fails, the client will remain in an unselected state until either the **ExamineMailbox** or **SelectMailbox** method is called

A mailbox cannot be deleted if it contains inferior hierarchical names and has the **imapFlagNoSelect** attribute. On most systems this is the case when the mailbox name references a directory on the server, and that directory contains other subdirectories or mailboxes. To remove the current mailbox, you must first delete any child mailboxes that exist.

The special mailbox named INBOX cannot be deleted.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.DeleteMailbox Overload List

InternetMail.DeleteMailbox Method (String)

Deletes a mailbox from the server.

[Visual Basic]
```
Overloads Public Function DeleteMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

[C#]
```
public bool DeleteMailbox(
   string mailboxName
);
```

Parameters

mailboxName
A string which specifies the name of the new mailbox to be deleted.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **DeleteMailbox** method deletes a mailbox from the server. A mailbox cannot be deleted if it contains inferior hierarchical names and has the **imapFlagNoSelect** attribute. On most systems this is the case when the mailbox name references a directory on the server, and that directory contains other subdirectories or mailboxes. To remove the mailbox, you must first delete any child mailboxes that exist.

If the mailbox that is deleted is the currently selected mailbox, it will be automatically unselected and any messages marked for deletion will be expunged before the mailbox is removed. If the delete operation fails, the client will remain in an unselected state until either the **ExamineMailbox** or **SelectMailbox** method is called.

The special mailbox named INBOX cannot be deleted.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.DeleteMailbox Overload List

InternetMail.DeleteMessage Method

Flags a message for deletion from the current mailbox.

[Visual Basic]

```
Public Function DeleteMessage( _
   ByVal messageId As Integer _
) As Boolean
```

[C#]

```
public bool DeleteMessage(
   int messageId
);
```

Parameters

messageId

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method only flags the message for deletion. The message is not actually deleted until the client disconnects from the server, however the deleted message will no longer be accessible to the client. To prevent deleted messages from actually being removed from the mailbox, call the **Reset** method.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.DeletePart Method

Delete the specified message part from the current message.

[Visual Basic]

```
Public Function DeletePart( _
   ByVal messagePart As Integer _
) As Boolean
```

[C#]

```
public bool DeletePart(
   int messagePart
);
```

Parameters

messagePart

An integer which specifies the message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This method cannot be used to delete part zero, which is the main body of the message. Instead use the **ClearMessage** method to clear the contents of the entire message.

The number of message parts in the current message is returned by the **PartCount** property.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Disconnect Method

Terminate the connection with the remote server.

[Visual Basic]

```
Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the connection with the remote host and closes the handle allocated by the class. Note that the handle is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the handle will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Dispose Method

Releases all resources used by InternetMail.

Overload List

Releases all resources used by InternetMail.

public void Dispose();

Releases the unmanaged resources allocated by the InternetMail class and optionally releases the managed resources.

protected virtual void Dispose(bool);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Dispose Method ()

Releases all resources used by InternetMail.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.Dispose Overload List

InternetMail.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the InternetMail class and optionally releases the managed resources.

[Visual Basic]

```
Overridable Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]

```
protected virtual void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **InternetMail** class so the memory they were occupying can be reclaimed by garbage collection.

InternetMail Class | SocketTools Namespace | InternetMail.Dispose Overload List

InternetMail.ExportMessage Method

Export the current message to a file on the local system.

Overload List

Export the current message to a file on the local system.

public bool ExportMessage(string);

Export the current message to a file on the local system.

public bool ExportMessage(string,MimeExportOptions);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ExportMessage Method (String)

Export the current message to a file on the local system.

[Visual Basic]

```
Overloads Public Function ExportMessage( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool ExportMessage(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the file that will contain the message. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ExportMessage** method writes the current message to a file. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

The value of the **Options** property determines the default export options, if any have been specified.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.ExportMessage Overload List

InternetMail.ExportMessage Method (String, MimeExportOptions)

Export the current message to a file on the local system.

[Visual Basic]

```
Overloads Public Function ExportMessage( _
   ByVal fileName As String, _
   ByVal options As MimeExportOptions _
) As Boolean
```

[C#]

```
public bool ExportMessage(
   string fileName,
   MimeExportOptions options
);
```

Parameters

fileName
A string which specifies the name of the file that will contain the message. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

options
A MimeExportOptions enumeration value which specifies one or more export options.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ExportMessage** method writes the current message to a file. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.ExportMessage Overload List

InternetMail.ExtractAllFiles Method

Extract all file attachments from the current message.

Overload List

Extract all file attachments from the current message.

public int ExtractAllFiles();

Extract all file attachments from the current message.

public int ExtractAllFiles(string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ExtractAllFiles Method ()

Extract all file attachments from the current message.

[Visual Basic]

```
Overloads Public Function ExtractAllFiles() As Integer
```

[C#]

```
public int ExtractAllFiles();
```

Return Value

This method returns an integer value. If the method succeeds, the return value is the number of attachments that were extracted from the message. A return value of zero indicates that the message did not contain any file attachments. If the method faile, the return value is -1. To get extended error information, check the value of the **LastError** property.

Remarks

This method will extract all of the files that are attached to the current message and store them in the current directory on the local system. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this method will automatically decode the contents of the attachment.

To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **ExtractFile** method.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.ExtractAllFiles Overload List

InternetMail.ExtractAllFiles Method (String)

Extract all file attachments from the current message.

[Visual Basic]

```
Overloads Public Function ExtractAllFiles( _
   ByVal pathName As String _
) As Integer
```

[C#]

```
public int ExtractAllFiles(
   string pathName
);
```

Parameters

pathName

A string that specifies the name of the directory where the file attachments should be stored. If this parameter is omitted or points to an empty string, the attached files will be stored in the current working directory on the local system.

Return Value

This method returns an integer value. If the method succeeds, the return value is the number of attachments that were extracted from the message. A return value of zero indicates that the message did not contain any file attachments. If the method faile, the return value is -1. To get extended error information, check the value of the **LastError** property.

Remarks

This method will extract all of the files that are attached to the current message and store them in the specified directory. The directory must exist and the current user must have the appropriate permissions to create files there. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this method will automatically decode the contents of the attachment.

To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **ExtractFile** method.

InternetMail Class | SocketTools Namespace | InternetMail.ExtractAllFiles Overload List

InternetMail.ExtractFile Method

Extract the contents of a file attachment and store it on the local system.

Overload List

Extract the contents of a file attachment and store it on the local system.

public bool ExtractFile(int,string);

Extract the contents of a file attachment and store it on the local system.

public bool ExtractFile(string);

Extract the contents of a file attachment and store it on the local system.

public bool ExtractFile(string,string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ExtractFile Method (String)

Extract the contents of a file attachment and store it on the local system.

[Visual Basic]

```
Overloads Public Function ExtractFile( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool ExtractFile(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the file that will contain the file attachment. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the attachment.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ExtractFile** method writes the contents of a message part, typically a file attachment, to a file on the local system. This method will automatically decode any binary file attachments.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.ExtractFile Overload List

InternetMail.ExtractFile Method (String, String)

Extract the contents of a file attachment and store it on the local system.

[Visual Basic]

```
Overloads Public Function ExtractFile( _
   ByVal attachName As String, _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool ExtractFile(
   string attachName,
   string fileName
);
```

Parameters

attachName

A string that specifies the name of the file attachment in the current message. This parameter should only specify a base file name; it should not include a file path and cannot be an empty string

fileName

A string which specifies the name of the file on the local system that will contain the file attachment. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the attachment.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

This version of the **ExtractFile** method will search the current message for a file attachment that matches the name specified by the ***attachName*** parameter. If an attachment with that name is found, its contents will be stored in the local file specified by the ***fileName*** parameter. If the message does not contain an attachment that matches the name provided, this method will fail.

To search for a file attachment by name, use the **FindAttachment** method.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.ExtractFile Overload List

InternetMail.ExtractFile Method (Int32, String)

Extract the contents of a file attachment and store it on the local system.

[Visual Basic]

```
Overloads Public Function ExtractFile( _
   ByVal messagePart As Integer, _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool ExtractFile(
   int messagePart,
   string fileName
);
```

Parameters

messagePart

An integer which specifies the message part.

fileName

A string which specifies the name of the file that will contain the file attachment. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the attachment.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ExtractFile** method writes the contents of a message part, typically a file attachment, to a file on the local system. This method will automatically decode any binary file attachments.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.ExtractFile Overload List

InternetMail.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the current message.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

InternetMail Class | SocketTools Namespace

InternetMail.FindAttachment Method

Search for a specific file attachment in the current message.

```
[Visual Basic]
Public Function FindAttachment( _
   ByVal fileName As String _
) As Integer
```

```
[C#]
public int FindAttachment(
   string fileName
);
```

Parameters

fileName

A string value that specifies the name of the file attachment to search for. This parameter should only specify a base file name; it should not include a file path and cannot be an empty string.

Return Value

An integer value which specifies the message part number that contains the file attachment with a matching name. If the message does not contain a file attachment with the specified name, this method will return -1.

Remarks

The **FindAttachment** method will search the current message for a attachment that matches the specified file name. The search is not case-sensitive, however it must match the attachment file name completely. This method will not match partial file names or names that include wildcard characters.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.GetFirstHeader Method

Return the first header in the current message part.

[Visual Basic]

```
Public Function GetFirstHeader( _
   ByRef headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetFirstHeader(
   ref string headerName,
   ref string headerValue
);
```

Parameters

headerName

A string passed by reference which will contain the name of the first header field when the method returns.

headerValue

A string passed by reference which will contain the value of the first header field when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetFirstHeader** method allows an application to enumerate all of the headers in the current message part. If the current message part does not contain any header fields, this method will return **false**.

The current message part is returned by the **Part** property.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.GetHeader Method

Return the value of a header field in the specified message part.

Overload List

Return the value of a header field in the specified message part.

public bool GetHeader(int,string,ref string);

Return the value of a header field in the current message part.

public bool GetHeader(string,ref string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.GetHeader Method (Int32, String, String)

Return the value of a header field in the specified message part.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal messagePart As Integer, _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   int messagePart,
   string headerName,
   ref string headerValue
);
```

Parameters

messagePart
An integer which specifies the message part.

headerName
A string which specifies the name of the header field.

headerValue
A string passed by reference which will contain the value of the header field when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method is used to retrieve the value for a specific header in the specified message part. If the header field exists, the method will return **true** and the ***headerValue*** argument will contain the header value. If the header does not exist, the method will return **false**.

If there are multiple headers with the same name, the first value will be returned. To enumerate all of the headers in a message, including duplicate header fields, use the **GetFirstHeader** and **GetNextHeader** methods.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.GetHeader Overload List

InternetMail.GetHeader Method (String, String)

Return the value of a header field in the current message part.

[Visual Basic]

```
Overloads Public Function GetHeader( _
   ByVal headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetHeader(
   string headerName,
   ref string headerValue
);
```

Parameters

headerName
A string which specifies the name of the header field.

headerValue
A string passed by reference which will contain the value of the header field when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeader** method is used to retrieve the value for a specific header in the current message part. If the header field exists, the method will return **true** and the ***headerValue*** argument will contain the header value. If the header does not exist, the method will return **false**.

If there are multiple headers with the same name, the first value will be returned. To enumerate all of the headers in a message, including duplicate header fields, use the **GetFirstHeader** and **GetNextHeader** methods.

The current message part is returned by the **Part** property.

InternetMail Class | SocketTools Namespace

InternetMail.GetHeaders Method ()

Retrieves the headers for the current message from the server.

[Visual Basic]

```
Overloads Public Function GetHeaders() As Boolean
```

[C#]

```
public bool GetHeaders();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeaders** method is used to retrieve the message headers from the server, replacing the contents of the current message with the header values. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This method will clear the contents of the current message, including the body of the current message text, and replace it with the header values returned by the server.

Note that the header data will be from the first part of the message, not from any additional sections of a multipart message. In other words, the headers such as From, To, Subject and Date will be returned in the buffer.

The current message number is specified by the value of the **Message** property.

InternetMail Class | SocketTools Namespace | InternetMail.GetHeaders Overload List

InternetMail.GetHeaders Method (Byte[], Int32)

Retrieves the headers for the current message from the server.

[Visual Basic]

```
Overloads Public Function GetHeaders( _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetHeaders(
   byte[] buffer,
   ref int length
);
```

Parameters

buffer
A byte array that will contain the message data when the method returns.

length
An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeaders** method is used to retrieve the message headers from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Note that the header data will be from the first part of the message, not from any additional sections of a multipart message. In other words, the headers such as From, To, Subject and Date will be returned in the buffer.

The current message number is specified by the value of the **Message** property.

InternetMail.GetHeaders Method (Int32)

Retrieves the headers for the specified message from the server.

[Visual Basic]

```
Overloads Public Function GetHeaders( _
   ByVal messageId As Integer _
) As Boolean
```

[C#]

```
public bool GetHeaders(
   int messageId
);
```

Parameters

messageId

Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeaders** method is used to retrieve the message headers from the server, replacing the contents of the current message with the header values. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

This method will clear the contents of the current message, including the body of the current message text, and replace it with the header values returned by the server.

Note that the header data will be from the first part of the message, not from any additional sections of a multipart message. In other words, the headers such as From, To, Subject and Date will be returned in the buffer.

InternetMail.GetHeaders Method (String)

Retrieves the headers for the current message from the server.

[Visual Basic]

```
Overloads Public Function GetHeaders( _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool GetHeaders(
   ref string buffer
);
```

Parameters

buffer
A string passed by reference that will contain the message data when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetHeaders** method is used to retrieve the message headers from the server and copy it into a local buffer. This method will cause the current thread to block until the article transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Note that the header data will be from the first part of the message, not from any additional sections of a multipart message. In other words, the headers such as From, To, Subject and Date will be returned in the buffer. To retrieve the headers from a specific section of a multipart message, you can use the **GetMessage** method and specify the **ImapSections.sectionHeader** option.

The current message number is specified by the value of the **Message** property.

Overloads Public Function GetMessage( _
   ByVal messageId As Integer, _
   ByVal buffer As Byte(), _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool GetMessage(
   int messageId,
   byte[] buffer,
   ref int length
);
```

Parameters

messageId
Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

buffer
A byte array that the message data will be stored in.

length
An integer value passed by reference which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller. When the method returns, this parameter will be updated with the actual number of bytes copied into the array.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. Retrieve a message from the server and return the contents in a string.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByVal messageId As Integer, _
   ByVal messagePart As Integer, _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool GetMessage(
   int messageId,
   int messagePart,
   ref string buffer
);
```

Parameters

messageId
Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

messagePart
An integer value that specifies the message part that should be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

buffer
A string passed by reference that will contain the message data when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

Overloads Public Function GetMessage( _
   ByVal messageId As Integer, _
   ByRef buffer As String, _
   ByVal options As ImapSections _
) As Boolean
```

[C#]

```
public bool GetMessage(
   int messageId,
   ref string buffer,
   ImapSections options
);
```

Parameters

messageId
Number of article to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

buffer
A string passed by reference that will contain the message data when the method returns.

options
An ImapSections enumeration value which specifies which section of the message to return.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve a message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

InternetMail.GetMessage Method (String)

Retrieve the current message from the server and return the contents in a string.

[Visual Basic]

```
Overloads Public Function GetMessage( _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool GetMessage(
   ref string buffer
);
```

Parameters

buffer

A string passed by reference that will contain the message data when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetMessage** method is used to retrieve the current message from the server and copy it into a local buffer. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The current message number is specified by the value of the **Message** property.

InternetMail.GetNextHeader Method

Return the next header in the current message part.

[Visual Basic]

```
Public Function GetNextHeader( _
   ByRef headerName As String, _
   ByRef headerValue As String _
) As Boolean
```

[C#]

```
public bool GetNextHeader(
   ref string headerName,
   ref string headerValue
);
```

Parameters

headerName

A string passed by reference which will contain the name of the first header field when the method returns.

headerValue

A string passed by reference which will contain the value of the first header field when the method returns.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **GetNextHeader** method allows an application to enumerate all of the headers in the current message part. If the current message part does not contain any header fields, this method will return **false**.

The current message part is returned by the **Part** property.

InternetMail Class | SocketTools Namespace

InternetMail.Idle Method

Enables mailbox status monitoring for the client session.

Overload List

Enables mailbox status monitoring for the client session.

public bool Idle();

Enables mailbox status monitoring for the client session.

public bool Idle(IdleOptions,int);

See Also

InternetMail Class | SocketTools Namespace | OnUpdate

InternetMail.Idle Method ()

Enables mailbox status monitoring for the client session.

[Visual Basic]

```
Overloads Public Function Idle() As Boolean
```

[C#]

```
public bool Idle();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Many IMAP servers support the ability to asynchronously send status updates to the client, rather than have the client periodically poll the server. The client enables this feature by calling the **Idle** method and providing an event handler for the **OnUpdate** event. Typically these events inform the client that a new message has arrived or that a message has been expunged from the mailbox.

The **Idle** method begins monitoring the client session asynchronously and returns control immediately to the caller. If the server sends a update notification to the client, the **OnUpdate** event will fire with information about the status change. Sending an IMAP command to the server will cause the client to stop monitoring the session for status changes. To explicitly stop monitoring the session, use the **Cancel** method.

This method works by sending the IDLE command to the server and starting a worker thread which monitors the connection and looks for untagged responses issued by the server. Events will be generated for EXISTS, EXPUNGE and RECENT messages. Note that some servers may periodically send untagged OK messages to the client, indicating that the connection is still active; these messages are explicitly ignored.

The **OnUpdate** event is invoked within the context of the worker thread that is monitoring the client session. Because of this, applications should not directly update the user interface from within the event handler. For example, if the server sends a notification that a new email message has arrived, the application should not attempt to read the new message and update the user interface directly from within the event handler. Instead, it should create a delegate and use the **Control.Invoke** method to marshal the call to the thread that owns the control's window handle. Failure to do this can cause the application to become unstable. For more information, refer to the **Control.Invoke** method in the .NET Framework documentation.

An application should never make an assumption about how a particular server may send update notifications to the client. Servers can be configured to use different intervals at which notifications are sent. For example, a server may send new message notifications immediately, but may periodically notify the client when a message has been expunged. Alternatively, a server may only send notifications at fixed intervals, in which case the client would not be notified of any new messages until the interval period is reached. It is not possible for a client to know what a particular server's update interval is. Applications that require that degree of control should not use the **Idle** method and should poll the server instead.

This method can only be used when connected to an IMAP server. Attempting to use this method when connected to a POP3 server will cause the method to fail, returning an error indicating that the feature is not supported.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.Idle Overload List | OnUpdate

InternetMail.Idle Method (IdleOptions, Int32)

Enables mailbox status monitoring for the client session.

[Visual Basic]

```
Overloads Public Function Idle( _
   ByVal options As IdleOptions, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Idle(
   IdleOptions options,
   int timeout
);
```

Parameters

options

One or more of the IdleOptions enumeration flags.

timeout

Specifies the timeout period in seconds to wait for a notification from the server. This parameter is only used when the **ImapIdle.idleWait** option has been specified.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

Many IMAP servers support the ability to asynchronously send status updates to the client, rather than have the client periodically poll the server. The client enables this feature by calling the **Idle** method and providing an event handler for the **OnUpdate** event. Typically these events inform the client that a new message has arrived or that a message has been expunged from the mailbox.

The **Idle** method can operate in one of two modes, based on the options specified by the caller. If the option **idleNoWait** is specified, the method begins monitoring the client session asynchronously and returns control immediately to the caller. If the server sends a update notification to the client, the **OnUpdate** event will fire with information about the status change. If the option **idleWait** is specified, the method will block waiting for the server to send a notification message to the client. The method will return when either a message is received or the timeout period is exceeded. Sending an IMAP command to the server will cause the client to stop monitoring the session for status changes. To explicitly stop monitoring the session, use the **Cancel** method.

This method works by sending the IDLE command to the server and starting a worker thread which monitors the connection and looks for untagged responses issued by the server. Events will be generated for EXISTS, EXPUNGE and RECENT messages. Note that some servers may periodically send untagged OK messages to the client, indicating that the connection is still active; these messages are explicitly ignored.

The **OnUpdate** event is invoked within the context of the worker thread that is monitoring the client session. Because of this, applications should not directly update the user interface from within the event handler. For example, if the server sends a notification that a new email message has arrived, the application should not attempt to read the new message and update the user interface directly from within the event handler. Instead, it should create a delegate and use the **Control.Invoke** method to marshal the call to the thread that owns the control's window handle. Failure to do this can cause the application to become unstable. For more information, refer to the **Control.Invoke** method in the .NET Framework documentation.

An application should never make an assumption about how a particular server may send update notifications to the client. Servers can be configured to use different intervals at which notifications are sent. For example, a server may send new message notifications immediately, but may periodically notify the client when a message has been expunged. Alternatively, a server may only send notifications at fixed intervals, in which case the client would not be notified of any new messages until the interval period is reached. It is not possible for a client to know what a particular server's update interval is. Applications that require that degree of control should not use the **Idle** method and should poll the server instead.

This method can only be used when connected to an IMAP server. Attempting to use this method when connected to a POP3 server will cause the method to fail, returning an error indicating that the feature is not supported.

InternetMail.ImportMessage Method

Replace the current message with the contents of a file.

[Visual Basic]

```
Public Function ImportMessage( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool ImportMessage(
   string fileName
);
```

Parameters

fileName

A string which specifies the name of the text file to import.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

InternetMail.Initialize Method

Initialize an instance of the InternetMail class.

Overload List

Initialize an instance of the InternetMail class.

public bool Initialize();

Initialize an instance of the InternetMail class.

public bool Initialize(string);

See Also

InternetMail Class | SocketTools Namespace | Uninitialize Method

InternetMail.Initialize Method ()

Initialize an instance of the InternetMail class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the InternetMail class, allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

InternetMail Class | SocketTools Namespace | InternetMail.Initialize Overload List | Uninitialize Method

InternetMail.Initialize Method (String)

Initialize an instance of the InternetMail class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the InternetMail class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the InternetMail class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.InternetMail mimeClient = new SocketTools.InternetMail();

if (mimeClient.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(mimeClient.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim mimeClient As New SocketTools.InternetMail

If mimeClient.Initialize(strLicenseKey) = False Then
    MsgBox(mimeClient.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

InternetMail.ParseAddress Method

Parse an Internet email address.

Overload List

Parse an Internet email address.

public bool ParseAddress(string,string,ref string);

Parse an Internet email address.

public bool ParseAddress(string,ref string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ParseAddress Method (String, String, String)

Parse an Internet email address.

[Visual Basic]

```
Overloads Public Function ParseAddress( _
   ByVal mailAddress As String, _
   ByVal mailDomain As String, _
   ByRef parsedAddress As String _
) As Boolean
```

[C#]

```
public bool ParseAddress(
   string mailAddress,
   string mailDomain,
   ref string parsedAddress
);
```

Parameters

mailAddress
A string which specifies the email address to be parsed.

mailDomain
A string which specifies a default domain for the address if no domain name is specified in the *mailAddress* parameter.

parsedAddress
A string passed by reference which will contain the parsed email address.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ParseAddress** method is useful for parsing the email addresses that may be specified in various header fields in the message. In many cases, the addresses have additional comment characters which are not part of the address itself. For example, one common format is "User Name" <user@domain.com>. In this case, the email address is enclosed in angle brackets and the name outside of the brackets is considered to be a comment which is not part of the address itself.

Another common format is user@domain.com (User Name). In this case, there is the address followed by a comment which is enclosed in parenthesis. The **ParseAddress** method recognizes both formats, and when passed either string, would return the address user@domain.com.

If there was no domain specified in the address, that is just a user name was specified, then the value the *mailDomain* parameter is added to the address.

InternetMail.ParseAddress Method (String, String)

Parse an Internet email address.

```
[Visual Basic]
Overloads Public Function ParseAddress( _
   ByVal mailAddress As String, _
   ByRef parsedAddress As String _
) As Boolean
```

```
[C#]
public bool ParseAddress(
   string mailAddress,
   ref string parsedAddress
);
```

Parameters

mailAddress
A string which specifies the email address to be parsed.

parsedAddress
A string passed by reference which will contain the parsed email address.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ParseAddress** method is useful for parsing the email addresses that may be specified in various header fields in the message. In many cases, the addresses have additional comment characters which are not part of the address itself. For example, one common format is "User Name" <user@domain.com>. In this case, the email address is enclosed in angle brackets and the name outside of the brackets is considered to be a comment which is not part of the address itself.

Another common format is user@domain.com (User Name). In this case, there is the address followed by a comment which is enclosed in parenthesis. The **ParseAddress** method recognizes both formats, and when passed either string, would return the address user@domain.com.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.ParseAddress Overload List

InternetMail.ParseMessage Method

Parse the specified string, adding the contents to the current message.

[Visual Basic]

```
Public Function ParseMessage( _
   ByVal messageText As String _
) As Boolean
```

[C#]

```
public bool ParseMessage(
   string messageText
);
```

Parameters

messageText

A string which contains the message text to be parsed.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ParseMessage** method parses a string which contains message data, adding it to the current message. This method is useful when the application needs to parse an arbitrary block of text and add it to the current message. If the string contains header fields, the values will be added to the message header. Once the end of the header block is detected, all subsequent text is added to the body of the message.

Note that unlike the **ImportMessage** method, the **ParseMessage** method does not clear the contents of the current message and may be called multiple times. Use the **ClearMessage** method to clear the current message before calling **ParseMessage** if necessary.

InternetMail Class | SocketTools Namespace

InternetMail.RenameMailbox Method

Change the name of a mailbox.

[Visual Basic]

```
Public Function RenameMailbox( _
   ByVal oldMailbox As String, _
   ByVal newMailbox As String _
) As Boolean
```

[C#]

```
public bool RenameMailbox(
   string oldMailbox,
   string newMailbox
);
```

Parameters

oldMailbox
A string that specifies the name of the mailbox to be renamed on the server. The mailbox must exist on the server, otherwise an error will be returned.

newMailbox
A string that specifies the new name for the mailbox. An error will be returned if a mailbox with that name already exists.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

If the existing mailbox name contains inferior hierarchical names (mailboxes under the specified mailbox) then those mailboxes will also be renamed. For example, if the mailbox "Mail/Pictures" contains two mailboxes, "Personal" and "Work" and it is renamed to "Mail/Images" then the two mailboxes under it would be automatically renamed to "Mail/Images/Personal" and "Mail/Images/Work".

If the mailbox being renamed is the currently selected mailbox, the current mailbox will be unselected and any messages marked for deletion will be expunged. The new mailbox name will then automatically be re-selected. To prevent deleted messages from being removed from the mailbox prior to being renamed, use the **UnselectMailbox** method to unselect the current mailbox before calling **RenameMailbox**. Note that if the rename operation fails, the client may be left in an unselected state.

It is permitted to rename the special mailbox INBOX. In this case, the messages will be moved from the INBOX mailbox to the new mailbox. If the INBOX mailbox is currently selected, the new mailbox will not automatically be selected. INBOX will remain the selected mailbox.

InternetMail Class | SocketTools Namespace

InternetMail.ReselectMailbox Method

Reselects the current mailbox.

[Visual Basic]

```
Public Function ReselectMailbox() As Boolean
```

[C#]

```
public bool ReselectMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **ReselectMailbox** method forces the current mailbox to be reselected and updates those properties which return information about the mailbox, such as the **MailboxFlags** property. Deleted messages are not expunged from the mailbox and remain marked for deletion.

Search the current mailbox for messages that match the specified criteria.

Overload List

Search the current mailbox for messages that match the specified criteria.

public int SearchMailbox(string,int[],int);

Search the current mailbox for messages that match the specified criteria and character set.

public int SearchMailbox(string,string,int[],int);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.SearchMailbox Method (String, Int32[], Int32)

Search the current mailbox for messages that match the specified criteria.

[Visual Basic]

```
Overloads Public Function SearchMailbox( _
   ByVal criteria As String, _
   ByVal messageList As Integer(), _
   ByVal maxMessages As Integer _
) As Integer
```

[C#]

```
public int SearchMailbox(
   string criteria,
   int[] messageList,
   int maxMessages
);
```

Parameters

criteria

A string which consists of one or more keywords which are used to define the search criteria. The following keywords are recognized:

Keyword	Description
ANSWERED	Match those messages which have the **ImapFlags.flagAnswered** flag set.
BCC *address*	Match those messages which contain the specified address in the BCC header field.
BEFORE *date*	Match those messages which were added to the mailbox prior to the specified date.
BODY *string*	Match those messages where the body contains the specified string.
CC *address*	Match those messages which contain the specified address in the CC header field.
DELETED	Match those messages which have the **ImapFlags.flagDeleted** flag set.
DRAFT	Match those messages which have the **ImapFlags.flagDraft** flag set.
FLAGGED	Match those messages which have the **ImapFlags.flagUrgent** flag set.
FROM *address*	Match those messages which contain the specified address in the FROM header field.
HEADER *field string*	Match those messages which contain the string in the specified header field. If no string is specified, then all messages which contain the header will be matched.
LARGER *size*	Match those messages which are larger than the

	specified size in bytes.
NEW	Match those messages which have the **ImapFlags.flagRecent** flag set, but not the **ImapFlags.flagSeen** flag.
OLD	Match those messages which do not have the **ImapFlags.flagRecent** flag set.
ON *date*	Match those messages which were added on the specified date.
RECENT	Match those messages which have the **ImapFlags.flagRecent** flag set.
SEEN	Match those messages which have the **ImapFlags.flagSeen** flag set.
SENTBEFORE *date*	Match those messages whose Date header value is earlier than the specified date.
SENTON *date*	Match those messages whose Date header value is the same as the specified date.
SENTSINCE *date*	Match those messages whose Date header value is later than the specified date.
SINCE *date*	Match those messages added to the mailbox after the specified date.
SMALLER *size*	Match those messages which are smaller than the specified size in bytes.
SUBJECT *string*	Match those messages whose Subject header contains the specified string.
TEXT *string*	Match those messages whose headers or body contains the specified string.
TO *address*	Match those messages which contain the specified address in the TO header field.
UID *sequence*	Match those messages with unique identifiers in the sequence set.
UNANSWERED	Match those messages which do not have the **ImapFlags.flagAnswered** flag set.
UNDELETED	Match those messages which do not have the **ImapFlags.flagDeleted** flag set.
UNDRAFT	Match those messages which do not have the **ImapFlags.flagDraft** flag set.
UNFLAGGED	Match those messages which do not have the **ImapFlags.flagUrgent** flag set.
UNSEEN	Match those messages which do not have the **ImapFlags.flagUnseen** flag set.

messageList

An array of integers which will contain the message numbers of those messages which match the search criteria.

maxMessages

An integer value which specifies the maximum number of message numbers which can be returned in the ***messageList*** array. This value cannot be larger than the size of the array.

Return Value

The number of messages which were found to match the search criteria. If no messages match the criteria, then the return value will be zero. A return value of -1 indicates an error, and the specific error code can be determined by checking the value of the **LastError** property.

Remarks

The **SearchMailbox** method is used to search a mailbox for messages which match a given criteria and return a list of the matching message numbers. The search criteria is composed of one or more search keywords and and optional value to match against. String searches are not case sensitive and partial matches in the message are returned. The message numbers returned by this method are only valid until the mailbox is expunged or another mailbox is selected.

In addition to the listed keywords, the keyword NOT may prefix a keyword to return those messages which do not match the search criteria. For example, "NOT TO user@domain.com" would return those messages which were not addressed to user@domain.com.

If multiple search keywords are specified, the result is the intersection of all those messages which meet the search criteria. For example, a search criteria of "DELETED SINCE 1-Jan-2003" would return all those messages which are marked for deletion and were added to the mailbox after 1 January 2003.

Those search keywords which expect dates must be specified in format ***dd-mmm-yyyy*** where the month is the three letter abbreviation for the month name. Note that the internal date the message was added to the mailbox is not the same as the value of the Date header field in the message.

If the search keyword requires a string value and the string contains one or more spaces, you must enclose the search string in quotes as part of the criteria string. The quotes around the search string prevents the server from interpreting it as a multiple search criteria to be evaluated. If you are using a search string provided by a user, it is recommended that you always enclose it in quotes to prevent any potential ambiguity in the search. Even if the search string does not contain any spaces, it is always safe to enclose it in quotes.

The UID keyword expects a one or more unique message identifiers. These values may provided as comma separated list, or a range delimited by a colon. For example, "UID 23000:24000" would return all those messages who have UIDs ranging from 23000 through to 24000.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.SearchMailbox Overload List

InternetMail.SearchMailbox Method (String, String, Int32[], Int32)

Search the current mailbox for messages that match the specified criteria and character set.

[Visual Basic]

```
Overloads Public Function SearchMailbox( _
   ByVal criteria As String, _
   ByVal charset As String, _
   ByVal messageList As Integer(), _
   ByVal maxMessages As Integer _
) As Integer
```

[C#]

```
public int SearchMailbox(
   string criteria,
   string charset,
   int[] messageList,
   int maxMessages
);
```

Parameters

criteria

A string which consists of one or more keywords which are used to define the search criteria. The following keywords are recognized:

Keyword	Description
ANSWERED	Match those messages which have the **ImapFlags.flagAnswered** flag set.
BCC *address*	Match those messages which contain the specified address in the BCC header field.
BEFORE *date*	Match those messages which were added to the mailbox prior to the specified date.
BODY *string*	Match those messages where the body contains the specified string.
CC *address*	Match those messages which contain the specified address in the CC header field.
DELETED	Match those messages which have the **ImapFlags.flagDeleted** flag set.
DRAFT	Match those messages which have the **ImapFlags.flagDraft** flag set.
FLAGGED	Match those messages which have the **ImapFlags.flagUrgent** flag set.
FROM *address*	Match those messages which contain the specified address in the FROM header field.
HEADER *field string*	Match those messages which contain the string in the specified header field. If no string is specified, then all messages which contain the header will be matched.

LARGER *size*	Match those messages which are larger than the specified size in bytes.
NEW	Match those messages which have the **ImapFlags.flagRecent** flag set, but not the **ImapFlags.flagSeen** flag.
OLD	Match those messages which do not have the **ImapFlags.flagRecent** flag set.
ON *date*	Match those messages which were added on the specified date.
RECENT	Match those messages which have the **ImapFlags.flagRecent** flag set.
SEEN	Match those messages which have the **ImapFlags.flagSeen** flag set.
SENTBEFORE *date*	Match those messages whose Date header value is earlier than the specified date.
SENTON *date*	Match those messages whose Date header value is the same as the specified date.
SENTSINCE *date*	Match those messages whose Date header value is later than the specified date.
SINCE *date*	Match those messages added to the mailbox after the specified date.
SMALLER *size*	Match those messages which are smaller than the specified size in bytes.
SUBJECT *string*	Match those messages whose Subject header contains the specified string.
TEXT *string*	Match those messages whose headers or body contains the specified string.
TO *address*	Match those messages which contain the specified address in the TO header field.
UID *sequence*	Match those messages with unique identifiers in the sequence set.
UNANSWERED	Match those messages which do not have the **ImapFlags.flagAnswered** flag set.
UNDELETED	Match those messages which do not have the **ImapFlags.flagDeleted** flag set.
UNDRAFT	Match those messages which do not have the **ImapFlags.flagDraft** flag set.
UNFLAGGED	Match those messages which do not have the **ImapFlags.flagUrgent** flag set.
UNSEEN	Match those messages which do not have the **ImapFlags.flagUnseen** flag set.

charset

An string which specifies the character set to use when searching the mailbox. If this argument is omitted, the default UTF-8 character set will be used. Note that not all servers support searches using anything but the default character set.

messageList

An array of integers which will contain the message numbers of those messages which match the search criteria.

maxMessages

An integer value which specifies the maximum number of message numbers which can be returned in the ***messageList*** array. This value cannot be larger than the size of the array.

Return Value

The number of messages which were found to match the search criteria. If no messages match the criteria, then the return value will be zero. A return value of -1 indicates an error, and the specific error code can be determined by checking the value of the **LastError** property.

Remarks

The **SearchMailbox** method is used to search a mailbox for messages which match a given criteria and return a list of the matching message numbers. The search criteria is composed of one or more search keywords and and optional value to match against. String searches are not case sensitive and partial matches in the message are returned. The message numbers returned by this method are only valid until the mailbox is expunged or another mailbox is selected.

In addition to the listed keywords, the keyword NOT may prefix a keyword to return those messages which do not match the search criteria. For example, "NOT TO user@domain.com" would return those messages which were not addressed to user@domain.com.

If multiple search keywords are specified, the result is the intersection of all those messages which meet the search criteria. For example, a search criteria of "DELETED SINCE 1-Jan-2003" would return all those messages which are marked for deletion and were added to the mailbox after 1 January 2003.

Those search keywords which expect dates must be specified in format ***dd-mmm-yyyy*** where the month is the three letter abbreviation for the month name. Note that the internal date the message was added to the mailbox is not the same as the value of the Date header field in the message.

If the search keyword requires a string value and the string contains one or more spaces, you must enclose the search string in quotes as part of the criteria string. The quotes around the search string prevents the server from interpreting it as a multiple search criteria to be evaluated. If you are using a search string provided by a user, it is recommended that you always enclose it in quotes to prevent any potential ambiguity in the search. Even if the search string does not contain any spaces, it is always safe to enclose it in quotes.

The UID keyword expects a one or more unique message identifiers. These values may provided as comma separated list, or a range delimited by a colon. For example, "UID 23000:24000" would return all those messages who have UIDs ranging from 23000 through to 24000.

InternetMail.SelectMailbox Method

Selects the specified mailbox for read-write access.

[Visual Basic]

```
Public Function SelectMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

[C#]

```
public bool SelectMailbox(
   string mailboxName
);
```

Parameters

mailboxName

A string argument which specifies the name of the mailbox to be selected.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SelectMailbox** method is used to select a mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **UnselectMailbox** method prior to selecting the new mailbox.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-only mode, use the **ExamineMailbox** method.

