DNS_OPTION_PROMOTE	Promotes the server that successfully completed the last query to the first server that will be used to resolve subsequent queries. This option can improve performance in some cases where one or more of the registered servers are non-responsive. This option takes precedence over the DNS_OPTION_ROTATE option.
DNS_OPTION_ROTATE	Enables a round-robin selection of nameservers when performing queries. Normally each nameserver is queried in the same order. This option rotates the available nameservers so a different server is used with each query.
DNS_OPTION_AUTHONLY	Require the answer from the nameserver to be authoritative, not from the server's cache. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_PRIMARY	Queries are only accepted from the primary nameserver. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_NORECURSE	Disable the sending of recursive queries to the nameserver. Specifying this option will disable the bit in

	the DNS request header that specifies recursion is desired.
DNS_OPTION_NOSEARCH	Disable additional queries of higher domains in the search list if the host name cannot be resolved. If this option is specified, and the host name cannot be resolved using the local domain name an error is returned immediately. This option is ignored if no local domain has been specified or if the DNS_OPTION_NOSUFFIX option has been specified.
DNS_OPTION_NOSUFFIX	Disable additional queries using the local domain name if the host name is not a fully qualified domain name and cannot be resolved. This option is ignored if no local domain has been specified.
DNS_OPTION_NONAMECHECK	Disable checking the host name for invalid characters, such as the underscore and control characters. By default, host names are checked to ensure they're valid before submitting a query to the nameserver.
DNS_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsCreateHandle** function returns a handle to the application which can be used to perform nameserver queries. By default, the library will use the nameservers which are configured for the local host. To determine the IP addresses of those nameservers, use the **DnsGetServerAddress** function.

To specify alternate nameservers, either as replacements for or additions to the default nameservers, use the **DnsRegisterServer** function.

It is recommended that most applications do not specify any resolver options and use the default behavior. Specifying these options without understanding how they can affect standard queries can result in unexpected failures. In particular, caution should be used when specifying the `DNS_OPTION_NORECURSE` and `DNS_OPTION_NOSEARCH` options as they change the normal process of resolving a host name.

Specifying the `DNS_OPTION_FREETHREAD` option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csdnsv11.lib

[DnsSetLocalDomain](#), [DnsSetResolverOptions](#)

DnsDisableTrace Function

```
BOOL WINAPI DnsDisableTrace();
```

The **DnsDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv11.dll** cannot be loaded on the local system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

See Also

[DnsEnableTrace](#)

DnsEnableTrace Function

```
BOOL WINAPI DnsEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **DnsEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv11.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the remote host.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[DnsDisableTrace](#)

DnsEnumHostAliases Function

```
INT WINAPI DnsEnumHostAliases(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    LPTSTR *lpszHostAlias,  
    INT nMaxAliases  
);
```

The **DnsEnumHostAliases** function returns a list of aliases for the specified host name or IP address.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string that contains the hostname to be resolved. If a fully qualified domain name is not provided, the default local domain will be used. This value may also be an IP address.

lpszHostAlias

Pointer to an array of string pointers which specify one or more host aliases. If the application needs to store these values, a local copy should be made because they are invalidated when another host name is resolved.

nMaxAliases

The maximum number of aliases in the array. This parameter must have a value of at least one, or an error will be returned.

Return Value

If the function succeeds, the return value is the number of host aliases. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify the host aliases or free any of the values. This function uses an internal data structure to store the host information and only one copy of this structure is allocated per thread. The application must copy any information it needs before issuing any other function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsGetHostAddress](#), [DnsGetHostName](#)

DnsEnumMailExchanges Function

```
INT WINAPI DnsEnumMailExchanges(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    LPTSTR *lpszMailExchanges,  
    INT nMaxMailExchanges  
);
```

The **DnsEnumMailExchanges** function returns a list of mail exchanges for the specified host name or IP address.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string that contains the hostname or domain name to be queried.

lpszMailExchanges

Pointer to an array of string pointers which specify one or more mail exchanges. If the application needs to store these values, a local copy should be made because they are invalidated when another host name is resolved. The list of mail exchange records is sorted in priority order, from highest (i.e., those whose preference value is smallest) to lowest.

nMaxMailExchanges

The maximum number of mail exchanges in the array. If this parameter is 0, then the function will return the number of mail exchanges, but the list of mail exchanges will not be output in *lpszMailExchanges*.

Return Value

If the function succeeds, the return value is the number of mail exchanges. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify the mail exchange host names or free any of the values. This function uses an internal data structure to store the host information and only one copy of this structure is allocated per thread. The application must copy any information it needs before issuing any other function calls.

Example

```
// Count the number of mail exchanges  
if ((nMX = DnsEnumMailExchanges(hClient,szHostName, NULL, 0)) == DNS_ERROR)  
{  
    dwError = DnsGetLastError();  
    DnsGetErrorString(dwError, szError, BUFSIZE);  
    printf("DnsEnumMailExchanges failed for %s: %s\n", szHostName, szError);  
}  
else  
{  
    int nIndex;  
    printf("%d MX for %s\n",nMX, szHostName);  
  
    // Allocate memory for the list of mail exchanges
```

```
lpszMailExchanges = (LPTSTR *)malloc(nMX * sizeof(LPTSTR));

// Retrieve the list of mail exchanges
nMX = DnsEnumMailExchanges(hClient, szHostName, lpszMailExchanges, nMX);

for (nIndex = 0; nIndex < nMX; nIndex++)
    printf("#%d: %s\n", nIndex+1, *lpszMailExchanges++);

free(lpszMailExchanges);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsFormatAddress Function

```
INT WINAPI DnsFormatAddress(  
    LPINTERNET_ADDRESS LpAddress,  
    LPTSTR LpszAddress,  
    INT nMaxLength  
);
```

The **DnsFormatAddress** function converts a numeric IPv4 or IPv6 address to a string.

Parameters

LpAddress

A pointer to an INTERNET_ADDRESS structure which specifies the numeric IPv4 or IPv6 address to be converted into a string.

LpszAddress

A pointer to a null-terminated array of characters which will contain the converted IPv4 address in dot-notation. This string should be at least 16 characters in length.

nMaxLength

The maximum number of characters which may be copied in to the string buffer.

Return Value

If the function succeeds, the return value is the length of the string buffer. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsGetAddress](#), [DnsGetHostAddress](#), [DnsGetHostInfo](#), [DnsGetHostServices](#), [DnsGetMailExchange](#), [DnsGetRecord](#), [INTERNET_ADDRESS](#)

DnsGetAddress Function

```
INT WINAPI DnsGetAddress(  
    LPCTSTR lpszAddress,  
    INT nAddressFamily,  
    LPINTERNET_ADDRESS lpAddress  
);
```

The **DnsGetAddress** function converts an address string to a numeric IPv4 or IPv6 address.

Parameters

lpszAddress

A pointer to a string which specifies an IPv4 address in dotted notation.

nAddressFamily

An integer value which specifies the type of IP address. If this parameter is zero, the address family will be determined automatically based on the format of the address string. If this parameter is DNS_ADDRESS_IPV4, the address must be in IPv4 format, and if it is DNS_ADDRESS_IPV6, the address must be in IPv6 format.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the numeric form of the IPv4 or IPv6 address in network byte order when the function returns.

Return Value

If the function succeeds, the return value is the address family for the IP address. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

This function will only accept a string that is in the proper format for an IP address, and cannot be used to resolve a host name. To perform host name resolution, use the **DnsGetHostAddress** function. To convert a numeric address to an address string, use the **DnsFormatAddress** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[DnsFormatAddress](#), [DnsGetHostAddress](#), [DnsGetHostInfo](#), [DnsGetHostServices](#), [DnsGetMailExchange](#), [DnsGetRecord](#), [INTERNET_ADDRESS](#)

DnsGetAddressFamily Function

```
INT WINAPI DnsGetAddressFamily(  
    LPCTSTR lpszAddress  
);
```

The **DnsGetAddressFamily** function returns the address family for the specified IP address.