Submit the current message to a mail server for delivery.

public bool SendMessage(string,string,string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.SendMessage Method ()

Submit the current message to a mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage() As Boolean
```

[C#]

```
public bool SendMessage();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send the current message directly to the recipient's mail server or through a relay server. The sender's return address is automatically determined by the value of the **From** property. The recipient addresses are automatically determined by the value of the **To**, **Cc** and **Bcc** properties.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

For each recipient specified in the message, the **SendMessage** method will determine the appropriate mail exchange server and deliver the message to that user. If the **RelayServer** and **RelayPort** properties are defined, then all messages will be relayed through that specific server, regardless of the recipient address. Note that the **Secure** property and related options only affects connections to relay mail servers. See the **RelayServer** and **RelayPort** properties for additional information.

If a relay server is being used, it may require authentication before accepting any messages for delivery. To enable authentication, specify the **optionAuthLogin** option by setting the **Options** property. Prior to calling the **SendMessage** method, the **UserName** and **Password** properties should be set to the values that will be used to authenticate the session. If the server does not support authentication, or the user name or password is invalid, an error will be returned. Note that authentication is only performed if a relay server is used, otherwise the option is ignored.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.SendMessage Overload List

InternetMail.SendMessage Method (String, Int32)

Submit the current message to a mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal hostName As String, _
   ByVal hostPort As Integer _
) As Boolean
```

[C#]

```
public bool SendMessage(
   string hostName,
   int hostPort
);
```

Parameters

hostName

A string value which specifies the host name or IP address of the mail server that the message will be submitted to for delivery.

hostPort

An integer value which specifies the port number which should be used to establish a connection with the mail server. The default port number is 25 for the Simple Mail Transfer Protocol.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send the current email message using the current mail server. The sender's return address will automatically be determined by the value of the **From** property. The recipients for the message will be automatically determined by the value of the **To**, **Cc** and **Bcc** properties.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The mail server that is specified must be configured to permit relaying messages, or the submission may fail. In most cases, the server will require that the client authenticate the session with a username and password. Alternatively, some mail servers require that you connect and authenticate with their POP3 service before the SMTP service will accept a message. Consult the documentation for your mail service provider for more information on the requirements for submitting messages for delivery.

InternetMail Class | SocketTools Namespace | InternetMail.SendMessage Overload List

InternetMail.SendMessage Method (String, Int32, Int32)

Submit the specified message to a mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool SendMessage(
   string hostName,
   int hostPort,
   int timeout
);
```

Parameters

hostName

A string value which specifies the host name or IP address of the mail server that the message will be submitted to for delivery.

hostPort

An integer value which specifies the port number which should be used to establish a connection with the mail server. The default port number is 25 for the Simple Mail Transfer Protocol.

timeout

An integer value which specifies a timeout period in seconds. If the message cannot be submitted within the specified time period, the method will fail. The default timeout value for connections is 20 seconds.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send a formatted email message using the current mail server. This provides a convenient one-step method of addressing and sending a message.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The mail server that is specified must be configured to permit relaying messages, or the submission may fail. In most cases, the server will require that the client authenticate the session with a username and password. Alternatively, some mail servers require that you connect and authenticate with their POP3 service before the SMTP service will accept a message. Consult the documentation for your mail service provider for more information on the requirements for submitting messages for delivery.

[C#]

```
public bool SendMessage(
   string hostName,
   int hostPort,
   int timeout,
   InternetMailOptions options
);
```

Parameters

hostName
A string value which specifies the host name or IP address of the mail server that the message will be submitted to for delivery.

hostPort
An integer value which specifies the port number which should be used to establish a connection with the mail server. The default port number is 25 for the Simple Mail Transfer Protocol.

timeout
An integer value which specifies a timeout period in seconds. If the message cannot be submitted within the specified time period, the method will fail. The default timeout value for connections is 20 seconds.

options
An InternetMailOptions enumeration which specifies the options that can be used when delivering the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send the current email message using the current mail server. The sender's return address will automatically be determined by the value of the **From** property. The recipients for the message will be automatically determined by the value of the **To**, **Cc** and **Bcc** properties.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The mail server that is specified must be configured to permit relaying messages, or the submission may fail. In most cases, the server will require that the client authenticate the session with a username and password. Alternatively, some mail servers require that you connect and authenticate with their POP3 service before the SMTP service will accept a message. Consult the documentation for your mail service provider for more information on the requirements for submitting messages for delivery.

InternetMail Class | SocketTools Namespace | InternetMail.SendMessage Overload List

InternetMail.SendMessage Method (String, Int32, String, String)

Submit the current message to a mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String _
) As Boolean
```

[C#]

```
public bool SendMessage(
   string hostName,
   int hostPort,
   string userName,
   string userPassword
);
```

Parameters

hostName
A string value which specifies the host name or IP address of the mail server that the message will be submitted to for delivery.

hostPort
An integer value which specifies the port number which should be used to establish a connection with the mail server. The default port number is 25 for the Simple Mail Transfer Protocol.

userName
A string value which specifies the user name that will be used to authenticate the client session with the mail server.

userPassword
A string value which specifies the password that will be used to authenticate the client session with the mail server.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send the current email message using the current mail server. The sender's return address will automatically be determined by the value of the **From** property. The recipients for the message will be automatically determined by the value of the **To**, **Cc** and **Bcc** properties.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The mail server that is specified must be configured to permit relaying messages, or the submission may fail. In most cases, the server will require that the client authenticate the session with a username and password. Alternatively, some mail servers require that you connect and authenticate with their POP3 service before the SMTP service will accept a message. InternetMail.SendMessage Method (String, Int32, String, String, String, String, String, Int32, InternetMailOptions)

Submit the specified message to a mail server for delivery.

[Visual Basic]

```
Overloads Public Function SendMessage( _
   ByVal hostName As String, _
   ByVal hostPort As Integer, _
   ByVal userName As String, _
   ByVal userPassword As String, _
   ByVal senderAddress As String, _
   ByVal recipientAddress As String, _
   ByVal messageText As String, _
   ByVal timeout As Integer, _
   ByVal options As InternetMailOptions _
) As Boolean
```

[C#]

```
public bool SendMessage(
   string hostName,
   int hostPort,
   string userName,
   string userPassword,
   string senderAddress,
   string recipientAddress,
   string messageText,
   int timeout,
   InternetMailOptions options
);
```

Parameters

hostName
A string value which specifies the host name or IP address of the mail server that the message will be submitted to for delivery.

hostPort
An integer value which specifies the port number which should be used to establish a connection with the mail server. The default port number is 25 for the Simple Mail Transfer Protocol.

userName
A string value which specifies the user name that will be used to authenticate the client session with the mail server.

userPassword
A string value which specifies the password that will be used to authenticate the client session with the mail server.

senderAddress
A string argument which specifies the email address of the person sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

recipientAddress
A string argument which specifies the email address of the person or persons to receive the message. Multiple addresses may be specified by separating each address with a comma. It should be noted that this protocol is only concerned with the delivery of a message and not its contents. Header fields

in the message are not parsed to automatically determine the recipients. This argument should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

messageText

A string that contains the message to be delivered to the specified recipients. The message must be text and conform to the basic structure defined in RFC 822. There must be one or more headers separated by a blank line, followed by the body of the message. Each line of text must be terminated by a carriage return and linefeed character sequence.

timeout

An integer value which specifies a timeout period in seconds. If the message cannot be submitted within the specified time period, the method will fail. The default timeout value for connections is 20 seconds.

options

An InternetMailOptions enumeration which specifies the options that can be used when delivering the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send a formatted email message using the current mail server. This provides a convenient one-step method of addressing and sending a message.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The mail server that is specified must be configured to permit relaying messages, or the submission may fail. In most cases, the server will require that the client authenticate the session with a username and password. Alternatively, some mail servers require that you connect and authenticate with their POP3 service before the SMTP service will accept a message. Consult the documentation for your mail service provider for more information on the requirements for submitting messages for delivery.

InternetMail Class | SocketTools Namespace | InternetMail.SendMessage Overload List

InternetMail.SendMessage Method (String, String)

Submit the current message to a mail server for delivery.

```
[Visual Basic]
Overloads Public Function SendMessage( _
   ByVal senderAddress As String, _
   ByVal recipientAddress As String _
) As Boolean
```

```
[C#]
public bool SendMessage(
   string senderAddress,
   string recipientAddress
);
```

Parameters

senderAddress

A string argument which specifies the email address of the person sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

recipientAddress

A string argument which specifies the email address of the person or persons to receive the message. Multiple addresses may be specified by separating each address with a comma. It should be noted that this protocol is only concerned with the delivery of a message and not its contents. Header fields in the message are not parsed to automatically determine the recipients. This argument should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send the current message directly to the recipient's mail server or through a relay server.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

For each recipient specified, the **SendMessage** method will determine the appropriate mail exchange server and deliver the message to that user. If the **RelayServer** and **RelayPort** properties are defined, then all messages will be relayed through that specific server, regardless of the recipient address. Note that the **Secure** property and related options only affects connections to relay mail servers. See the **RelayServer** and **RelayPort** properties for additional information.

If a relay server is being used, it may require authentication before accepting any messages for delivery. To enable authentication, specify the **optionAuthLogin** option by setting the **Options** property. Prior to calling the **SendMessage** method, the **UserName** and **Password** properties should be set to the values that will be used to authenticate the session. If the server does not support authentication, or the user name or password is invalid, an error will be returned. Note that authentication is only performed if a relay server is used, otherwise the option is ignored.

InternetMail.SendMessage Method (String, String, String)

Submit the current message to a mail server for delivery.

```
[Visual Basic]
Overloads Public Function SendMessage( _
   ByVal senderAddress As String, _
   ByVal recipientAddress As String, _
   ByVal messageText As String _
) As Boolean
```

```
[C#]
public bool SendMessage(
   string senderAddress,
   string recipientAddress,
   string messageText
);
```

Parameters

senderAddress
A string argument which specifies the email address of the person sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

recipientAddress
A string argument which specifies the email address of the person or persons to receive the message. Multiple addresses may be specified by separating each address with a comma. It should be noted that this protocol is only concerned with the delivery of a message and not its contents. Header fields in the message are not parsed to automatically determine the recipients. This argument should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

messageText
A string that contains the message to be delivered to the specified recipients. The message must be text and conform to the basic structure defined in RFC 822. There must be one or more headers separated by a blank line, followed by the body of the message. Each line of text must be terminated by a carriage return and linefeed character sequence.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SendMessage** method enables an application to send a formatted email message using the current mail server. This provides a convenient one-step method of addressing and sending a message.

This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

For each recipient specified, the **SendMessage** method will determine the appropriate mail exchange server and deliver the message to that user. If the **RelayServer** and **RelayPort** properties are defined, then all messages will be relayed through that specific server, regardless of the recipient address. Note that the **Secure** property and related options only affects connections to relay mail servers. See the

RelayServer and **RelayPort** properties for additional information.

If a relay server is being used, it may require authentication before accepting any messages for delivery. To enable authentication, specify the **optionAuthLogin** option by setting the **Options** property. Prior to calling the **SendMessage** method, the **UserName** and **Password** properties should be set to the values that will be used to authenticate the session. If the server does not support authentication, or the user name or password is invalid, an error will be returned. Note that authentication is only performed if a relay server is used, otherwise the option is ignored.

InternetMail.SetHeader Method

Set the value for a header in the specified message part.

Overload List

Set the value for a header in the specified message part.

public bool SetHeader(int,string,string);

Set the value for a header in the current message part.

public bool SetHeader(string,string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.SetHeader Method (Int32, String, String)

Set the value for a header in the specified message part.

[Visual Basic]

```
Overloads Public Function SetHeader( _
   ByVal messagePart As Integer, _
   ByVal headerName As String, _
   ByVal headerValue As String _
) As Boolean
```

[C#]

```
public bool SetHeader(
   int messagePart,
   string headerName,
   string headerValue
);
```

Parameters

messagePart

An integer which specifies the message part.

headerName

A string which specifies the name of the header field.

headerValue

A string which specifies the value of the header field. If an empty string is specified, the header field is removed from the header block in the specified message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.SetHeader Overload List

InternetMail.SetHeader Method (String, String)

Set the value for a header in the current message part.

[Visual Basic]

```
Overloads Public Function SetHeader( _
   ByVal headerName As String, _
   ByVal headerValue As String _
) As Boolean
```

[C#]

```
public bool SetHeader(
   string headerName,
   string headerValue
);
```

Parameters

headerName

A string which specifies the name of the header field.

headerValue

A string which specifies the value of the header field. If an empty string is specified, the header field is removed from the header block in the current message part.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The current message part is returned by the **Part** property.

InternetMail.StoreMessage Method

Retrieve a message from the current mailbox and store it in a file on the local system.

Overload List

Retrieve a message from the current mailbox and store it in a file on the local system.

public bool StoreMessage(int,string);

Retrieve the current message and store it in a file on the local system.

public bool StoreMessage(string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.StoreMessage Method (Int32, String)

Retrieve a message from the current mailbox and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function StoreMessage( _
   ByVal messageId As Integer, _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool StoreMessage(
   int messageId,
   string fileName
);
```

Parameters

messageId

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

fileName

A string which specifies the file that the message will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **StoreMessage** method retrieves a message from the server and stores it in a file on the local system. The contents of the message is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.StoreMessage Overload List

InternetMail.StoreMessage Method (String)

Retrieve the current message and store it in a file on the local system.

[Visual Basic]

```
Overloads Public Function StoreMessage( _
   ByVal fileName As String _
) As Boolean
```

[C#]

```
public bool StoreMessage(
   string fileName
);
```

Parameters

fileName

A string which specifies the file that the message will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the message.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **StoreMessage** method retrieves the current message from the server and stores it in a file on the local system. The contents of the message is stored as a text file, using the specified file name. This method will cause the current thread to block until the message transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **OnProgress** event will fire periodically, enabling the application to update any user interface objects such as a progress bar.

The current message number is specified by the value of the **Message** property.

See Also

InternetMail.SubscribeMailbox Method

Subscribes the user to the current mailbox.

Overload List

Subscribes the user to the current mailbox.

public bool SubscribeMailbox();

Subscribes the user to the specified mailbox.

public bool SubscribeMailbox(string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.SubscribeMailbox Method ()

Subscribes the user to the current mailbox.

[Visual Basic]

```
Overloads Public Function SubscribeMailbox() As Boolean
```

[C#]

```
public bool SubscribeMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SubscribeMailbox** method adds the current mailbox to the current user's list of active or subscribed mailboxes. The user will remain subscribed to the mailbox across multiple sessions, until the **UnsubscribeMailbox** method is called to remove the mailbox from the subscription list.

Note that if a user subscribes to a mailbox and that mailbox is later renamed or deleted, the mailbox will not be automatically removed from the user's subscription list. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

The current mailbox is specified by the value of the **MailboxName** property.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.SubscribeMailbox Overload List

InternetMail.SubscribeMailbox Method (String)

Subscribes the user to the specified mailbox.

[Visual Basic]

```
Overloads Public Function SubscribeMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

[C#]

```
public bool SubscribeMailbox(
   string mailboxName
);
```

Parameters

mailboxName

A string which specifies the name of the mailbox to subscribe to.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **SubscribeMailbox** method adds the specified mailbox to the current user's list of active or subscribed mailboxes. The user will remain subscribed to the mailbox across multiple sessions, until the **UnsubscribeMailbox** method is called to remove the mailbox from the subscription list.

Note that if a user subscribes to a mailbox and that mailbox is later renamed or deleted, the mailbox will not be automatically removed from the user's subscription list. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.SubscribeMailbox Overload List

InternetMail.UndeleteMessage Method

Removes the deletion flag for the specified message.

[Visual Basic]

```
Public Function UndeleteMessage( _
   ByVal messageId As Integer _
) As Boolean
```

[C#]

```
public bool UndeleteMessage(
   int messageId
);
```

Parameters

messageId

Number of message to undelete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UndeleteMessage** method removes the deletion flag for the specified message in the current mailbox. To determine if a message has been marked for deletion, set the **Message** property to the message number and then check the value of the **MessageFlags** property to determine if the **imapFlagDeleted** bit flag has been set.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.Uninitialize Method

Uninitialize the class library and release any resources allocated for the current thread.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method releases resources allocated for the current process. After this method has been called, no further operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

InternetMail Class | SocketTools Namespace | Initialize Method

InternetMail.UnselectMailbox Method

Unselects the current mailbox and expunges deleted messages.

Overload List

Unselects the current mailbox and expunges deleted messages.

public bool UnselectMailbox();

Unselects the current mailbox.

public bool UnselectMailbox(bool);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.UnselectMailbox Method ()

Unselects the current mailbox and expunges deleted messages.

[Visual Basic]

```
Overloads Public Function UnselectMailbox() As Boolean
```

[C#]

```
public bool UnselectMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UnselectMailbox** method unselects the current mailbox. Once the mailbox has been unselected, no messages in that mailbox can be accessed, and any messages which have been flagged for deletion are removed.

See Also

InternetMail Class | SocketTools Namespace | InternetMail.UnselectMailbox Overload List

InternetMail.UnselectMailbox Method (Boolean)

Unselects the current mailbox.

[Visual Basic]

```
Overloads Public Function UnselectMailbox( _
   ByVal expunge As Boolean _
) As Boolean
```

[C#]

```
public bool UnselectMailbox(
   bool expunge
);
```

Parameters

expunge

An boolean value which determines if deleted messages will be expunged from the mailbox. A value of **true** specifies that messages that have been marked for deletion will be removed from the mailbox. A value of **false** specifies that no messages will be removed from the mailbox.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UnselectMailbox** method unselects the current mailbox. Once the mailbox has been unselected, no messages in that mailbox can be accessed.

InternetMail Class | SocketTools Namespace | InternetMail.UnselectMailbox Overload List

InternetMail.UnsubscribeMailbox Method

Unsubscribes the user from the current mailbox.

Overload List

Unsubscribes the user from the current mailbox.

public bool UnsubscribeMailbox();

Unsubscribes the user from the specified mailbox.

public bool UnsubscribeMailbox(string);

See Also

InternetMail Class | SocketTools Namespace

InternetMail.UnsubscribeMailbox Method ()

Unsubscribes the user from the current mailbox.

[Visual Basic]

```
Overloads Public Function UnsubscribeMailbox() As Boolean
```

[C#]

```
public bool UnsubscribeMailbox();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UnsubscribeMailbox** method removes the current mailbox from the current user's list of active or subscribed mailboxes. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

The current mailbox is specified by the value of the **MailboxName** property.

InternetMail.UnsubscribeMailbox Method (String)

Unsubscribes the user from the specified mailbox.

[Visual Basic]

```
Overloads Public Function UnsubscribeMailbox( _
   ByVal mailboxName As String _
) As Boolean
```

[C#]

```
public bool UnsubscribeMailbox(
   string mailboxName
);
```

Parameters

mailboxName

A string which specifies the name of the mailbox to unsubscribe from.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **UnsubscribeMailbox** method removes the specified mailbox from the current user's list of active or subscribed mailboxes. To determine if the current mailbox is in the user's subscription list, check the **Subscribed** property.

InternetMail Class | SocketTools Namespace | InternetMail.UnsubscribeMailbox Overload List

InternetMail Events

The events of the **InternetMail** class are listed below. For a complete list of **InternetMail** class members, see the InternetMail Members topic.

Public Instance Events

⚡ OnCancel	Occurs when a blocking client operation is canceled.
⚡ OnDelivered	Occurs when a message has been submitted for delivery.
⚡ OnError	Occurs when an client operation fails.
⚡ OnProgress	Occurs as a data stream is being read or written to the client.
⚡ OnRecipient	Occurs when a message is about to be submitted for delivery.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnUpdate	Occurs when the server sends a mailbox update notification to the client.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.OnCancel Event

Occurs when a blocking client operation is canceled.

[Visual Basic]

```
Public Event OnCancel As EventHandler
```

[C#]

```
public event EventHandler OnCancel;
```

Remarks

The **OnCancel** event is generated when a blocking network operation, such as sending or receiving a message, is canceled with the **Cancel** method. To assist in determining which operation was canceled, check the value of the **Status** property.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.OnDelivered Event

Occurs when a message has been submitted for delivery.

[Visual Basic]
```
Public Event OnDelivered As OnDeliveredEventHandler
```

[C#]
```
public event OnDeliveredEventHandler OnDelivered;
```

Event Data

The event handler receives an argument of type InternetMail.DeliveredEventArgs containing data related to this event. The following **InternetMail.DeliveredEventArgs** properties provide information specific to this event.

Property	Description
Address	Gets the email address of the message recipient.
MessageSize	Gets a value which specifies the total number of bytes in the message.

Remarks

The **OnDelivered** event is generated when a message has been successfully submitted to the mail server for delivery. If multiple recipients have been specified for the message, this event will fire for each recipient, enabling the application to update its user interface as the message is delivered.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.DeliveredEventArgs Class

Provides data for the OnDelivered event.

For a list of all members of this type, see InternetMail.DeliveredEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.InternetMail.DeliveredEventArgs

[Visual Basic]

```
Public Class InternetMail.DeliveredEventArgs
    Inherits EventArgs
```

[C#]

```
public class InternetMail.DeliveredEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

DeliveredEventArgs specifies the address of the message recipient and the size of the message that was delivered in bytes.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

InternetMail.DeliveredEventArgs Members

InternetMail.DeliveredEventArgs overview

Public Instance Constructors

InternetMail.DeliveredEventArgs Constructor	Initializes a new instance of the InternetMail.DeliveredEventArgs class.

Public Instance Properties

Address	Gets the email address of the message recipient.
MessageSize	Gets a value which specifies the total number of bytes in the message.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetMail.DeliveredEventArgs Class | SocketTools Namespace

InternetMail.DeliveredEventArgs Properties

The properties of the **InternetMail.DeliveredEventArgs** class are listed below. For a complete list of **InternetMail.DeliveredEventArgs** class members, see the InternetMail.DeliveredEventArgs Members topic.

Public Instance Properties

Address	Gets the email address of the message recipient.
MessageSize	Gets a value which specifies the total number of bytes in the message.

See Also

InternetMail.DeliveredEventArgs Class | SocketTools Namespace

InternetMail.DeliveredEventArgs.Address Property

Gets the email address of the message recipient.

[Visual Basic]

```
Public ReadOnly Property Address As String
```

[C#]

```
public string Address {get;}
```

Property Value

A string value which specifies the recipient of the email message.

Remarks

The **Address** property returns the email address of the recipient for the message that was submitted to the mail server for delivery.

See Also

InternetMail.DeliveredEventArgs Class | SocketTools Namespace | MessageSize Property

InternetMail.DeliveredEventArgs.MessageSize Property

Gets a value which specifies the total number of bytes in the message.

[Visual Basic]

```
Public ReadOnly Property MessageSize As Integer
```

[C#]

```
public int MessageSize {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **MessageSize** property specifies the size of the message submitted for delivery to the mail server.

InternetMail.DeliveredEventArgs Class | SocketTools Namespace | Address Property

InternetMail.OnError Event

Occurs when an client operation fails.

[Visual Basic]
```
Public Event OnError As OnErrorEventHandler
```

[C#]
```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type InternetMail.ErrorEventArgs containing data related to this event. The following **InternetMail.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

Remarks

The **OnError** event occurs when a client operation fails.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ErrorEventArgs Class

Provides data for the OnError event.

For a list of all members of this type, see InternetMail.ErrorEventArgs Members.

System.Object
  System.EventArgs

[Visual Basic]

```
Public Class InternetMail.ErrorEventArgs
    Inherits EventArgs
```

[C#]

```
public class InternetMail.ErrorEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ErrorEventArgs specifies the numeric error code and a description of the error that has occurred.

An OnError event occurs when a method fails.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

InternetMail.ErrorEventArgs Properties

The properties of the **InternetMail.ErrorEventArgs** class are listed below. For a complete list of **InternetMail.ErrorEventArgs** class members, see the InternetMail.ErrorEventArgs Members topic.

Public Instance Properties

Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.

See Also

InternetMail.ErrorEventArgs Class | SocketTools Namespace

InternetMail.ErrorEventArgs.Description Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Description As String
```

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

InternetMail.ErrorEventArgs Class | SocketTools Namespace | Error Property

InternetMail.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public InternetMail.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

InternetMail.ErrorEventArgs Class | SocketTools Namespace | Description Property

InternetMail.OnProgress Event

Occurs as a data stream is being read or written to the client.

[Visual Basic]
```
Public Event OnProgress As OnProgressEventHandler
```

[C#]
```
public event OnProgressEventHandler OnProgress;
```

Event Data

The event handler receives an argument of type InternetMail.ProgressEventArgs containing data related to this event. The following **InternetMail.ProgressEventArgs** properties provide information specific to this event.

Property	Description
Message	Gets the message number.
MessageCopied	Gets a value which specifies the number of bytes of data that has been read or written.
MessageSize	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Remarks

The **OnProgress** event occurs as a data stream is being read or written to the client. If large amounts of data are being read or written, this event can be used to update a progress bar or other user-interface component to provide the user with some visual feedback on the progress of the operation.

This event is only generated when the **ReadStream**, **WriteStream** or **StoreStream** methods are called.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.ProgressEventArgs Class

Provides data for the OnProgress event.

For a list of all members of this type, see InternetMail.ProgressEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.InternetMail.ProgressEventArgs

[Visual Basic]

```
Public Class InternetMail.ProgressEventArgs
    Inherits EventArgs
```

[C#]

```
public class InternetMail.ProgressEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ProgressEventArgs specifies the number of bytes exchanged with the mail server. This event occurs when retrieving a message from the server, and when submitting a message to the server for delivery.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

InternetMail.ProgressEventArgs Members | SocketTools Namespace

InternetMail.ProgressEventArgs overview

Public Instance Constructors

InternetMail.ProgressEventArgs Constructor	Initializes a new instance of the InternetMail.ProgressEventArgs class.

Public Instance Properties

Message	Gets the message number.
MessageCopied	Gets a value which specifies the number of bytes of data that has been read or written.
MessageSize	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetMail.ProgressEventArgs Properties

The properties of the **InternetMail.ProgressEventArgs** class are listed below. For a complete list of **InternetMail.ProgressEventArgs** class members, see the InternetMail.ProgressEventArgs Members topic.

Public Instance Properties

Message	Gets the message number.
MessageCopied	Gets a value which specifies the number of bytes of data that has been read or written.
MessageSize	Gets a value which specifies the total number of bytes in the data stream.
Percent	Gets a value which specifies the percentage of data that has been read or written.

See Also

InternetMail.ProgressEventArgs Class | SocketTools Namespace

InternetMail.ProgressEventArgs.Message Property

Gets the message number.

[Visual Basic]
```
Public ReadOnly Property Message As Integer
```

[C#]
```
public int Message {get;}
```

Property Value

An integer value which specifies the message number.

Remarks

The **Message** property specifies the message number for the current message that is being downloaded from the mail server to the local host. If the **OnProgress** event occurs while message data is being submitted to the server, this property will return a value of zero.

See Also

InternetMail.ProgressEventArgs Class | SocketTools Namespace

InternetMail.ProgressEventArgs.MessageCopied Property

Gets a value which specifies the number of bytes of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property MessageCopied As Integer
```

[C#]

```
public int MessageCopied {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **MessageCopied** property specifies the number of bytes that have been read from the client and stored in the local stream buffer, or written from the stream buffer to the client.

See Also

InternetMail.ProgressEventArgs Class | SocketTools Namespace | MessageSize Property | Percent Property

InternetMail.ProgressEventArgs.MessageSize Property

Gets a value which specifies the total number of bytes in the data stream.

[Visual Basic]

```
Public ReadOnly Property MessageSize As Integer
```

[C#]

```
public int MessageSize {get;}
```

Property Value

An integer value which specifies the number of bytes of data.

Remarks

The **MessageSize** property specifies the total amount of data being read from the client and stored in the data stream, or written from the data stream to the client. If the amount of data was unknown or unspecified at the time the method call was made, then this value will always be the same as the **MessageCopied** property.

See Also

InternetMail.ProgressEventArgs Class | SocketTools Namespace | MessageCopied Property | Percent Property

InternetMail.ProgressEventArgs.Percent Property

Gets a value which specifies the percentage of data that has been read or written.

[Visual Basic]

```
Public ReadOnly Property Percent As Integer
```

[C#]

```
public int Percent {get;}
```

Property Value

An integer value which specifies a percentage.

Remarks

The **Percent** property specifies the percentage of data that has been transmitted, expressed as an integer value between 0 and 100, inclusive. If the maximum size of the data stream was not specified by the caller, this value will always be 100.

See Also

InternetMail.ProgressEventArgs Class | SocketTools Namespace | MessageCopied Property | MessageSize Property

InternetMail.OnRecipient Event

Occurs when a message is about to be submitted for delivery.

[Visual Basic]
```
Public Event OnRecipient As OnRecipientEventHandler
```

[C#]
```
public event OnRecipientEventHandler OnRecipient;
```

Event Data

The event handler receives an argument of type InternetMail.RecipientEventArgs containing data related to this event. The following **InternetMail.RecipientEventArgs** property provides information specific to this event.

Property	Description
Address	Gets the email address of the message recipient.

Remarks

The **OnRecipient** event is generated when a message is about to be submitted to the mail server for delivery. If multiple recipients have been specified for the message, this event will fire for each recipient. To prevent the message from being delivered to the specified recipient, call the **Cancel** method.

See Also

InternetMail Class | SocketTools Namespace

InternetMail.RecipientEventArgs Class

Provides data for the OnRecipient event.

For a list of all members of this type, see InternetMail.RecipientEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.InternetMail.RecipientEventArgs

[Visual Basic]

```
Public Class InternetMail.RecipientEventArgs
    Inherits EventArgs
```

[C#]

```
public class InternetMail.RecipientEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

RecipientEventArgs specifies recipient of a message that is about to be submitted to the mail server for delivery.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

InternetMail.RecipientEventArgs Class | SocketTools Namespace

InternetMail.RecipientEventArgs.Address Property

Gets the email address of the message recipient.

[Visual Basic]

```
Public ReadOnly Property Address As String
```

[C#]

```
public string Address {get;}
```

Property Value

A string value which specifies the recipient of the email message.

Remarks

The **Address** property returns the email address of the recipient for the message that is about to be submitted to the mail server for delivery.

See Also

InternetMail.RecipientEventArgs Class | SocketTools Namespace

InternetMail.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As EventHandler
```

[C#]

```
public event EventHandler OnTimeout;
```

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the client, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

InternetMail.UpdateEventArgs Constructor

Initializes a new instance of the InternetMail.UpdateEventArgs class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public InternetMail.UpdateEventArgs();
```

See Also

InternetMail.UpdateEventArgs Class | SocketTools Namespace

InternetMail.UpdateEventArgs Properties

The properties of the **InternetMail.UpdateEventArgs** class are listed below. For a complete list of **InternetMail.UpdateEventArgs** class members, see the InternetMail.UpdateEventArgs Members topic.

Public Instance Properties

Message	Gets the message number.
UpdateType	Gets the type of update notification that has been sent by the server.

See Also

InternetMail.UpdateEventArgs Class | SocketTools Namespace

InternetMail.UpdateEventArgs.Message Property

Gets the message number.

[Visual Basic]

```
Public ReadOnly Property Message As Integer
```

[C#]

```
public int Message {get;}
```

Property Value

An integer value which specifies the message number.

Remarks

The **Message** property specifies the message number for the message that has been added to or expunged from the current mailbox. A value of zero indicates that the update notification does not reference a specific message in the mailbox.

See Also

InternetMail.UpdateEventArgs Class | SocketTools Namespace

InternetMail.UpdateEventArgs.UpdateType Property

Gets the type of update notification that has been sent by the server.

[Visual Basic]

```
Public ReadOnly Property UpdateType As IdleUpdate
```

[C#]

```
public InternetMail.IdleUpdate UpdateType {get;}
```

Property Value

One or more of the IdleUpdate enumeration flags.

See Also

InternetMail.UpdateEventArgs Class | SocketTools Namespace

InternetMail.OnUpdate Event

Occurs when the server sends a mailbox update notification to the client.

[Visual Basic]

```
Public Event OnUpdate As OnUpdateEventHandler
```

[C#]

```
public event OnUpdateEventHandler OnUpdate;
```

Event Data

The event handler receives an argument of type InternetMail.UpdateEventArgs containing data related to this event. The following **InternetMail.UpdateEventArgs** properties provide information specific to this event.

Property	Description
Message	Gets the message number.
UpdateType	Gets the type of update notification that has been sent by the server.

Remarks

This event is only generated when the **Idle** method has been used to enable mailbox status monitoring.

See Also

InternetMail Class | SocketTools Namespace | Idle Method | OnUpdateEventHandler Delegate

InternetMail.OnDeliveredEventHandler Delegate

Represents the method that will handle the OnDelivered event.

[Visual Basic]

```
Public Delegate Sub InternetMail.OnDeliveredEventHandler( _
   ByVal sender As Object, _
   ByVal e As DeliveredEventArgs _
)
```

[C#]

```
public delegate void InternetMail.OnDeliveredEventHandler(
      object sender,
      DeliveredEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An DeliveredEventArgs that contains the event data.

Remarks

When you create an **OnDeliveredEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnDeliveredEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

SocketTools Namespace

InternetMail.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub InternetMail.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void InternetMail.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

SocketTools Namespace

InternetMail.OnProgressEventHandler Delegate

Represents the method that will handle the OnProgress event.

```
[Visual Basic]
Public Delegate Sub InternetMail.OnProgressEventHandler( _
   ByVal sender As Object, _
   ByVal e As ProgressEventArgs _
)
```

```
[C#]
public delegate void InternetMail.OnProgressEventHandler(
      object sender,
      ProgressEventArgs e
   );
```

Parameters

sender

The source of the event.

e

A ProgressEventArgs that contains the event data.

Remarks

When you create an **OnProgressEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnProgressEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

SocketTools Namespace

InternetMail.OnRecipientEventHandler Delegate

Represents the method that will handle the OnRecipient event.

[Visual Basic]

```
Public Delegate Sub InternetMail.OnRecipientEventHandler( _
   ByVal sender As Object, _
   ByVal e As RecipientEventArgs _
)
```

[C#]

```
public delegate void InternetMail.OnRecipientEventHandler(
      object sender,
      RecipientEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An RecipientEventArgs that contains the event data.

Remarks

When you create an **OnRecipientEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnRecipientEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

SocketTools Namespace

InternetMail.OnUpdateEventHandler Delegate

Represents the method that will handle the OnUpdate event.

[Visual Basic]

```
Public Delegate Sub InternetMail.OnUpdateEventHandler( _
   ByVal sender As Object, _
   ByVal e As UpdateEventArgs _
)
```

[C#]

```
public delegate void InternetMail.OnUpdateEventHandler(
      object sender,
      UpdateEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An UpdateEventArgs that contains the event data.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

SocketTools Namespace | UpdateEventArgs Class

InternetMail.ErrorCode Enumeration

Specifies the error codes returned by the InternetMail class.

[Visual Basic]
```
Public Enum InternetMail.ErrorCode
```

[C#]
```
public enum InternetMail.ErrorCode
```

Remarks

The InternetMail class uses the **ErrorCode** enumeration to specify what error has occurred when a network operation fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous network operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote

	host.
errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.

errorSecurityCertificate	Unable to validate the certificate chain for this session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.

errorProxyAuthenticationRequired	Proxy authentication required.
errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.

errorUnsupportedMediaType	Request specified an unsupported media type.
errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.

errorNoMoreMailboxes	No more mailboxes exist on this server.
errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.

errorInvalidThreadHandle	The specified thread handle is no longer valid.
errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been

	defined.
errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or

	unrecognized.
errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

InternetMail.IdleOptions Enumeration

Specifies the idle monitoring options that the InternetMail class supports.

[Visual Basic]
```
Public Enum InternetMail.IdleOptions
```

[C#]
```
public enum InternetMail.IdleOptions
```

Remarks

The **Idle** method can operate in two modes, based on the options specified by the caller. If the option **imapIdleNoWait** is specified, the method begins monitoring the client session asynchronously and returns control immediately to the caller. If the server sends a update notification to the client, the **OnUpdate** event will fire with information about the status change. If the option **imapIdleWait** is specified, the method will block waiting for the server to send a notification message to the client. The method will return when either a message is received or the timeout period is exceeded.

Members

Member Name	Description
idleNoWait	The **Idle** method should return immediately after idle processing has been enabled. When this option is used, the application may continue to perform other functions while the client session is monitored for status updates sent by the server. The client will continue to monitor status changes until an IMAP command issued or the client disconnects from the server. This is the default option.
idleWait	The **Idle** method should wait until the server sends a status update, or until the timeout period is reached. The client will stop monitoring status changes when the function returns. If this option is used in a single-threaded application, normal message processing can be impeded, causing the application to appear non-responsive until the timeout period is reached. It is strongly recommended that single-threaded applications with a user interface specify the **imapIdleNoWait** option instead.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

SocketTools Namespace | Idle Method (SocketTools.InternetMail) | OnUpdate Event (SocketTools.InternetMail)

InternetMail.IdleUpdate Enumeration

Specifies the types of update notification messages that the InternetMail class supports.

[Visual Basic]

```
Public Enum InternetMail.IdleUpdate
```

[C#]

```
public enum InternetMail.IdleUpdate
```

Members

Member Name	Description
updateUnknown	The server has sent an unrecognized notification message. This does not necessarily reflect an error condition, as some servers may send additional notification messages beyond the standard EXISTS, EXPUNGE and RECENT messages. Most applications should ignore this type of notification.
updateMessage	The server has sent notification message to the client indicating that a new message has arrived. Typically this update notification occurs shortly after the new message has been stored in the current mailbox.
updateExpunge	The server has sent a notification message to the client indicating that a message has been removed from the current mailbox. It is recommended that the application re-examine the mailbox when this notification is received. Typically this notification is only sent periodically by the server, and may not be sent immediately after a message has been expunged from the mailbox.
updateMailbox	The server has sent notification message to the client indicating that the state of the mailbox has changed. This message is sent periodically by the server and may not be sent immediately after a new message arrives or a message is flagged as unread. It is recommended that the application re-examine the mailbox when this notification is received.

SocketTools Namespace | OnUpdate

InternetMail.ImapFlags Enumeration

Specifies the mailbox and message flags that the InternetMail class supports when connected to a mail server using the IMAP4 protocol.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetMail.ImapFlags
```

[C#]

```
[Flags]
public enum InternetMail.ImapFlags
```

Members

Member Name	Description	Value
flagNone	No flags have been set for the current message or mailbox.	0
flagAnswered	The message has been answered.	1
flagDraft	The message is a draft copy and has not been delivered.	2
flagUrgent	The message has been flagged for urgent or special attention.	4
flagSeen	The message has been read.	8
flagRecent	The message has been added to the mailbox recent.	256
flagDeleted	The message has been marked for deletion.	512
flagNoInferiors	The mailbox does not contain any child mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.	65536
flagNoSelect	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not an actual mailbox.	131072
flagMarked	The mailbox is marked as being of interest to a client. If this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.	262144
flagUnmarked	The mailbox is marked as not being of	524288

	interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

SocketTools Namespace

InternetMail.ImapResult Enumeration

Specifies the result codes that the InternetMail class supports.

[Visual Basic]
```
Public Enum InternetMail.ImapResult
```

[C#]
```
public enum InternetMail.ImapResult
```

Members

Member Name	Description
resultUnknown	An unknown result code was returned by the server.
resultOk	The previous command completed successfully. The result string contains information about the results of the command.
resultNo	The previous command could not be completed. The result string contains information about why the command failed.
resultBad	The previous command could not be completed, the command may be invalid or not supported on the server. The result string contains information about why the command failed.
resultContinue	The command has executed and is waiting for additional data from the client.

InternetMail.ImapSections Enumeration

Specifies the message sections that the InternetMail class supports when connected to a mail server using the IMAP4 protocol.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum InternetMail.ImapSections
```

```
[C#]
[Flags]
public enum InternetMail.ImapSections
```

Members

Member Name	Description	Value
sectionDefault	All headers and the complete body of the specified message or message part are to be retrieved. The client application is responsible for parsing the header block. If the message is a MIME multipart message and the complete message is returned, the application is responsible for parsing the individual message parts if necessary.	0
sectionHeader	All headers for the specified message or message part are to be retrieved. The client application is responsible for parsing the header block.	1
sectionMimeHeader	The MIME headers for the specified message or message are to be retrieved. Only those header fields which are used in MIME messages, such as Content-Type will be returned to the client. This is typically useful when processing the header for a multipart message which contains file attachments. The client application is responsible for parsing the header block.	2
sectionBody	The body of the specified message or message part will be retrieved. For a MIME formatted message, this may include data that is uuencoded or base64 encoded. The application is responsible for decoding this data.	4
sectionPreview	The message header or body is being previewed and should not be marked as read by the server. This prevents the	4096

	message from having the IMAP_FLAG_SEEN flag from being automatically set when the message data is retrieved.	

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

SocketTools Namespace

InternetMail.InternetMailOptions Enumeration

Specifies the options that the InternetMail class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetMail.InternetMailOptions
```

[C#]

```
[Flags]
public enum InternetMail.InternetMailOptions
```

Remarks

The InternetMail class uses the **InternetMailOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionAuthLogin	This option specifies the client should attempt to authenticate with the mail server when submitting messages for delivery. This option is typically required when relaying messages through a server to a recipient in a different domain.	1
optionAllHeaders	Preserves all headers in the message when it is exported, including the Received and Return-Path headers which are normally excluded.	256
optionKeepOrder	Preserves the order of the headers when it is exported; by default, some headers may be re-ordered.	512
optionSecure	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using either the SSL or TLS protocol.	4096
optionExplicitSSL	This option specifies the client should attempt to establish a secure explicit SSL session. The initial connection to the server is not encrypted, and the client will attempt to negotiate a secure connection by sending a command to the server. Some servers may require this option when connecting to the	4096

	server on ports other than the default secure port.	
optionImplicitSSL	This option specifies the client should attempt to establish a secure implicit SSL session. The SSL handshake is initiated immediately after the connection to the server has been established.	8192
optionSecureFallback	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768
optionFreeThread	This option specifies that class methods may be called from any thread, and not only the thread that established the connection. Using this option disables certain internal safety checks that are made by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads.	524288
optionNotify	Notify the sender of the delivery status of the message, if the server supports delivery status notification. This option is a combination of the optionNotifySuccess, optionNotifyFailure, optionNotifyDelay and optionReturnHeaders options.	983040
optionNotifySuccess	If the mail server supports delivery status notification, this causes a message to be returned to the sender once it has been successfully delivered.	65536
optionNotifyFailure	If the mail server supports delivery status notification, this causes a message to be returned to the sender if it could not be delivered.	131072
optionNotifyDelay	If the mail server supports delivery status notification, this causes a message to be returned to the sender if delivery has been delayed.	262144
optionReturnHeaders	If the mail server supports delivery status notification, this causes a message to be returned which contains the headers of the message that was sent.	524288

optionReturnMessage	If the mail server supports delivery status notification, this causes a message to be returned which contains the complete message that was sent.	1048576

SocketTools Namespace

InternetMail.MailServerType Enumeration

Specifies the type of mail server that the client is connected to.

[Visual Basic]
```
Public Enum InternetMail.MailServerType
```

[C#]
```
public enum InternetMail.MailServerType
```

Members

Member Name	Description
serverUnknown	The server type has not been explicitly set. The server type will be automatically determined by the value of the service port number specified by the value of the **ServerPort** property.
serverPop3	The Post Office Protocol is used when establishing a connection to the mail server.
serverImap4	The Internet Message Access Protocol is used when establishing a connection to the mail server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

SocketTools Namespace | ServerType Property (SocketTools.InternetMail)

InternetMail.MimeAttachment Enumeration

Specifies the file attachment options supported by the InternetMail class.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum InternetMail.MimeAttachment
```

```
[C#]
[Flags]
public enum InternetMail.MimeAttachment
```

Remarks

The **attachAlternative** and **attachInline** values can be combined with one of the attachment options using a bitwise OR operator.

Members

Member Name	Description	Value
attachDefault	The file attachment encoding is based on the file content type. Text files are not encoded, and binary files are encoded using the standard base64 encoding algorithm. This is the default option for file attachments.	0
attachBase64	The file attachment is always encoded using the standard base64 algorithm, even if the attached file is a plain text file.	1
attachUucode	The file attachment is always encoded using the uuencode algorithm, even if the attached file is a plain text file.	2
attachQuoted	The file attachment is always encoded using the quoted-printable algorithm, even if the attached file is a plain text file.	3
attachAlternative	The attached data is an alternative format for the contents of the message. This can only be used with textual data.	65536
attachInline	The attached data will be displayed inline with the contents of the message. This is typically used with images that are to be displayed along with the message text.	131072

SocketTools Namespace

InternetMail.MimeCharacterSet Enumeration

Specifies the character sets recognized by the InternetMail class.

[Visual Basic]

```
Public Enum InternetMail.MimeCharacterSet
```

[C#]

```
public enum InternetMail.MimeCharacterSet
```

Members

Member Name	Description
charsetUnknown	The character set is unknown.
charsetDefault	The default character set. This is the same as specifying the character set **charsetUTF8**.
charsetUSASCII	A character set using US-ASCII which defines 7-bit printable characters with values ranging from 20h to 7Eh. An application that uses this character set has the broadest compatibility with most mail servers (MTAs) because it does not require the server to handle 8-bit characters correctly when the message is delivered. This is the most commonly used character set for plain text email messages in the English language and is the default character set used by the class.
charsetISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1. The Windows code page for this character set is 28591, however Windows code page 1252 (Windows-1252) is typically used to represent this character set in most applications.
charsetISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2. This character set is similar to Windows code page 1250, however the characters are arranged differently.
charsetISO8859_3	A character set for southern European languages such as Maltese and Esperanto. This character set was also used with the Turkish language, but it was superseded by ISO 8859-9 which is the preferred character set for Turkish. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
charsetISO8859_4	A character set for northern European languages such as Latvian, Lithuanian and Greenlandic. This character set is not widely used in mail messages

	and it is recommended that you use UTF-8 instead.
charsetISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian. The Windows code page for this character set is 28595. This character set is not widely used and it is recommended that you use UTF-8 instead.
charsetISO8859_6	An 8-bit character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs. This character set is not widely used and it is recommended that you use UTF-8 instead.
charsetISO8859_7	An 8-bit character set for the Greek language. This character set is also commonly referred to as Latin/Greek. The Windows code page for this character set is 28597.
charsetISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English. The Windows code page for this character set is 28598.
charsetISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5. The Windows code page for this character set is 28599.
charsetISO8859_10	A character set for the Danish, Icelandic, Norwegian and Swedish languages. This character set is also commonly referred to as Latin-6 and is similar to ISO 8859-4.
charsetISO8859_13	A character set for Baltic languages. This character set is also commonly referred to as Latin-7. This character set is similar to ISO 8859-4, except it adds certain Polish characters and does not support Nordic languages.
charsetISO8859_14	A character set for Gaelic languages such as Irish, Manx and Scottish Gaelic. This character set is also commonly referred to as Latin-8. This character set replaced ISO 8859-12 which was never fully implemented.
charsetISO8859_15	A character set for western European languages. This character set is also commonly referred to as Latin-9 and is nearly identical to ISO8859-1 except

	that it replaces lesser-used symbols with the Euro sign and some letters.
charsetISO2022_JP	A multi-byte character encoding for Japanese that is widely used with mail messages. This is a 7-bit encoding where all characters start with ASCII and uses escape sequences to switch to the double-byte character sets.
charsetISO2022_KR	A multi-byte character encoding for Korean which encodes both ASCII and Korean double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
charsetISO2022_CN	A multi-byte character encoding for Simplified Chinese which encodes both ASCII and Chinese double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
charsetKOI8R	A character set for Russian using the Cyrillic alphabet. This character set also covers the Bulgarian language. Most mail messages in the Russian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
charsetKOI8U	A character set for Ukrainian using the Cyrillic alphabet. This character set is similar to the KOI8-R character set, but replaces certain symbols with Ukrainian letters. Most mail messages in the Ukrainian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
charsetGB2312	A multi-byte character encoding which can represent ASCII and simplified Chinese characters. It has been superseded by GB18030, however it remains widely used in China.
charsetGB18030	A Unicode transformation format which can represent all Unicode code points and supports both simplified and traditional Chinese characters. It is backwards compatible with GB2312 and supersedes that character set.
charsetBIG5	A multi-byte character set that supports both ASCII characters and traditional Chinese characters. It is widely used in Taiwan, Hong Kong and Macau. It is no longer commonly used in China, which has developed GB18030 as a standard encoding. Note that Microsoft's implementation of Big5 on Windows does not support all of the extensions and is missing certain

	code points.
charsetUTF7	A 7-bit Unicode Transformation Format that uses variable-length character encoding to represent Unicode text as a stream of ASCII characters that are safe to transport between mail servers that only support 7-bit printable characters. It is primarily used as an alternative to UTF-8 which requires that the mail server support 8-bit text or use quoted-printable encoding.
charsetUTF8	An 8-bit Unicode Transformation Format that uses multibyte character sequences to represent Unicode text. It is backwards compatible with the ASCII character set, however because it uses 8-bit text, it should be encoded using either quoted-printable or base64 encoding to ensure that mail servers that do not support 8-bit characters.
charsetUTF16	A 16-bit Unicode Transformation Format that uses two bytes to represent each Unicode character. Messages that use UTF-16 are commonly encoded using the base64 algorithm. It is recommended that most applications use the UTF-8 character set, which is capable of representing all Unicode characters.

InternetMail.MimeContent Enumeration

Specifies the content types supported by the InternetMail class.

[Visual Basic]

```
Public Enum InternetMail.MimeContent
```

[C#]

```
public enum InternetMail.MimeContent
```

Members

Member Name	Description
contentUnknown	The content type is unknown. This value may be returned if the message handle is invalid, or if the file extension is unknown and the file could not be opened for read access.
contentDefault	The default content type. This is the same as specifying the content type **contentText**.
contentApplication	The content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
contentAudio	The content is audio data in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
contentImage	The content is an image data in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
contentMessage	The content is an email message encapsulated within the current message.
contentMultipart	The content is a multipart MIME email message which contains additional message parts. For example, an email message which contains both a text message and file attachment would be identified as a multipart message.
contentText	The content is textual data. This is also the default type for files which have an unrecognized file name extension and contain only printable text.
contentVideo	The content is video data in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.
contentWideText	The content is Unicode text. This is also the default type for files which have an unrecognized file

	name extension. The content must be prefixed with a byte order mark (BOM) to be recognized as Unicode text.

SocketTools Namespace

InternetMail.MimeEncoding Enumeration

Specifies the encoding types supported by the InternetMail class.

[Visual Basic]
```
Public Enum InternetMail.MimeEncoding
```

[C#]
```
public enum InternetMail.MimeEncoding
```

Members

Member Name	Description
encodingUnknown	The encoding type is unknown.
encodingDefault	The encoding type is based on the content type. Text data is not encoded, and binary data is encoded using the standard base64 encoding algorithm. This is the default option for file attachments.
encoding7Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
encoding8Bit	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
encodingBinary	The data contains unmodified 8-bit data. This encoding type is rarely specified for email messages because not all mail servers are capable of transmitting 8-bit data. In most cases, messages which contain binary data are encoded using the base64 algorithm.
encodingQuoted	The data is encoded using quoted-printable encoding. Printable ASCII characters are left as-is, with non-printable characters encoded as their hexadecimal value. Quoted-printable encoding is commonly used with HTML formatted email messages.
encodingBase64	The data is encoded using the standard base64 algorithm. This is the most common encoding method for binary data in an email message.
encodingUucode	The data is encoded using the uuencode algorithm. This encoding method is common for binary attachments to news articles, but is rarely

	used with email messages.

InternetMail.MimeExportOptions Enumeration

Specifies the export options that the InternetMail class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetMail.MimeExportOptions
```

[C#]

```
[Flags]
public enum InternetMail.MimeExportOptions
```

Members

Member Name	Description	Value
exportDefault	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.	0
exportAllHeaders	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.	1
exportKeepOrder	The original order in which the message header fields were set or imported are preserved when the message is exported.	2

InternetMail.PopAuthentication Enumeration

Specifies the authentication methods supported by the InternetMail class when connected to a mail server using the POP3 protocol.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetMail.PopAuthentication
```

[C#]

```
[Flags]
public enum InternetMail.PopAuthentication
```

Members

Member Name	Description	Value
authDefault	The default authentication type. This is the same as specifying the **authPass** authentication type.	0
authPassword	Standard cleartext username and password is sent to the server. This authentication method is supported by all servers.	0
authApop	The APOP authentication method which uses an MD5 digest of the password. This method is not supported by all servers and should only be specified if required by the server.	1

InternetMail.SecureCipherAlgorithm Enumeration

Specifies the encryption algorithms that the InternetMail class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]
```
<Flags>
Public Enum InternetMail.SecureCipherAlgorithm
```

[C#]
```
[Flags]
public enum InternetMail.SecureCipherAlgorithm
```

Remarks

The InternetMail class uses the **SecureCipherAlgorithm** enumeration to identify which encryption algorithm was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
cipherNone	No cipher has been selected. A secure connection has not been established with the remote host.	0
cipherRC2	The RC2 block cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	1
cipherRC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40- and 128-bits in length, in 8-bit increments.	2
cipherRC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.	4
cipherDES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher using 56-bit keys.	8
cipherDES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively using a 168-bit key length.	16
cipherDESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.	32
cipherAES	The Advanced Encryption Standard	64

	cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 SP3 and later versions of the operating system.	
cipherSkipjack	The Skipjack block cipher was selected. This is a fixed key length cipher, using 80-bit keys.	128

InternetMail.SecureHashAlgorithm Enumeration

Specifies the hash algorithms that the InternetMail class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum InternetMail.SecureHashAlgorithm
```

```
[C#]
[Flags]
public enum InternetMail.SecureHashAlgorithm
```

Remarks

The InternetMail class uses the **SecureHashAlgorithm** enumeration to identify the message digest (hash) algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
hashNone	No hash algorithm has been selected. This is not a secure connection with the server.	0
hashMD5	The MD5 algorithm was selected. This algorithm produces a 128-bit message digest. This algorithm is no longer considered to be cryptographically secure.	1
hashSHA	The SHA-1 algorithm was selected. This algorithm produces a 160-bit message digest. This algorithm is no longer considered to be cryptographically secure.	2
hashSHA256	The SHA-256 algorithm was selected. This algorithm produces a 256-bit message digest.	4
hashSHA384	The SHA-384 algorithm was selected. This algorithm produces a 384-bit message digest.	8
hashSHA512	The SHA-512 algorithm was selected. This algorithm produces a 512-bit message digest.	16

InternetMail.SecureKeyAlgorithm Enumeration

Specifies the key exchange algorithms that the InternetMail class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetMail.SecureKeyAlgorithm
```

[C#]

```
[Flags]
public enum InternetMail.SecureKeyAlgorithm
```

Remarks

The InternetMail class uses the **SecureKeyAlgorithm** enumeration to identify the key exchange algorithm that was selected when a secure connection was established with the remote host.

Members

Member Name	Description	Value
keyExchangeNone	No key exchange algorithm has been selected. This is not a secure connection with the server.	0
keyExchangeRSA	The RSA public key exchange algorithm has been selected.	1
keyExchangeKEA	The KEA public key exchange algorithm has been selected. This is an improved version of the Diffie-Hellman public key algorithm.	2
keyExchangeDH	The Diffie-Hellman public key exchange algorithm has been selected.	4
keyExchangeECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 SP3 and later versions of the operating system.	8

SocketTools Namespace

InternetMail.SecurityCertificate Enumeration

Specifies the security certificate status values that may be returned by the InternetMail class.

[Visual Basic]

```
Public Enum InternetMail.SecurityCertificate
```

[C#]

```
public enum InternetMail.SecurityCertificate
```

Remarks

The InternetMail class uses the **SecurityCertificate** enumeration to identify the current status of the certificate that was provided by the remote host when a secure connection was established.

Members

Member Name	Description
certificateNone	No certificate information is available. A secure connection was not established with the server.
certificateValid	The certificate is valid.
certificateNoMatch	The certificate is valid, however the domain name specified in the certificate does not match the domain name of the remote host. The application can examine the **CertificateSubject** property to determine the site the certificate was issued to.
certificateExpired	The certificate has expired and is no longer valid. The application can examine the **CertificateExpires** property to determine when the certificate expired.
certificateRevoked	The certificate has been revoked and is no longer valid. It is recommended that the application immediately terminate the connection if this status is returned.
certificateUntrusted	The certificate has not been issued by a trusted authority, or the certificate is not trusted on the local host. It is recommended that the application immediately terminate the connection if this status is returned.
certificateInvalid	The certificate is invalid. This typically indicates that the internal structure of the certificate is damaged. It is recommended that the application immediately terminate the connection if this status is returned.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

SocketTools Namespace

InternetMail.SecurityProtocols Enumeration

Specifies the security protocols that the InternetMail class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetMail.SecurityProtocols
```

[C#]

```
[Flags]
public enum InternetMail.SecurityProtocols
```

Remarks

The InternetMail class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when creating a secure connection.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

InternetMail.ThreadingModel Enumeration

Specifies the threading model used by the class instance.

[Visual Basic]

```
Public Enum InternetMail.ThreadingModel
```

[C#]

```
public enum InternetMail.ThreadingModel
```

Remarks

The threading model **modelSingleThread** does not limit the application to a single thread of execution. It specifies that only a single thread may invoke methods in a class instance. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

The threading model **modelFreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Members

Member Name	Description
modelSingleThread	Methods in the class instance may only be invoked by a single thread. This threading model specifies that only the thread which established the connection should be permitted to invoke methods. This is the default threading model.
modelFreeThread	Methods in the class instance may be invoked by any thread. This threading model permits methods to be invoked across multiple threads without being explicitly attached to the object.

InternetMail.ThreadModelAttribute.Model Enumeration

Specifies the threading model used by the class instance.

[Visual Basic]
```
Public Enum InternetMail.ThreadModelAttribute.Model
```

[C#]
```
public enum InternetMail.ThreadModelAttribute.Model
```

Remarks

The threading model **SingleThread** does not limit the application to a single thread of execution. It specifies that only a single thread may invoke methods in a class instance. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

The threading model **FreeThread** disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Members

Member Name	Description
SingleThread	Methods in the class instance may only be invoked by a single thread. This threading model specifies that only the thread which established the connection should be permitted to invoke methods. This is the default threading model.
FreeThread	Methods in the class instance may be invoked by any thread. This threading model permits methods to be invoked across multiple threads without being explicitly attached to the object.

InternetMail.TraceOptions Enumeration

Specifies the logging options that the InternetMail class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetMail.TraceOptions
```

[C#]

```
[Flags]
public enum InternetMail.TraceOptions
```

Remarks

The InternetMail class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

SocketTools Namespace

InternetMail.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see InternetMail.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.InternetMail.RuntimeLicenseAttribute

[Visual Basic]
```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class InternetMail.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]
```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class InternetMail.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the InternetMail class.

Example

```
<Assembly: SocketTools.InternetMail.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.InternetMail.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

InternetMail.RuntimeLicenseAttribute overview

Public Instance Constructors

InternetMail.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetMail.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetMail.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public InternetMail.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key for your copy of SocketTools can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the InternetMail class.

InternetMail.RuntimeLicenseAttribute Properties

The properties of the **InternetMail.RuntimeLicenseAttribute** class are listed below. For a complete list of **InternetMail.RuntimeLicenseAttribute** class members, see the InternetMail.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

InternetMail.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetMail.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

InternetMail.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetMail.ThreadModelAttribute Class

Attribute that defines the threading model for the class.

For a list of all members of this type, see InternetMail.ThreadModelAttribute Members.

System.Object
  System.Attribute
    SocketTools.InternetMail.ThreadModelAttribute

[Visual Basic]
```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False, Inherited:=True)>
Public Class InternetMail.ThreadModelAttribute
    Inherits Attribute
```

[C#]
```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False, Inherited=True)]
public class InternetMail.ThreadModelAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The ThreadModel attribute is used to define the threading model that is to be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#.

Example

```
<Assembly:
SocketTools.InternetMail.ThreadModel(SocketTools.InternetMail.ThreadModelAttribute.Model.SingleThread)>
```

```
[assembly:
SocketTools.InternetMail.ThreadModel(SocketTools.InternetMail.ThreadModelAttribute.Model.SingleThread)]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

InternetMail.ThreadModelAttribute overview

Public Instance Constructors

InternetMail.ThreadModelAttribute Constructor	Constructor for the ThreadModel attribute which defines the threading model.

Public Instance Properties

ThreadModel	Returns the threading model used by the class.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetMail.ThreadModelAttribute Class | SocketTools Namespace | ThreadModel Property (SocketTools.InternetMail)

InternetMail.ThreadModelAttribute Constructor

Constructor for the ThreadModel attribute which defines the threading model.

[Visual Basic]

```
Public Sub New( _
   ByVal threadModel As Model _
)
```

[C#]

```
public InternetMail.ThreadModelAttribute(
   Model threadModel
);
```

Parameters

threadModel

A Model enumeration value which specifies the threading model which will be used when creating an instance of the class. A value of zero specifies a single threaded model, while a non-zero value specifies a free threaded model.

Remarks

The **ThreadModel** attribute specifies the threading model that is used by the class instance when a connection is established. The default threading model is single threaded, which specifies that only the thread that established the connection should be permitted to invoke methods.

It is important to note that the single threading model does not limit the application to a single thread of execution. When a session is established using the **Connect** method, that session is attached to the thread that created it. From that point on, until the session is terminated, only the owner may invoke methods in that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Setting this attribute to a non-zero value disables certain internal safety checks that are performed by the class and may result in unexpected behavior unless you ensure that access to the class instance is synchronized across multiple threads. The application must ensure that no two threads will attempt to invoke a blocking method at the same time. In other words, if one thread invokes a method, the application must ensure that another thread will not attempt to invoke any other method at the same time using the same instance of the class.

Changing the value of this attribute will also change the default value for the **ThreadModel** property for all instances of the class.

InternetMail.ThreadModelAttribute Properties

The properties of the **InternetMail.ThreadModelAttribute** class are listed below. For a complete list of **InternetMail.ThreadModelAttribute** class members, see the InternetMail.ThreadModelAttribute Members topic.

Public Instance Properties

ThreadModel	Returns the threading model used by the class.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

InternetMail.ThreadModelAttribute Class | SocketTools Namespace | ThreadModel Property (SocketTools.InternetMail)

InternetMail.ThreadModelAttribute.ThreadModel Property

Returns the threading model used by the class.

[Visual Basic]

```
Public Property ThreadModel As Model
```

[C#]

```
public InternetMail.ThreadModelAttribute.Model ThreadModel {get; set;}
```

Property Value

A Model enumeration value which specifies the threading model which will be used when an instance of the class is created.

See Also

InternetMail.ThreadModelAttribute Class | SocketTools Namespace

InternetMailException Class

The exception that is thrown when a client error occurs.

For a list of all members of this type, see InternetMailException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.InternetMailException

[Visual Basic]

```
Public Class InternetMailException
    Inherits ApplicationException
```

[C#]

```
public class InternetMailException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A InternetMailException is thrown by the InternetMail class when an error occurs.

The default constructor for the InternetMailException class sets the **ErrorCode** property to the last client error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetMail (in SocketTools.InternetMail.dll)

See Also

InternetMailException Members | SocketTools Namespace

InternetMailException overview

Public Instance Constructors

InternetMailException	Overloaded. Initializes a new instance of the InternetMailException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetMailException Class | SocketTools Namespace

InternetMailException Constructor

Initializes a new instance of the InternetMailException class with the last network error code.

Overload List

Initializes a new instance of the InternetMailException class with the last network error code.

public InternetMailException();

Initializes a new instance of the InternetMailException class with a specified error number.

public InternetMailException(int);

Initializes a new instance of the InternetMailException class with a specified error message.

public InternetMailException(string);

Initializes a new instance of the InternetMailException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public InternetMailException(string,Exception);

See Also

InternetMailException Class | SocketTools Namespace

InternetMailException Constructor ()

Initializes a new instance of the InternetMailException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public InternetMailException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last client error that occurred. For more information about the errors that may occur, refer to the InternetMail.ErrorCode enumeration.

See Also

InternetMailException Class | SocketTools Namespace | InternetMailException Constructor Overload List

InternetMailException Constructor (String)

Initializes a new instance of the InternetMailException class with a specified error message.

```
[Visual Basic]
Overloads Public Sub New( _
   ByVal message As String _
)
```

```
[C#]
public InternetMailException(
   string message
);
```

Parameters

message
The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

InternetMailException Class | SocketTools Namespace | InternetMailException Constructor Overload List

InternetMailException Constructor (String, Exception)

Initializes a new instance of the InternetMailException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public InternetMailException(
   string message,
   Exception innerException
);
```

Parameters

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the ***innerException*** parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

InternetMailException Class | SocketTools Namespace | InternetMailException Constructor Overload List

InternetMailException Constructor (Int32)

Initializes a new instance of the InternetMailException class with a specified error number.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal code As Integer _
)
```

[C#]

```
public InternetMailException(
   int code
);
```

Parameters

code

An integer value which specifies an error code.

Remarks

This constructor sets the **ErrorCode** property to the specified error code. For more information about the errors that may occur, refer to the InternetMail.ErrorCode enumeration.

See Also

InternetMailException Class | SocketTools Namespace | InternetMailException Constructor Overload List

InternetMailException Properties

The properties of the **InternetMailException** class are listed below. For a complete list of **InternetMailException** class members, see the InternetMailException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

InternetMailException Class | SocketTools Namespace

InternetMailException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public InternetMail.ErrorCode ErrorCode {get;}
```

Property Value

Returns a InternetMail.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the InternetMailException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the InternetMail.ErrorCode enumeration.

See Also

InternetMailException Class | SocketTools Namespace

InternetMailException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

InternetMailException Class | SocketTools Namespace

InternetMailException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value is the same as the values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

See Also

InternetMailException Class | SocketTools Namespace

InternetMailException Methods

The methods of the **InternetMailException** class are listed below. For a complete list of **InternetMailException** class members, see the InternetMailException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetMailException Class | SocketTools Namespace

InternetMailException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

InternetMailException Class | SocketTools Namespace

InternetServer Class

A general purpose class for developing Internet server applications.

For a list of all members of this type, see InternetServer Members.

System.Object
  SocketTools.InternetServer

[Visual Basic]
```
Public Class InternetServer
    Implements IDisposable
```

[C#]
```
public class InternetServer : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The **InternetServer** class provides a simplified interface for creating event-driven, multithreaded server applications using the TCP/IP protocol. The class interface is similar to the **SocketWrench** class, however it is designed specifically to make it easier to implement a server application without requiring the need to manage multiple socket classes. In addition, the **InternetServer** class supports secure communications using the Transport Layer Security (TLS) protocol.

Each instance of the class represents a server, and each active client connection is managed internally and referenced by an integer value which uniquely identifies the client session. All interaction with the server and the clients connected to it uses an event-driven model, with the server application written to respond to events such as **OnConnect**, **OnRead** and **OnWrite**.

Developers who have used the **SocketWrench** class will find the **InternetServer** class has a familiar interface, with a subset of properties and methods that are specific to creating a server application. Each of the network events have an extra parameter which specifies the socket handle which should be used when communicating with the client. This enables the application to communicate with multiple clients without having to create multiple socket classes.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

InternetServer overview

Public Instance Constructors

InternetServer Constructor	Initializes a new instance of the InternetServer class.

Public Instance Fields

AdapterAddress	Returns the IP address associated with the specified network adapter.
ClientHandle	Return the socket handle associated with a specific client session.