Parameters

lpszAddress

A pointer to a string which specifies an IPv4 or IPv6 address.

Return Value

If the function succeeds, the return value is DNS_ADDRESS_IPV4 if the address is in IPv4 format, or DNS_ADDRESS_IPV6 if the address is in IPv6 format. If the address string is not in a recognized format, it returns DNS_ADDRESS_ANY.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsGetDefaultHostFile Function

```
INT WINAPI DnsGetDefaultHostFile(  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

The **DnsGetDefaultHostFile** function returns the fully qualified path name of the host file on the local system. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **DnsGetHostAddress** and **DnsGetHostName** functions. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

lpszFileName

Pointer to a string buffer that will contain the fully qualified path to the default host file. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. A return value of zero indicates that the default host file could not be determined for the current platform. To get extended error information, call **DnsGetLastError**.

Remarks

This function returns the location of the host file and does not determine if the file actually exists. The default location for this file is in a protected area of the Windows operating system and can only be modified by a process with administrative privileges.

The default host file is processed before performing a nameserver lookup when resolving a hostname into an IP address, or an IP address into a hostname. To specify an alternate local host file, use the **DnsSetHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[DnsGetDefaultServicesFile](#), [DnsGetHostAddress](#), [DnsGetHostFile](#), [DnsGetHostName](#), [DnsSetHostFile](#)

DnsGetDefaultServicesFile Function

```
INT WINAPI DnsGetDefaultServicesFile(  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

The **DnsGetDefaultServicesFile** function returns the fully qualified path name of the services file on the local system. The services file is used as a database that maps a port number to a service name, and is used by the **DnsGetServiceName** and **DnsGetServicePort** functions. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
name port/protocol [alias ...]
```

For example, one typical entry maps the service name "http" to port 80, the standard port for the Hypertext Transfer Protocol. This would be entered as:

```
http 80/tcp www www-http
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

lpszFileName

Pointer to a string buffer that will contain the fully qualified path to the default services file. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. A return value of zero indicates that the default services file could not be determined for the current platform. To get extended error information, call **DnsGetLastError**.

Remarks

This function returns the location of the services file and does not determine if the file actually exists. The default location for this file is in a protected area of the Windows operating system and can only be modified by a process with administrative privileges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsGetErrorString Function

```
INT WINAPI DnsGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT nMaxLength  
);
```

The **DnsGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **DnsGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsGetLastError](#), [DnsSetLastError](#)

DnsGetHostAddress Function

```
INT WINAPI DnsGetHostAddress(  
    HCLIENT hClient,  
    INT nAddressFamily,  
    LPCTSTR lpszHostName,  
    LPTSTR lpszHostAddress,  
    INT nMaxLength  
);
```

The **DnsGetHostAddress** function resolves the specified host name, storing the IP address in the provided buffer.

Parameters

hClient

Handle to the client session.

nAddressFamily

An integer value which specifies the type of address that should be returned. A value of DNS_ADDRESS_IPV4 specifies that the IPv4 address for the host should be returned. A value of DNS_ADDRESS_IPV6 specifies that the IPv6 address for the host should be returned. A value of DNS_ADDRESS_ANY specifies that if the host only has an IPv6 address, that value should be returned, otherwise return the IPv4 address for the host.

lpszHostName

Pointer to the string that contains the hostname to be resolved. If a fully qualified domain name is not provided, the default local domain will be used.

lpszHostAddress

Pointer to the buffer that will contain the IP address, stored as a string in dot notation. This buffer should be at least 48 characters in length to accommodate both IPv4 and IPv6 addresses. The format of the address is determined by the address family specified.

nMaxLength

The maximum length of the string buffer. The maximum length of the buffer must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the host address buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetHostAddress** function may return an address in either IPv4 or IPv6 format, depending on the address family that is specified and what records exist for the host. If your application does not support the IPv6 address format, you must specify the *nAddressFamily* parameter as DNS_ADDRESS_IPV4 to prevent the possibility of an IPv6 address being returned.

If the *nAddressFamily* parameter is specified as DNS_ADDRESS_ANY, this function will first check for an IPv4 address record for the host. If it exists, it will return that address. If the host does not have an IPv4 address, it will then check for an IPv6 address record and return that address. This gives preference to IPv4 addresses, but your application should never depend on this behavior. In the future, this function may change to give preference to IPv6 addresses.

To determine what format an address is in, use the **DnsGetAddressFamily** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsEnumHostAliases](#), [DnsGetAddressFamily](#), [DnsGetHostName](#), [DnsGetMailExchange](#), [DnsGetRecord](#)

DnsGetHostByAddress Function

```
LPHOSTENT WINAPI DnsGetHostByAddress(  
    HCLIENT hClient,  
    LPVOID lpvAddress,  
    INT cbAddress,  
    INT nAddressFamily  
);
```

The **DnsGetHostByAddress** function returns a pointer to a [HOSTENT](#) structure which contains the results of a successful search for the host specified by address parameter.

Parameters

hClient

Handle to the client session.

lpvAddress

Pointer to an integer IPv4 address in network byte order.

cbAddress

The length of the address in bytes; this value should always be 4.

nAddressFamily

The type of address being resolved; this value should always be DNS_ADDRESS_IPV4 as defined in the Windows Sockets header file.

Return Value

If the function succeeds, the return value is a pointer to a HOSTENT structure. If the function fails, the return value is NULL. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify this structure or to free any of its components. Only one copy of this structure is allocated per thread, so the application should copy any information it needs before issuing any other function calls. To convert an IPv4 address string in dotted notation to a 32-bit IP address, use the **DnsGetAddress** function.

This function is included for compatibility with existing applications which already use the HOSTENT structure. Because this function returns a pointer to a complex structure, it may not be suitable for some programming languages. There is no Unicode version of the HOSTENT structure and members will return pointers to ANSI strings even if the application is compiled to use Unicode.

This function is not compatible with IPv6 addresses. For applications that must support both IPv4 and IPv6 address formats, use the **DnsGetHostAddress** and **DnsGetHostName** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[DnsGetHostAddress](#), [DnsGetHostByName](#), [DnsGetHostInfo](#), [DnsGetHostName](#), [DnsGetHostServices](#), [DnsGetRecord](#), [DnsGetResolverAddress](#), [DnsRegisterServer](#)

DnsGetHostByName Function

```
LPHOSTENT WINAPI DnsGetHostByName(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName  
);
```

The **DnsGetHostByName** function returns a pointer to a [HOSTENT](#) structure which contains the results of a successful search for the host specified in the name parameter.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string that contains the hostname to be resolved. If a fully qualified domain name is not provided, the default local domain will be used.

Return Value

If the function succeeds, the return value is a pointer to a [HOSTENT](#) structure. If the function fails, the return value is NULL. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify this structure or to free any of its components. Only one copy of this structure is allocated per thread, so the application should copy any information it needs before issuing any other function calls. This function will automatically resolve an IP address passed as a string, converting it to numeric form and calling the **DnsGetHostByAddress** function.

This function is included for compatibility with existing applications which already use the [HOSTENT](#) structure. Because this function returns a pointer to a complex structure, it may not be suitable for some programming languages. There is no Unicode version of the [HOSTENT](#) structure and members will return pointers to ANSI strings even if the application is compiled to use Unicode.