Public Instance Properties

AdapterCount	Get the number of available local and remote network adapters.
Backlog	Gets and sets the number of client connections that may be queued by the server.
CertificateName	Gets and sets a value that specifies the name of the server certificate.
CertificatePassword	Gets and sets the password associated with the server certificate.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateUser	Gets and sets the user that owns the server certificate.
ClientAddress	Gets a value that specifies the Internet address of the current client session.
ClientCount	Gets the number of active client sessions connected to the server.
ClientHost	Gets a value that specifies the hostname for the current client session.
ClientId	Gets the unique client identifier for the current client session.
ClientName	Gets and sets a unique string moniker that is associated with the current client session.
ClientPort	Gets a value that specifies the port number used by the current client session.
ClientThread	Gets the thread ID for the current client session.
CodePage	Gets and sets the code page used when reading and writing text.
ExternalAddress	Gets a value that specifies the external Internet

	address for the local system.
IdleTime	Gets a value which specifies the amount of time a socket has been idle
IsActive	Gets a value which indicates if the server is active.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking socket operation.
IsClosed	Gets a value which indicates if the connection to the client has been closed.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsListening	Gets a value which indicates if the server is listening for client connections.
IsLocked	Gets a value which indicates if the server has been locked.
IsReadable	Gets a value which indicates if there is data available to be read from the current client.
IsWritable	Gets a value which indicates if data can be written to the current client without blocking.
KeepAlive	Gets and sets a value which indicates if keep-alive packets are sent on a connected socket.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
MaxClients	Gets and sets the maximum number of clients that can connect to the server.
NoDelay	Gets and sets a value which specifies if the Nagle algorithm should be enabled or disabled.
Options	Gets and sets a value which specifies one or more server options.
Priority	Gets and sets a value which specifies the server priority.
ReuseAddress	Gets and sets a value which indicates if the server address can be reused.
Secure	Gets and sets a value which specifies if client connections are secure.
SecureProtocol	Gets and sets a value which specifies the protocol used for secure client connections.
ServerAddress	Gets and sets the address that will be used by the server to listen for connections.
ServerHandle	Gets the handle to the socket created to listen for client connections.

ServerName	Gets a value which specifies the host name for the local system.
ServerPort	Gets and sets the port number that will be used by the server to listen for connections.
ServerThread	Gets the thread ID for the current server.
StackSize	Gets and sets the size of the stack allocated for threads created by the server.
Status	Gets a value which specifies the current status of the server.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the network function tracing logfile.
TraceFlags	Gets and sets a value which specifies the network function tracing flags.
Version	Gets a value which returns the current version of the InternetServer class library.

Public Instance Methods

Abort	Overloaded. Abort the connection with a remote host.
Broadcast	Overloaded. Broadcast data to all active clients connected to the server
Cancel	Overloaded. Cancel the current blocking socket operation.
Disconnect	Overloaded. Disconnect the specified client connection from the server.
Dispose	Overloaded. Releases all resources used by InternetServer.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
FindClient	Overloaded. Return the socket handle for the client session with the specified moniker.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the

	InternetServer class.
Lock	Lock the server to synchronize access to shared data for all active client sessions.
Peek	Overloaded. Read data from the client and store it in a byte array, but do not remove the data from the socket buffers.
Read	Overloaded. Read data from the client socket and store it in a byte array.
ReadLine	Overloaded. Read up to a line of data from the client and return it in a string buffer.
Reject	Overloaded. Rejects a connection request from a client.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Resolve	Resolves a host name to a host IP address.
Restart	Restarts the server and terminates all active client connections.
Resume	Resume accepting new client connections.
Start	Overloaded. Start listening for client connections on the specified IP address and port number.
Stop	Stop listening for new client connections and terminate all active clients already connected to the server.
Suspend	Overloaded. Suspend accepting new client connections with additional options.
Throttle	Overloaded. Limit the maximum number of client connections, connections per IP address and connection rate.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the server.
Unlock	Unlock the server and allow other server threads to resume execution.
Write	Overloaded. Write one or more bytes of data to a client.
WriteLine	Overloaded. Send a line of text to a client, terminated by a carriage-return and linefeed.

Public Instance Events

OnAccept	Occurs when a client attempts to establish a connection with the server.
OnCancel	Occurs when a blocking socket operation is canceled.

OnConnect	Occurs when a connection is established with the remote host.
OnDisconnect	Occurs when the remote host disconnects from the local system.
OnError	Occurs when an socket operation fails.
OnIdle	Occurs when the there are no clients connected to the server.
OnRead	Occurs when data is available to be read from the client.
OnStart	Occurs when the server starts accepting connections.
OnStop	Occurs when the server stops accepting connections.
OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
OnWrite	Occurs when data can be written to the client.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the InternetServer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetServer Class | SocketTools Namespace

InternetServer Constructor

Initializes a new instance of the InternetServer class.

[Visual Basic]

```
Public Sub New()
```

[C#]

```
public InternetServer();
```

Example

The following example demonstrates creating an instance of the **InternetServer** class object and starting a server using the Start method.

```
Dim Server As SocketTools.InternetServer
Dim strLocalAddress As String
Dim nLocalPort As Integer

Server = New SocketTools.InternetServer

strLocalAddress = TextBox1.Text.Trim()
nLocalPort = Val(TextBox2.Text)

If Server.Start(strLocalAddress, nLocalPort) Then
    StatusBar1.Text = "The server has started listening for connections"
Else
    StatusBar1.Text = "The server could not be started"
End If
```

See Also

InternetServer Class | SocketTools Namespace

InternetServer Fields

The fields of the **InternetServer** class are listed below. For a complete list of **InternetServer** class members, see the InternetServer Members topic.

Public Instance Fields

◆ AdapterAddress	Returns the IP address associated with the specified network adapter.
◆ ClientHandle	Return the socket handle associated with a specific client session.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.AdapterAddress Field

Returns the IP address associated with the specified network adapter.

[Visual Basic]

```
Public ReadOnly AdapterAddress As AdapterAddressArray
```

[C#]

```
public readonly AdapterAddressArray AdapterAddress;
```

Remarks

The **AdapterAddress** array returns the IP addresses that are associated with the local network or remote dial-up network adapters configured on the system. The **AdapterCount** property can be used to determine the number of adapters that are available.

Multihomed systems with more than one local network adapter, or a combination of local and dial-up adapters will not be listed in a specific order. An application should not make the assumption that the first address returned by **AdapterAddress** always refers to a local network adapter.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress** property will return the IP address allocated for that connection.

See Also

InternetServer Class | SocketTools Namespace | AdapterAddressArray Class | AdapterCount Property

InternetServer.ClientHandle Field

Return the socket handle associated with a specific client session.

[Visual Basic]
```
Public ReadOnly ClientHandle As ClientHandleArray
```

[C#]
```
public readonly ClientHandleArray ClientHandle;
```

Remarks

The **ClientHandle** array is a read-only, zero-based property array that returns the socket handle allocated for the client session specified by the Index parameter. An exception will be thrown if the index value exceeds the maximum number of active client sessions. To determine the number of clients that are currently connected to the server, use the **ClientCount** property.

You should always check the value of the **ClientCount** property prior to enumerating through the client connections using the **ClientHandle** array. Never assume that a particular client session will always be found in the same position in the array. The socket handles returned by the array can be used in conjunction with the **Read** and **Write** methods to exchange data with a particular client session outside of an event handler.

The index into this array may also be a string which specifies the name of a client session, as set by the **ClientName** property. This can be a convenient way to obtain the socket handle for a specific client by name, rather than a numeric index.

InternetServer Class | SocketTools Namespace

InternetServer Properties

The properties of the **InternetServer** class are listed below. For a complete list of **InternetServer** class members, see the InternetServer Members topic.

Public Instance Properties

AdapterCount	Get the number of available local and remote network adapters.
Backlog	Gets and sets the number of client connections that may be queued by the server.
CertificateName	Gets and sets a value that specifies the name of the server certificate.
CertificatePassword	Gets and sets the password associated with the server certificate.
CertificateStore	Gets and sets a value that specifies the name of the local certificate store.
CertificateUser	Gets and sets the user that owns the server certificate.
ClientAddress	Gets a value that specifies the Internet address of the current client session.
ClientCount	Gets the number of active client sessions connected to the server.
ClientHost	Gets a value that specifies the hostname for the current client session.
ClientId	Gets the unique client identifier for the current client session.
ClientName	Gets and sets a unique string moniker that is associated with the current client session.
ClientPort	Gets a value that specifies the port number used by the current client session.
ClientThread	Gets the thread ID for the current client session.
CodePage	Gets and sets the code page used when reading and writing text.
ExternalAddress	Gets a value that specifies the external Internet address for the local system.
IdleTime	Gets a value which specifies the amount of time a socket has been idle
IsActive	Gets a value which indicates if the server is active.
IsBlocked	Gets a value which indicates if the current thread is performing a blocking socket operation.
IsClosed	Gets a value which indicates if the connection to the client has been closed.

IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
IsListening	Gets a value which indicates if the server is listening for client connections.
IsLocked	Gets a value which indicates if the server has been locked.
IsReadable	Gets a value which indicates if there is data available to be read from the current client.
IsWritable	Gets a value which indicates if data can be written to the current client without blocking.
KeepAlive	Gets and sets a value which indicates if keep-alive packets are sent on a connected socket.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
MaxClients	Gets and sets the maximum number of clients that can connect to the server.
NoDelay	Gets and sets a value which specifies if the Nagle algorithm should be enabled or disabled.
Options	Gets and sets a value which specifies one or more server options.
Priority	Gets and sets a value which specifies the server priority.
ReuseAddress	Gets and sets a value which indicates if the server address can be reused.
Secure	Gets and sets a value which specifies if client connections are secure.
SecureProtocol	Gets and sets a value which specifies the protocol used for secure client connections.
ServerAddress	Gets and sets the address that will be used by the server to listen for connections.
ServerHandle	Gets the handle to the socket created to listen for client connections.
ServerName	Gets a value which specifies the host name for the local system.
ServerPort	Gets and sets the port number that will be used by the server to listen for connections.
ServerThread	Gets the thread ID for the current server.
StackSize	Gets and sets the size of the stack allocated for threads created by the server.
Status	Gets a value which specifies the current status of

	the server.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
Timeout	Gets and sets a value which specifies a timeout period in seconds.
Trace	Gets and sets a value which indicates if network function logging is enabled.
TraceFile	Gets and sets a value which specifies the name of the network function tracing logfile.
TraceFlags	Gets and sets a value which specifies the network function tracing flags.
Version	Gets a value which returns the current version of the InternetServer class library.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.AdapterCount Property

Get the number of available local and remote network adapters.

[Visual Basic]
```
Public ReadOnly Property AdapterCount As Integer
```

[C#]
```
public int AdapterCount {get;}
```

Property Value

Returns the number of available local and remote network adapters.

Remarks

The **AdapterCount** property returns the number of local and remote dial-up networking adapters available on the local system. This value can be used in conjunction with the **AdapterAddress** array to enumerate the IP addresses assigned to the various network adapters.

Note that it is possible that the **AdapterCount** property will return 0, and **AdapterAddress** will return an empty string. This indicates that the system does not have a physical network adapter with an assigned IP address, and there are no dial-up networking connections currently active. If a dial-up networking connection is established at some later point, the **AdapterCount** property will change to 1, and the **AdapterAddress** property will return the IP address allocated for that connection.

See Also

InternetServer Class | SocketTools Namespace | AdapterAddress Field

InternetServer.Backlog Property

Gets and sets the number of client connections that may be queued by the server.

[Visual Basic]
```
Public Property Backlog As Integer
```

[C#]
```
public int Backlog {get; set;}
```

Property Value

Returns an integer value that specifies the size of the backlog queue. The default value is 5.

Remarks

The **Backlog** property specifies the maximum size of the queue used to manage pending connections to the service. If the property is set to value which exceeds the maximum size for the underlying service provider, it will be silently adjusted to the nearest legal value. There is no standard way to determine what the maximum backlog value is.

This property should be set to the desired value before the **Start** method is called. The default backlog value is 5 on all Windows platforms. The Windows Server platforms support a maximum backlog value of 200.

Note that this property does not specify the total number of connections that the server application may accept. It only specifies the size of the backlog queue which is used to manage pending client connections. Once the client connection has been accepted, it is removed from the queue. Set the **MaxClients** property to specify the maximum number of clients that may connect with the server.

InternetServer Class | SocketTools Namespace | IsListening Property | MaxClients Property | Start Method

InternetServer.CertificateName Property

Gets and sets a value that specifies the name of the server certificate.

[Visual Basic]

```
Public Property CertificateName As String
```

[C#]

```
public string CertificateName {get; set;}
```

Property Value

A string which specifies the server certificate name.

Remarks

The **CertificateName** property sets the common name or friendly name of the certificate that should be used when starting a secure server. If the **Secure** property is set to True, this property must be specify a valid certificate name. The certificate must have a private key associated with it, otherwise client connections will fail because the class will be unable to create a security context for the session.

When the certificate store is searched for a matching certificate, it will first search for any certificate with a friendly name that matches the property value. If no valid certificate is found, it will then search for a certificate with a matching common name.

Certificates may be installed and viewed on the local system using the Certificate Manager that is included with the Windows operating system. For more information, refer to the documentation for the Microsoft Management Console.

See Also

InternetServer Class | SocketTools Namespace | CertificateStore Property | Secure Property

InternetServer.CertificateStore Property

Gets and sets a value that specifies the name of the local certificate store.

[Visual Basic]
```
Public Property CertificateStore As String
```

[C#]
```
public string CertificateStore {get; set;}
```

Property Value

A string which specifies the certificate store name. The default value is the current user's personal certificate store.

Remarks

The **CertificateStore** property is used to specify the name of the certificate store which contains the security certificate to use when security is enabled for the server. The certificate may either be stored in the registry or in a file. If the certificate is stored in the registry, then this property should be set to one of the following predefined values:

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as VeriSign and Thawte act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. If a certificate store is not specified, this is the default value that is used.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as VeriSign and Thawte are installed as part of the operating system and periodically updated by Microsoft.

In most cases the server certificate will be installed in the user's personal certificate store, and therefore it is not necessary to set this property value because that is the default location that will be used to search for the certificate. This property is only used if the **CertificateName** property is also set to a valid certificate name.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU" for the current user, or "HKLM" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, it will default to the certificate store for the current user.

This property may also be used to specify a file that contains the server certificate. In this case, the property should specify the full path to the file and must contain both the certificate and private key in

PKCS12 format. If the file is protected by a password, the **CertificatePassword** property must also be set to specify the password.

See Also

InternetServer Class | SocketTools Namespace | CertificatePassword Property | Secure Property

InternetServer.ClientAddress Property

Gets a value that specifies the Internet address of the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientAddress As String
```

[C#]

```
public string ClientAddress {get;}
```

Property Value

A string which specifies an Internet address in dotted notation.

Remarks

The **ClientAddress** property returns the address of the current client session which has connected to the server. This property only returns a meaningful value inside an event handler such as **OnAccept** or **OnConnect**.

If this property is accessed inside an **OnAccept** event handler, it will return the address of the client that is requesting the connection. The server application may use this information to determine if it wishes to accept or reject the client connection.

See Also

InternetServer Class | SocketTools Namespace | ClientHost Property | ClientPort Property

InternetServer.ClientCount Property

Gets the number of active client sessions connected to the server.

[Visual Basic]

```
Public ReadOnly Property ClientCount As Integer
```

[C#]

```
public int ClientCount {get;}
```

Property Value

An integer value which specifies the number of active client sessions.

Remarks

The **ClientCount** read-only property returns the number of active client sessions that have been established with the server. This property is typically used in conjunction with the **ClientHandle** array to enumerate the handles for all client sessions.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.ClientHost Property

Gets a value that specifies the hostname for the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientHost As String
```

[C#]

```
public string ClientHost {get;}
```

Property Value

A string which specifies the peer host name.

Remarks

The **ClientHost** property returns the hostname of the current client session which has established a connection with the server. This property value is only meaningful when accessed within an event handler, such as the **OnConnect** event.

Accessing this property causes the class to perform a blocking reverse DNS lookup, attempting to match the client Internet address with a hostname. Not all addresses have a reverse DNS record, in which case this property will return an empty string. It is recommended that most applications use the value of the **ClientAddress** property rather than use the **ClientHost** property to distinguish between client connections.

See Also

InternetServer Class | SocketTools Namespace | ClientAddress Property | ClientPort Property

InternetServer.ClientId Property

Gets the unique client identifier for the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientId As Integer
```

[C#]

```
public int ClientId {get;}
```

Property Value

An integer value which uniquely identifies the client session.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be used by the application to identify that client session, and is different than the socket handle allocated for the client. While it is possible for a client socket handle to be reused by the operating system, client IDs are unique throughout the life of the server session and are never duplicated.

It is important to note that the actual value of the client ID should be considered opaque. It is only guaranteed that the value will be greater than zero, and that it will be unique to the client session.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.ClientName Property

Gets and sets a unique string moniker that is associated with the current client session.

[Visual Basic]

```
Public Property ClientName As String
```

[C#]

```
public string ClientName {get; set;}
```

Property Value

A string moniker which uniquely identifies the client session. If no moniker has been specified for the client session, this property will return an empty string.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session by setting the **ClientName** property from within a class event handler such as the **OnConnect** event.

Monikers are not case-sensitive, and they must be unique so that no client socket for a particular server can have the same moniker. The maximum length for a moniker is 127 characters.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

Example

The following example sets the moniker for the client session in the OnConnect event handler.

```
private void Server1_OnConnect(object sender,
SocketTools.InternetServer.ConnectEventArgs e)
{
    Server1.ClientName = "Client" + Server1.ClientId.ToString();
}
```

See Also

InternetServer Class | SocketTools Namespace

InternetServer.ClientPort Property

Gets a value that specifies the port number used by the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientPort As Integer
```

[C#]

```
public int ClientPort {get;}
```

Property Value

An integer value which specifies the peer port number.

Remarks

The **ClientPort** property returns the port number that the current client has used when establishing a connection with the server. This property value is only meaningful when accessed within an event handler such as the **OnConnect** event.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.ClientThread Property

Gets the thread ID for the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientThread As Integer
```

[C#]

```
public int ClientThread {get;}
```

Property Value

An integer value which identifies the client thread that was created to manage the client session.

Remarks

Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.CodePage Property

Gets and sets the code page used when reading and writing text.

[Visual Basic]
```
Public Property CodePage As Integer
```

[C#]
```
public int CodePage {get; set;}
```

Property Value

An integer value which specifies the current code page. A value of zero specifies the default code page for the current locale should be used. To preserve the original Unicode text, you can use code page 65001 which specifies UTF-8 character encoding.

Remarks

All data which is exchanged over a socket is sent and received as 8-bit bytes, typically referred to as "octets" in networking terminology. However, strings in .NET are Unicode where each character is represented by 16 bits. To send and receive data using strings, these Unicode strings are converted to a stream of bytes.

By default, strings are converted to an array of bytes using the code page for the current locale, mapping the 16-bit Unicode characters to bytes. Similarly, when reading data from the socket into a string buffer, the stream of bytes received from the remote host are converted to Unicode before they are returned to your application.

If you are exchanging text with another system and it appears to corrupted or characters are being replaced with question marks or other symbols, it is likely the system is sending text which is using a different character encoding. Most services use UTF-8 encoding to represent non-ASCII characters and selecting the UTF-8 code page will typically resolve the issue.

Strings are only guaranteed to be safe when sending and receiving text. Using a string data type is not recommended when reading or writing binary data to a socket. If possible, you should always use a byte array as the buffer parameter for the Read and Write methods whenever you are exchanging binary data.

For backwards compatibility, this class defaults to using the code page for the current locale. This property value directly corresponds to Windows code page identifiers, and will accept any valid code page supported by the .NET Framework. Setting this property to an invalid code page will generate an exception.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.ExternalAddress Property

Gets a value that specifies the external Internet address for the local system.

[Visual Basic]

```
Public ReadOnly Property ExternalAddress As String
```

[C#]

```
public string ExternalAddress {get;}
```

Property Value

A string which specifies an Internet address using dotted notation.

Remarks

The **ExternalAddress** property returns the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). The **ExternalAddress** property can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router.

Using this property requires that you have an active connection to the Internet; checking the value of this property on a system that uses dial-up networking may cause the operating system to automatically connect to the Internet service provider. The class may be unable to determine the external IP address for the local host for a number of reasons, particularly if the system is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the external address for the local host cannot be determined, the property will return an empty string.

If the class is able to obtain a valid external address for the local host, that address will be cached for sixty minutes. Because dial-up connections typically have different IP addresses assigned to them each time the system is connected to the Internet, it is recommended that this property only be used in conjunction with broadband connections using a NAT router.

It is important to note that checking this property value may cause the current thread to block until the external IP address can be resolved.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.IsBlocked Property

Gets a value which indicates if the current thread is performing a blocking socket operation.

[Visual Basic]
```
Public ReadOnly Property IsBlocked As Boolean
```

[C#]
```
public bool IsBlocked {get;}
```

Property Value

Returns **true** if the current thread is blocking, otherwise returns **false**.

Remarks

The **IsBlocked** property returns **true** if the current thread is blocked performing an operation. Because the Windows Sockets API only permits one blocking operation per thread of execution, this property should be checked before starting any blocking operation in response to an event.

If the **IsBlocked** property returns **false**, this means there are no blocking operations on the current thread at that time. However, this does not guarantee that the next socket operation will not fail. An application should always check the return value from a socket operation and check the value of the **LastError** property if an error occurs.

Note that this property will return **true** if there is any blocking operation being performed by the current thread, regardless of whether this specific instance of the class is responsible for the blocking operation or not.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.IsClosed Property

Gets a value which indicates if the connection to the client has been closed.

[Visual Basic]

```
Public ReadOnly Property IsClosed As Boolean
```

[C#]

```
public bool IsClosed {get;}
```

Property Value

Returns **true** if the connection has been closed; otherwise returns **false**.

Remarks

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required networking libraries or not being able to access the system registry.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.IsListening Property

Gets a value which indicates if the server is listening for client connections.

[Visual Basic]

```
Public ReadOnly Property IsListening As Boolean
```

[C#]

```
public bool IsListening {get;}
```

Property Value

Returns **true** if the server is listening for client connections; otherwise returns **false**.

Remarks

The **IsListening** property will return **true** if the **Start** method was called and the server is currently accepting incoming client connections. In all other situations, this property will return **false**.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.IsLocked Property

Gets a value which indicates if the server has been locked.

[Visual Basic]
```
Public ReadOnly Property IsLocked As Boolean
```

[C#]
```
public bool IsLocked {get;}
```

Property Value

Returns **true** if the server has been locked; otherwise returns **false**.

Remarks

The **IsLocked** property returns **true** if the server has been locked using the **Lock** method. When a server is locked, all background threads created by the server will block, waiting for the lock to be released. If this property returns a value of **true**, no client connections can be accepted by the server, and no network events will be generated.

The **Lock** method creates a critical section which prevents other threads from performing any network operation. This is useful when the program needs to update global data and wants to ensure that no network operations occur while the data is being modified. However, applications must take care to release the lock as quickly as possible. If a function locks the server, it must make sure that it releases the lock before exiting that function. Leaving the server locked across function calls or event handlers can result in the server becoming non-responsive.

See Also

InternetServer Class | SocketTools Namespace | Lock Method | Unlock Method

InternetServer.IsReadable Property

Gets a value which indicates if there is data available to be read from the current client.

[Visual Basic]
```
Public ReadOnly Property IsReadable As Boolean
```

[C#]
```
public bool IsReadable {get;}
```

Property Value

Returns **true** if there is data available to be read; otherwise returns **false**.

Remarks

The **IsReadable** property returns **true** if data can be read from the current client session without causing the current thread to block. Note that even if this property does return **true** indicating that there is data available to be read, applications should always check the return value from the **Read** method.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.IsWritable Property

Gets a value which indicates if data can be written to the current client without blocking.

[Visual Basic]

```
Public ReadOnly Property IsWritable As Boolean
```

[C#]

```
public bool IsWritable {get;}
```

Property Value

Returns **true** if data can be written to the client; otherwise returns **false**.

Remarks

The **IsWritable** property returns **true** if data can be written to the client without causing the current thread to block. Note that even if this property does return **true** indicating that data can be written to the client, applications should always check the return value from the **Write** method.

This property only returns a meaningful value when accessed from within a class event handler, or a method that has been invoked from within an event handler.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.KeepAlive Property

Gets and sets a value which indicates if keep-alive packets are sent on a connected socket.

[Visual Basic]

```
Public Property KeepAlive As Boolean
```

[C#]

```
public bool KeepAlive {get; set;}
```

Property Value

Returns **true** if keep-alive packets are enabled, otherwise returns **false**. The default value is **false**.

Remarks

Setting the **KeepAlive** property to a value of **true** specifies that special packets are to be sent to the remote system when no data is being exchanged to ensure the connection remains active. This property can only be set for sockets that were created with the **Protocol** property set to a value of **SocketProtocol.protocolStream**.

It is important to note that the system will not start generating keep-alive packets until two hours after it has been enabled, so this option is only relevant for connections that will be maintained for long periods of time. The actual interval for the keep-alive period can only be changed in the system registry and affects all sockets, system-wide. For more information, refer to Microsoft Knowledge Base article 314053.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public InternetServer.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property LastErrorString As String
```

[C#]

```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.MaxClients Property

Gets and sets the maximum number of clients that can connect to the server.

[Visual Basic]

```
Public Property MaxClients As Integer
```

[C#]

```
public int MaxClients {get; set;}
```

Property Value

An integer value which specifies the maximum number of client sessions that will be accepted by the server. A value of zero specifies that there is no fixed limit to the maximum number of clients.

Remarks

The **MaxClients** property specifies the maximum number of client connections that will be accepted by the server. Once the maximum number of connections has been established, the server will reject any subsequent connections until the number of active client connections drops below the specified value. A value of zero specifies that there should be no limit on the number of clients.

Changing the value of this property while a server is actively listening for connections will modify the maximum number of client connections permitted, but it will not affect connections that have already been established.

By default, there are no limits on the number of client connections or the connection rate when a server is started. Use the **Throttle** method to change the maximum number of client connections per IP address or the overall connection rate threshold for the server.

It is important to note that regardless of the maximum number of clients specified by this property, the actual number of client connections that can be managed by the server depends on the number of sockets that can be allocated from the operating system. The amount of physical memory installed on the system affects the number of connections that can be maintained because each connection allocates memory for the socket context from the non-paged memory pool.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.NoDelay Property

Gets and sets a value which specifies if the Nagle algorithm should be enabled or disabled.

[Visual Basic]
```
Public Property NoDelay As Boolean
```

[C#]
```
public bool NoDelay {get; set;}
```

Property Value

Returns **true** if the Nagle algorithm has been disabled; otherwise it returns **false**. The default value is **false**.

Remarks

The **NoDelay** property is used to enable or disable the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host. By default this property value is set to **false**, which enables the Nagle algorithm (in other words, the data being written may not actually be sent until it is optimal to do so). Setting this property to **true** disables the Nagle algorithm, maintaining the time delays between the data packets being sent.

This property should be set to **true** only if it is absolutely required and the implications of doing so are understood. Disabling the Nagle algorithm can have a significant negative impact on the performance of your server.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Options Property

Gets and sets a value which specifies one or more server options.

[Visual Basic]

```
Public Property Options As ServerOptions
```

[C#]

```
public InternetServer.ServerOptions Options {get; set;}
```

Property Value

Returns one or more ServerOptions enumeration flags which specify the options for the server. The default value for this property is **serverOptionNone**.

Remarks

The **Options** property specifies one or more default options which are used when starting the server using the **Start** method.

See Also

InternetServer Class | SocketTools Namespace | Start Method

InternetServer.Priority Property

Gets and sets a value which specifies the server priority.

[Visual Basic]

```
Public Property Priority As ServerPriority
```

[C#]

```
public InternetServer.ServerPriority Priority {get; set;}
```

Property Value

Returns a ServerPriority enumeration value which specifies the current server priority. The default value for this property is **priorityNormal**.

Remarks

The **Priority** property can be used to control the processor usage, memory and network bandwidth allocated by the server for client sessions. The default priority balances resource utilization and client throughput while ensuring that the user interface remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of throughput.

Higher priority values increases the thread priority and processor utilization for the client sessions. It is not recommended that you increase the server priority unless you understand the implications of doing so and have thoroughly tested your application. Raising the priority of the server can have a negative impact on the responsiveness of the user interface.

See Also

InternetServer Class | SocketTools Namespace | ServerPriority Enumeration

InternetServer.ReuseAddress Property

Gets and sets a value which indicates if the server address can be reused.

[Visual Basic]

```
Public Property ReuseAddress As Boolean
```

[C#]

```
public bool ReuseAddress {get; set;}
```

Property Value

Returns **true** if an address can be reused; otherwise returns **false**. The default value is **true**.

Remarks

The **ReuseAddress** property is used to determine if the local address and port number can be reused when starting a new instance of the server. Setting this property to **true** enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable the server to close the listening socket and immediately reopen it without getting an error that the address is in use.

When a listening socket closed, the socket will normally go into a TIME-WAIT state where the local address and port number cannot be immediately reused. A consequence of this is that calling the **Stop** method immediately followed by the **Start** method using the same address and port number values may result in an error indicating that the specified address is already in use. By setting this property to **true**, that error is avoided and the listening socket can be created immediately without waiting for the TIME-WAIT period to elapse. Note that calling the **Restart** method allows the local address and port number to be reused, regardless of this property value.

If you wish to determine if a local port number is already in use by another application, set this property to **false** and attempt to start the server using that port number. If another application is already using that port number, an error will be generated indicating that the address is in use and the server could not be started.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Secure Property

Gets and sets a value which specifies if client connections are secure.

[Visual Basic]
```
Public Property Secure As Boolean
```

[C#]
```
public bool Secure {get; set;}
```

Property Value

Returns **true** if a secure connections are enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Secure** property determines if client connections are encrypted using the standard SSL or TLS security protocols. The default value for this property is **false**, which specifies that clients will use a standard, unencrypted connection to the server. To enable secure connections, the application should set this property value to **true** prior to calling the **Start** method.

When secure connections are enabled, the server will accept the client connection and then wait for the client to initiate the handshake where both the client and server negotiate the various encryption options available. This process is handled automatically by the server, and all that is required is that the application specify the server certificate which should be used. This is done by setting the **CertificateName** property, and optionally the **CertificateStore** property if required.

It is recommended that the application use exception handling to catch any errors that may occur when changing the value of this property. If the class is unable to initialize the Windows security libraries, an exception will be thrown when this property value is modified.

See Also

InternetServer Class | SocketTools Namespace | CertificateName Property | CertificateStore Property | SecureProtocol Property

InternetServer.SecureProtocol Property

Gets and sets a value which specifies the protocol used for secure client connections.

[Visual Basic]
```
Public Property SecureProtocol As SecurityProtocols
```

[C#]
```
public InternetServer.SecurityProtocols SecureProtocol {get; set;}
```

Property Value

A SecurityProtocols enumeration value which identifies the protocol to be used when accepting a secure client connection.

Remarks

The **SecureProtocol** property can be used to specify the security protocol to be used when accepting a secure connection. By default, the class will attempt to use either SSL v3 or TLS v1 to accept the connection, with the appropriate protocol automatically selected based on the capabilities of the client. It is recommended that you only change this property value if you fully understand the implications of doing so. Assigning a value to this property will override the default protocol and force the class to attempt to use only the protocol specified.

Attempting to set this property after the server has been started will result in an exception being thrown. This property should only be set after setting the **Secure** property to **true** and before calling the **Start** method.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.ServerAddress Property

Gets and sets the address that will be used by the server to listen for connections.

[Visual Basic]

```
Public Property ServerAddress As String
```

[C#]

```
public string ServerAddress {get; set;}
```

Property Value

A string which specifies the IP address that the server will use to listen for incoming client connections. An empty string indicates that the server will accept connections on any valid network interface configured for the local system.

Remarks

The **ServerAddress** property is used to specify the default address that the server will use when listening for connections. Setting this property to the value 0.0.0.0 or an empty string indicates that the server should listen for client connections using any valid network interface. If an address is specified, it must be a valid Internet address that is bound to a network adapter configured on the local system. Clients will only be able to connect to the server using that specific address.

It is common to set this property to the value 127.0.0.1 for testing purposes. It is a non-routable address that specifies the local system, and most software firewalls are configured so they do not block applications using this address.

See Also

InternetServer Class | SocketTools Namespace | ServerName Property | ServerPort Property

InternetServer.ServerName Property

Gets a value which specifies the host name for the local system.

[Visual Basic]

```
Public ReadOnly Property ServerName As String
```

[C#]

```
public string ServerName {get;}
```

Property Value

A string which specifies the local host name.

Remarks

The **ServerName** property returns the fully-qualified host name assigned to the local system. This consists of the local computer name and its domain name. The actual value returned depends on the system configuration. If no domain has been specified for the system, then only the machine name will be returned.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.ServerPort Property

Gets and sets the port number that will be used by the server to listen for connections.

[Visual Basic]

```
Public Property ServerPort As Integer
```

[C#]

```
public int ServerPort {get; set;}
```

Property Value

An integer value which specifies the port number.

Remarks

The **ServerPort** property is used to set the port number that server will use to listen for incoming client connections. Valid port numbers are in the range of 1 to 65535. It is recommended that most custom servers specify a port number larger than 5000 to avoid potential conflicts with standard Internet services and ephemeral ports used by client applications.

If a port number is specified that is already in use by another application, the **OnError** event will fire and the background server thread will terminate. To enable a server to be stopped and immediately restarted using the same address and port number, make sure that the **ReuseAddress** property is set to a value of **true**.

InternetServer Class | SocketTools Namespace | ServerAddress Property | ServerName Property

InternetServer.ServerThread Property

Gets the thread ID for the current server.

[Visual Basic]
```
Public ReadOnly Property ServerThread As Integer
```

[C#]
```
public int ServerThread {get;}
```

Property Value

An integer value which identifies the server thread that was created. A return value of zero specifies that no server has been started.

Remarks

Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Status Property

Gets a value which specifies the current status of the server.

[Visual Basic]

```
Public ReadOnly Property Status As ServerStatus
```

[C#]

```
public InternetServer.ServerStatus Status {get;}
```

Property Value

A ServerStatus enumeration value which specifies the current server status.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.ThrowError Property

Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.

[Visual Basic]

```
Public Property ThrowError As Boolean
```

[C#]

```
public bool ThrowError {get; set;}
```

Property Value

Returns **true** if method calls will generate exceptions when an error occurs; otherwise returns **false**. The default value is **false**.

Remarks

Error handling for when calling class methods can be done in either of two different styles, according to the value of this property.

If the **ThrowError** property is set to **false**, the application should check the return value of any method that is used, and report errors based upon the documented value of the return code. It is the responsibility of the application to interpret the error code, if it is desired to explain the error in addition to reporting it. This is the default behavior.

If the **ThrowError** property is set to **true**, then exceptions will be generated whenever a method call fails. The program must be written to catch these exceptions and take the appropriate action when an error occurs. Failure to handle an exception will cause the program to terminate abnormally.

Note that if an error occurs while a property is being read or modified, an exception will be raised regardless of the value of the **ThrowError** property.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Timeout Property

Gets and sets a value which specifies a timeout period in seconds.

[Visual Basic]

```
Public Property Timeout As Integer
```

[C#]

```
public int Timeout {get; set;}
```

Property Value

An integer value which specifies a timeout period in seconds.

Remarks

Setting the **Timeout** property specifies the number of seconds until a socket operation fails and returns an error.

For most server applications it is recommended the timeout period be set between 10 and 20 seconds. It is not recommended that you set the timeout period to zero.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Trace Property

Gets and sets a value which indicates if network function logging is enabled.

[Visual Basic]
```
Public Property Trace As Boolean
```

[C#]
```
public bool Trace {get; set;}
```

Property Value

Returns **true** if network function tracing is enabled; otherwise returns **false**. The default value is **false**.

Remarks

The **Trace** property is used to enable (or disable) the tracing of network function calls. When enabled, each function call is logged to a file, including the function parameters, return value and error code if applicable. This facility can be enabled and disabled at run time, and the trace log file can be specified by setting the **TraceFile** property. All function calls that are being logged are appended to the trace file, if it exists. If no trace file exists when tracing is enabled, the trace file is created.

The tracing facility is available in all of the SocketTools networking classes and is enabled or disabled for an entire process. This means that once trace logging is enabled for a given component, all of the function calls made by the process using any of the SocketTools classes will be logged. For example, if you have an application using both the File Transfer Protocol and Post Office Protocol classes, and you set the **Trace** property to **true**, function calls made by both classes will be logged. Additionally, enabling a trace is cumulative, and tracing is not stopped until it is disabled for all classes used by the process.

If trace logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which multiple processes are being traced or the logfile is fairly large. Since logfiles can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

When redistributing your application, make sure that you include the **SocketTools10.TraceLog.dll** module with your installation. If this library is not present, then no trace output will be generated and the value of the **Trace** property will be ignored. Only those function calls made by the SocketTools networking classes will be logged. Calls made directly to the Windows Sockets API, or calls made by other classes, will not be logged.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.TraceFile Property

Gets and sets a value which specifies the name of the network function tracing logfile.

[Visual Basic]
```
Public Property TraceFile As String
```

[C#]
```
public string TraceFile {get; set;}
```

Property Value

A string which specifies the name of the file.

Remarks

The **TraceFile** property is used to specify the name of the trace file that is created when network function tracing is enabled. If this property is set to an empty string (the default value), then a file named **SocketTools.log** is created in the system's temporary directory. If no temporary directory exists, then the file is created in the current working directory.

If the file exists, the trace output is appended to the file, otherwise the file is created. Since network function tracing is enabled per-process, the trace file is shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFile** property should be set to the same value for each instance. Since trace files can grow very quickly, even with modest applications, it is recommended that you delete the file when it is no longer needed.

The trace file has the following format:

```
 MyApp INF: WSAAsyncSelect(46, 0xcc4, 0x7e9, 0x27) returned 0 MyApp WRN:
connect(46, 192.0.0.1:1234, 16) returned -1 [10035] MyApp ERR: accept(46,
NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process that is being traced. The second column identifies if the trace record is reporting information, a warning, or an error. What follows is the name of the function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record (the value is placed inside brackets).

If parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a pointer (a memory address), it is recorded as a hexadecimal value preceded with "0x". A special type of pointer, called a null pointer, is recorded as NULL. Those functions which expect socket addresses are displayed in the following format:

```
aa.bb.cc.dd:nnnn
```

The first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. Note that in the second line of the above example, the control is attempting to connect to a system with the IP address 192.0.0.1 on port 1234.

Note that if the specified file cannot be created, or the user does not have permission to modify an existing file, the error is silently ignored and no trace output will be generated.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.TraceFlags Property

Gets and sets a value which specifies the network function tracing flags.

[Visual Basic]

```
Public Property TraceFlags As TraceOptions
```

[C#]

```
public InternetServer.TraceOptions TraceFlags {get; set;}
```

Property Value

A TraceOptions enumeration which specifies the amount of detail written to the trace logfile.

Remarks

The **TraceFlags** property is used to specify the type of information written to the trace file when network function tracing is enabled.

Because network function tracing is enabled per-process, the trace flags are shared by all instances of the class being used. If multiple class instances have tracing enabled, the **TraceFlags** property should be set to the same value for each instance. Changing the trace flags for any one instance of the class will affect the logging performed for all SocketTools classes used by the application.

Warnings are generated when a non-fatal error is returned by a network function. For example, if data is being written and the error **errorOperationWouldBlock** occurs, a warning is generated because the application simply needs to attempt to write the data at a later time.

InternetServer Class | SocketTools Namespace

InternetServer.Version Property

Gets a value which returns the current version of the InternetServer class library.

[Visual Basic]
```
Public ReadOnly Property Version As String
```

[C#]
```
public string Version {get;}
```

Property Value

A string which specifies the version of the class library.

Remarks

The **Version** property returns a string which identifies the current version and build of the InternetServer class library. This value can be used by an application for validation and debugging purposes.

InternetServer Class | SocketTools Namespace

InternetServer Methods

The methods of the **InternetServer** class are listed below. For a complete list of **InternetServer** class members, see the InternetServer Members topic.

Public Instance Methods

Abort	Overloaded. Abort the connection with a remote host.
Broadcast	Overloaded. Broadcast data to all active clients connected to the server
Cancel	Overloaded. Cancel the current blocking socket operation.
Disconnect	Overloaded. Disconnect the specified client connection from the server.
Dispose	Overloaded. Releases all resources used by InternetServer.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
FindClient	Overloaded. Return the socket handle for the client session with the specified moniker.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
Initialize	Overloaded. Initialize an instance of the InternetServer class.
Lock	Lock the server to synchronize access to shared data for all active client sessions.
Peek	Overloaded. Read data from the client and store it in a byte array, but do not remove the data from the socket buffers.
Read	Overloaded. Read data from the client socket and store it in a byte array.
ReadLine	Overloaded. Read up to a line of data from the client and return it in a string buffer.
Reject	Overloaded. Rejects a connection request from a client.
Reset	Reset the internal state of the object, resetting all properties to their default values.
Resolve	Resolves a host name to a host IP address.
Restart	Restarts the server and terminates all active client connections.

Resume	Resume accepting new client connections.
Start	Overloaded. Start listening for client connections on the specified IP address and port number.
Stop	Stop listening for new client connections and terminate all active clients already connected to the server.
Suspend	Overloaded. Suspend accepting new client connections with additional options.
Throttle	Overloaded. Limit the maximum number of client connections, connections per IP address and connection rate.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the server.
Unlock	Unlock the server and allow other server threads to resume execution.
Write	Overloaded. Write one or more bytes of data to a client.
WriteLine	Overloaded. Send a line of text to a client, terminated by a carriage-return and linefeed.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the InternetServer class and optionally releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetServer Class | SocketTools Namespace

InternetServer.Abort Method

Abort the connection with a remote host.

Overload List

Abort the connection with a remote host.

public void Abort();

Abort the connection with a remote host.

public void Abort(int);

See Also

InternetServer Class | SocketTools Namespace | Disconnect Method

InternetServer.Abort Method ()

Abort the connection with a remote host.

[Visual Basic]

```
Overloads Public Sub Abort()
```

[C#]

```
public void Abort();
```

Remarks

The **Abort** method immediately terminates the client connection, without waiting for any remaining data in the socket buffer to be written out. This method should only be used when the connection must be closed immediately. If this method is used, the client will see the connection as being terminated abnormally.

It is recommended that applications using the **Disconnect** method unless it is absolutely necessary to terminate the connection and immediately release the socket handle.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Abort** method outside of an event handler, you must explicitly specify the client handle.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Abort Overload List | Disconnect Method

InternetServer.Abort Method (Int32)

Abort the connection with a remote host.

[Visual Basic]

```
Overloads Public Sub Abort( _
   ByVal handle As Integer _
)
```

[C#]

```
public void Abort(
   int handle
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

Remarks

The **Abort** method immediately terminates the client connection, without waiting for any remaining data in the socket buffers to be written out. This method should only be used when the connection must be closed immediately. If this method is used, the client will see the connection as being terminated abnormally.

It is recommended that applications using the **Disconnect** method unless it is absolutely necessary to terminate the connection and immediately release the socket handle.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Abort Overload List | Disconnect Method

InternetServer.Broadcast Method

Broadcast data to all active clients connected to the server

Overload List

Broadcast data to all active clients connected to the server

public int Broadcast(byte[]);

Broadcast data to all active clients connected to the server

public int Broadcast(byte[],int);

Broadcast data to all active clients connected to the server

public int Broadcast(string);

Broadcast data to all active clients connected to the server

public int Broadcast(string,int);

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Broadcast Method (Byte[])

Broadcast data to all active clients connected to the server

[Visual Basic]

```
Overloads Public Function Broadcast( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Broadcast(
   byte[] buffer
);
```

Parameters

buffer

A byte array that contains the data that will be broadcast.

Return Value

An integer value which specifies the number of clients that the data was broadcast to. A return value of -1 indicates an error condition, and the value of the **LastError** property will indicate the cause of the failure.

Remarks

The **Broadcast** method broadcasts contents of the specified byte array to all clients connected to the server. If this method is called inside a server event handler, the message is broadcast to all clients except for the current, active client that is processing the event notification. If this method is called outside of an event handler, the data is broadcast to all connected clients.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Broadcast Overload List

InternetServer.Broadcast Method (Byte[], Int32)

Broadcast data to all active clients connected to the server

[Visual Basic]

```
Overloads Public Function Broadcast( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Broadcast(
   byte[] buffer,
   int length
);
```

Parameters

buffer
A byte array that contains the data that will be broadcast.

length
An integer value which specifies the maximum number of bytes of data to broadcast. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of clients that the data was broadcast to. A return value of -1 indicates an error condition, and the value of the **LastError** property will indicate the cause of the failure.

Remarks

The **Broadcast** method broadcasts contents of the specified byte array to all clients connected to the server. If this method is called inside a server event handler, the message is broadcast to all clients except for the current, active client that is processing the event notification. If this method is called outside of an event handler, the data is broadcast to all connected clients.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Broadcast Overload List

InternetServer.Broadcast Method (String)

Broadcast data to all active clients connected to the server

[Visual Basic]
```
Overloads Public Function Broadcast( _
   ByVal buffer As String _
) As Integer
```

[C#]
```
public int Broadcast(
   string buffer
);
```

Parameters

buffer
A string that contains the data that will be broadcast.

Return Value

An integer value which specifies the number of clients that the data was broadcast to. A return value of -1 indicates an error condition, and the value of the **LastError** property will indicate the cause of the failure.

Remarks

The **Broadcast** method broadcasts contents of the specified string to all clients connected to the server. If this method is called inside a server event handler, the message is broadcast to all clients except for the current, active client that is processing the event notification. If this method is called outside of an event handler, the data is broadcast to all connected clients.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Broadcast Overload List

InternetServer.Broadcast Method (String, Int32)

Broadcast data to all active clients connected to the server

[Visual Basic]

```
Overloads Public Function Broadcast( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Broadcast(
   string buffer,
   int length
);
```

Parameters

buffer

A string that contains the data that will be broadcast.

length

An integer value which specifies the maximum number of bytes of data to broadcast. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of clients that the data was broadcast to. A return value of -1 indicates an error condition, and the value of the **LastError** property will indicate the cause of the failure.

Remarks

The **Broadcast** method broadcasts contents of the specified string to all clients connected to the server. If this method is called inside a server event handler, the message is broadcast to all clients except for the current, active client that is processing the event notification. If this method is called outside of an event handler, the data is broadcast to all connected clients.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Broadcast Overload List

InternetServer.Cancel Method

Cancel the current blocking socket operation.

Overload List

Cancel the current blocking socket operation.

public void Cancel();

Cancel the current blocking socket operation.

public void Cancel(int);

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Cancel Method ()

Cancel the current blocking socket operation.

[Visual Basic]

```
Overloads Public Sub Cancel()
```

[C#]

```
public void Cancel();
```

Remarks

When the **Cancel** method is called, the blocking socket operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Cancel** method outside of an event handler, you must explicitly specify the client handle.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Cancel Overload List

InternetServer.Cancel Method (Int32)

Cancel the current blocking socket operation.

[Visual Basic]

```
Overloads Public Sub Cancel( _
   ByVal handle As Integer _
)
```

[C#]

```
public void Cancel(
   int handle
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

Remarks

When the **Cancel** method is called, the blocking socket operation will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other blocking function. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Cancel Overload List

InternetServer.Disconnect Method

Disconnect the specified client connection from the server.

Overload List

Disconnect the specified client connection from the server.

public void Disconnect();

Disconnect the specified client connection from the server.

public void Disconnect(int);

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Disconnect Method ()

Disconnect the specified client connection from the server.

[Visual Basic]

```
Overloads Public Sub Disconnect()
```

[C#]

```
public void Disconnect();
```

Remarks

The **Disconnect** method terminates the specified client connection with the server and closes the socket handle allocated by the class. Note that the client socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the socket will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Disconnect** method outside of an event handler, you must explicitly specify the client handle.

To immediately terminate the connection and release the socket, use the **Abort** method.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Disconnect Overload List

InternetServer.Disconnect Method (Int32)

Disconnect the specified client connection from the server.

[Visual Basic]

```
Overloads Public Sub Disconnect( _
   ByVal handle As Integer _
)
```

[C#]

```
public void Disconnect(
   int handle
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

Remarks

The **Disconnect** method terminates the specified client connection with the server and closes the socket handle allocated by the class. Note that the client socket is not immediately released when the connection is terminated and will enter a wait state for two minutes. After the time wait period has elapsed, the socket will be released by the operating system. This is a normal safety mechanism to handle any packets that may arrive after the connection has been closed.

To immediately terminate the connection and release the socket, use the **Abort** method.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Disconnect Overload List | Abort Method

InternetServer.Dispose Method

Releases all resources used by InternetServer.

Overload List

Releases all resources used by InternetServer.

public void Dispose();

Releases the unmanaged resources allocated by the InternetServer class and optionally releases the managed resources.

protected void Dispose(bool);

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Dispose Method ()

Releases all resources used by InternetServer.

[Visual Basic]

```
NotOverridable Overloads Public Sub Dispose() _
    Implements IDisposable.Dispose
```

[C#]

```
public void Dispose();
```

Implements

IDisposable.Dispose

Remarks

The **Dispose** method stops the server, terminates all active client sessions and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Dispose Overload List

InternetServer.Dispose Method (Boolean)

Releases the unmanaged resources allocated by the InternetServer class and optionally releases the managed resources.

[Visual Basic]
```
Overloads Protected Sub Dispose( _
   ByVal disposing As Boolean _
)
```

[C#]
```
protected void Dispose(
   bool disposing
);
```

Parameters

disposing

A boolean value which should be specified as **true** to release both managed and unmanaged resources; **false** to release only unmanaged resources.

Remarks

The **Dispose** method terminates any active connection and explicitly releases the resources allocated for this instance of the class. In some cases, better performance can be achieved if the programmer explicitly releases resources when they are no longer being used. The **Dispose** method provides explicit control over these resources.

Unlike the **Uninitialize** method, once the **Dispose** method has been called, that instance of the class cannot be re-initialized and you should not attempt to access class properties or invoke any methods. Note that this method can be called even if other references to the object are active.

You should call **Dispose** in your derived class when you are finished using the derived class. The **Dispose** method leaves the derived class in an unusable state. After calling **Dispose**, you must release all references to the derived class and the **InternetServer** class so the memory they were occupying can be reclaimed by garbage collection.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Dispose Overload List

InternetServer.Finalize Method

Destroys an instance of the class, releasing the resources allocated for the session and unloading the networking library.

[Visual Basic]

```
Overrides Protected Sub Finalize()
```

[C#]

```
protected override void Finalize();
```

See Also

InternetServer Class | SocketTools Namespace

InternetServer.FindClient Method

Return the socket handle for the client session with the specified ID.

Overload List

Return the socket handle for the client session with the specified ID.

public int FindClient(int);

Return the socket handle for the client session with the specified moniker.

public int FindClient(string);

See Also

InternetServer Class | SocketTools Namespace | ClientId Property

InternetServer.FindClient Method (Int32)

Return the socket handle for the client session with the specified ID.

[Visual Basic]

```
Overloads Public Function FindClient( _
   ByVal clientId As Integer _
) As Integer
```

[C#]

```
public int FindClient(
   int clientId
);
```

Parameters

clientId

An integer value which uniquely identifies the client session.

Return Value

An integer value which specifies the socket handle for the client session. If the specified client ID does not match an active client session, the method will return a value of -1 and the value of the **LastError** property will indicate the cause of the failure.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be used by the application to identify that client session, and is different than the socket handle allocated for the client. While it is possible for a client socket handle to be reused by the operating system, client IDs are unique throughout the life of the server session and are never duplicated.

The application can determine the ID assigned to the current client session using the **ClientId** property from within an event handler such as **OnConnect**.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.FindClient Overload List | ClientId Property

InternetServer.FindClient Method (String)

Return the socket handle for the client session with the specified moniker.

[Visual Basic]

```
Overloads Public Function FindClient( _
   ByVal clientName As String _
) As Integer
```

[C#]

```
public int FindClient(
   string clientName
);
```

Parameters

clientName

A string which specifies the moniker for the client session.

Return Value

An integer value which specifies the socket handle for the client session. If the specified moniker does not match an active client session, the method will return a value of -1 and the value of the **LastError** property will indicate the cause of the failure.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session by setting the **ClientName** property from within a class event handler such as the **OnConnect** event.

Monikers are not case-sensitive, and they must be unique so that no client socket for a particular server can have the same moniker. The maximum length for a moniker is 127 characters.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.FindClient Overload List | ClientName Property

InternetServer.Initialize Method

Initialize an instance of the InternetServer class.

Overload List

Initialize an instance of the InternetServer class.

public bool Initialize();

Initialize an instance of the InternetServer class.

public bool Initialize(string);

See Also

InternetServer Class | SocketTools Namespace | Uninitialize Method

InternetServer.Initialize Method ()

Initialize an instance of the InternetServer class.

[Visual Basic]

```
Overloads Public Function Initialize() As Boolean
```

[C#]

```
public bool Initialize();
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the InternetServer class, loading the networking library and allocating resources for the current thread. Typically it is not necessary to explicitly call this method because the instance of the class is initialized by the class constructor. However, if the **Uninitialize** method is called, the class must be re-initialized before any other methods are called.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Initialize Overload List | Uninitialize Method

InternetServer.Initialize Method (String)

Initialize an instance of the InternetServer class.

[Visual Basic]

```
Overloads Public Function Initialize( _
   ByVal licenseKey As String _
) As Boolean
```

[C#]

```
public bool Initialize(
   string licenseKey
);
```

Return Value

A boolean value which specifies if the class was initialized successfully.

Remarks

The Initialize method can be used to explicitly initialize an instance of the InternetServer class, loading the networking library and allocating resources for the current thread. Typically an application would define the license key as a custom attribute, however this method can be used to initialize the class directly.

The runtime license key for your copy of InternetServer can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the InternetServer class.

Example

The following example shows how to use the Initialize method to initialize an instance of the class. This example assumes that the license key string has been defined in code.

```
SocketTools.InternetServer server = new SocketTools.InternetServer();

if (server.Initialize(strLicenseKey) == false)
{
    MessageBox.Show(server.LastErrorString, "Error",
                    MessageBoxButtons.OK, MessageBoxIcon.Exclamation);
    return;
}
```

```
Dim Server As New SocketTools.InternetServer

If Server.Initialize(strLicenseKey) = False Then
    MsgBox(Server.LastErrorString, vbIconExclamation)
    Exit Sub
End If
```

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Initialize Overload List | RuntimeLicenseAttribute Class | Uninitialize Method

InternetServer.Lock Method

Lock the server to synchronize access to shared data for all active client sessions.

[Visual Basic]
```
Public Function Lock() As Boolean
```

[C#]
```
public bool Lock();
```

Return Value

A boolean value which specifies if the server was locked. A return value of **true** specifies that the server was locked, and all other threads being managed by the server have been blocked. A return value of **false** indicates that the server could not be locked, typically because a potential deadlock was detected.

Remarks

The **Lock** method causes the server to enter a locked state where only the current thread may interact with the server and the clients that are connected to it. While a server is locked, all other threads will block when they attempt to perform a network operation. When the server is unlocked, the blocked threads will resume normal execution.

This method should be used carefully, and a server should never be left in a locked state for an extended period of time. It is meant to be used when the server process updates a global data structure and it must prevent any other threads from performing a network operation during the update. Only one server can be locked at any one time, and once a server has been locked, it can only be unlocked by the same thread.

The program should always check the return value from this method, and should never assume that the lock has been established. If more than one thread attempts to lock a server at the same time, there is no guarantee as to which thread will actually establish the lock. If a potential deadlock situation is detected, this function will fail and return a value of false.

Every time the **Lock** method is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to the **Lock** method must be matched by an equal number of calls to the **Unlock** method. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

The **IsLocked** property can be used to determine if the server has been locked.

InternetServer.Peek Method

Return the number of bytes available to be read from the client socket.

Overload List

Return the number of bytes available to be read from the client socket.

public int Peek();

Read data from the client and store it in a byte array, but do not remove the data from the socket buffers.

public int Peek(byte[]);

Read data from the client and store it in a byte array, but do not remove the data from the socket buffers.

public int Peek(byte[],int);

Return the number of bytes available to be read from the client socket.

public int Peek(int);

Read data from the client and store it in a byte array, but do not remove the data from the socket buffers.

public int Peek(int,byte[]);

Read data from the client and store it in a byte array, but do not remove the data from the socket buffers.

public int Peek(int,byte[],int);

Read data from the client and store it in a string, but do not remove the data from the socket buffers.

public int Peek(int,ref string);

Read data from the client and store it in a string, but do not remove the data from the socket buffers.

public int Peek(int,ref string,int);

Read data from the client and store it in a string, but do not remove the data from the socket buffers.

public int Peek(ref string);

Read data from the client and store it in a string, but do not remove the data from the socket buffers.

public int Peek(ref string,int);

InternetServer.Peek Method ()

Return the number of bytes available to be read from the client socket.

[Visual Basic]
```
Overloads Public Function Peek() As Integer
```

[C#]
```
public int Peek();
```

Return Value

An integer value which specifies the number of bytes available to be read from the client socket. A return value of zero specifies that there is no data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Peek** method returns the number of bytes that can be read in a single operation. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. Using this method in a loop to poll a socket can cause the application to become non-responsive. To determine if there is data available to be read, use the **IsReadable** property.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Peek** method outside of an event handler, you must explicitly specify the client handle.

InternetServer.Peek Method (Byte[])

Read data from the client and store it in a byte array, but do not remove the data from the socket buffers.

[Visual Basic]

```
Overloads Public Function Peek( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Peek(
   byte[] buffer
);
```

Parameters

buffer

A byte array that the data will be stored in.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that there is no data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Peek** method returns data that is available to read from the client. The data returned by this method is not removed from the socket buffers. It must be consumed by a subsequent call to the **Read** method. The return value indicates the number of bytes that can be read in a single operation. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. To determine if there is data available to be read, use the **IsReadable** property.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Peek** method outside of an event handler, you must explicitly specify the client handle.

InternetServer.Peek Method (Byte[], Int32)

Read data from the client and store it in a byte array, but do not remove the data from the socket buffers.

[Visual Basic]

```
Overloads Public Function Peek( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Peek(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that the data will be stored in.

length

An integer value which specifies the maximum number of bytes of data to read. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually read from the client. A return value of zero specifies that there is no data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Peek** method returns data that is available to read from the socket, up to the number of bytes specified. The data returned by this method is not removed from the socket buffers. It must be consumed by a subsequent call to the **Read** method. The return value indicates the number of bytes that can be read in a single operation. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. To determine if there is data available to be read, use the **IsReadable** property.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Peek** method outside of an event handler, you must explicitly specify the client handle.

InternetServer Class | SocketTools Namespace | InternetServer.Peek Overload List | Read Method | OnRead Event

InternetServer.Peek Method (Int32, String)

Read data from the client and store it in a string, but do not remove the data from the socket buffers.

[Visual Basic]

```
Overloads Public Function Peek( _
   ByVal handle As Integer, _
   ByRef buffer As String _
) As Integer
```

[C#]

```
public int Peek(
   int handle,
   ref string buffer
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

buffer

A string that will contain the data read from the socket.

Return Value

An integer value which specifies the number of bytes actually read from the socket. A return value of zero specifies that there is no data available to be read. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Peek** method returns data that is available to read from the socket, up to a maximum of 8192 bytes. The data returned by this method is not removed from the socket buffers. It must be consumed by a subsequent call to the **Read** method. The return value indicates the number of bytes that can be read in a single operation. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

This method should only be used if the remote host is sending data that consists of printable characters. Binary data should be read using the method that accepts a byte array as the buffer parameter.

Read up to a line of data from the client and return it in a string buffer.

public bool ReadLine(int,ref string);

Read up to a line of data from the client and return it in a string buffer.

public bool ReadLine(int,ref string,int);

Read up to a line of data from the client and return it in a string buffer.

public bool ReadLine(ref string);

Read up to a line of data from the client and return it in a string buffer.

public bool ReadLine(ref string,int);

See Also

InternetServer Class | SocketTools Namespace

InternetServer.ReadLine Method (Int32, String)

Read up to a line of data from the client and return it in a string buffer.

[Visual Basic]

```
Overloads Public Function ReadLine( _
   ByVal handle As Integer, _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool ReadLine(
   int handle,
   ref string buffer
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

buffer

A string which will contain the data read from the client.

Return Value

This method returns a Boolean value which specifies if a line of data has been read. A value of **true** indicates a line of data has been read. If an error occurs or there is no more data available to read, then the method will return **false**. It is possible for data to be returned in the string buffer even if the return value is **false**. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Remarks

The **ReadLine** method reads data from the client until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the calling thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

InternetServer.ReadLine Method (Int32, String, Int32)

Read up to a line of data from the client and return it in a string buffer.

[Visual Basic]

```
Overloads Public Function ReadLine( _
   ByVal handle As Integer, _
   ByRef buffer As String, _
   ByVal length As Integer _
) As Boolean
```

[C#]

```
public bool ReadLine(
   int handle,
   ref string buffer,
   int length
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

buffer

A string which will contain the data read from the client.

length

An integer value which specifies the maximum number of bytes of data to read.

Return Value

This method returns a Boolean value which specifies if a line of data has been read. A value of **true** indicates a line of data has been read. If an error occurs or there is no more data available to read, then the method will return **false**. It is possible for data to be returned in the string buffer even if the return value is **false**. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Remarks

The **ReadLine** method reads data from the client up to the specified number of bytes or until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the calling thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

InternetServer Class | SocketTools Namespace | InternetServer.ReadLine Overload List

InternetServer.ReadLine Method (String)

Read up to a line of data from the client and return it in a string buffer.

[Visual Basic]

```
Overloads Public Function ReadLine( _
   ByRef buffer As String _
) As Boolean
```

[C#]

```
public bool ReadLine(
   ref string buffer
);
```

Parameters

buffer

A string which will contain the data read from the client.

Return Value

This method returns a Boolean value which specifies if a line of data has been read. A value of **true** indicates a line of data has been read. If an error occurs or there is no more data available to read, then the method will return **false**. It is possible for data to be returned in the string buffer even if the return value is **false**. Applications should check the length of the string after the method returns to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Remarks

The **ReadLine** method reads data from the client until an end-of-line character sequence is encountered. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string variable. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point; the string will not contain the carriage-return or linefeed characters.

There are some limitations when using the **ReadLine** method. The method should only be used to read text, never binary data. In particular, it will discard nulls, linefeed and carriage return control characters. This method will force the calling thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection.

The **Read** and **ReadLine** methods can be intermixed, however be aware that the **Read** method will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **ReadLine** method outside of an event handler, you must explicitly specify the client handle.

InternetServer.Reject Method

Rejects a connection request from a client.

Overload List

Rejects a connection request from a client.

public bool Reject();

Rejects a connection request from a client.

public bool Reject(int);

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Reject Method ()

Rejects a connection request from a client.

[Visual Basic]
```
Overloads Public Function Reject() As Boolean
```

[C#]
```
public bool Reject();
```

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Reject** method rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this method will immediately return with an error indicating that the operation would cause the thread to block.

This method is typically called from within the **OnAccept** event handler when the application determines that it does not wish to accept the incoming client connection.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Reject** method outside of an event handler, you must explicitly specify the client handle.

InternetServer Class | SocketTools Namespace | InternetServer.Reject Overload List

InternetServer.Reject Method (Int32)

Rejects a connection request from a client.

[Visual Basic]

```
Overloads Public Function Reject( _
   ByVal handle As Integer _
) As Boolean
```

[C#]

```
public bool Reject(
   int handle
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

Return Value

This method returns a Boolean value. If the method succeeds, the return value is **true**. If the method fails, the return value is **false**. To get extended error information, check the value of the **LastError** property.

Remarks

The **Reject** method rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this method will immediately return with an error indicating that the operation would cause the thread to block.

This method is typically called from within the **OnAccept** event handler when the application determines that it does not wish to accept the incoming client connection.

InternetServer.Reset Method

Reset the internal state of the object, resetting all properties to their default values.

[Visual Basic]

```
Public Sub Reset()
```

[C#]

```
public void Reset();
```

Remarks

The **Reset** method returns the object to its default state. If a server has been started, it will be stopped and any active client connections will be terminated. All properties will be reset to their default values.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Resolve Method

Resolves a host name to a host IP address.

[Visual Basic]

```
Public Function Resolve( _
   ByVal hostName As String, _
   ByRef hostAddress As String _
) As Boolean
```

[C#]

```
public bool Resolve(
   string hostName,
   ref string hostAddress
);
```

Parameters

hostName
A string which specifies the host name to be resolved.

hostAddress
A string which will contain the Internet address for the specified host.

Return Value

This method returns a Boolean value. If the host name can be resolved, the return value is **true**. If the host name cannot be resolved, the return value is **false**. To get extended error information, check the value of the **LastError** property.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Restart Method

Restarts the server and terminates all active client connections.

[Visual Basic]
```
Public Function Restart() As Boolean
```

[C#]
```
public bool Restart();
```

Return Value

A boolean value which specifies if the server was restarted. A return value of **true** specifies that the server has been successfully restarted. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Restart** method terminates all active client connections, recreates a new listening socket bound to the same address and port number, and then resumes accepting new client connections.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Resume Method

Resume accepting new client connections.

[Visual Basic]

```
Public Function Resume() As Boolean
```

[C#]

```
public bool Resume();
```

Return Value

A boolean value which specifies if the server has resumed accepting client connections. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Resume** method instructs the server to resume accepting new client connections. Any pending client connections that were requested while the server was suspended will be accepted.

InternetServer.Start Method

Start listening for client connections.

Overload List

Start listening for client connections.

public bool Start();

Start listening for client connections on the specified port number.

public bool Start(int);

Start listening for client connections on the specified IP address and port number.

public bool Start(string,int);

Start listening for client connections on the specified IP address and port number.

public bool Start(string,int,int);

Start listening for client connections on the specified IP address and port number.

public bool Start(string,int,int,int);

Start listening for client connections on the specified IP address and port number.

public bool Start(string,int,int,int,int);

Start listening for client connections on the specified IP address and port number.

public bool Start(string,int,int,int,int,ServerOptions);

See Also

InternetServer Class | SocketTools Namespace | Backlog Property | MaxClients Property | Options Property | ServerAddress Property | ServerPort Property | Timeout Property

InternetServer.Start Method ()

Start listening for client connections.

[Visual Basic]
```
Overloads Public Function Start() As Boolean
```

[C#]
```
public bool Start();
```

Return Value

A boolean value which specifies if the server has been started. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Start** method begins listening for client connections on the default local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

The value of the **Backlog** property will determine the default size of the queue for incoming client connections. The value of the **MaxClients** property will determine the maximum number of clients that may connect to the server. The value of the **Options** property will determine the default options used when starting the server. The value of the **ServerAddress** and **ServerPort** properties will determine the address and port number that the server will accept client connections on. The value of the **Timeout** property will determine the default timeout period.

Example

The following example demonstrates creating an instance of the **InternetServer** class object and starting a server using the **Start** method.

```
Dim Server As SocketTools.InternetServer

Server = New SocketTools.InternetServer
Server.ServerAddress = TextBox1.Text.Trim()
Server.ServerPort = Val(TextBox2.Text)

If Server.Start() Then
    StatusBar1.Text = "The server has started listening for connections"
Else
    StatusBar1.Text = "The server could not be started"
End If
```

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Start Overload List | Backlog Property | MaxClients Property | Options Property | ServerAddress Property | ServerPort Property | Timeout Property

InternetServer.Start Method (Int32)

Start listening for client connections on the specified port number.

```
[Visual Basic]
Overloads Public Function Start( _
   ByVal localPort As Integer _
) As Boolean
```

```
[C#]
public bool Start(
   int localPort
);
```

Parameters

localPort
An integer value which specifies the port number that the server should use when listening for incoming client connections. Valid port numbers are in the range of 1 through 65535.

Return Value

A boolean value which specifies if the server has been started. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

The value of the **Backlog** property will determine the default size of the queue for incoming client connections. The value of the **MaxClients** property will determine the maximum number of clients that may connect to the server. The value of the **Options** property will determine the default options used when starting the server. The value of the **ServerAddress** property will determine the address that the server will accept client connections on. The value of the **Timeout** property will determine the default timeout period.

Example

The following example demonstrates creating an instance of the **InternetServer** class object and starting a server using the Start method.

```
Dim Server As SocketTools.InternetServer
Dim nLocalPort As Integer

nLocalPort = Val(TextBox1.Text)

If Server.Start(nLocalPort) Then
    StatusBar1.Text = "The server has started listening for connections"
Else
    StatusBar1.Text = "The server could not be started"
End If
```

InternetServer.Start Method (String, Int32)

Start listening for client connections on the specified IP address and port number.

[Visual Basic]

```
Overloads Public Function Start( _
   ByVal localAddress As String, _
   ByVal localPort As Integer _
) As Boolean
```

[C#]

```
public bool Start(
   string localAddress,
   int localPort
);
```

Parameters

localAddress

A string value which specifies the IP address of the network adapter that the control should use when listening for connection requests. If this is an empty string or the special address "0.0.0.0" is specified, the server will listen for connection on all valid network interfaces configured for the local system.

localPort

An integer value which specifies the port number that the server should use when listening for incoming client connections. Valid port numbers are in the range of 1 through 65535.

Return Value

A boolean value which specifies if the server has been started. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

The value of the **Backlog** property will determine the default size of the queue for incoming client connections. The value of the **MaxClients** property will determine the maximum number of clients that may connect to the server. The value of the **Options** property will determine the default options used when starting the server. The value of the **Timeout** property will determine the default timeout period.

Example

The following example demonstrates creating an instance of the **InternetServer** class object and starting a server using the Start method.

```
Dim Server As SocketTools.InternetServer
Dim strLocalAddress As String
Dim nLocalPort As Integer

Server = New SocketTools.InternetServer

strLocalAddress = TextBox1.Text.Trim()
nLocalPort = Val(TextBox2.Text)

If Server.Start(strLocalAddress, nLocalPor) Then
    StatusBar1.Text = "The server has started listening for connections"
```

```
Else
    StatusBar1.Text = "The server could not be started"
End If
```

InternetServer.Start Method (String, Int32, Int32)

Start listening for client connections on the specified IP address and port number.

[Visual Basic]

```
Overloads Public Function Start( _
   ByVal localAddress As String, _
   ByVal localPort As Integer, _
   ByVal maxClients As Integer _
) As Boolean
```

[C#]

```
public bool Start(
   string localAddress,
   int localPort,
   int maxClients
);
```

Parameters

localAddress
A string value which specifies the IP address of the network adapter that the control should use when listening for connection requests. If this is an empty string or the special address "0.0.0.0" is specified, the server will listen for connection on all valid network interfaces configured for the local system.

localPort
An integer value which specifies the port number that the server should use when listening for incoming client connections. Valid port numbers are in the range of 1 through 65535.

maxClients
An integer value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of active client connections that may be established with the server. This value can be adjusted after the server has been created by calling the **Throttle** method.

Return Value

A boolean value which specifies if the server has been started. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

The value of the **Backlog** property will determine the default size of the queue for incoming client connections. ) As Boolean
```

[C#]

```
public bool Start(
   string localAddress,
   int localPort,
   int backlog,
   int maxClients
);
```

Parameters

localAddress

A string value which specifies the IP address of the network adapter that the control should use when listening for connection requests. If this is an empty string or the special address "0.0.0.0" is specified, the server will listen for connection on all valid network interfaces configured for the local system.

localPort

An integer value which specifies the port number that the server should use when listening for incoming client connections. Valid port numbers are in the range of 1 through 65535.

backlog

An integer value which specifies the maximum size of the queue used to manage pending connections to the service. If the argument is set to value which exceeds the maximum size for the underlying service provider, it will be silently adjusted to the nearest legal value. On Windows workstations, the maximum backlog value is 5. On Windows servers, the maximum value is 200.

maxClients

An integer value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of active client connections that may be established with the server. This value can be adjusted after the server has been created by calling the **Throttle** method.