This function is not compatible with IPv6 addresses. For applications that must support both IPv4 and IPv6 address formats, use the **DnsGetHostAddress** and **DnsGetHostName** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csdnsv11.lib`

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsGetHostAddress](#), [DnsGetHostByAddress](#), [DnsGetHostInfo](#), [DnsGetHostName](#), [DnsGetHostServices](#), [DnsGetMailExchange](#), [DnsGetRecord](#), [DnsGetResolverAddress](#), [DnsRegisterServer](#)

DnsGetHostFile Function

```
INT WINAPI DnsGetHostFile(  
    HCLIENT hClient,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

The **DnsGetHostFile** function returns the name of the host file previously set using the **DnsSetHostFile** function. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **DnsGetHostAddress** and **DnsGetHostName** function.

Parameters

hClient

Handle to the client session.

lpszFileName

Pointer to a string buffer that will contain the host file name. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null character.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. A return value of zero indicates no host file has been specified or the function was unable to determine the file name. To get extended error information, call **DnsGetLastError**.

Remarks

This function returns the name of the host file that is cached in memory for the current thread. If an alternate host file has not been specified, this function will return the path to the default host file. The contents of the file on the disk may have changed after the file was loaded into memory. To reload the host file or clear the cache, call the **DnsSetHostFile** function.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

The host file returned by this function may be different than the default host file for the local system. To determine the file name for the default host file, use the **DnsGetDefaultHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

);
```

The **DnsGetHostInfo** function returns the HINFO record for the specified hostname. This information, if it is provided, typically specifies the operating system type and hardware platform.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the host information buffer is returned. A return value of zero indicates that no information is available for the specified host. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

Many systems do not maintain HINFO records for a site since that information can potentially be used to compromise system security. The information is typically used for administrative purposes with internal networks.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsGetHostByAddress](#), [DnsGetHostByName](#), [DnsGetHostServices](#), [DnsGetMailExchange](#),
[DnsGetRecord](#), [DnsGetResolverAddress](#), [DnsRegisterServer](#)

DnsGetHostName Function

```
INT WINAPI DnsGetHostName(  
    HCLIENT hClient,  
    LPCTSTR lpszHostAddress,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

The **DnsGetHostName** function resolves the specified IP address, storing the fully qualified host name in the provided buffer.

Parameters

hClient

Handle to the client session.

lpszHostAddress

Pointer to a string that specifies an IPv4 or IPv6 formatted address.

lpszHostName

Pointer to the buffer that will contain the fully qualified domain name for the specified host. This buffer should be at least 64 characters in length.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the host name buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetHostName** function first looks to see if there is an entry in the local host file for the specified IP address, and if one exists, it will return the host name for that address. If you do not want to use the local host file at all, and only return an host name if a DNS query resolves the address, use the **DnsGetRecord** function and specify a record type of DNS_RECORD_PTR.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsGetHostServices Function

```
INT WINAPI DnsGetHostServices(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    INT nProtocol,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **DnsGetHostServices** function returns the WKS (Well Known Services) record for the specified hostname and protocol. This information, if it is provided, typically specifies the names of those services supported on the host.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

nProtocol

The protocol for those services that information should be returned about. The following protocols are recognized:

Value	Description
INET_PROTOCOL_TCP	Services that use the Transmission Control Protocol (TCP)
INET_PROTOCOL_UDP	Services that use the User Datagram Protocol (UDP)

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the host services buffer is returned. A return value of zero indicates that no information is available for the specified host. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

Many systems do not maintain complete services records for a site since that information can potentially be used to compromise system security. An application should not depend on this information being available for any given record.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsGetResolverAddress](#), [DnsRegisterServer](#)

DnsGetLastError Function

DWORD WINAPI DnsGetLastError();

Parameters

None.

Return Value

The return value is the calling thread's last-error code value. Functions set this value by calling the **DnsSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last-error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **DnsGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **DnsSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or DNS_ERROR. Those functions which call **DnsSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

[DnsGetErrorString](#), [DnsSetLastError](#)

DnsGetLocalAddress Function

```
INT WINAPI DnsGetLocalAddress(  
    HCLIENT hClient,  
    INT nAddressFamily,  
    LPTSTR LpszAddress,  
    INT nMaxLength  
);
```

The **DnsGetLocalAddress** function returns the IP address for the local host.

hClient

Handle to the client session.

nAddressFamily

An integer value which specifies the type of address that should be returned. A value of DNS_ADDRESS_IPV4 specifies that the IPv4 address for the host should be returned. A value of DNS_ADDRESS_IPV6 specifies that the IPv6 address for the host should be returned. A value of DNS_ADDRESS_ANY specifies that if the host only has an IPv6 address, that value should be returned, otherwise return the IPv4 address for the host.

lpszAddress

Pointer to the buffer that will contain the IP address, stored as a string in dot notation. This buffer should be at least 40 characters in length to accommodate both IPv4 and IPv6 addresses.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the host address buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetLocalAddress** function may return an address in either IPv4 or IPv6 format, depending on the address family that is specified and what records exist for the host. If your application does not support the IPv6 address format, you must specify the *nAddressFamily* parameter as DNS_ADDRESS_IPV4 to prevent the possibility of an IPv6 address being returned.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsGetLocalDomain Function

```
INT WINAPI DnsGetLocalDomain(  
    HCLIENT hClient,  
    LPTSTR lpszDomain,  
    INT nMaxLength  
);
```

The **DnsGetLocalDomain** function copies the local domain name into the specified buffer. The value returned is the same value that was set with the **DnsSetLocalDomain** function. If no local domain name has been set, an empty string is returned.

Parameters

hClient

Handle to the client session.

lpszDomain

Pointer to the buffer that is used to store the local domain name. If no local domain name has been set, this buffer will be set to zero length.

nMaxLength

The maximum number of bytes to copy into the buffer, including the null character terminator.

Return Value

If the function succeeds, the return value is the length of the domain name string. A return value of zero indicates that no local domain name has been set. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsGetLocalName Function

```
INT WINAPI DnsGetLocalName(  
    HCLIENT hClient,  
    LPTSTR lpszLocalName,  
    INT nMaxLength  
);
```

The **DnsGetLocalName** function returns the local host name.

Parameters

hClient

Handle to the client session.

lpszLocalName

Pointer to a string buffer that will contain the local host name. It is recommended that this buffer be at least 64 characters in size.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is the length of the local host name. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[DnsGetHostByAddress](#), [DnsGetHostByName](#), [DnsGetHostInfo](#), [DnsGetHostServices](#),
[DnsGetMailExchange](#), [DnsGetRecord](#)

DnsGetMailExchange Function

```
INT WINAPI DnsGetMailExchange(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    LPINT lpnPreference,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **DnsGetMailExchange** function returns the mail exchange (MX) record information for the specified domain. This information, if it is provided, identifies a server responsible for processing mail for the given domain.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

lpnPreference

Pointer to the integer which will contain the preference for the specified mail exchange host.

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the buffer is returned. A return value of zero indicates that no information is available for the specified host. If the function fails, the return value is `DNS_ERROR`. To get extended error information, call **DnsGetLastError**.

Remarks

The mail exchange record is typically used by mail delivery agents to determine what system is responsible for accepting mail addressed to a given domain. This function will return the first MX record provided by the server. Note that some domains may have multiple mail servers. To enumerate all of the mail exchange records for a domain, use the **DnsEnumMailExchanges** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csdnsv11.lib`

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsGetHostByAddress](#), [DnsGetHostByName](#), [DnsGetHostInfo](#), [DnsGetHostServices](#), [DnsGetRecord](#), [DnsGetResolverAddress](#), [DnsRegisterServer](#), [DnsEnumMailExchanges](#)

DnsGetRecord Function

```
INT WINAPI DnsGetRecord(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    INT nRecordType,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **DnsGetRecord** function returns the specified record information for the given hostname.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

nRecordType

The record type for the information that should be returned. The following record types are recognized:

Value	Description
DNS_RECORD_NONE	No record type
DNS_RECORD_ADDRESS	IPv4 host address
DNS_RECORD_NS	Authoritative nameserver
DNS_RECORD_CNAME	Canonical host name (alias)
DNS_RECORD_SOA	Start of Authority
DNS_RECORD_WKS	Well known services
DNS_RECORD_PTR	Domain name
DNS_RECORD_HINFO	Host information
DNS_RECORD_MINFO	Mailbox information
DNS_RECORD_MX	Mail exchange host
DNS_RECORD_TXT	Text strings
DNS_RECORD_AAAA	IPv6 host address
DNS_RECORD_LOC	Location information
DNS_RECORD_UINFO	User information
DNS_RECORD_UID	User ID
DNS_RECORD_GID	Group ID

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the information buffer is returned. A return value of zero indicates that no information for that record is available for the specified host. If the function fails, the return value is `DNS_ERROR`. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetRecord** function can be used to resolve a host name into an IPv4 address using the record type `DNS_RECORD_ADDRESS`, or an IPv6 address using the record type `DNS_RECORD_AAAA`. It can also be used to perform a reverse lookup and resolve an IP address into a host name by using the record type `DNS_RECORD_PTR`.