Return Value

A boolean value which specifies if the server has been started. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

The value of the **Options** property will determine the default options used when starting the server. The value of the **Timeout** property will determine the default timeout period.

Example

The following example demonstrates creating an instance of the **InternetServer** class object and starting a server using the Start method.

InternetServer Class | SocketTools Namespace | InternetServer.Start Overload List | Options Property | Timeout Property

InternetServer.Start Method (String, Int32, Int32, Int32, Int32)

Start listening for client connections on the specified IP address and port number.

[Visual Basic]

```
Overloads Public Function Start( _
   ByVal localAddress As String, _
   ByVal localPort As Integer, _
   ByVal backlog As Integer, _
   ByVal maxClients As Integer, _
   ByVal timeout As Integer _
) As Boolean
```

[C#]

```
public bool Start(
   string localAddress,
   int localPort,
   int backlog,
   int maxClients,
   int timeout
);
```

Parameters

localAddress

A string value which specifies the IP address of the network adapter that the control should use when listening for connection requests. If this is an empty string or the special address "0.0.0.0" is specified, the server will listen for connection on all valid network interfaces configured for the local system.

localPort

An integer value which specifies the port number that the server should use when listening for incoming client connections. Valid port numbers are in the range of 1 through 65535.

backlog

An integer value which specifies the maximum size of the queue used to manage pending connections to the service. If the argument is set to value which exceeds the maximum size for the underlying service provider, it will be silently adjusted to the nearest legal value. On Windows workstations, the maximum backlog value is 5. On Windows servers, the maximum value is 200.

maxClients

An integer value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of active client connections that may be established with the server. This value can be adjusted after the server has been created by calling the **Throttle** method.

timeout

An integer value which specifies the number of seconds the control will wait for a network operation to complete. The default timeout period of 20 seconds is sufficient for most applications.

Return Value

A boolean value which specifies if the server has been started. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Start** method begins listening for client connections on the specified local address and port number.

The server is started in its own thread and manages the client sessions independently of the calling thread.

The value of the **Options** property determines the default options that will be used when starting the server.

Example

The following example demonstrates creating an instance of the **InternetServer** class object and starting a server using the Start method.

```
Dim Server As SocketTools.InternetServer
Dim strLocalAddress As String
Dim nLocalPort As Integer
Dim nBacklog As Integer
Dim nMaxClients As Integer
Dim nTimeout As Integer

Server = New SocketTools.InternetServer

strLocalAddress = TextBox1.Text.Trim()
nLocalPort = Val(TextBox2.Text)
nBacklog = Val(TextBox3.Text)
nMaxClients = Val(TextBox4.Text)
nTimeout = Val(TextBox5.Text)

If Server.Start(strLocalAddress, nLocalPort, nBacklog, nMaxClients, nTimeout) Then
    StatusBar1.Text = "The server has started listening for connections"
Else
    StatusBar1.Text = "The server could not be started"
End If
```

InternetServer Class | SocketTools Namespace | InternetServer.Start Overload List | Options Property

InternetServer.Start Method (String, Int32, Int32, Int32, Int32, ServerOptions)

Start listening for client connections on the specified IP address and port number.

[Visual Basic]
```
Overloads Public Function Start( _
   ByVal localAddress As String, _
   ByVal localPort As Integer, _
   ByVal backlog As Integer, _
   ByVal maxClients As Integer, _
   ByVal timeout As Integer, _
   ByVal options As ServerOptions _
) As Boolean
```

[C#]
```
public bool Start(
   string localAddress,
   int localPort,
   int backlog,
   int maxClients,
   int timeout,
   ServerOptions options
);
```

Parameters

localAddress

A string value which specifies the IP address of the network adapter that the control should use when listening for connection requests. If this is an empty string or the special address "0.0.0.0" is specified, the server will listen for connection on all valid network interfaces configured for the local system.

localPort

An integer value which specifies the port number that the server should use when listening for incoming client connections. Valid port numbers are in the range of 1 through 65535.

backlog

An integer value which specifies the maximum size of the queue used to manage pending connections to the service. If the argument is set to value which exceeds the maximum size for the underlying service provider, it will be silently adjusted to the nearest legal value. On Windows workstations, the maximum backlog value is 5. On Windows servers, the maximum value is 200.

maxClients

An integer value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of active client connections that may be established with the server. This value can be adjusted after the server has been created by calling the **Throttle** method.

timeout

An integer value which specifies the number of seconds the control will wait for a network operation to complete. The default timeout period of 20 seconds is sufficient for most applications.

options

One or more of the ServerOptions enumeration flags.

Return Value

A boolean value which specifies if the server has been started. A return value of **true** specifies that the operation was successful. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Start** method begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread.

Example

The following example demonstrates creating an instance of the **InternetServer** class object and starting a server using the Start method.

```
Dim Server As SocketTools.InternetServer
Dim strLocalAddress As String
Dim nLocalPort As Integer
Dim nBacklog As Integer
Dim nMaxClients As Integer
Dim nTimeout As Integer

Server = New SocketTools.InternetServer

strLocalAddress = TextBox1.Text.Trim()
nLocalPort = Val(TextBox2.Text)
nBacklog = Val(TextBox3.Text)
nMaxClients = Val(TextBox4.Text)
nTimeout = Val(TextBox5.Text)

If Server.Start(strLocalAddress, nLocalPort, nBacklog, nMaxClients, nTimeout) Then
    StatusBar1.Text = "The server has started listening for connections"
Else
    StatusBar1.Text = "The server could not be started"
End If
```

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Start Overload List

InternetServer.Stop Method

Stop listening for new client connections and terminate all active clients already connected to the server.

[Visual Basic]

```
Public Function Stop() As Boolean
```

[C#]

```
public bool Stop();
```

Return Value

A boolean value which specifies if the server was stopped. A return value of **true** specifies that the server has been successfully stopped. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Stop** method instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session.

If this method is called when there is one or more clients connected to the server, it will signal each client thread to terminate and then wait for the server thread to terminate. As the client sessions are terminated, the **OnDisconnect** event handler will not be invoked. If you wish to ensure that all clients are disconnected normally before stopping the server, call the **Suspend** method with the **suspendDisconnect** option and then stop the server after the last client has disconnected.

After the server has been terminated, the closed listening socket will go into a TIME-WAIT state which prevents an application from reusing the same address and port number bound to that socket for a brief period of time, typically two to four minutes. This is normal behavior designed to prevent delayed or misrouted packets of data from being read by a subsequent connection. To immediately start a new server using the same local address and port number, set the **ReuseAddress** property to a value of **true**.

InternetServer.Suspend Method

Suspend accepting new client connections.

Overload List

Suspend accepting new client connections.

public bool Suspend();

Suspend accepting new client connections with additional options.

public bool Suspend(SuspendOptions);

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Suspend Method (SuspendOptions)

Suspend accepting new client connections with additional options.

[Visual Basic]

```
Overloads Public Function Suspend( _
   ByVal options As SuspendOptions _
) As Boolean
```

[C#]

```
public bool Suspend(
   SuspendOptions options
);
```

Parameters

options
One or more of the SuspendOptions enumeration flags.

Return Value

A boolean value which specifies if the server was suspended. A return value of **true** specifies that the server has suspended accepting new client connections. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Suspend** method instructs the server to suspend accepting new client connections. By default, any incoming client connections will be queued up to the maximum backlog value specified when the server was started. To resume accepting client connections, call the **Resume** method.

If the **suspendDisconnect** option is specified, the server will signal each client to disconnect and will stop accepting new connections. The **OnDisconnect** event handler will be invoked for each client that disconnects from the server. If the **suspendWait** option is also specified, this method will wait until the last client has disconnected from the server before returning to the caller. If there are a large number of clients connected to the server, this process may cause the application to block for an extended period of time and appear to be non-responsive to the user. For this reason, you should not specify the **suspendWait** option if the method is being called from the application's main UI thread.

To perform a graceful shutdown of the server, it is recommended that you call the **Suspend** method with the **suspendReject** and **suspendDisconnect** options. This will allow each client to disconnect from the server and the server will reject any new incoming connections. After the last client has disconnected from the server, the **OnIdle** event handler will be invoked and the application can call the **Stop** method to complete the shutdown process.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Suspend Overload List | SuspendOptions Enumeration

InternetServer.Suspend Method ()

Suspend accepting new client connections.

[Visual Basic]
```
Overloads Public Function Suspend() As Boolean
```

[C#]
```
public bool Suspend();
```

Return Value

A boolean value which specifies if the server was suspended. A return value of **true** specifies that the server has suspended accepting new client connections. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Suspend** method instructs the server to suspend accepting new client connections. By default, any incoming client connections will be queued up to the maximum backlog value specified when the server was started. To resume accepting client connections, call the **Resume** method.

It is not recommended that you leave a server in a suspended state for extended periods of time. Once the connection backlog queue has filled, subsequent incoming client connections will be rejected. If you wish to suspend the server for more than a few seconds, call the overloaded version of this method and specify the **suspendReject** option. This will reject all incoming client connections to the server, rather than forcing clients to wait.

InternetServer Class | SocketTools Namespace | InternetServer.Suspend Overload List

InternetServer.Throttle Method

Limit the maximum number of client connections.

Overload List

Limit the maximum number of client connections.

public bool Throttle(int);

Limit the maximum number of client connections and connections per IP address.

public bool Throttle(int,int);

Limit the maximum number of client connections, connections per IP address and connection rate.

public bool Throttle(int,int,int);

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Throttle Method (Int32)

Limit the maximum number of client connections.

[Visual Basic]

```
Overloads Public Function Throttle( _
   ByVal maxClients As Integer _
) As Boolean
```

[C#]

```
public bool Throttle(
   int maxClients
);
```

Parameters

maxClients

An integer value that specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

Return Value

A boolean value which specifies if the method was successful. A return value of **true** indicates success. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then the **Throttle** method is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Throttle Overload List

InternetServer.Throttle Method (Int32, Int32)

Limit the maximum number of client connections and connections per IP address.

[Visual Basic]

```
Overloads Public Function Throttle( _
   ByVal maxClients As Integer, _
   ByVal maxClientsPerAddress As Integer _
) As Boolean
```

[C#]

```
public bool Throttle(
   int maxClients,
   int maxClientsPerAddress
);
```

Parameters

maxClients
An integer value that specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

maxClientsPerAddress
An integer value that specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

Return Value

A boolean value which specifies if the method was successful. A return value of **true** indicates success. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then the **Throttle** method is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Throttle Overload List

InternetServer.Throttle Method (Int32, Int32, Int32)

Limit the maximum number of client connections, connections per IP address and connection rate.

[Visual Basic]

```
Overloads Public Function Throttle( _
   ByVal maxClients As Integer, _
   ByVal maxClientsPerAddress As Integer, _
   ByVal connectionRate As Integer _
) As Boolean
```

[C#]

```
public bool Throttle(
   int maxClients,
   int maxClientsPerAddress,
   int connectionRate
);
```

Parameters

maxClients

An integer value that specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

maxClientsPerAddress

An integer value that specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

connectionRate

An integer value that specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

A boolean value which specifies if the method was successful. A return value of **true** indicates success. If an error occurs, the method returns **false** and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **Start** method is called with the maximum number of clients set to 100, and then the **Throttle** method is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

InternetServer Class | SocketTools Namespace | InternetServer.Throttle Overload List

InternetServer.Uninitialize Method

Uninitialize the class library and release any resources allocated for the server.

[Visual Basic]

```
Public Sub Uninitialize()
```

[C#]

```
public void Uninitialize();
```

Remarks

The **Uninitialize** method terminates any active connection, releases resources allocated for the server and unloads the networking library. After this method has been called, no further network operations may be performed until the class instance has been re-initialized.

If the **Initialize** method is explicitly called by the application, it should be matched by a call to the **Uninitialize** method when that instance of the class is no longer needed.

See Also

InternetServer Class | SocketTools Namespace | Initialize Method

InternetServer.Unlock Method

Unlock the server and allow other server threads to resume execution.

[Visual Basic]
```
Public Function Unlock() As Boolean
```

[C#]
```
public bool Unlock();
```

Return Value

A boolean value which specifies if the server was unlocked. A return value of **true** specifies that the server was unlocked, and the threads being managed by the server have resumed normal execution. A return value of **false** indicates that the server could not be unlocked, typically because a potential deadlock was detected.

Remarks

The **Unlock** method releases the lock on the server and allows any blocked threads to resume execution. Only one server may be locked at any one time, and only the thread which established the lock can unlock the server.

Every time the **Lock** method is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to the **Lock** method must be matched by an equal number of calls to the **Unlock** method. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

The program should always check the return value from this method, and should never assume that the lock has been released. If a potential deadlock situation is detected, this method will fail and return a value of false.

The **IsLocked** property can be used to determine if the server has been locked.

InternetServer Class | SocketTools Namespace | Lock Method | IsLocked Property

InternetServer.Write Method

Write one or more bytes of data to a client.

Overload List

Write one or more bytes of data to a client.

public int Write(byte[]);

Write one or more bytes of data to a client.

public int Write(byte[],int);

Write one or more bytes of data to a client.

public int Write(int,byte[]);

Write one or more bytes of data to a client.

public int Write(int,byte[],int);

Write a string of characters to a client.

public int Write(int,string);

Write a string of characters to a client.

public int Write(int,string,int);

Write a string of characters to a client.

public int Write(string);

Write a string of characters to a client.

public int Write(string,int);

See Also

InternetServer Class | SocketTools Namespace

InternetServer.Write Method (Byte[])

Write one or more bytes of data to a client.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer
);
```

Parameters

buffer

A byte array that contains the data to be written to the client.

Return Value

An integer value which specifies the number of bytes actually written to the client. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to a client. If there is enough room in the client socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space the method will block the current thread until the data can be sent.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Write** method outside of an event handler, you must explicitly specify the client handle.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.Write Overload List

InternetServer.Write Method (Byte[], Int32)

Write one or more bytes of data to a client.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   byte[] buffer,
   int length
);
```

Parameters

buffer

A byte array that contains the data to be written to the client.

length

An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the client. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to a client. If there is enough room in the client socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space the method will block the current thread until the data can be sent.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Write** method outside of an event handler, you must explicitly specify the client handle.

InternetServer.Write Method (Int32, Byte[])

Write one or more bytes of data to a client.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal handle As Integer, _
   ByVal buffer As Byte() _
) As Integer
```

[C#]

```
public int Write(
   int handle,
   byte[] buffer
);
```

Parameters

handle
: An integer value which specifies the handle to the client session.

buffer
: A byte array that contains the data to be written to the client.

Return Value

An integer value which specifies the number of bytes actually written to the client. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the specified client. If there is enough room in the client socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space the method will block the current thread until the data can be sent.

```
Overloads Public Function Write( _
   ByVal handle As Integer, _
   ByVal buffer As Byte(), _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   int handle,
   byte[] buffer,
   int length
);
```

Parameters

handle
An integer value which specifies the handle to the client session.

buffer
A byte array that contains the data to be written to the client.

length
An integer value which specifies the maximum number of bytes of data to write. This value cannot be larger than the size of the buffer specified by the caller.

Return Value

An integer value which specifies the number of bytes actually written to the client. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends one or more bytes of data to the specified client. If there is enough room in the client socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space the method will block the current thread until the data can be sent.

InternetServer Class | SocketTools Namespace | InternetServer.Write Overload List | Broadcast Method

InternetServer.Write Method (Int32, String)

Write a string of characters to a client.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal handle As Integer, _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   int handle,
   string buffer
);
```

Parameters

handle
An integer value which specifies the handle to the client session.

buffer
A string which contains the data to be written to the client.

Return Value

An integer value which specifies the number of characters actually written to the client. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to a client. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space the method will block the current thread until the data can be sent.

InternetServer Class | SocketTools Namespace | InternetServer.Write Overload List

InternetServer.Write Method (Int32, String, Int32)

Write a string of characters to a client.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal handle As Integer, _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   int handle,
   string buffer,
   int length
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

buffer

A string which contains the data to be written to the client.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the client. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to a client. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space the method will block the current thread until the data can be sent.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

You should never use strings to read and write binary data. Always use byte arrays to ensure that no character conversion is performed.

InternetServer Class | SocketTools Namespace | InternetServer.Write Overload List

InternetServer.Write Method (String)

Write a string of characters to a client.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String _
) As Integer
```

[C#]

```
public int Write(
   string buffer
);
```

Parameters

buffer

A string which contains the data to be written to the client.

Return Value

An integer value which specifies the number of characters actually written to the client. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to a client. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space the method will block the current thread until the data can be sent.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Write** method outside of an event handler, you must explicitly specify the client handle.

Write a string of characters to a client.

[Visual Basic]

```
Overloads Public Function Write( _
   ByVal buffer As String, _
   ByVal length As Integer _
) As Integer
```

[C#]

```
public int Write(
   string buffer,
   int length
);
```

Parameters

buffer

A string which contains the data to be written to the client.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

An integer value which specifies the number of characters actually written to the client. If an error occurs, a value of -1 is returned and the application should check the value of the **LastError** property to determine the cause of the failure.

Remarks

The **Write** method sends a string of characters to a client. If there is enough room in the socket's internal send buffer to accommodate all of the data, it is copied to the send buffer and control immediately returns to the caller. If amount of data exceeds the available buffer space the method will block the current thread until the data can be sent.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **Write** method outside of an event handler, you must explicitly specify the client handle.

InternetServer Class | SocketTools Namespace

InternetServer.WriteLine Method ()

Send an empty line of text to a client, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine() As Boolean
```

[C#]

```
public bool WriteLine();
```

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method will send an empty line of text to the client, terminated by a carriage-return and linefeed. Calling this method will force the calling thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **WriteLine** method outside of an event handler, you must explicitly specify the client handle.

The **Write** and **WriteLine** methods can be safely intermixed.

InternetServer Class | SocketTools Namespace | InternetServer.WriteLine Overload List

InternetServer.WriteLine Method (Int32)

Send an empty line of text to a client, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine( _
   ByVal handle As Integer _
) As Boolean
```

[C#]

```
public bool WriteLine(
   int handle
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method will send an empty line of text to the specified client, terminated by a carriage-return and linefeed. Calling this method will force the calling thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection.

The **Write** and **WriteLine** methods can be safely intermixed.

InternetServer Class | SocketTools Namespace | InternetServer.WriteLine Overload List

InternetServer.WriteLine Method (Int32, String)

Send a line of text to a client, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine( _
   ByVal handle As Integer, _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool WriteLine(
   int handle,
   string buffer
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

buffer

A string which contains the data that will be sent to the specified client. The data will always be terminated with a carriage-return and linefeed control character sequence. If the string is empty, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null character will be discarded.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method should only be used to send text, never binary data. In particular, this method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this method will force the current thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection.

The **Write** and **WriteLine** methods can be safely intermixed.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.WriteLine Overload List

InternetServer.WriteLine Method (Int32, String, Int32)

Send a line of text to a client, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine( _
   ByVal handle As Integer, _
   ByVal buffer As String, _
   ByRef length As Integer _
) As Boolean
```

[C#]

```
public bool WriteLine(
   int handle,
   string buffer,
   ref int length
);
```

Parameters

handle

An integer value which specifies the handle to the client session.

buffer

A string which contains the data that will be sent to the specified client. The data will always be terminated with a carriage-return and linefeed control character sequence. If the string is empty, then a only a carriage-return and linefeed are written to the client. Note that if the string contains a null character, any data that follows the null character will be discarded.

length

An integer value which specifies the maximum number of characters to write. This value cannot be larger than the length of the string specified by the caller.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method should only be used to send text, never binary data. In particular, this method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this method will force the current thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection.

The string will be converted to an array of bytes before being written to the socket. By default, the character encoding used will be for the current locale. Depending on the contents of the string, the number of bytes written may be different than the string length specified. This is because the conversion from Unicode to a byte array may result in a multi-byte character sequence.

You should never use strings to read and write binary data. Always use byte arrays to ensure that no character conversion is performed.

The **Write** and **WriteLine** methods can be safely intermixed.

See Also

InternetServer Class | SocketTools Namespace | InternetServer.WriteLine Overload List

InternetServer.WriteLine Method (String)

Send a line of text to a client, terminated by a carriage-return and linefeed.

[Visual Basic]

```
Overloads Public Function WriteLine( _
   ByVal buffer As String _
) As Boolean
```

[C#]

```
public bool WriteLine(
   string buffer
);
```

Parameters

buffer

A string which contains the data that will be sent to the client. The data will always be terminated with a carriage-return and linefeed control character sequence. If the string is empty, then a only a carriage-return and linefeed are written to the socket. Note that if the string contains a null character, any data that follows the null byte will be discarded.

Return Value

A boolean value which specifies if the operation completed successfully. A return value of **false** indicates an error has occurred. To get extended error information, check the value of the **LastError** property.

Remarks

The **WriteLine** method should only be used to send text, never binary data. In particular, this method will discard any data that follows a null character and will append linefeed and carriage return control characters to the data stream. Calling this method will force the current thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection.

This implementation of the method can only be used within a class event handler, or a method that has been invoked from within an event handler. If you need to call the **WriteLine** method outside of an event handler, you must explicitly specify the client handle.

The **Write** and **WriteLine** methods can be safely intermixed.

InternetServer Events

The events of the **InternetServer** class are listed below. For a complete list of **InternetServer** class members, see the InternetServer Members topic.

Public Instance Events

⚡ OnAccept	Occurs when a client attempts to establish a connection with the server.
⚡ OnCancel	Occurs when a blocking socket operation is canceled.
⚡ OnConnect	Occurs when a connection is established with the remote host.
⚡ OnDisconnect	Occurs when the remote host disconnects from the local system.
⚡ OnError	Occurs when an socket operation fails.
⚡ OnIdle	Occurs when the there are no clients connected to the server.
⚡ OnRead	Occurs when data is available to be read from the client.
⚡ OnStart	Occurs when the server starts accepting connections.
⚡ OnStop	Occurs when the server stops accepting connections.
⚡ OnTimeout	Occurs when a blocking operation fails to complete before the timeout period elapses.
⚡ OnWrite	Occurs when data can be written to the client.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.OnAccept Event

Occurs when a client attempts to establish a connection with the server.

```
[Visual Basic]
Public Event OnAccept As OnAcceptEventHandler
```

```
[C#]
public event OnAcceptEventHandler OnAccept;
```

Event Data

The event handler receives an argument of type InternetServer.AcceptEventArgs containing data related to this event. The following **InternetServer.AcceptEventArgs** properties provide information specific to this event.

Property	Description
ClientAddress	Gets a value that specifies the Internet address of the current client session.
ClientPort	Gets a value that specifies the port number used by the current client session.
Handle	Gets a value that specifies the socket handle for the listening server.

Remarks

The **OnAccept** event occurs when a client attempts to connect to the local system. A connection is not actually established until it has been accepted by the server.

The **ClientAddress** or **ClientHost** properties may be used to determine the Internet address and host name of the remote host that is establishing the connection. To prevent the client from completing the connection, call the **Reject** method.

After the client connection has been established and the worker thread for that client session has started, the **OnConnect** event will fire.

User interface controls can only be accessed from the UI thread that created them, and attempting to update a control from another thread can result in the program becoming non-responsive or terminating abnormally. Because this event is generated in the context of the server thread, not the thread that created the class instance, you cannot directly modify a control from within this event handler. Instead, you must create a delegate and use the **Invoke** method to marshal invocations to the associated UI thread. For more information, refer to the documentation for the control.

See Also

InternetServer Class | SocketTools Namespace

InternetServer.AcceptEventArgs Class

Provides data for the OnAccept event.

For a list of all members of this type, see InternetServer.AcceptEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.InternetServer.AcceptEventArgs

[Visual Basic]
```
Public Class InternetServer.AcceptEventArgs
    Inherits EventArgs
```

[C#]
```
public class InternetServer.AcceptEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

AcceptEventArgs specifies the socket handle for the server that should accept the incoming client connection.

The OnAccept event occurs when a remote host attempts to establish a connection with the local system.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

InternetServer.AcceptEventArgs Members

InternetServer.AcceptEventArgs overview

Public Instance Constructors

InternetServer.AcceptEventArgs Constructor	Initializes a new instance of the InternetServer.AcceptEventArgs class.

Public Instance Properties

ClientAddress	Gets a value that specifies the Internet address of the current client session.
ClientPort	Gets a value that specifies the port number used by the current client session.
Handle	Gets a value that specifies the socket handle for the listening server.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetServer.AcceptEventArgs Class | SocketTools Namespace

InternetServer.AcceptEventArgs Properties

The properties of the **InternetServer.AcceptEventArgs** class are listed below. For a complete list of **InternetServer.AcceptEventArgs** class members, see the InternetServer.AcceptEventArgs Members topic.

Public Instance Properties

ClientAddress	Gets a value that specifies the Internet address of the current client session.
ClientPort	Gets a value that specifies the port number used by the current client session.
Handle	Gets a value that specifies the socket handle for the listening server.

See Also

InternetServer.AcceptEventArgs Class | SocketTools Namespace | OnAccept Event (SocketTools.InternetServer)

InternetServer.AcceptEventArgs.ClientAddress Property

Gets a value that specifies the Internet address of the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientAddress As String
```

[C#]

```
public string ClientAddress {get;}
```

Remarks

The **ClientAddress** property will return the address of the client that is requesting the connection. The server application may use this information to determine if it wishes to accept or reject the client connection.

See Also

InternetServer.AcceptEventArgs Class | SocketTools Namespace

InternetServer.AcceptEventArgs.ClientPort Property

Gets a value that specifies the port number used by the current client session.

[Visual Basic]

```
Public ReadOnly Property ClientPort As Integer
```

[C#]

```
public int ClientPort {get;}
```

Remarks

The **ClientPort** property returns the port number that the client has used when establishing a connection with the server.

See Also

InternetServer.AcceptEventArgs Class | SocketTools Namespace

InternetServer.AcceptEventArgs.Handle Property

Gets a value that specifies the socket handle for the listening server.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer value which specifies the server socket handle.

Remarks

The **Handle** property returns the socket handle for the server that generated the event. This value is used for identification purposes only and should not be used in conjunction with methods such as **Read** and **Write**, which may only be used with client handles.

See Also

InternetServer.AcceptEventArgs Class | SocketTools Namespace

InternetServer.OnCancel Event

Occurs when a blocking socket operation is canceled.

[Visual Basic]
```
Public Event OnCancel As OnCancelEventHandler
```

[C#]
```
public event OnCancelEventHandler OnCancel;
```

Event Data

The event handler receives an argument of type InternetServer.CancelEventArgs containing data related to this event. The following **InternetServer.CancelEventArgs** property provides information specific to this event.

Property	Description
Handle	Gets a value that specifies the socket handle for the client session.

Remarks

The **OnCancel** event is generated when a blocking socket operation, such as sending or receiving data, is canceled with the **Cancel** method.

User interface controls can only be accessed from the UI thread that created them, and attempting to update a control from another thread can result in the program becoming non-responsive or terminating abnormally. Because this event is generated in the context of the client thread, not the thread that created the class instance, you cannot directly modify a control from within this event handler. Instead, you must create a delegate and use the **Invoke** method to marshal invocations to the associated UI thread. For more information, refer to the documentation for the control.

Provides data for the OnCancel event.

For a list of all members of this type, see InternetServer.CancelEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.InternetServer.CancelEventArgs

[Visual Basic]

```
Public Class InternetServer.CancelEventArgs
    Inherits EventArgs
```

[C#]

```
public class InternetServer.CancelEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

CancelEventArgs specifies the socket handle for the current client session.

The OnCancel event occurs when a blocking network operation has been canceled.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

InternetServer.CancelEventArgs.Handle Property

Gets a value that specifies the socket handle for the client session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer value which specifies the client socket handle.

Remarks

The **Handle** property returns the socket handle for the client that generated the event. This handle can be used in conjunction with methods such as **Read** and **Write** to exchange data with the client.

See Also

InternetServer.CancelEventArgs Class | SocketTools Namespace

InternetServer.OnConnect Event

Occurs when a connection is established with the remote host.

[Visual Basic]

```
Public Event OnConnect As OnConnectEventHandler
```

[C#]

```
public event OnConnectEventHandler OnConnect;
```

Event Data

The event handler receives an argument of type InternetServer.ConnectEventArgs containing data related to this event. The following **InternetServer.ConnectEventArgs** property provides information specific to this event.

Property	Description
Handle	Gets a value that specifies the socket handle for the client session.

Remarks

The **OnConnect** event occurs when the client connection to the server has completed.

The **ClientAddress** property can be used to determine the IP address of the client which established the connection. To terminate the client connection, use the **Disconnect** method.

User interface controls can only be accessed from the UI thread that created them, and attempting to update a control from another thread can result in the program becoming non-responsive or terminating abnormally. Because this event is generated in the context of the client thread, not the thread that created the class instance, you cannot directly modify a control from within this event handler. Instead, you must create a delegate and use the **Invoke** method to marshal invocations to the associated UI thread. For more information, refer to the documentation for the control.

System.Object
  System.EventArgs
    SocketTools.InternetServer.ConnectEventArgs

[Visual Basic]
```
Public Class InternetServer.ConnectEventArgs
    Inherits EventArgs
```

[C#]
```
public class InternetServer.ConnectEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ConnectEventArgs specifies the socket handle for the current client session.

The OnConnect event occurs when the client connection to the server has completed. The **Handle** property specifies the handle to the client socket that was allocated for the session. This handle can be used with methods such as **Read** and **Write** to exchange information with the client.

The **ClientAddress** property can be used to determine the IP address of the client which established the connection. To terminate the client connection, use the **Disconnect** method.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

See Also

InternetServer.ConnectEventArgs Class | SocketTools Namespace

InternetServer.ConnectEventArgs Properties

The properties of the **InternetServer.ConnectEventArgs** class are listed below. For a complete list of **InternetServer.ConnectEventArgs** class members, see the InternetServer.ConnectEventArgs Members topic.

Public Instance Properties

Handle	Gets a value that specifies the socket handle for the client session.

See Also

InternetServer.ConnectEventArgs Class | SocketTools Namespace | OnConnect Event (SocketTools.InternetServer)

InternetServer.ConnectEventArgs.Handle Property

Gets a value that specifies the socket handle for the client session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer value which specifies the client socket handle.

Remarks

The **Handle** property returns the socket handle for the client that generated the event. This handle can be used in conjunction with methods such as **Read** and **Write** to exchange data with the client.

See Also

InternetServer.ConnectEventArgs Class | SocketTools Namespace

InternetServer.OnDisconnect Event

Occurs when the remote host disconnects from the local system.

[Visual Basic]

```
Public Event OnDisconnect As OnDisconnectEventHandler
```

[C#]

```
public event OnDisconnectEventHandler OnDisconnect;
```

Event Data

The event handler receives an argument of type InternetServer.DisconnectEventArgs containing data related to this event. The following **InternetServer.DisconnectEventArgs** property provides information specific to this event.

Property	Description
Handle	Gets a value that specifies the socket handle for the client session.

Remarks

The **OnDisconnect** event is generated when the connection is terminated by the client and there is no more data available to be read.

It is not necessary to call the **Disconnect** method inside the **OnDisconnect** event handler because the client session is already in the process of disconnecting from the server.

User interface controls can only be accessed from the UI thread that created them, and attempting to update a control from another thread can result in the program becoming non-responsive or terminating abnormally. Because this event is generated in the context of the client thread, not the thread that created the class instance, you cannot directly modify a control from within this event handler. Instead, you must create a delegate and use the **Invoke** method to marshal invocations to the associated UI thread. For more information, refer to the documentation for the control.

[Visual Basic]

```
Public Class InternetServer.DisconnectEventArgs
    Inherits EventArgs
```

[C#]

```
public class InternetServer.DisconnectEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

DisconnectEventArgs specifies the socket handle for the current client session.

The OnDisconnect event is generated when the connection is terminated by the client and there is no more data available to be read. The **Handle** property specifies the socket handle of the client session which has terminated. It is important to note that the client handle is provided for informational purposes only and the application should not attempt to read or write data using this handle from within this event handler.

It is not necessary to call the **Disconnect** method inside the **OnDisconnect** event handler because the client session is already in the process of disconnecting from the server.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

InternetServer.DisconnectEventArgs.Handle Property

Gets a value that specifies the socket handle for the client session.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer value which specifies the client socket handle.

Remarks

The **Handle** property returns the socket handle for the client that generated the event. This handle can be used in conjunction with methods such as **Read** and **Write** to exchange data with the client.

See Also

InternetServer.DisconnectEventArgs Class | SocketTools Namespace

InternetServer.OnError Event

Occurs when an socket operation fails.

[Visual Basic]

```
Public Event OnError As OnErrorEventHandler
```

[C#]

```
public event OnErrorEventHandler OnError;
```

Event Data

The event handler receives an argument of type InternetServer.ErrorEventArgs containing data related to this event. The following **InternetServer.ErrorEventArgs** properties provide information specific to this event.

Property	Description
Description	Gets a value which describes the last error that has occurred.
Error	Gets a value which specifies the last error that has occurred.
Handle	Gets a value that specifies the socket handle that generated the error.

Remarks

The **OnError** event occurs when a socket operation fails.

User interface controls can only be accessed from the UI thread that created them, and attempting to update a control from another thread can result in the program becoming non-responsive or terminating abnormally. Because this event may be generated in the context of the client or server thread, not the thread that created the class instance, you cannot directly modify a control from within this event handler. Instead, you must create a delegate and use the **Invoke** method to marshal invocations to the associated UI thread. For more information, refer to the documentation for the control.

[C#]

```
public string Description {get;}
```

Property Value

A string which describes the last error that has occurred.

See Also

InternetServer.ErrorEventArgs Class | SocketTools Namespace | Error Property

InternetServer.ErrorEventArgs.Error Property

Gets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public ReadOnly Property Error As ErrorCode
```

[C#]

```
public InternetServer.ErrorCode Error {get;}
```

Property Value

ErrorCode enumeration which specifies the error.

See Also

InternetServer.ErrorEventArgs Class | SocketTools Namespace | Description Property

InternetServer.ErrorEventArgs.Handle Property

Gets a value that specifies the socket handle that generated the error.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer value which specifies a socket handle.

Remarks

The **Handle** property returns the socket handle for the client or server that generated the event. If no server is active, then this property will return a value of -1.

See Also

InternetServer.ErrorEventArgs Class | SocketTools Namespace

InternetServer.OnRead Event

Occurs when data is available to be read from the client.

```
[Visual Basic]
Public Event OnRead As OnReadEventHandler
```

```
[C#]
public event OnReadEventHandler OnRead;
```

Event Data

The event handler receives an argument of type InternetServer.ReadEventArgs containing data related to this event. The following **InternetServer.ReadEventArgs** property provides information specific to this event.

Property	Description
Handle	Gets a value that specifies the socket handle for the client session.

Remarks

The **OnRead** event is generated when the client sends data to the server. The **Handle** event argument property specifies the handle to the client socket which can be used with the **Read** or **ReadLine** methods to read the data that was sent.

When this event fires, it guarantees that data can be read from the specified client without causing the current thread to enter a blocked state. However, calling this method multiple times inside the event handler may cause the current thread to block when there is no more data available to read. The **IsReadable** property can be used to determine if there is additional data available to be read.

User interface controls can only be accessed from the UI thread that created them, and attempting to update a control from another thread can result in the program becoming non-responsive or terminating abnormally. Because this event is generated in the context of the client thread, not the thread that created the class instance, you cannot directly modify a control from within this event handler. Instead, you must create a delegate and use the **Invoke** method to marshal invocations to the associated UI thread. For more information, refer to the documentation for the control.

Example

```
Private Sub Server_OnRead(ByVal sender As Object, ByVal e As System.EventArgs)
Handles Socket.OnRead
    Dim strBuffer As String
    Dim nRead As Integer

    ' Read up to m_nBufferSize bytes of data from the client
    nRead = Server1.Read(e.Handle, strBuffer, m_nBufferSize)

    If nRead > 0 Then
        ' Process the data that has been read from the client
        ProcessData(strBuffer)
    End If
End Sub
```

InternetServer.ReadEventArgs Class

Provides data for the OnRead event.

For a list of all members of this type, see InternetServer.ReadEventArgs Members.

System.Object
  System.EventArgs
    SocketTools.InternetServer.ReadEventArgs

[Visual Basic]

```
Public Class InternetServer.ReadEventArgs
    Inherits EventArgs
```

[C#]

```
public class InternetServer.ReadEventArgs : EventArgs
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

ReadEventArgs specifies the socket handle for the current client session.

The OnRead event is generated when the client sends data to the server. The **Handle** event argument property specifies the handle to the client socket which can be used with the **Read** or **ReadLine** methods to read the data that was sent.

When this event fires, it guarantees that data can be read from the specified client without causing the current thread to enter a blocked state. However, calling this method multiple times inside the event handler may cause the current thread to block when there is no more data available to read. The **IsReadable** property can be used to determine if there is additional data available to be read.

InternetServer.ReadEventArgs overview

Public Instance Constructors

InternetServer.ReadEventArgs Constructor	Initializes a new instance of the InternetServer.ReadEventArgs class.

Public Instance Properties

Handle	Gets a value that specifies the socket handle for the client session.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetServer.OnTimeout Event

Occurs when a blocking operation fails to complete before the timeout period elapses.

[Visual Basic]

```
Public Event OnTimeout As OnTimeoutEventHandler
```

[C#]

```
public event OnTimeoutEventHandler OnTimeout;
```

Event Data

The event handler receives an argument of type InternetServer.TimeoutEventArgs containing data related to this event. The following **InternetServer.TimeoutEventArgs** property provides information specific to this event.

Property	Description
Handle	Gets a value that specifies the socket handle for the client session.

Remarks

The **OnTimeout** event occurs when a blocking operation, such as sending or receiving data on the socket, fails to complete before the specified timeout period elapses. The timeout period for a blocking operation can be adjusted by setting the **Timeout** property.

User interface controls can only be accessed from the UI thread that created them, and attempting to update a control from another thread can result in the program becoming non-responsive or terminating abnormally. Because this event is generated in the context of the client thread, not the thread that created the class instance, you cannot directly modify a control from within this event handler. Instead, you must create a delegate and use the **Invoke** method to marshal invocations to the associated UI thread. For more information, refer to the documentation for the control.

InternetServer.TimeoutEventArgs Class | SocketTools Namespace

InternetServer.OnWrite Event

Occurs when data can be written to the client.

[Visual Basic]

```
Public Event OnWrite As OnWriteEventHandler
```

[C#]

```
public event OnWriteEventHandler OnWrite;
```

Event Data

The event handler receives an argument of type InternetServer.WriteEventArgs containing data related to this event. The following **InternetServer.WriteEventArgs** property provides information specific to this event.

Property	Description
Handle	Gets a value that specifies the socket handle for the client session.

Remarks

The **OnWrite** event is generated when the client can accept data from the server. The **Handle** event argument property specifies the handle to the client socket and can be used in conjunction with the **Write** or **WriteLine** methods.

This event is typically fired once when the client connection is established with the server, the session thread starts and the client socket enters a writable state. If the internal send buffer for the client socket becomes full, this event will fire again when more data can be written to the socket. It is important to note that this event is level-triggered and will not fire repeatedly if the client socket is writable. Under most circumstances this event fire only once for each client session after the initial connection has been established.

User interface controls can only be accessed from the UI thread that created them, and attempting to update a control from another thread can result in the program becoming non-responsive or terminating abnormally. Because this event is generated in the context of the client thread, not the thread that created the class instance, you cannot directly modify a control from within this event handler. Instead, you must create a delegate and use the **Invoke** method to marshal invocations to the associated UI thread. For more information, refer to the documentation for the control.

InternetServer.WriteEventArgs Class | SocketTools Namespace

InternetServer.OnAcceptEventHandler Delegate

Represents the method that will handle the OnAccept event.

[Visual Basic]

```
Public Delegate Sub InternetServer.OnAcceptEventHandler( _
   ByVal sender As Object, _
   ByVal e As AcceptEventArgs _
)
```

[C#]

```
public delegate void InternetServer.OnAcceptEventHandler(
      object sender,
      AcceptEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An AcceptEventArgs that contains the event data.

Remarks

When you create an **OnAcceptEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnAcceptEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

See Also

SocketTools Namespace | OnAccept Event

InternetServer.OnCancelEventHandler Delegate

Represents the method that will handle the OnCancel event.

[Visual Basic]

```
Public Delegate Sub InternetServer.OnCancelEventHandler( _
   ByVal sender As Object, _
   ByVal e As CancelEventArgs _
)
```

[C#]

```
public delegate void InternetServer.OnCancelEventHandler(
      object sender,
      CancelEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An CancelEventArgs that contains the event data.

Remarks

When you create an **OnCancelEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnCancelEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

SocketTools Namespace

InternetServer.OnConnectEventHandler Delegate

Represents the method that will handle the OnConnect event.

[Visual Basic]

```
Public Delegate Sub InternetServer.OnConnectEventHandler( _
   ByVal sender As Object, _
   ByVal e As ConnectEventArgs _
)
```

[C#]

```
public delegate void InternetServer.OnConnectEventHandler(
      object sender,
      ConnectEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ConnectEventArgs that contains the event data.

Remarks

When you create an **OnConnectEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnConnectEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

See Also

SocketTools Namespace

InternetServer.OnDisconnectEventHandler Delegate

Represents the method that will handle the OnDisconnect event.

[Visual Basic]

```
Public Delegate Sub InternetServer.OnDisconnectEventHandler( _
   ByVal sender As Object, _
   ByVal e As DisconnectEventArgs _
)
```

[C#]

```
public delegate void InternetServer.OnDisconnectEventHandler(
      object sender,
      DisconnectEventArgs e
   );
```

Parameters

sender
: The source of the event.

e
: An DisconnectEventArgs that contains the event data.

Remarks

When you create an **OnDisconnectEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnDisconnectEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

See Also

SocketTools Namespace

InternetServer.OnErrorEventHandler Delegate

Represents the method that will handle the OnError event.

[Visual Basic]

```
Public Delegate Sub InternetServer.OnErrorEventHandler( _
   ByVal sender As Object, _
   ByVal e As ErrorEventArgs _
)
```

[C#]

```
public delegate void InternetServer.OnErrorEventHandler(
      object sender,
      ErrorEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ErrorEventArgs that contains the event data.

Remarks

When you create an **OnErrorEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnErrorEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

See Also

SocketTools Namespace

InternetServer.OnReadEventHandler Delegate

Represents the method that will handle the OnRead event.

[Visual Basic]

```
Public Delegate Sub InternetServer.OnReadEventHandler( _
   ByVal sender As Object, _
   ByVal e As ReadEventArgs _
)
```

[C#]

```
public delegate void InternetServer.OnReadEventHandler(
      object sender,
      ReadEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An ReadEventArgs that contains the event data.

Remarks

When you create an **OnReadEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnReadEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

SocketTools Namespace

InternetServer.OnTimeoutEventHandler Delegate

Represents the method that will handle the OnTimeout event.

[Visual Basic]

```
Public Delegate Sub InternetServer.OnTimeoutEventHandler( _
   ByVal sender As Object, _
   ByVal e As TimeoutEventArgs _
)
```

[C#]

```
public delegate void InternetServer.OnTimeoutEventHandler(
      object sender,
      TimeoutEventArgs e
   );
```

Parameters

sender

The source of the event.

e

An TimeoutEventArgs that contains the event data.

Remarks

When you create an **OnTimeoutEventHandler** delegate, you identify the method that will handle the event. To associate the event with your event handler, add an instance of the delegate to the event. The event handler is called whenever the event occurs, until you remove the delegate.

Note that the declaration of your event handler must have the same parameters as the **OnTimeoutEventHandler** delegate declaration.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

InternetServer.ErrorCode Enumeration

Specifies the error codes returned by the InternetServer class.

[Visual Basic]
```
Public Enum InternetServer.ErrorCode
```

[C#]
```
public enum InternetServer.ErrorCode
```

Remarks

The InternetServer class uses the **ErrorCode** enumeration to specify what error has occurred when a method fails. The current error code may be determined by checking the value of the **LastError** property.

Note that the last error code is only meaningful if the previous operation has failed.

Members

Member Name	Description
errorNone	No error.
errorNotHandleOwner	Handle not owned by the current thread.
errorFileNotFound	The specified file or directory does not exist.
errorFileNotCreated	The specified file could not be created.
errorOperationCanceled	The blocking operation has been canceled.
errorInvalidFileType	The specified file is a block or character device, not a regular file.
errorInvalidDevice	The specified file type is invalid or not a regular file.
errorTooManyParameters	The maximum number of function parameters has been exceeded.
errorInvalidFileName	The specified file name contains invalid characters or is too long.
errorInvalidFileHandle	Invalid file handle passed to function.
errorFileReadFailed	Unable to read data from the specified file.
errorFileWriteFailed	Unable to write data to the specified file.
errorOutOfMemory	Out of memory.
errorAccessDenied	Access denied.
errorInvalidParameter	Invalid argument passed to function.
errorClipboardUnavailable	The system clipboard is currently unavailable.
errorClipboardEmpty	The system clipboard is empty or does not contain any text data.
errorFileEmpty	The specified file does not contain any data.
errorFileExists	The specified file already exists.

errorEndOfFile	End of file.
errorDeviceNotFound	The specified device could not be found.
errorDirectoryNotFound	The specified directory could not be found.
errorInvalidbuffer	Invalid memory address passed to function.
errorBufferTooSmall	The specified buffer is not large enough to contain the data.
errorNoHandles	No more handles are available to this process.
errorOperationWouldBlock	The specified operation would block the current thread.
errorOperationInProgress	A blocking operation is currently in progress.
errorAlreadyInProgress	The specified operation is already in progress.
errorInvalidHandle	Invalid handle passed to function.
errorInvalidAddress	Invalid network address specified.
errorInvalidSize	Datagram is too large to fit in specified buffer.
errorInvalidProtocol	Invalid network protocol specified.
errorProtocolNotAvailable	The specified network protocol is not available.
errorProtocolNotSupported	The specified protocol is not supported.
errorSocketNotSupported	The specified socket type is not supported.
errorInvalidOption	The specified option is invalid.
errorProtocolFamily	Specified protocol family is not supported.
errorProtocolAddress	The specified address is invalid for this protocol family.
errorAddressInUse	The specified address is in use by another process.
errorAddressUnavailable	The specified address cannot be assigned.
errorNetworkUnavailable	The networking subsystem is unavailable.
errorNetworkUnreachable	The specified network is unreachable.
errorNetworkReset	Network dropped connection on remote reset.
errorConnectionAborted	Connection was aborted due to timeout or other failure.
errorConnectionReset	Connection was reset by remote network.
errorOutOfBuffers	No buffer space is available.
errorAlreadyConnected	Connection already established with remote host.
errorNotConnected	No connection established with remote host.
errorConnectionShutdown	Unable to send or receive data after connection shutdown.
errorOperationTimeout	The specified operation has timed out.
errorConnectionRefused	The connection has been refused by the remote host.

errorHostUnavailable	The specified host is unavailable.
errorHostUnreachable	Remote host is unreachable.
errorTooManyProcesses	Too many processes are using the networking subsystem.
errorTooManyThreads	Too many threads have been created by the current process.
errorTooManySessions	Too many client sessions have been created by the current process.
errorInternalFailure	An unexpected internal error has occurred.
errorNetworkNotReady	Network subsystem is not ready for communication.
errorInvalidVersion	This version of the operating system is not supported.
errorNetworkNotInitialized	The networking subsystem has not been initialized.
errorRemoteShutdown	The remote host has initiated a graceful shutdown sequence.
errorInvalidHostName	The specified hostname is invalid or could not be resolved.
errorHostNameNotFound	The specified hostname could not be found.
errorHostNameRefused	Unable to resolve hostname, request refused.
errorHostNameNotResolved	Unable to resolve hostname, no address for specified host.
errorInvalidLicense	The license for this product is invalid.
errorProductNotLicensed	This product is not licensed to perform this operation.
errorNotImplemented	This function has not been implemented on this platform.
errorUnknownLocalhost	Unable to determine local host name.
errorInvalidHostAddress	Invalid host address specified.
errorInvalidServicePort	Invalid service port number specified.
errorInvalidServiceName	Invalid or unknown service name specified.
errorInvalidEventId	Invalid event identifier specified.
errorOperationNotBlocking	No blocking operation in progress on this socket.
errorSecurityNotInitialized	Unable to initialize security interface for this process.
errorSecurityContext	Unable to establish security context for this session.
errorSecurityCredentials	Unable to open certificate store or establish security credentials.
errorSecurityCertificate	Unable to validate the certificate chain for this

	session.
errorSecurityDecryption	Unable to decrypt data stream.
errorSecurityEncryption	Unable to encrypt data stream.
errorOperationNotSupported	The specified operation is not supported.
errorInvalidProtocolVersion	Invalid application protocol version specified.
errorNoServerResponse	No data returned from server.
errorInvalidServerResponse	Invalid data returned from server.
errorUnexpectedServerResponse	Unexpected response code returned from server.
errorServerTransactionFailed	Server transaction failed.
errorServiceUnavailable	The service is currently unavailable.
errorServiceNotReady	The service is not ready, try again later.
errorServerResyncFailed	Unable to resynchronize with server.
errorInvalidProxyType	Invalid proxy server type specified.
errorProxyRequired	Resource must be accessed through specified proxy.
errorInvalidProxyLogin	Unable to login to proxy server using specified credentials.
errorProxyResyncFailed	Unable to resynchronize with proxy server.
errorInvalidCommand	Invalid command specified.
errorInvalidCommandParameter	Invalid command parameter specified.
errorInvalidCommandSequence	Invalid command sequence specified.
errorCommandNotImplemented	Specified command not implemented on this server.
errorCommandNotAuthorized	Specified command not authorized for the current user.
errorCommandAborted	Specified command was aborted by the remote host.
errorOptionNotSupported	The specified option is not supported on this server.
errorRequestNotCompleted	The current client request has not been completed.
errorInvalidUserName	The specified username is invalid.
errorInvalidPassword	The specified password is invalid.
errorInvalidAccount	The specified account name is invalid.
errorAccountRequired	Account name has not been specified.
errorInvalidAuthenticationType	Invalid authentication protocol specified.
errorAuthenticationRequired	User authentication is required.
errorProxyAuthenticationRequired	Proxy authentication required.

errorAlreadyAuthenticated	User has already been authenticated.
errorAuthenticationFailed	Unable to authenticate the specified user.
errorNetworkAdapter	Unable to determine network adapter configuration.
errorInvalidRecordType	Invalid record type specified.
errorInvalidRecordName	Invalid record name specified.
errorInvalidRecordData	Invalid record data specified.
errorConnectionOpen	Data connection already established.
errorConnectionClosed	Server closed data connection.
errorConnectionPassive	Data connection is passive.
errorConnectionFailed	Unable to open data connection to server.
errorInvalidSecurityLevel	Data connection cannot be opened with this security setting.
errorCachedTLSRequired	Data connection requires cached TLS session.
errorDataReadOnly	Data connection is read-only.
errorDataWriteOnly	Data connection is write-only.
errorEndOfData	End of data.
errorRemoteFileUnavailable	Remote file is unavailable.
errorInsufficientStorage	Insufficient storage on server.
errorStorageallocation	File exceeded storage allocation on server.
errorDirectoryExists	The specified directory already exists.
errorDirectoryEmpty	No files returned by the server for the specified directory.
errorEndOfDirectory	End of directory listing.
errorUnknownDirectoryFormat	Unknown directory format.
errorInvalidResource	Invalid resource name specified.
errorResourceRedirected	The specified resource has been redirected.
errorResourceRestricted	Access to this resource has been restricted.
errorResourceNotModified	The specified resource has not been modified.
errorResourceNotFound	The specified resource cannot be found.
errorResourceConflict	Request could not be completed due to the current state of the resource.
errorResourceRemoved	The specified resource has been permanently removed from this server.
errorContentLengthRequired	Request must include the content length.
errorRequestPrecondition	Request could not be completed due to server precondition.
errorUnsupportedMediaType	Request specified an unsupported media type.

errorInvalidContentRange	Content range specified for this resource is invalid.
errorInvalidMessagePart	Message is not multipart or an invalid message part was specified.
errorInvalidMessageHeader	The specified message header is invalid or has not been defined.
errorInvalidMessageBoundary	The multipart message boundary has not been defined.
errorNoFileAttachment	The current message part does not contain a file attachment.
errorUnknownFileType	The specified file type could not be determined.
errorDataNotEncoded	The specified data block could not be encoded.
errorDataNotDecoded	The specified data block could not be decoded.
errorFileNotEncoded	The specified file could not be encoded.
errorFileNotDecoded	The specified file could not be decoded.
errorNoMessageText	No message text.
errorInvalidCharacterSet	Invalid character set specified.
errorInvalidEncodingType	Invalid encoding type specified.
errorInvalidMessageNumber	Invalid message number specified.
errorNoReturnAddress	No valid return address specified.
errorNoValidRecipients	No valid recipients specified.
errorInvalidRecipient	The specified recipient address is invalid.
errorRelayNotAuthorized	The specified domain is invalid or server will not relay messages.
errorMailboxUnavailable	Specified mailbox is currently unavailable.
errorMailboxReadOnly	The selected mailbox cannot be modified.
errorMailboxNotSelected	No mailbox has been selected.
errorInvalidMailbox	Specified mailbox is invalid.
errorInvalidDomain	The specified domain name is invalid or not recognized.
errorInvalidSender	The specified sender address is invalid or not recognized.
errorMessageNotDelivered	Message not delivered to any of the specified recipients.
errorEndOfMessageData	No more message data available to be read
errorInvalidmessageSize	The specified message size is invalid.
errorMessageNotCreated	The message could not be created in the specified mailbox.
errorNoMoreMailboxes	No more mailboxes exist on this server.

errorInvalidEmulationType	The specified terminal emulation type is invalid.
errorInvalidFontHandle	The specified font handle is invalid.
errorInvalidFontName	The specified font name is invalid or unavailable.
errorInvalidPacketSize	The specified packet size is invalid.
errorInvalidPacketData	The specified packet data is invalid.
errorInvalidPacketId	The unique packet identifier is invalid.
errorPacketTTLExpired	The specified packet time-to-live period has expired.
errorInvalidNewsGroup	Invalid newsgroup specified.
errorNoNewsgroupSelected	No newsgroup selected.
errorEmptyNewsgroup	No articles in specified newsgroup.
errorInvalidArticle	Invalid article number specified.
errorNoArticleSelected	No article selected in the current newsgroup.
errorFirstArticle	First article in current newsgroup.
errorLastArticle	Last article in current newsgroup.
errorArticleExists	Unable to transfer article, article already exists.
errorArticleRejected	Unable to transfer article, article rejected.
errorArticleTransferFailed	Article transfer failed.
errorArticlePostingDenied	Posting is not permitted on this server.
errorArticlePostingFailed	Unable to post article on this server.
errorInvalidDateFormat	The specified date format is not recognized.
errorFeatureNotSupported	The specified feature is not supported on this server.
errorInvalidFormHandle	The specified form handle is invalid or a form has not been created.
errorInvalidFormAction	The specified form action is invalid or has not been specified.
errorInvalidFormMethod	The specified form method is invalid or not supported.
errorInvalidFormType	The specified form type is invalid or not supported.
errorInvalidFormField	The specified form field name is invalid or does not exist.
errorEmptyForm	The specified form does not contain any field values.
errorMaximumConnections	The maximum number of client connections exceeded.
errorThreadCreationFailed	Unable to create a new thread for the current process.
errorInvalidThreadHandle	The specified thread handle is no longer valid.

errorThreadTerminated	The specified thread has been terminated.
errorThreadDeadlock	The operation would result in the current thread becoming deadlocked.
errorInvalidClientMoniker	The specified moniker is not associated with any client session.
errorClientMonikerExists	The specified moniker has been assigned to another client session.
errorServerInactive	The specified server is not listening for client connections.
errorServerSuspended	The specified server is suspended and not accepting client connections.
errorNoMessageStore	No message store has been specified.
errorMessageStoreChanged	The message store has changed since it was last accessed.
errorMessageNotFound	No message was found that matches the specified criteria.
errorMessageDeleted	The specified message has been deleted.
errorFileChecksumMismatch	The local and remote file checksums do not match.
errorFileSizeMismatch	The local and remote file sizes do not match.
errorInvalidFeedUrl	The news feed URL is invalid or specifies an unsupported protocol.
errorInvalidFeedFormat	The internal format of the news feed is invalid.
errorInvalidFeedVersion	This version of the news feed is not supported.
errorChannelEmpty	There are no valid items found in this news feed.
errorInvalidItemNumber	The specified channel item identifier is invalid.
errorItemNotFound	The specified channel item could not be found.
errorItemEmpty	The specified channel item does not contain any data.
errorInvalidItemProperty	The specified item property name is invalid.
errorItemPropertyNotFound	The specified item property has not been defined.
errorInvalidChannelTitle	The channel title is invalid or has not been defined.
errorInvalidChannelLink	The channel hyperlink is invalid or has not been defined.
errorInvalidChannelDescription	The channel description is invalid or has not been defined.
errorInvalidItemText	The description for an item is invalid or has not been defined.
errorInvalidItemLink	The hyperlink for an item is invalid or has not been defined.

errorInvalidServiceType	The specified service type is invalid.
errorServiceSuspended	Access to the specified service has been suspended.
errorServiceRestricted	Access to the specified service has been restricted.
errorInvalidProviderName	The specified provider name is invalid or unknown.
errorInvalidPhoneNumber	The specified phone number is invalid or not supported in this region.
errorGatewayNotFound	A message gateway cannot be found for the specified provider.
errorMessageTooLong	The message exceeds the maximum number of characters permitted.
errorInvalidProviderData	The request returned invalid or incomplete service provider data.
errorInvalidGatewayData	The request returned invalid or incomplete message gateway data.
errorMultipleProviders	The request has returned multiple service providers.
errorProviderNotFound	The specified service provider could not be found.
errorInvalidMessageService	The specified message is not supported with this service type.
errorInvalidMessageFormat	The specified message format is invalid.
errorInvalidConfiguration	The specified configuration options are invalid.
errorServerActive	The requested action is not permitted while the server is active.
errorServerPortBound	Unable to obtain exclusive use of the specified local port.
errorInvalidClientSession	The specified client identifier is invalid for this session.
errorClientNotIdentified	The specified client has not provided user credentials.
errorInvalidClientState	The requested action cannot be performed at this time.
errorInvalidResultCode	The specified result code is not valid for this protocol
errorCommandRequired	The specified command is required and cannot be disabled.
errorCommandDisabled	The specified command has been disabled.
errorCommandSequence	The command cannot be processed at this time.
errorCommandCompleted	The previous command has completed.
errorInvalidProgramName	The specified program name is invalid or unrecognized.

errorInvalidRequestHeader	The request header contains one or more invalid values.
errorInvalidVirtualHost	The specified virtual host name is invalid.
errorVirtualHostNotFound	The specified virtual host does not exist.
errorTooManyVirtualHosts	Too many virtual hosts created for this server.
errorInvalidVirtualPath	The specified virtual path name is invalid.
errorVirtualPathNotFound	The specified virtual path does not exist.
errorTooManyVirtualPaths	Too many virtual paths created for this server.
errorInvalidTask	The asynchronous task identifier is invalid.
errorTaskActive	The asynchronous task has not finished.
errorTaskQueued	The asynchronous task has been queued.
errorTaskSuspended	The asynchronous task has been suspended.
errorTaskFinished	The asynchronous task has finished.

InternetServer.SecurityProtocols Enumeration

Specifies the security protocols that the InternetServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetServer.SecurityProtocols
```

[C#]

```
[Flags]
public enum InternetServer.SecurityProtocols
```

Remarks

The InternetServer class uses the **SecurityProtocols** enumeration to specify one or more security protocols to be used when establishing a connection with a remote host. Multiple protocols may be specified if necessary and the actual protocol used will be negotiated with the remote host. It is recommended that most applications use **protocolDefault** when starting a secure server.

Members

Member Name	Description	Value
protocolNone	No security protocol will be used, a secure connection will not be established.	0
protocolSSL2	The SSL 2.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections.	1
protocolSSL3	The SSL 3.0 protocol has been selected. This protocol has been deprecated and is no longer widely used. It is not recommended that this protocol be used when establishing secure connections. In most cases, this protocol is only selected if TLS is not supported by the server.	2
protocolTLS10	The TLS 1.0 protocol has been selected. This version of the protocol is commonly used by older servers and is the only version of TLS supported on Windows platforms prior to Windows 7 SP1 and Windows Server 2008 R2.	4
protocolTLS11	The TLS 1.1 protocol has been selected. This version of TLS is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of the	8

	operating system.	
protocolTLS12	The TLS 1.2 protocol has been selected. This is the default version of the protocol and is supported on Windows 7 SP1 and Windows Server 2008 R2 and later versions of Windows. It is recommended that you use this version of TLS.	16
protocolSSL	Any version of the Secure Sockets Layer (SSL) protocol should be used. The actual protocol version used will be negotiated with the remote host.	3
protocolTLS	Any version of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with with preference for TLS 1.2.	28
protocolTLS1	Version 1.0, 1.1 or 1.2 of the the Transport Layer Security (TLS) protocol should be used. The actual protocol version used will be negotiated with the remote host, with preference for TLS 1.2.	28
protocolDefault	The default selection of security protocols will be used when establishing a connection. The TLS 1.2, 1.1 and 1.0 protocols will be negotiated with the host, in that order of preference. This option will always request the latest version of the preferred security protocols and is the recommended value.	16
protocolUnknown	An unknown or unsupported security protocol has been specified. This value indicates an error condition.	4096

InternetServer.ServerOptions Enumeration

Specifies the options that the InternetServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetServer.ServerOptions
```

[C#]

```
[Flags]
public enum InternetServer.ServerOptions
```

Remarks

The InternetServer class uses the **ServerOptions** enumeration to specify one or more options to be used when establishing a connection with a remote host. Multiple options may be specified if necessary.

Members

Member Name	Description	Value
optionNone	No option specified.	0
optionDontRoute	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.	2
optionKeepAlive	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This option is only valid for stream sockets.	4
optionReuseAddress	This option specifies the local address can be reused. This option is commonly used by server applications.	8
optionNoDelay	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.	16
optionSecure	This option specifies that a secure, encrypted connection will be established with the remote host.	4096
optionSecureFallback	This option specifies the server should permit the use of less secure cipher suites for compatibility with legacy clients. If this option is specified, the server will permit connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.	32768

SocketTools Namespace

InternetServer.ServerPriority Enumeration

Specifies the priorities that the InternetServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

[Visual Basic]

```
<Flags>
Public Enum InternetServer.ServerPriority
```

[C#]

```
[Flags]
public enum InternetServer.ServerPriority
```

Members

Member Name	Description	Value
priorityBackground	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. Each client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.	0
priorityLow	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. Each client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.	1
priorityNormal	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.	2
priorityHigh	This priority increases the overall resource utilization for each client session and their threads will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.	3
priorityCritical	This priority can significantly increase processor, memory and network utilization. Each client thread will be given higher scheduling priority and will be more responsive to network events. It is not recommended that this priority be used on a system with a single	4

	processor.	
priorityInvalid	An invalid transfer priority which indicates an error condition.	-1
priorityDefault	The default server priority. This is the same as specifying **priorityNormal**.	2
priorityLowest	The lowest valid server priority. This is the same as specifying **priorityBackground**.	0
priorityHighest	The highest valid server priority. This is the same as specifying **priorityCritical**.	4

InternetServer.ServerStatus Enumeration

Specifies the status values that may be returned by the InternetServer class.

[Visual Basic]
```
Public Enum InternetServer.ServerStatus
```

[C#]
```
public enum InternetServer.ServerStatus
```

Remarks

The InternetServer class uses the **ServerStatus** enumeration to identify the current status of the server.

Members

Member Name	Description
serverInactive	The server is currently inactive. This status is returned when no server has been started, or after a server has been stopped.
serverStarted	The server has initialized and is preparing to listen for client connections. This status is returned after the server thread has been started, but before the listening socket has been created.
serverListening	The server is actively listening for incoming client connections. This status is returned after the server thread has been started and the listening socket has been created.
serverSuspended	The server has been suspended and is no longer accepting client connections. Any incoming client connection is queued, and will be accepted when the server resumes normal operation.
serverShutdown	The server has been stopped and is in the process of terminating all active client sessions.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

SocketTools Namespace

InternetServer.TraceOptions Enumeration

Specifies the logging options that the InternetServer class supports.

This enumeration has a FlagsAttribute attribute that allows a bitwise combination of its member values.

```
[Visual Basic]
<Flags>
Public Enum InternetServer.TraceOptions
```

```
[C#]
[Flags]
public enum InternetServer.TraceOptions
```

Remarks

The InternetServer class uses the **TraceOptions** enumeration to specify what kind of debugging information is written to the trace logfile. These options are only meaningful when trace logging is enabled by setting the **Trace** property to **true**.

Members

Member Name	Description	Value
traceDefault	The default trace logging option. This is the same as specifying the **traceInfo** option.	0
traceInfo	All network function calls are written to the trace file. This is the default value.	0
traceError	Only those network function calls which fail are recorded in the trace file.	1
traceWarning	Only those network function calls which fail, or return values which indicate a warning, are recorded in the trace file.	2
traceHexDump	All network function calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.	4
traceProcess	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.	4096

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

See Also

SocketTools Namespace

InternetServer.RuntimeLicenseAttribute Class

Attribute that defines the runtime license key for the class.

For a list of all members of this type, see InternetServer.RuntimeLicenseAttribute Members.

System.Object
  System.Attribute
    SocketTools.InternetServer.RuntimeLicenseAttribute

[Visual Basic]

```
<AttributeUsage(ValidOn:=AttributeTargets.Assembly, AllowMultiple:=False,
   Inherited:=True)>
Public Class InternetServer.RuntimeLicenseAttribute
    Inherits Attribute
```

[C#]

```
[AttributeUsage(ValidOn=AttributeTargets.Assembly, AllowMultiple=False,
   Inherited=True)]
public class InternetServer.RuntimeLicenseAttribute : Attribute
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The RuntimeLicense attribute is used to define the runtime license key that will be used when an instance of the class is created. This attribute is defined in the assembly information module for the language, such as AssemblyInfo.cs when programming C#. The runtime license key must be defined if you wish to redistribute your application.

The runtime license key can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the InternetServer class.

Example

```
<Assembly: SocketTools.InternetServer.RuntimeLicense("abcdefghijklmnop")>
```

```
[assembly: SocketTools.InternetServer.RuntimeLicense("abcdefghijklmnop")]
```

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

InternetServer.RuntimeLicenseAttribute overview

Public Instance Constructors

InternetServer.RuntimeLicenseAttribute Constructor	Constructor for the RuntimeLicense attribute which defines the runtime license key.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

Public Instance Methods

Equals (inherited from Attribute)	
GetHashCode (inherited from Attribute)	Returns the hash code for this instance.
GetType (inherited from Object)	Gets the Type of the current instance.
IsDefaultAttribute (inherited from Attribute)	When overridden in a derived class, returns an indication whether the value of this instance is the default value for the derived class.
Match (inherited from Attribute)	When overridden in a derived class, returns a value indicating whether this instance equals a specified object.
ToString (inherited from Object)	Returns a String that represents the current Object.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetServer.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetServer.RuntimeLicenseAttribute Constructor

Constructor for the RuntimeLicense attribute which defines the runtime license key.

[Visual Basic]

```
Public Sub New( _
   ByVal licenseKey As String _
)
```

[C#]

```
public InternetServer.RuntimeLicenseAttribute(
   string licenseKey
);
```

Parameters

licenseKey

A string argument which specifies the runtime license key which will be used to initialize the class library.

Remarks

The runtime license key can be generated using the License Manager utility that is included with the product. Note that if you have installed an evaluation license, you will not have a runtime license key and cannot redistribute any applications which use the InternetServer class.

InternetServer.RuntimeLicenseAttribute Properties

The properties of the **InternetServer.RuntimeLicenseAttribute** class are listed below. For a complete list of **InternetServer.RuntimeLicenseAttribute** class members, see the InternetServer.RuntimeLicenseAttribute Members topic.

Public Instance Properties

LicenseKey	Returns the value of the runtime license key.
TypeId (inherited from Attribute)	When implemented in a derived class, gets a unique identifier for this Attribute.

See Also

InternetServer.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetServer.RuntimeLicenseAttribute.LicenseKey Property

Returns the value of the runtime license key.

[Visual Basic]

```
Public Property LicenseKey As String
```

[C#]

```
public string LicenseKey {get; set;}
```

Property Value

A string which contains the runtime license key.

See Also

InternetServer.RuntimeLicenseAttribute Class | SocketTools Namespace

InternetServerException Class

The exception that is thrown when a socket error occurs.

For a list of all members of this type, see InternetServerException Members.

System.Object
  System.Exception
    System.ApplicationException
      SocketTools.InternetServerException

[Visual Basic]
```
Public Class InternetServerException
    Inherits ApplicationException
```

[C#]
```
public class InternetServerException : ApplicationException
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

A InternetServerException is thrown by the InternetServer class when an error occurs.

The default constructor for the InternetServerException class sets the **ErrorCode** property to the last socket error that occurred.

Requirements

Namespace: SocketTools

Assembly: SocketTools.InternetServer (in SocketTools.InternetServer.dll)

InternetServerException Members

InternetServerException overview

Public Instance Constructors

InternetServerException	Overloaded. Initializes a new instance of the InternetServerException class.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
Handle	Gets a value which specifies the socket handle that generated the error.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

InternetServerException Class | SocketTools Namespace

InternetServerException Constructor

Initializes a new instance of the InternetServerException class with the last network error code.

Overload List

Initializes a new instance of the InternetServerException class with the last network error code.

public InternetServerException();

Initializes a new instance of the InternetServerException class with the last network error code for the specified socket.

public InternetServerException(int);

Initializes a new instance of the InternetServerException class with a specified error number.

public InternetServerException(int,int);

Initializes a new instance of the InternetServerException class with a specified error message.

public InternetServerException(int,string);

Initializes a new instance of the InternetServerException class with a specified error message and a reference to the inner exception that is the cause of this exception.

public InternetServerException(int,string,Exception);

See Also

InternetServerException Class | SocketTools Namespace

InternetServerException Constructor ()

Initializes a new instance of the InternetServerException class with the last network error code.

[Visual Basic]

```
Overloads Public Sub New()
```

[C#]

```
public InternetServerException();
```

Remarks

The ctor constructor sets the **ErrorCode** property to the last socket error that occurred. For more information about the errors that may occur, refer to the InternetServer.ErrorCode enumeration.

See Also

InternetServerException Class | SocketTools Namespace | InternetServerException Constructor Overload List

InternetServerException Constructor (Int32)

Initializes a new instance of the InternetServerException class with the last network error code for the specified socket.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal handle As Integer _
)
```

[C#]

```
public InternetServerException(
   int handle
);
```

Parameters

handle

An integer value which specifies the handle to the socket which generated the error.