To determine the host that serves as the primary or master DNS for a zone, the record name should be specified as the domain name (e.g.: `microsoft.com`) and the record type should be `DNS_RECORD_SOA`. The value returned will be the fully qualified domain name for host.

Note that this function does not reference a local host file when resolving host names or addresses. If the record lookup fails, this function will return an error even if there's an entry for the host in the file that has been specified by a call to **DnsSetHostFile**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csdnsv11.lib`

Unicode: Implemented as Unicode and ANSI versions

DnsGetResolverAddress Function

```
INT WINAPI DnsGetResolverAddress(  
    HCLIENT hClient,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **DnsGetResolverAddress** returns the address of the nameserver that resolved the last query.

Parameters

hClient

Handle to the client session.

lpszAddress

A pointer to a string buffer that will contain the address of the nameserver when the function returns. This buffer should be large enough to store both IPv4 and IPv6 addresses, with a minimum length of 40 characters. If this parameter is NULL, it will be ignored.

nMaxLength

The maximum number of characters that can be copied into the string buffer. If this value is zero, the *lpszAddress* parameter will be ignored and the function will return the length of the address.

Return Value

If the function succeeds, the return value is the length of the address, not including the terminating null character. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsGetResolverOptions Function

```
DWORD WINAPI DnsGetResolverOptions(  
    HCLIENT hClient  
);
```

The **DnsGetResolverOptions** function returns the options that have been set for the client session.

Parameters

hClient

Handle to the client session

Return Value

If the function succeeds, the return value is the resolver options set for the client session. If the client handle is invalid or no resolver options have been specified, the function will return zero.

Remarks

The **DnsGetResolverOptions** function can be used to determine which resolver options have been specified for the client session. For a list of the available options, refer to the documentation for the **DnsSetResolverOptions** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

See Also

DnsGetRetryCount Function

```
INT WINAPI DnsGetRetryCount(  
    HCLIENT hClient  
);
```

The **DnsGetRetryCount** returns the retry count for the current client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the retry count. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The retry count determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

DnsGetServerAddress Function

```
INT WINAPI DnsGetServerAddress(  
    HCLIENT hClient,  
    INT nServer,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **DnsGetServerAddress** function returns the address of the registered nameserver.

Parameters

hClient

Handle the client session.

nServer

The index into the client's nameserver table. This index is the same value that is passed to the **DnsRegisterServer** function when the nameserver is registered.

lpszAddress

A pointer to a string buffer that will contain the address of the nameserver when the function returns. This buffer should be large enough to store both IPv4 and IPv6 addresses, with a minimum length of 40 characters. If this parameter is NULL, it will be ignored.

nMaxLength

The maximum number of characters that can be copied into the string buffer. If this value is zero, the *lpszAddress* parameter will be ignored and the function will return the length of the address.

Return Value

If the function succeeds, the return value is the length of the address, not including the terminating null character. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsGetServerPort Function

```
INT WINAPI DnsGetServerPort(  
    HCLIENT hClient,  
    INT nServer  
);
```

The **DnsGetServerPort** function returns the port number registered to the specified nameserver.

Parameters

hClient

Handle the client session.

nServer

The index into the client's nameserver table. This index is the same value that is passed to the **DnsRegisterServer** function when the nameserver is registered.

Return Value

If the function succeeds, the return value is the specified port number. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

See Also

[DnsGetResolverAddress](#), [DnsGetServerAddress](#), [DnsRegisterServer](#), [DnsUnregisterServer](#)

DnsGetServiceName Function

```
INT WINAPI DnsGetServiceName(  
    HCLIENT hClient,  
    INT nServicePort,  
    INT nServiceType,  
    LPTSTR lpszServiceName,  
    INT nMaxLength  
);
```

The **DnsGetServiceName** function returns the service name assigned to the specified port number.

Parameters

hClient

Handle to the client session.

nServicePort

An integer which specifies the port number. This value must be a valid port number in the range of 1 through 65535.

nServiceType

An integer which specifies the protocol associated with the service. This may be one of the following values:

Value	Description
DNS_SERVICE_ANY	Match the first service entry for the specified port number regardless of the protocol used.
DNS_SERVICE_TCP	Match a service entry for the specified port number which uses the TCP protocol.
DNS_SERVICE_UDP	Match a service entry for the specified port number which uses the UDP protocol.

lpszServiceName

A pointer to a string buffer which will contain the name of the service assigned to the port number when the function returns. This parameter cannot be NULL and the buffer must be large enough to store the complete service name, including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Remarks

Port numbers can be assigned human readable service names to make them easier to reference. This function will return the name assigned to the specified port number. If the port number does not have an assigned name, this function will return zero and the last error code will be set to ST_ERROR_INVALID_SERVICE_NAME.

Most applications should use `DNS_SERVICE_ANY` to return the service name assigned to a port number. Services typically use the same name and port number regardless of the protocol used to establish a connection with them. However, specifying a protocol can enable your application to determine if the service supports the protocol. For example, calling this function with port number 21 and `DNS_SERVICE_UDP` would result in an error because FTP only supports TCP connections.

Service names are assigned by the Internet Assigned Numbers Authority (IANA) and the database of recognized service names can be returned by calling the **DnsGetDefaultServicesFile** function. The default location for this file is in a protected area of the Windows operating system and can only be modified by a process with administrative privileges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csdnsv11.lib`

Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetServicePort Function

```
INT WINAPI DnsGetServicePort(  
    HCLIENT hClient,  
    LPCTSTR lpszServiceName,  
    INT nServiceType  
);
```

The **DnsGetServicePort** function returns the port number assigned to the specified service.

Parameters

- hClient***
Handle to the client session.
- lpszServiceName***
A pointer to a null terminated string which specifies the service name. Service names are not case sensitive.
- nServiceType***
An integer which specifies the protocol associated with the service. This may be one of the following values:

Value	Description
DNS_SERVICE_ANY	Match the first service entry for the specified port number regardless of the protocol used.
DNS_SERVICE_TCP	Match a service entry for the specified port number which uses the TCP protocol.
DNS_SERVICE_UDP	Match a service entry for the specified port number which uses the UDP protocol.

Return Value

If the function succeeds, the return value is the port number assigned to the service name. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

Port numbers can be assigned human readable service names to make them easier to reference. This function will return the port number assigned to the specified service name. If the service name does not exist, this function will return DNS_ERROR and the last error code will be set to ST_ERROR_INVALID_SERVICE_NAME.

Most applications should use DNS_SERVICE_ANY to return the port number assigned to a service. Services typically use the same name and port number regardless of the protocol used to establish a connection with them. However, specifying a protocol can enable your application to determine if the service supports the protocol. For example, calling this function with the service name "ftp" and DNS_SERVICE_UDP would result in an error because FTP only supports TCP connections.

Service names are assigned by the Internet Assigned Numbers Authority (IANA) and the database of recognized service names can be returned by calling the **DnsGetDefaultServicesFile** function. The default location for this file is in a protected area of the Windows operating system and can only be modified by a process with administrative privileges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsGetTimeout Function

```
INT WINAPI DnsGetTimeout(  
    HCLIENT hClient  
);
```

The **DnsGetTimeout** function returns the timeout value for the current client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The timeout value determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

See Also

DnsHostNameToUnicode Function

```
INT WINAPI DnsHostNameToUnicode(  
    LPCTSTR lpszHostName,  
    LPTSTR lpszUnicodeName,  
    INT nMaxLength  
);
```

The **DnsHostNameToUnicode** function converts the canonical form of a host name to its Unicode version.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero length string.

lpszUnicodeName

Pointer to the string buffer that will contain the original Unicode version of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that can be copied to the *lpszUnicodeName* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsHostNameToUnicode** function will convert the encoded ASCII version of a host name to its Unicode version. Although any valid host name is accepted by this function, it is intended to convert a Punycode encoded host name to its original Unicode character encoding.

If the Unicode version of this function is used, the value returned in *lpszUnicodeName* will be a Unicode string using UTF-16 encoding. If the ANSI version of this function, the value returned will be a Unicode string using UTF-8 encoding. To display a UTF-8 encoded host name, your application will need to convert it to UTF-16 using the **MultiByteToWideChar** function.

Although this function performs checks to ensure that the *lpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the [DnsGetHostAddress](#) function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

DnsInitialize Function

```
BOOL WINAPI DnsInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **DnsInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **DnsInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **DnsUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **DnsInitialize** or **DnsUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsCloseHandle](#), [DnsCreateHandle](#), [DnsUninitialize](#)

DnsMatchHostName Function

```
BOOL WINAPI DnsMatchHostName(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName,  
    LPCTSTR lpszHostMask  
    BOOL bResolve  
);
```

The **DnsMatchHostName** function matches a host name against one or more strings that may contain wildcards.

Parameters

hClient

Handle to the client session.

lpszHostName

A pointer to a string which specifies the host name or IP address to match.

lpszHostMask

A pointer to a string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

bResolve

A boolean value which specifies if the host name or IP address should be resolved when matching the host against the mask string. If this parameter is non-zero, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is zero, then the match is made only against the host name string provided.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsMatchHostName** function provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the function would return a non-zero value indicating the host name matched the mask. However, if the mask string was "*.net" then the function would return zero, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

If an internationalized domain name (IDN) is specified, it will be converted internally to an ASCII string using Punycode encoding. The host mask will be matched against this encoded version of the host name, not its Unicode version.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[DnsGetAddress](#), [DnsGetHostAddress](#), [DnsGetHostName](#), [DnsGetLocalAddress](#)

DnsNormalizeHostName Function

```
INT WINAPI DnsNormalizeHostName(  
    LPCTSTR lpszHostName,  
    LPTSTR lpszNormalized,  
    INT nMaxLength  
);
```

The **DnsNormalizeHostName** function returns the canonical form of a host name in the specified buffer.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero length string.

lpszNormalized

Pointer to the string buffer that will contain the canonical form of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that can be copied to the *lpszNormalized* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsNormalizeHostName** function will remove all leading and trailing whitespace characters from the host name and fold all upper-case characters to lower-case. If an internationalized domain name (IDN) containing Unicode characters is passed to this function, it will be converted to an ASCII compatible format for domain names.

If the Unicode version of this function is used, the host name will be converted from UTF-16 to UTF-8 and then processed. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended that you use the Unicode version.

Although this function performs checks to ensure that the *lpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the [DnsGetHostAddress](#) function.

It is recommended that you use this function if your application needs to store the host name, and if accepts a host name as user input. It is not necessary to call this function prior to calling the other DNS API functions that accept a host name as a parameter. Those functions already normalize the host name and perform checks to ensure it is in the correct format.

If the *lpszHostName* parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address. To determine if the IP address has a corresponding host name, use the [DnsGetHostName](#) method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsRegisterServer Function

```
INT WINAPI DnsRegisterServer(  
    HCLIENT hClient,  
    INT nServer,  
    LPCTSTR lpszHostAddress,  
    INT nPort  
);
```

The **DnsRegisterServer** function registers a nameserver with the current client session. The nameserver is used to resolve queries issued by the client, such as returning the IP address for a given host name. At least one nameserver must be registered by the client before queries are issued.

Parameters

hClient

Handle to the client session.

nServer

The index into the client nameserver table. This index, starting at 0, is used to specify which slot in the client's nameserver table will be used to store the nameserver information.

lpszHostAddress

A pointer to a string that specifies the IP address of the nameserver to be registered. Note that hostnames cannot be specified.

nPort

The port number that the specified nameserver is accepting queries on. This value may be set to zero, in which case it will use the default port value.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is **DNS_ERROR**. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsReset Function

```
INT WINAPI DnsReset(  
    HCLIENT hClient  
);
```

The **DnsReset** function resets the current state of the client session. The timeout and retry counts are set to their default values, the local domain name is cleared and all registered servers are removed from the client nameserver table.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

See Also

[DnsRegisterServer](#), [DnsSetLocalDomain](#), [DnsSetRetryCount](#), [DnsSetTimeout](#), [DnsUnregisterServer](#)

DnsSetHostFile Function

```
INT WINAPI DnsSetHostFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName  
);
```

The **DnsSetHostFile** function specifies the name of an alternate file to use when resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **DnsGetHostAddress** and **DnsGetHostName** functions. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

hClient

Handle to the client session.

lpszFileName

Pointer to a string that specifies the name of the file. If the parameter is NULL, then the current host file is cleared from the cache and only the default host file will be used to resolve hostnames and addresses.

Return Value

If the function succeeds, the return value is the number of entries in the host file. A return value of DNS_ERROR indicates failure. To get extended error information, call **DnsGetLastError**.

Remarks

This function loads the file into memory allocated for the current thread. If the contents of the file have changed after the function has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, call this function again with the same file name. To remove the alternate host file from memory, specify a NULL pointer as the parameter.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

To determine if an alternate host file has been specified, use the **DnsGetHostFile** function. A return value of zero indicates that no alternate host file has been cached for the current thread.

A system may have a default host file, which is used to resolve hostnames before performing a nameserver lookup. To determine the name of this file, use the **DnsGetDefaultHostFile** function. It is not necessary to specify this default host file, since it is always used to resolve host names and addresses.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsSetLastError Function

```
VOID WINAPI DnsSetLastError(  
    DWORD dwErrorCode  
);
```

The **DnsSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread. A value of zero clears the last error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or DNS_ERROR. Those functions which call **DnsSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **DnsGetLastError** function. The use of **DnsGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

DnsSetLocalDomain Function

```
INT WINAPI DnsSetLocalDomain(  
    HCLIENT hClient,  
    LPCTSTR lpszDomain  
);
```

Parameters

hClient

Handle to the client session.

lpszDomain

Pointer to the string which contains the local domain name. This is used as a default value when a query does not explicitly specify a domain name.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

Unicode: Implemented as Unicode and ANSI versions

DnsSetResolverOptions Function