Remarks

The ctor constructor sets the **ErrorCode** property to the last socket error that occurred. For more information about the errors that may occur, refer to the InternetServer.ErrorCode enumeration.

See Also

InternetServerException Class | SocketTools Namespace | InternetServerException Constructor Overload List

InternetServerException Constructor (Int32, String)

Initializes a new instance of the InternetServerException class with a specified error message.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal handle As Integer, _
   ByVal message As String _
)
```

[C#]

```
public InternetServerException(
   int handle,
   string message
);
```

Parameters

handle

An integer value which specifies the handle to the socket which generated the error.

message

The error message that explains the reason for the exception.

Remarks

The content of the ***message*** parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

See Also

InternetServerException Class | SocketTools Namespace | InternetServerException Constructor Overload List

InternetServerException Constructor (Int32, String, Exception)

Initializes a new instance of the InternetServerException class with a specified error message and a reference to the inner exception that is the cause of this exception.

[Visual Basic]

```
Overloads Public Sub New( _
   ByVal handle As Integer, _
   ByVal message As String, _
   ByVal innerException As Exception _
)
```

[C#]

```
public InternetServerException(
   int handle,
   string message,
   Exception innerException
);
```

Parameters

handle

An integer value which specifies the handle to the socket which generated the error.

message

The error message that explains the reason for the exception.

innerException

The exception that is the cause of the current exception. If the *innerException* parameter is not a null reference, the current exception is raised in a **catch** block that handles the inner exception.

Remarks

The content of the message parameter is intended to be understood by humans. The caller of this constructor is required to ensure that this string has been localized for the current system culture.

An exception that is thrown as a direct result of a previous exception should include a reference to the previous exception in the **InnerException** property. The **InnerException** property returns the same value that is passed into the constructor, or a null reference if the **InnerException** property does not supply the inner exception value to the constructor.

InternetServerException Class | SocketTools Namespace | InternetServerException Constructor Overload List

InternetServerException Properties

The properties of the **InternetServerException** class are listed below. For a complete list of **InternetServerException** class members, see the InternetServerException Members topic.

Public Instance Properties

ErrorCode	Gets a value which specifies the error that caused the exception.
Handle	Gets a value which specifies the socket handle that generated the error.
HelpLink (inherited from Exception)	Gets or sets a link to the help file associated with this exception.
InnerException (inherited from Exception)	Gets the Exception instance that caused the current exception.
Message	Gets a value which describes the error that caused the exception.
Number	Gets a value which specifies the numeric value of the error that caused the exception.
Source (inherited from Exception)	Gets or sets the name of the application or the object that causes the error.
StackTrace (inherited from Exception)	Gets a string representation of the frames on the call stack at the time the current exception was thrown.
TargetSite (inherited from Exception)	Gets the method that throws the current exception.

Protected Instance Properties

HResult (inherited from Exception)	Gets or sets HRESULT, a coded numerical value that is assigned to a specific exception.

See Also

InternetServerException Class | SocketTools Namespace

InternetServerException.ErrorCode Property

Gets a value which specifies the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property ErrorCode As ErrorCode
```

[C#]

```
public InternetServer.ErrorCode ErrorCode {get;}
```

Property Value

Returns a InternetServer.ErrorCode enumeration value which specifies the error code.

Remarks

The **ErrorCode** property returns the error code that specifies the cause of the exception.

The default constructor for the InternetServerException class sets the error code to the last network error that occurred. For more information about the errors that may occur, refer to the InternetServer.ErrorCode enumeration.

See Also

InternetServerException Class | SocketTools Namespace

InternetServerException.Message Property

Gets a value which describes the error that caused the exception.

[Visual Basic]

```
Overrides Public ReadOnly Property Message As String
```

[C#]

```
public override string Message {get;}
```

Property Value

A string which describes the error that caused the exception.

Remarks

The **Message** property returns a string which describes the error that caused the exception.

See Also

InternetServerException Class | SocketTools Namespace

InternetServerException.Number Property

Gets a value which specifies the numeric value of the error that caused the exception.

[Visual Basic]

```
Public ReadOnly Property Number As Integer
```

[C#]

```
public int Number {get;}
```

Property Value

An integer value that specifies the error that caused the exception.

Remarks

The **Number** property returns an integer value which specifies the numeric value of the error that caused the exception. This value may be the same as values returned by the Windows Sockets API. For more information about socket error codes, see the Windows Socket Version 2 API error code documentation in MSDN.

InternetServerException Class | SocketTools Namespace

InternetServerException Methods

The methods of the **InternetServerException** class are listed below. For a complete list of **InternetServerException** class members, see the InternetServerException Members topic.

Public Instance Methods

Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
GetBaseException (inherited from Exception)	When overridden in a derived class, returns the Exception that is the root cause of one or more subsequent exceptions.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetObjectData (inherited from Exception)	When overridden in a derived class, sets the SerializationInfo with information about the exception.
GetType (inherited from Object)	Gets the Type of the current instance.
ToString	Creates and returns a string representation of the current exception.

Protected Instance Methods

Finalize (inherited from Object)	Allows an Object to attempt to free resources and perform other cleanup operations before the Object is reclaimed by garbage collection.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

See Also

InternetServerException Class | SocketTools Namespace

InternetServerException.ToString Method

Creates and returns a string representation of the current exception.

[Visual Basic]
```
Overrides Public Function ToString() As String
```

[C#]
```
public override string ToString();
```

Return Value

A string representation of the current exception.

Remarks

The **ToString** method returns a representation of the current exception that is intended to be understood by humans. Where the exception contains culture-sensitive data, the string representation returned by **ToString** is required to take into account the current system culture. Although there are no exact requirements for the format of the returned string, it should attempt to reflect the value of the object as perceived by the user.

This implementation of **ToString** obtains the numeric error code value and a description of the error that caused the current exception. If there is no error message or it is an empty string, then no error message is returned.

This method overrides **ApplicationException.ToString**.

InternetServerException Class | SocketTools Namespace

MailMessage Class

Implements the Multipurpose Internet Mail Extensions standard.

For a list of all members of this type, see MailMessage Members.

System.Object
  SocketTools.MailMessage

[Visual Basic]
```
Public Class MailMessage
    Implements IDisposable
```

[C#]
```
public class MailMessage : IDisposable
```

Thread Safety

Public static (**Shared** in Visual Basic) members of this type are safe for multithreaded operations. Instance members are **not** guaranteed to be thread-safe.

Remarks

The MailMessage class provides an interface for composing and processing email messages and newsgroup articles which are structured according to the Multipurpose Internet Mail Extensions (MIME) standard. Using this class, an application can easily create complex messages which include multiple alternative content types, such as plain text and styled HTML text, file attachments and customized headers.

It is not required that the developer understand the complex MIME standard; a single method can be used to create multipart message, complete with a styled HTML text body and support for international character sets. The MailMessage class can be easily integrated with the other mail related protocol classes, making it extremely easy to create and process MIME formatted messages.

Requirements

Namespace: SocketTools

Assembly: SocketTools.MailMessage (in SocketTools.MailMessage.dll)

MailMessage Members

MailMessage overview

Public Instance Constructors

MailMessage Constructor	Initializes a new instance of the MailMessage class.

Public Instance Fields

Recipient	Gets the recipients specified in the current message.

Public Instance Properties

AllHeaders	Gets a value which returns a list of all message recipients.
AllRecipients	Gets a value which returns a list of all message recipients.
Attachment	Gets and sets the name of the current file attachment.
Bcc	Gets and sets the blind carbon-copy header field value.
Boundary	Gets the boundary string used to separate parts in a multipart message.
Cc	Gets and sets the carbon-copy header field value.
ContentId	Gets the content identifier for the current message part.
ContentLength	Gets the size of the data stored in the current message part.
ContentType	Gets and sets the content type of the selected message part.
Date	Gets and sets the date for the current message.
Encoding	Gets and sets the content encoding method used for the current message part.
From	Gets and sets the address of the user who sent the message.
Handle	Gets a value that specifies the client handle allocated for the current message.
HeaderField	Gets and sets the current header field name.
HeaderValue	Gets and sets the value of the current header field.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.

LastErrorString	Gets a value which describes the last error that has occurred.
Localize	Gets and sets a value which specifies if date and time values should be localized.
Mailer	Gets and sets the name of the mailer application.
Message	Gets and sets the current message headers and body.
MessageID	Gets the current message identifier.
MimeVersion	Gets and sets the MIME version number for the current message.
Options	Gets and sets a value which specifies one or more message export options.
Organization	Gets and sets the name of the organization that originated the message.
Part	Gets and sets the current message part.
PartCount	Gets the number of parts in the current message.
Priority	Gets and sets the current message priority.
Recipients	Gets the number of recipients specified in the current message.
ReplyTo	Gets and sets the address of the user who should receive replies to this message.
Sender	Gets and sets the address of the user who originated the message.
StoreCount	Gets the number of messages in the current storage file, not including deleted messages.
StoreFile	Gets and sets the name of the file used to store messages.
StoreIndex	Gets and sets the current message index for the current storage file.
StoreSize	Gets the total number of messages in the current storage file, including deleted messages.
Subject	Gets and sets the subject of the current message.
Text	Gets and sets the text body of the current message part.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
TimeZone	Gets and sets the current timezone offset in seconds.
To	Gets and sets the address of the message recipient.

Version	Gets a value which returns the current version of the MailMessage class library.

Public Instance Methods

AppendMessage	Append text to the body of the current message part.
AttachData	Overloaded. Attach the contents of a byte array to the current message.
AttachFile	Overloaded. Attach the specified file to the current message.
AttachImage	Overloaded. Attach an inline image to the current message.
AttachThread	Obsolete. Attach an instance of the class to the current thread.
ClearMessage	Clear the header and body of the current message.
CloseStore	Close the current message storage file.
ComposeMessage	Overloaded. Compose a new mail message.
CreatePart	Overloaded. Create a new message part in a multipart message.
DecodeText	Overloaded. Decode a string which was previously encoded using base64 or quoted-printable encoding.
DeleteHeader	Overloaded. Delete a header field from the specified message part.
DeleteMessage	Overloaded. Remove the specified message from the current message store.
DeletePart	Delete the specified message part from the current message.
Dispose	Overloaded. Releases all resources used by MailMessage.
EncodeText	Overloaded. Encodes a string using base64 or quoted-printable encoding.
Equals (inherited from Object)	Determines whether the specified Object is equal to the current Object.
ExportMessage	Overloaded. Export the current message to a file on the local system.
ExtractAllFiles	Overloaded. Extract all file attachments from the current message.
ExtractFile	Overloaded. Extract the contents of a file attachment and store it on the local system.
FindAttachment	Search for a specific file attachment in the current message.

FindMessage	Overloaded. Search for a message in the current message store.
GetFirstHeader	Return the first header in the current message part.
GetHashCode (inherited from Object)	Serves as a hash function for a particular type, suitable for use in hashing algorithms and data structures like a hash table.
GetHeader	Overloaded. Return the value of a header field in the specified message part.
GetNextHeader	Return the next header in the current message part.
GetType (inherited from Object)	Gets the Type of the current instance.
ImportMessage	Replace the current message with the contents of a file.
Initialize	Overloaded. Initialize an instance of the MailMessage class.
OpenStore	Overloaded. Open the specified message storage file.
ParseAddress	Overloaded. Parse an Internet email address.
ParseMessage	Parse the specified string, adding the contents to the current message.
PurgeStore	Purge all deleted messages from the current message store.
ReadStore	Overloaded. Retrieve a message from the message store, replacing the current message.
ReplaceMessage	Overloaded. Replace the specified message in the current message store.
Reset	Reset the internal state of the object, resetting all properties to their default values.
SetHeader	Overloaded. Set the value for a header in the specified message part.
ToString (inherited from Object)	Returns a String that represents the current Object.
Uninitialize	Uninitialize the class library and release any resources allocated for the current thread.
WriteStore	Store the current message in the message store.

Public Instance Events

OnError	Occurs when an client operation fails.

Protected Instance Methods

Dispose	Overloaded. Releases the unmanaged resources allocated by the MailMessage class and optionally

	releases the managed resources.
Finalize	Destroys an instance of the class, releasing the resources allocated for the current message.
MemberwiseClone (inherited from Object)	Creates a shallow copy of the current Object.

MailMessage Properties

The properties of the **MailMessage** class are listed below. For a complete list of **MailMessage** class members, see the MailMessage Members topic.

Public Instance Properties

AllHeaders	Gets a value which returns a list of all message recipients.
AllRecipients	Gets a value which returns a list of all message recipients.
Attachment	Gets and sets the name of the current file attachment.
Bcc	Gets and sets the blind carbon-copy header field value.
Boundary	Gets the boundary string used to separate parts in a multipart message.
Cc	Gets and sets the carbon-copy header field value.
ContentId	Gets the content identifier for the current message part.
ContentLength	Gets the size of the data stored in the current message part.
ContentType	Gets and sets the content type of the selected message part.
Date	Gets and sets the date for the current message.
Encoding	Gets and sets the content encoding method used for the current message part.
From	Gets and sets the address of the user who sent the message.
Handle	Gets a value that specifies the client handle allocated for the current message.
HeaderField	Gets and sets the current header field name.
HeaderValue	Gets and sets the value of the current header field.
IsInitialized	Gets a value which indicates if the current instance of the class has been initialized successfully.
LastError	Gets and sets a value which specifies the last error that has occurred.
LastErrorString	Gets a value which describes the last error that has occurred.
Localize	Gets and sets a value which specifies if date and time values should be localized.
Mailer	Gets and sets the name of the mailer application.

Message	Gets and sets the current message headers and body.
MessageID	Gets the current message identifier.
MimeVersion	Gets and sets the MIME version number for the current message.
Options	Gets and sets a value which specifies one or more message export options.
Organization	Gets and sets the name of the organization that originated the message.
Part	Gets and sets the current message part.
PartCount	Gets the number of parts in the current message.
Priority	Gets and sets the current message priority.
Recipients	Gets the number of recipients specified in the current message.
ReplyTo	Gets and sets the address of the user who should receive replies to this message.
Sender	Gets and sets the address of the user who originated the message.
StoreCount	Gets the number of messages in the current storage file, not including deleted messages.
StoreFile	Gets and sets the name of the file used to store messages.
StoreIndex	Gets and sets the current message index for the current storage file.
StoreSize	Gets the total number of messages in the current storage file, including deleted messages.
Subject	Gets and sets the subject of the current message.
Text	Gets and sets the text body of the current message part.
ThrowError	Gets and sets a value which specifies if method calls should throw exceptions when an error occurs.
TimeZone	Gets and sets the current timezone offset in seconds.
To	Gets and sets the address of the message recipient.
Version	Gets a value which returns the current version of the MailMessage class library.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.AllHeaders Property

Gets a value which returns a list of all message recipients.

[Visual Basic]

```
Public ReadOnly Property AllHeaders As String
```

[C#]

```
public string AllHeaders {get;}
```

Property Value

A string which contains the complete RFC822 headers for the message.

Remarks

The **AllHeaders** property will return all of the RFC 822 header values in a string. This includes the message headers that are most commonly referred to, such as the To, From and Subject headers. Each header and its value are separated by a colon, and terminated with a carriage return and linefeed (CRLF) pair.

The headers and their values returned by this property will not be identical to the header block in the original message. If a header value is split across multiple lines, the text returned by this property will be folded, with the complete header value on a single line of text and removing any extraneous whitespace. If the header value has been encoded by the mail client, this property will return the decoded value, not the original encoded value.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.AllRecipients Property

Gets a value which returns a list of all message recipients.

[Visual Basic]

```
Public ReadOnly Property AllRecipients As String
```

[C#]

```
public string AllRecipients {get;}
```

Property Value

A string which contains a comma-separated list of all message recipients.

Remarks

The **AllRecipients** property returns a string value that contains a comma-separated list of all message recipients. To individually enumerate through each of the recipient addresses, you can use the **Recipient** property array and **Recipients** property.

Note that this property value will include those addresses specified by the **Bcc** property, even though they are not included in the message header.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Attachment Property

Gets and sets the name of the current file attachment.

[Visual Basic]

```
Public ReadOnly Property Attachment As String
```

[C#]

```
public string Attachment {get;}
```

Property Value

A string which specifies the name of an attached file.

Remarks

The **Attachment** property specifies the name of the file attachment in a multipart message. When a new part is selected that contains an attached file, the **Attachment** property is updated to reflect the attached file's name.

This property is used by the attach and extract actions to specify the local file name that will be used. Changing its value does not change the attached file name in the multipart message itself.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Bcc Property

Gets and sets the blind carbon-copy header field value.

[Visual Basic]

```
Public Property Bcc As String
```

[C#]

```
public string Bcc {get; set;}
```

Property Value

A string which specifies one or more blind carbon-copy recipients.

Remarks

The **Bcc** property returns the list of addresses that are to receive blind carbon copies of the message. Setting the property creates or modifies the Bcc header field. Multiple addresses can be specified by separating them with commas.

A blind carbon copy is when a copy of a message is delivered to a recipient, but that recipient is not listed in the message headers. Because the other recipients of that same message will not see the address in the headers, they will not know it was delivered to that person. As a result, the Bcc header field is not normally exported when the **ExportMessage** method is called, or when the contents of the message are referenced using the **Message** property. To include the Bcc header in the message, use the **exportAllHeaders** option. Of course, if this option is specified, the addresses in the Bcc list will no longer be blind to the other recipients.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Boundary Property

Gets the boundary string used to separate parts in a multipart message.

[Visual Basic]

```
Public ReadOnly Property Boundary As String
```

[C#]

```
public string Boundary {get;}
```

Property Value

A string which specifies the current boundary in a multipart message.

Remarks

The **Boundary** property returns the current boundary string being used in a multipart message. When the class is used to create a multipart message, a unique boundary string is created and the **Boundary** property is updated to reflect it's value.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Cc Property

Gets and sets the carbon-copy header field value.

[Visual Basic]
```
Public Property Cc As String
```

[C#]
```
public string Cc {get; set;}
```

Property Value

A string which specifies one or more carbon-copy recipients.

Remarks

The **Cc** property returns the list of addresses that were delivered carbon copies of the message. Setting the property creates or modifies the Cc header field. Multiple addresses can be specified by separating them with commas.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ContentId Property

Gets the content identifier for the current message part.

[Visual Basic]

```
Public ReadOnly Property ContentId As String
```

[C#]

```
public string ContentId {get;}
```

Property Value

A string which specifies the content identifier.

Remarks

The **ContentId** property returns the unique content identifier string for the current message part. This multipart header field is not commonly used, and if undefined, will return an empty string.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ContentLength Property

Gets the size of the data stored in the current message part.

[Visual Basic]

```
Public ReadOnly Property ContentLength As Integer
```

[C#]

```
public int ContentLength {get;}
```

Property Value

An integer which specifies the size of the current message part in bytes.

Remarks

The **ContentLength** property returns the size of the data stored in the selected message part. This property is read-only, and is updated when the current message part changes.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.ContentType Property

Gets and sets the content type of the selected message part.

[Visual Basic]
```
Public Property ContentType As String
```

[C#]
```
public string ContentType {get; set;}
```

Property Value

A string which specifies the content type.

Remarks

The **ContentType** property returns the MIME type for the currently selected message part. The type string consists of a primary type and secondary sub-type separated by a slash, followed by one or more optional parameters delimited by semi-colons. For example, this is a common content type for text messages:

```
    text/plain; charset=utf-8
```

The **text** designation indicates that this message part contains readable text, and the **plain** sub-type indicates that the text does not contain any special encoding. The optional parameter which follows the content type provides additional information about the content. In this example, it specifies which character set should be used to display the text. The two common character sets used are UTF-8 and US-ASCII.

There are seven predefined, standard content types, each with their own sub-types. The following table lists these types, along with some common sub-types that are found in messages:

Type	Description
text	Indicates that the message part contains text. This is the most common type found in mail messages; if no content type is explicitly defined, then it is assumed to be plain text. Examples are text/plain, text/richtext and text/html.
image	Indicates that the message part contains a graphics image. Examples are image/gif and image/jpeg.
audio	Indicates that the message part contains audio data; the basic sub-type is 8-bit PCM encoded audio (commonly found with the .au filename extension). Examples are audio/basic, audio/aiff and audio/wav.
video	Indicates that the message part contains a video clip in the specified format. Examples are video/mpeg and video/avi.
application	Indicates that the message part contains application specific data, typically used with the octet-stream sub-type to indicate binary file attachments for executable programs, compressed

	file archives, etc. Examples are application/octet-stream and application/postscript.
message	Indicates that the message part contains a complete RFC 822 compliant message, complete with headers. An example is message/rfc822.
multipart	Indicates that this is part of a mixed message (a message that contains multiple parts of different content types). Examples are multipart/alternative and multipart/mixed.

The three most common content types that are used in applications are text/plain for the mail message body, application/octet-stream for binary file attachments and multipart/mixed for messages that contain both text and attached files. For more information about the different content types, refer to the Multipurpose Internet Mail Extensions (MIME) standards document RFC 1521.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Date Property

Gets and sets the date for the current message.

[Visual Basic]

```
Public Property Date As String
```

[C#]

```
public string Date {get; set;}
```

Property Value

A string which specifies the date in RFC 822 format.

Remarks

The **Date** property returns the value of the date field in the current message header. Setting this property causes the date field to be updated with the specified value. When setting the date, any one of the following formats may be used:

Format	Example
mm/dd/yy[yy] hh:mm[:ss]	03/01/2006 12:00:00
yy[yy]/mm/dd hh:mm[:ss]	2006/03/01 12:00:00
dd mmm yy[yy] hh:mm[:ss]	01 Mar 2006 12:00:00
mmm dd yy[yy] hh:mm[:ss]	Mar 01 2006 12:00:00

Any extraneous information that may be included in the date string, such as the day of the week, is ignored. In addition to the date and time, the string may also include a time zone specification at the end. If no time zone is specified, the current time zone is used.

When specifying a time zone, the value should either be prefixed by a plus sign (+) to indicate that the time zone is to the east of GMT, or a minus sign (-) to indicates that it's to the west. Four digits follow, with the first two indicating the number of hours east or west of GMT, and the last two digits indicating the number of minutes. Therefore, a value of -0800 means that the time zone is eight hours to the west of GMT, or in other words, the Pacific time zone.

Regardless of the format of the string assigned to the property, it always returns the date in the same format (which conforms to the RFC 822 specification). Using the above examples, the date would be returned as "Wed, 01 Mar 2006 12:00:00 -0800" if you are located in the Pacific timezone.

The **Localize** property affects how dates are processed by the control. If enabled, dates are automatically adjusted for the local time zone. By default, localization is disabled.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Encoding Property

Gets and sets the content encoding method used for the current message part.

[Visual Basic]
```
Public Property Encoding As String
```

[C#]
```
public string Encoding {get; set;}
```

Property Value

A string which specifies the encoding type.

Remarks

The **Encoding** property returns the method used for encoding the current message part. Setting this property causes the Content-Transfer-Encoding header value to be updated. The following values are commonly used:

Type	Description
7bit	Printable ASCII text characters that only use 7-bit characters This may be used for backwards compatibility with older mail servers that do not support 8-bit message text.
8bit	Printable ANSI characters, including those characters with the high-bit set. This includes UTF-8 and the ISO Latin-1 character set.
binary	All characters; binary transfer encoding is rarely used.
quoted-printable	Printable ASCII characters, with non-printable or extended characters represented using their hexadecimal equivalents.
base64	The transfer encoding type commonly used to convert binary data into 7-bit ASCII characters so that it may be transported safely through the mail system.
x-uuencode	A transfer encoding type similar in function to the base64 encoding method.

Note that setting this property only updates the Content-Transfer-Encoding header value. To control the actual encoding method used for attachments, specify the encoding method when calling the **AttachFile** method.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.From Property

Gets and sets the address of the user who sent the message.

[Visual Basic]

```
Public Property From As String
```

[C#]

```
public string From {get; set;}
```

Property Value

A string which specifies the sender of the message.

Remarks

The **From** property returns the address of the user who sent the message. Setting the property causes the From header field to be updated with the new value.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Handle Property

Gets a value that specifies the client handle allocated for the current message.

[Visual Basic]

```
Public ReadOnly Property Handle As Integer
```

[C#]

```
public int Handle {get;}
```

Property Value

An integer which represents a client handle. If there is no current message, a value of -1 is returned.

Remarks

The **Handle** property specifies the numeric descriptor of the current message.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.HeaderField Property

Gets and sets the current header field name.

[Visual Basic]
```
Public Property HeaderField As String
```

[C#]
```
public string HeaderField {get; set;}
```

Property Value

A string which specifies the current header field.

Remarks

The **HeaderField** property returns the name of the current header field. Setting this property causes the control to determine if that header field exists, and if it does, to update the **HeaderValue** property with it's value. This property can be used to obtain the value of any header in the current message part, and in conjunction with the **HeaderValue** property, can be used to create new headers.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.HeaderValue Property

Gets and sets the value of the current header field.

[Visual Basic]

```
Public Property HeaderValue As String
```

[C#]

```
public string HeaderValue {get; set;}
```

Property Value

A string which specifies the value of the current header field.

Remarks

The **HeaderValue** property returns the value of the header specified by the **HeaderField** property. Setting this property updates the specified header value. If the **HeaderField** property refers to a header field that does not exist, then it is created in the current message part.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.IsInitialized Property

Gets a value which indicates if the current instance of the class has been initialized successfully.

[Visual Basic]

```
Public ReadOnly Property IsInitialized As Boolean
```

[C#]

```
public bool IsInitialized {get;}
```

Property Value

Returns **true** if the class instance has been initialized; otherwise returns **false**.

Remarks

The **IsInitialized** property is used to determine if the current instance of the class has been initialized properly. Normally this is done automatically by the class constructor, however there are circumstances where the class may not be able to initialize itself.

The most common reasons that a class instance may not initialize correctly is that no runtime license key has been defined in the assembly or the license key provided is invalid. It may also indicate a problem with the system configuration or user access rights, such as not being able to load the required libraries or not being able to access the system registry.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.LastError Property

Gets and sets a value which specifies the last error that has occurred.

[Visual Basic]

```
Public Property LastError As ErrorCode
```

[C#]

```
public MailMessage.ErrorCode LastError {get; set;}
```

Property Value

Returns an ErrorCode enumeration value which specifies the last error code.

Remarks

The **LastError** property returns the error code associated with the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

It is possible to explicitly clear the last error code by assigning the property to the value **ErrorCode.errorNone**.

The error code value can be cast to an integer value for display purposes if required. For a description of the error that can be displayed using a message box or some other similar mechanism, get the value of the **LastErrorString** property.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.LastErrorString Property

Gets a value which describes the last error that has occurred.

[Visual Basic]
```
Public ReadOnly Property LastErrorString As String
```

[C#]
```
public string LastErrorString {get;}
```

Property Value

A string which describes the last error that has occurred.

Remarks

The **LastErrorString** property can be used to obtain a description of the last error that occurred for the current instance of the class. It is important to note that this value only has meaning if the previous method indicates that an error has actually occurred.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Localize Property

Gets and sets a value which specifies if date and time values should be localized.

[Visual Basic]

```
Public Property Localize As Boolean
```

[C#]

```
public bool Localize {get; set;}
```

Property Value

A boolean value which specifies if date and time values should be localized.

Remarks

The **Localize** property is used to enable or disable localization features of the class. Currently this only affects the way in which dates are processed by the class. If set to **true**, the control will adjust for the local time zone when setting and reading the **Date** property. The default value for this property is **false**.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Mailer Property

Gets and sets the name of the mailer application.

[Visual Basic]

```
Public Property Mailer As String
```

[C#]

```
public string Mailer {get; set;}
```

Property Value

A string which specifies the name of the mailer application.

Remarks

The **Mailer** property returns the value of the X-Mailer field in the current message header. Setting this property causes the field to be updated with the specified value. This is typically used to identify the program which generated the message.

See Also

MailMessage Class | SocketTools Namespace

MailMessage.Message Property

Gets and sets the current message headers and body.

[Visual Basic]

```
Public Property Message As String
```

[C#]

```
public string Message {get; set;}
```

Property Value

A string which contains the complete message.

Remarks

The **Message** property returns the current message, including the headers and all message parts, as a string. Setting this property will cause the current message to be cleared and replaced by the new value. The contents must follow the standard specifications for a message. If the property is set to an empty string, the current message is cleared.

MailMessage Class | SocketTools Namespace

MailMessage.MessageID Property

Gets the current message identifier.

[Visual Basic]

```
Public Property MessageID As String
```

[C#]

```
public string MessageID {get; set;}
```

Property Value

A string which specifies the message identifier.

Remarks

The **MessageID** property returns a unique string that can be used to identify the message.

MailMessage.MimeVersion Property

Gets and sets the MIME version number for the current message.

[Visual Basic]

```
Public Property MimeVersion As String
```

[C#]

```
public string MimeVersion {get; set;}
```

Property Value

A string that specifies the version number.

Remarks

The **MimeVersion** property returns the version number for the current message. Setting this property causes the MIME-Version header value to be changed to the specified value. An empty string causes the MIME version number to be set to the default value of "1.0". It is recommended that you do not change the value of this property.

MailMessage.Options Property

Gets and sets a value which specifies one or more message export options.

[Visual Basic]

```
Public Property Options As MimeExportOptions
```

[C#]

```
public MailMessage.MimeExportOptions Options {get; set;}
```

Property Value

Returns one or more MimeExportOptions enumeration flags which specify the options for the exporting the contents of a message. The default value for this property is **exportDefault**.

MailMessage.Organization Property

Gets and sets the name of the organization that originated the message.

[Visual Basic]
```
Public Property Organization As String
```

[C#]
```
public string Organization {get; set;}
```

Property Value

A string which specifies the organization name.

Remarks

The **Organization** property returns the name of the organization that originated the current message. Setting this property updates the specified header value. Note that many mail clients do not generate an Organization header field, in which case the property value will be an empty string.

MailMessage.Part Property

Gets and sets the current message part.

[Visual Basic]

```
Public Property Part As Integer
```

[C#]

```
public int Part {get; set;}
```

Property Value

An integer which specifies the current message part.

Remarks

The **Part** property returns the current message part index. All messages have at least one part, which consists of one or more header fields, followed by the body of the message. The default part, part 0, refers to the main message header and body. If the message contains multiple parts (as with a message that contains one or more attached files), the **Part** property can be set to refer to that specific part of the message.

For example, messages with file attachments typically consist of a message part which describes the contents of the attachment, followed by the attachment itself. For a message with one attached file, there would be a total of three parts. Part 0 would refer to the main message part, which contains the headers such as From, To, Subject, Date and so on. For multipart messages, part 0 typically does not have a message body, since any text is usually created as a separate part (for those messages that do not contain multiple parts, the part 0 body contains the text message). Part 1 would contain the text describing the attachment, and part 2 would contain the attachment itself. If the attached file is binary, then the transfer encoding type would usually be base64.

MailMessage.PartCount Property

Gets the number of parts in the current message.

[Visual Basic]

```
Public ReadOnly Property PartCount As Integer
```

[C#]

```
public int PartCount {get;}
```

Property Value

An integer value which specifies the number of message parts.

Remarks

The **PartCount** property returns the number of parts in the current message. All messages have at least one part, referenced as part 0. Multipart messages will consist of additional parts which may be accessed by setting the **Part** property.

MailMessage.Priority Property

Gets and sets the current message priority.

[Visual Basic]

```
Public Property Priority As String
```

[C#]

```
public string Priority {get; set;}
```

Property Value

A string which specifies the message priority.

Remarks

The **Priority** property returns the current priority for the message. Setting this property value causes the X-Priority header to be updated with the specified value.

There is no standard for specifying message priority. The convention is to use a number from 1-5, with 1 indicating the highest priority, 3 as normal priority and 5 as the lowest priority. Some mailers follow the number with a space and then text that describes the priority level.

MailMessage.Recipient Field

Gets the recipients specified in the current message.

[Visual Basic]

```
Public ReadOnly Recipient As RecipientArray
```

[C#]

```
public readonly RecipientArray Recipient;
```

Remarks

The **Recipient** array is used to enumerate the recipient addresses that have been specified in the current message. This includes all of the addresses listed in the To, Cc and Bcc header fields. Only the address itself will be returned, not any comments or extraneous text such as the full name of the recipient. This array is zero based, meaning that the first index value is zero. The total number of recipients specified in the message can be determined by checking the value of the **Recipients** property.

MailMessage.Recipients Property

Gets the number of recipients specified in the current message.

[Visual Basic]

```
Public ReadOnly Property Recipients As Integer
```

[C#]

```
public int Recipients {get;}
```

Property Value

An integer which specifies the number of recipients.

Remarks

The **Recipients** property returns the number of recipient addresses that have been specified in the current message. This includes all of the addresses listed in the To, Cc and Bcc header fields. This property can be used in conjunction with the **Recipient** array to enumerate all of the recipient addresses in the message.

MailMessage.ReplyTo Property

Gets and sets the address of the user who should receive replies to this message.

[Visual Basic]

```
Public Property ReplyTo As String
```

[C#]

```
public string ReplyTo {get; set;}
```

Property Value

A string that specifies an email address.

Remarks

The **ReplyTo** property returns the address of the user who should receive replies to the current message. Setting this property updates the Reply-To header with the specified value.

MailMessage.Sender Property

Gets and sets the address of the user who originated the message.

[Visual Basic]
```
Public Property Sender As String
```

[C#]
```
public string Sender {get; set;}
```

Property Value

A string which specifies the sender's email address.

Remarks

The **Sender** property returns the address of the user who originated the message. Setting this property updates the X-Sender header with the specified value.

MailMessage.StoreCount Property

Gets the number of messages in the current storage file, not including deleted messages.

[Visual Basic]
```
Public ReadOnly Property StoreCount As Integer
```

[C#]
```
public int StoreCount {get;}
```

Property Value

An integer value which specifies the number of messages in the message store, not including those messages that have been marked for deletion.

Remarks

The **StoreCount** property returns the number of messages in the message store. It is important to note that does not count those messages which have been marked for deletion. This means that the value returned by this method will decrease as messages are deleted. To determine the total number of messages, including deleted messages, use the **StoreSize** property.

MailMessage.StoreFile Property

Gets and sets the name of the file used to store messages.

[Visual Basic]

```
Public Property StoreFile As String
```

[C#]

```
public string StoreFile {get; set;}
```

Property Value

A string value which specifies the name of the storage file.

Remarks

The **StoreFile** property returns the name of the current storage file. Setting this property changes the default filename that is used when opening a new storage file.