```
DWORD WINAPI DnsSetResolverOptions(  
    HCLIENT hClient,  
    DWORD dwOptions  
);
```

The **DnsSetResolverOptions** function changes the resolver options for the specified client session.

Parameters

hClient

Handle to the client session.

dwOptions

An unsigned integer that specifies one or more resolver options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
DNS_OPTION_NONE	No additional resolver options specified. This is the default value, and it is recommended that most applications do not specify additional options unless the implications of doing so are understood.
DNS_OPTION_PROMOTE	Promotes the server that successfully completed the last query to the first server that will be used to resolve subsequent queries. This option can improve performance in some cases where one or more of the registered servers are non-responsive. This option takes precedence over the DNS_OPTION_ROTATE option.
DNS_OPTION_ROTATE	Enables a round-robin selection of nameservers when performing queries. Normally each nameserver is queried in the same order. This option rotates the available nameservers so a different server is used with each query.
DNS_OPTION_AUTHONLY	Require the answer from the nameserver to be authoritative, not from the server's cache. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_PRIMARY	Queries are only accepted from the primary nameserver. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_NORECURSE	Disable the sending of recursive queries to the nameserver. Specifying this option will disable the bit in the DNS request header that specifies recursion is desired.
DNS_OPTION_NOSEARCH	Disable additional queries of higher domains in the search list if the host name cannot be resolved. If this option is specified, and the host name cannot be resolved using the local domain name an error is

	returned immediately. This option is ignored if no local domain has been specified or if the DNS_OPTION_NOSUFFIX option has been specified.
DNS_OPTION_NOSUFFIX	Disable additional queries using the local domain name if the host name is not a fully qualified domain name and cannot be resolved. This option is ignored if no local domain has been specified.
DNS_OPTION_NONAMECHECK	Disable checking the host name for invalid characters, such as the underscore and control characters. By default, host names are checked to ensure they're valid before submitting a query to the nameserver.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsSetResolverOptions** function changes the resolver options for the specified client session, modifying how nameserver queries are processed. It is recommended that most applications do not specify any resolver options and use the default behavior. Specifying these options without understanding how they can affect standard queries can result in unexpected failures. In particular, caution should be used when specifying the DNS_OPTION_NORECURSE and DNS_OPTION_NOSEARCH options as they change the normal process of resolving a host name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

See Also

DnsSetRetryCount Function

```
INT WINAPI DnsSetRetryCount(  
    HCLIENT hClient,  
    INT nRetries  
);
```

The **DnsSetRetryCount** function sets the number of attempts that the client will make attempting to resolve a query. When used in conjunction with the **DnsSetTimeout** function, it determines the total amount of time the client will spend attempting to resolve a query.

Parameters

hClient

Handle to the client session.

nRetries

The number of attempts the client will make, per nameserver, to resolve a query.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `DNS_ERROR`. To get extended error information, call **DnsGetLastError**.

Remarks

The retry count determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csdnsv11.lib`

See Also

[DnsGetRetryCount](#), [DnsGetTimeout](#), [DnsSetTimeout](#)

DnsSetTimeout Function

```
INT WINAPI DnsSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **DnsSetTimeout** function sets the number of seconds that the client will wait for a response from a nameserver. The timeout value is used each time a server in the client's nameserver table is queried. When used in conjunction with the **DnsSetRetryCount** function, it determines the total amount of time the client will spend attempting to resolve a query.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds until the client times out waiting for a response from a nameserver.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `DNS_ERROR`. To get extended error information, call **DnsGetLastError**.

Remarks

The timeout value determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, with two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csdnsv11.lib`

See Also

[DnsGetRetryCount](#), [DnsGetTimeout](#), [DnsSetRetryCount](#)

DnsUninitialize Function

```
VOID WINAPI DnsUninitialize();
```

The **DnsUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **DnsInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **DnsUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **DnsUninitialize** for every successful call to **DnsInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csdnsv11.lib

See Also

[DnsInitialize](#), [DnsCloseHandle](#), [DnsCreateHandle](#)

DnsUnregisterServer Function

```
INT WINAPI DnsUnregisterServer(  
    HCLIENT hClient,  
    INT nServer  
);
```

The **DnsUnregisterServer** function removes the specified nameserver information from the client. Unregistering a server prevents the client from using that server to satisfy subsequent DNS queries.

Parameters

hClient

Handle to the client session.

nServer

The index into the client's nameserver table. This index is the same value that is passed to the **DnsRegisterServer** function when the nameserver is registered.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Domain Name Service Data Structures

- HOSTENT
- INITDATA
- INTERNET_ADDRESS

HOSTENT

The **HOSTENT** structure contains information about a domain name, including its IP address and any aliases which may be defined.

```
typedef struct _HOSTENT
{
    char *   h_name;
    char **  h_aliases;
    short    h_addrtype;
    short    h_length;
    char **  h_addr_list;
} HOSTENT, *LPHOSTENT;
```

Members

h_name

The fully qualified domain name (FQDN) that caused the nameserver server to return a reply.

h_aliases

A NULL-terminated array of alternate names.

h_addrtype

The type of address being returned.

h_length

The length, in bytes, of each address.

h_addr_list

A NULL-terminated list of addresses for the host. Addresses are returned in network byte order. The macro **h_addr** is defined to be **h_addr_list[0]** for compatibility with older software.

Remarks

This structure is intended to be used for backwards compatibility with legacy applications and should not be used with new applications. You cannot use this structure to obtain information for a host which is assigned an IPv6 address. Applications should use the **DnsGetHostAddress** and **DnsGetHostName** functions which support both IPv4 and IPv6 addresses.

The application must never attempt to modify this structure or free any of its members. There is no Unicode version of this structure, string pointers will always specify ANSI strings, even if the application is compiled to use Unicode. Only one copy of this structure is allocated per thread, so the application should copy any information it needs before calling any other functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: winsock2.h.

See Also

[DnsGetHostAddress](#), [DnsGetHostByAddress](#), [DnsGetHostByName](#), [DnsGetHostName](#)

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

INTERNET_ADDRESS

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
    INT    ipFamily;
    BYTE   ipNumber[16];
} INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the <i>ipNumber</i> array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the *ipNumber* array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the *ipFamily* member first to make sure that it is actually an IPv4 address.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
- Minimum Server Platform:** Windows Server 2008 R2 Service Pack 1
- Header File:** ctools11.h

Domain Name Service Constants

Value	Description
DNS_RECORD_NONE	No record type
DNS_RECORD_ADDRESS	Host address
DNS_RECORD_NS	Authoritative nameserver
DNS_RECORD_CNAME	Canonical name (alias)
DNS_RECORD_SOA	Start of Authority
DNS_RECORD_WKS	Well known services
DNS_RECORD_PTR	Domain name
DNS_RECORD_HINFO	Host information
DNS_RECORD_MINFO	Mailbox information
DNS_RECORD_MX	Mail exchange host
DNS_RECORD_TXT	Text strings
DNS_RECORD_LOC	Location information
DNS_RECORD_UINFO	User information
DNS_RECORD_UID	User ID
DNS_RECORD_GID	Group ID

Encoding and Compression Library

Encode and decode files using standard algorithms such as base64, uuencode and quoted-printable. The library can also be used to compress and expand files, as well as encrypt or decrypt file data using AES encryption.

Reference

- [Functions](#)

Library Information

File Name	CSNCDV11.DLL
Version	11.0.2218.1855
LibID	FADF1E51-9CCE-489E-AF00-B81A5EC77CD7
Import Library	CSNCDV11.LIB
Dependencies	None
Standards	RFC 1738, RFC 1951, RFC 2045

Overview

The Encoding and Compression library provides functions for encoding and decoding binary files, typically attachments to email messages. The process of encoding converts the contents of a binary file to printable 7-bit ASCII text. Decoding reverses the process, converting a previously encoded text file back into a binary file.

There are two primary types of encoding methods used with various Internet applications: base64 and uuencode. The base64 algorithm is most commonly used with email attachments, and is often referred to as MIME encoding since this is the encoding method specified in the MIME standards document. The uuencode algorithm (so called because the programs to perform the encoding were called uuencode and uudecode) is often used when attaching binary files to Usenet newsgroup posts. The library also supports an alternate encoding format called yEnc which is also widely used to attach files to Usenet posts.

In addition to encoding and decoding data files, this library includes functions to compress and expand data, as well as encrypt and decrypt files using 256-bit AES encryption.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Encoding and Compression Functions

Function	Description
AesDecryptBuffer	Decrypt a buffer previously encrypted using the AesEncryptBuffer function
AesDecryptFile	Decrypt a file previously encrypted using the AesEncryptFile function
AesDecryptString	Decrypt a string previously encrypted using the AesEncryptString function
AesEncryptBuffer	Encrypt a memory buffer using 256-bit AES encryption
AesEncryptFile	Encrypt the contents of a file using 256-bit AES encryption
AesEncryptString	Encrypt a null-terminated string using 256-bit AES encryption
CompareFile	Compare the contents of two files to determine if they are identical
CompareFileEx	Compare the contents of two files or the contents of a file against message digest
CompressBuffer	Compress the contents of the specified buffer
CompressFile	Compress the contents of the specified file
CompressFileEx	Compress the contents of the specified file with additional options
DecodeBuffer	Decode an encoded string, storing the result in the specified buffer
DecodeFile	Decode the contents of a file using the specified decoding method
EncodeBuffer	Encode the contents of a buffer using the specified encoding method
EncodeFile	Encode the contents of a file using the specified encoding method
ExpandBuffer	Expand the contents of a previously compressed buffer
ExpandFile	Expand the contents of a previously compressed file
ExpandFileEx	Expand the contents of a previously compressed file with additional options
GetMessageDigest	Compute a message digest for a buffer, string or data file
IsUnicodeText	Determine if a text buffer contains valid Unicode characters
UnicodeDecodeText	Decode UTF-8 encoded text and return a localized string
UnicodeEncodeText	Encode a text buffer and return a UTF-8 encoded string

AesDecryptBuffer Function

```
BOOL WINAPI AesDecryptBuffer(  
    LPCTSTR lpszPassword,  
    LPVOID lpvInputBuffer,  
    DWORD dwInputSize  
    LPVOID lpvOutputBuffer,  
    LPDWORD lpdwOutputSize  
);
```

The **AesDecryptBuffer** function decrypts the contents of a memory buffer.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the decryption key. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

lpvInputBuffer

A pointer to the buffer which contains the data to be decrypted.

dwInputSize

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

A pointer to the buffer which will contain the decrypted data when the function returns. This memory must be allocated by the application and be large enough to contain all of the decrypted data. If the output buffer is not large enough, the function will fail. This parameter cannot be NULL.

lpdwOutputSize

A pointer to the number of bytes that may be copied into the output buffer. This parameter must be initialized to a non-zero value. When the function returns, the actual number of bytes of decrypted data is returned in this parameter. This parameter cannot be NULL.

Return Value

A non-zero value is returned if the data was successfully decrypted. A zero value indicates that the data could not be decrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesDecryptBuffer** function will decrypt a block of memory using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The *lpszPassword* value must be identical to the value used to encrypt the data using the **AesEncryptBuffer** function.

Due to how the SHA-256 hash is generated, this function cannot be used to decrypt data that was encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using **AesEncryptBuffer**.

If you wish to decrypt the contents of a file, use the **AesDecryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
BOOL bIsDecrypted = FALSE;
DWORD dwOutputSize = MAX_BUFFER_SIZE;
BYTE *lpOutputBuffer = (BYTE *)LocalAlloc(LPTR, dwOutputSize);

if (lpOutputBuffer != NULL)
{
    bIsDecrypted = AesDecryptBuffer(lpszPassword,
                                   lpInputBuffer,
                                   dwInputSize,
                                   lpOutputBuffer,
                                   &dwOutputSize);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

[AesDecryptFile](#), [AesDecryptString](#), [AesEncryptBuffer](#), [CompressBuffer](#)

AesDecryptFile Function

```
BOOL WINAPI AesDecryptFile(  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile  
);
```

The **AesDecryptFile** function decrypts the contents of a file.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the decryption key. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

lpszInputFile

A pointer to a null terminated string which specifies the name of the file to be decrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

A pointer to a null terminated string which specifies the name of the file that will contain the decrypted data. If the file exists, it will be overwritten. It must be a regular file that can be opened for writing by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesDecryptFile** function will decrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and stores the decrypted data in the specified output file. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The *lpszPassword* value must be identical to the value used to encrypt the data using the **AesEncryptFile** function.

Due to how the SHA-256 hash is generated, this function cannot be used to decrypt files that were encrypted using another third-party library. It can only be used to decrypt data that was previously encrypted using **AesEncryptFile**.

A temporary file is created during the decryption process and the output file is created or overwritten only if the input file could be successfully decrypted. If the decryption fails, no output file will be created.

If you wish to decrypt the contents of a memory buffer or string, use the **AesDecryptBuffer** or **AesDecryptString** functions.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

[AesDecryptBuffer](#), [AesDecryptString](#), [AesEncryptFile](#)

AesDecryptString Function

```
BOOL WINAPI AesDecryptString(  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszInputString,  
    LPCTSTR lpszOutputString,  
    LONG nMaxLength  
);
```

The **AesDecryptString** function decrypts the contents of a string.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the decryption key. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

lpszInputString

A pointer to a null terminated string which contains the data to be decrypted. The encrypted input data must be base64 encoded and identical to the encrypted string returned by the **AesEncryptString** function. If this parameter is NULL or points to an empty string the function will fail.

lpszOutputString

A pointer to the buffer which will contain the decrypted string data. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that can be copied to the output string buffer. The output buffer must be large enough to store the complete decrypted string and is terminated with a null character. This value must be greater than zero. If the output string buffer is not large enough, the function will fail.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be decrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesDecryptString** function will decrypt a string using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted string to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The *lpszPassword* value must be identical to the value used to encrypt the data using the **AesEncryptString** function.

Due to how the SHA-256 hash is generated, this function cannot be used to decrypt strings that were encrypted using another third-party library. It can only be used to decrypt strings that were previously encrypted using **AesEncryptString**.

If you wish to decrypt the contents of a file, use the **AesDecryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
BOOL bIsDecrypted = FALSE;
LPCTSTR lpszPassword = _T("NFr-E{Ki3_1w0iV+LI@z}");
TCHAR szDecryptedText[MAX_STRING_LENGTH];

bIsDecrypted = AesDecryptString(lpszPassword,
                                szEncryptedText,
                                szDecryptedText,
                                MAX_STRING_LENGTH);

if (bIsDecrypted)
{
    _tprintf(_T("The decrypted string is \"%s\"\n"), szDecryptedText);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

AesEncryptBuffer Function

```
BOOL WINAPI AesEncryptBuffer(  
    LPCTSTR lpszPassword,  
    LPVOID lpvInputBuffer,  
    DWORD dwInputSize  
    LPVOID lpvOutputBuffer,  
    LPDWORD lpdwOutputSize  
);
```

The **AesEncryptBuffer** function encrypts the contents of a memory buffer.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this function. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

lpvInputBuffer

A pointer to the buffer which contains the data to be encrypted.

dwInputSize

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

A pointer to the buffer which will contain the encrypted data when the function returns. This memory must be allocated by the application and be large enough to contain all of the encrypted data. The amount encrypted data returned will always be larger than the amount of data specified by *dwInputSize*. If the output buffer is not large enough, the function will fail. This parameter cannot be NULL.

lpdwOutputSize

A pointer to the number of bytes that may be copied into the output buffer. This parameter must be initialized to a non-zero value. When the function returns, the actual number of bytes of encrypted data is returned in this parameter. This parameter cannot be NULL.

Return Value

A non-zero value is returned if the data was successfully encrypted. A zero value indicates that the data could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesEncryptBuffer** function will encrypt a block of memory using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process. The identical password is required to decrypt the data using the **AesDecryptBuffer** function.

It is recommended that most applications specify a password value. If the *lpszPassword* parameter is NULL or specifies a zero-length string, a default internal hash value is used. This means that any other application which uses a NULL password value will be able to decrypt the data. If the Unicode version of this function is called, the *lpszPassword* value will be encoded using UTF-8 prior to the hash value being generated.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **AesDecryptBuffer** function.

The amount of encrypted data returned by this function will always be somewhat larger than original unencrypted data. If your application dynamically allocates a block of memory to store the encrypted data, provide a maximum buffer size that is at least several hundred bytes larger than the unencrypted data. If the output buffer provided is not large enough, the function will fail and the **GetLastError** function will return ERROR_INSUFFICIENT_BUFFER.

The encrypted data returned by this function can contain embedded nulls and should be typically handled as unsigned char (byte) values. If you wish to encrypt strings and store the encrypted values, use the **AesEncryptString** function. It will perform the same 256-bit AES encryption, but return the encrypted data as a base64 encoded string rather than binary data.

If your application is also using the **CompressBuffer** function to compress the data, it is recommended that you call **CompressBuffer** before calling **AesEncryptBuffer**. You will typically achieve a better compression rate on unencrypted data than attempting to compress data which has been encrypted with this function.

If you wish to encrypt the contents of a file, use the **AesEncryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
BOOL bIsEncrypted = FALSE;
DWORD dwOutputSize = MAX_BUFFER_SIZE;
BYTE *lpOutputBuffer = (BYTE *)LocalAlloc(LPTR, dwOutputSize);

if (lpOutputBuffer != NULL)
{
    bIsEncrypted = AesEncryptBuffer(lpszPassword,
                                   lpInputBuffer,
                                   dwInputSize,
                                   lpOutputBuffer,
                                   &dwOutputSize);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

AesEncryptFile Function

```
BOOL WINAPI AesEncryptFile(  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile  
);
```

The **AesEncryptFile** function encrypts the contents of a file.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this function. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

lpszInputFile

A pointer to a null terminated string which specifies the name of the file to be encrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

A pointer to a null terminated string which specifies the name of the file that will contain the encrypted data. If the file exists, it will be overwritten. It must be a regular file that can be opened for writing by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesEncryptFile** function will encrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and stores the encrypted data in the specified output file. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process. The identical password is required to decrypt the data using the **AesDecryptFile** function.

It is recommended that most applications specify a password value. If the *lpszPassword* parameter is NULL or specifies a zero-length string, a default internal hash value is used. This means that any other application which uses a NULL password value will be able to decrypt the data. If the Unicode version of this function is called, the *lpszPassword* value will be encoded using UTF-8 prior to the hash value being generated.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **AesDecryptFile** function.

A temporary file is created during the encryption process and the output file is created or overwritten only if the input file could be successfully encrypted. If the encryption fails, no output file will be created.

The input file contents will always be processed as a binary data stream. If you use this function to

encrypt a text file, the output file will contain binary characters, not printable text. If you wish to transfer or store the encrypted data as text, it should be encoded using the **EncodeFile** function after calling **AesEncryptFile**.

If your application is also using the **CompressFile** function to compress the data, it is recommended that you call **CompressFile** before calling **AesEncryptFile**. You will typically achieve a better compression rate on unencrypted data than attempting to compress data which has been encrypted with this function.

If you wish to encrypt the contents of a memory buffer or string, use the **AesEncryptBuffer** or **AesEncryptString** functions.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

[AesDecryptFile](#), [AesEncryptBuffer](#), [AesEncryptString](#), [CompressFile](#), [EncodeFile](#)

AesEncryptString Function

```
BOOL WINAPI AesEncryptString(  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszInputString,  
    LONG nInputLength  
    LPCTSTR lpszOutputString,  
    LONG nMaxLength  
);
```

The **AesEncryptString** function encrypts the contents of a string.

Parameters

lpszPassword

A pointer to a null terminated string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this function. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

lpszInputString

A pointer to a null terminated string which contains the text to be encrypted. If the Unicode version of this function is called, the string is automatically UTF-8 encoded prior to being encrypted.

nInputLength

The number of characters in the input string which will be encrypted. If this value is -1, the length of the input string is determined automatically by counting the number of characters up to the terminating null byte. Note that with Unicode strings, this value must represent the number of characters in the string, not the number of bytes allocated for the string.

lpszOutputString

A pointer to the buffer which will contain a base64 encoded encrypted string when the function returns. This memory must be allocated by the application and be large enough to contain all of the encrypted data. The amount encrypted data returned will always be larger than the amount of data specified by *nInputLength*. If the output string buffer is not large enough, the function will fail. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that can be copied to the output string buffer. The output buffer must be large enough to store the complete encrypted string which is encoded using base64 and terminated with a null character. This value must be greater than zero. If the output string buffer is not large enough, the function will fail.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesEncryptString** function will encrypt a string using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data as a base64 encoded string to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process. The identical password is required to decrypt the data using the **AesDecryptString** function.

It is recommended that most applications specify a password value. If the *lpszPassword* parameter is NULL or specifies a zero-length string, a default internal hash value is used. This means that any other application which uses a NULL password value will be able to decrypt the data. If the Unicode version of this function is called, the *lpszPassword* value will be encoded using UTF-8 prior to the hash value being generated.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **AesDecryptString** function.

The amount of encrypted data returned by this function will always be larger than original unencrypted data. If your application dynamically allocates a block of memory to store the encrypted string, provide a maximum output string size that is at least several hundred bytes larger than the unencrypted data. If the output string is not large enough, the function will fail and the **GetLastError** function will return ERROR_INSUFFICIENT_BUFFER.

The string provided to this function cannot contain embedded nulls and should not be used to encrypt binary data. If you wish to encrypt binary data, use the **AesEncryptBuffer** function. It will perform the same 256-bit AES encryption and return the encrypted data into a buffer provided by the caller.

If you wish to encrypt the contents of a file, use the **AesEncryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
BOOL bIsEncrypted = FALSE;
LPCTSTR lpszPassword = _T("NFr-E{Ki3_1w0iV+LI@z}");
LPCTSTR lpszPlainText = _T("The quick brown fox jumped over the lazy dog.");
TCHAR szEncryptedText[MAX_STRING_LENGTH];

bIsEncrypted = AesEncryptString(lpszPassword,
                               lpszPlainText,
                               -1,
                               szEncryptedText,
                               MAX_STRING_LENGTH);

if (bIsEncrypted)
{
    _tprintf(_T("The encrypted string is \"%s\"\n"), szEncryptedText);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

[AesDecryptString](#), [AesEncryptBuffer](#), [AesEncryptFile](#)

CompareFile Function

```
BOOL WINAPI CompareFile(  
    LPCTSTR lpszFile1,  
    LPCTSTR lpszFile2  
);
```

The **CompareFile** function compares the contents of two files to determine if they are identical.

Parameters

lpszFile1

A pointer to a null-terminated string which specifies the name of the first file to compare. This parameter must specify the name of a file which exists and can be opened for read access by the current process. If the file name specifies a directory or device name, the function will fail. This parameter cannot be NULL or a zero-length string. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters after the variable expansion, they will be removed.

lpszFile2

A pointer to a null-terminated string which specifies the name of the second file to compare. This parameter must specify the name of a file which exists and can be opened for read access by the current process. If the file name specifies a directory or device name, the function will fail. This parameter cannot be NULL or a zero-length string. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters after the variable expansion, they will be removed.

Return Value

A non-zero value is returned if the two files are identical. A value of zero indicates the files are different or an error has occurred. Check the value returned by the **GetLastError** function to determine the reason the file comparison was not successful. If the files are identical, this function will clear the last error code for the current thread.

Remarks

The **CompareFile** function can be used compare the contents of two files to determine if they are the same. If you need to perform a more complex file comparison, such as comparing the file creation or modification timestamps or verifying the file contents match a computed hash value, use the **CompareFileEx** function.

If the *lpszFile1* and *lpszFile2* file names resolve to the same file on the disk, this function will succeed without checking the contents of the file. This check is performed immediately after the file names have been expanded and converted to absolute paths. The function will still return an error if the file not does actually exist or is not a regular file.

To avoid potential problems with relative pathing in multithreaded applications, it is recommended you use absolute paths whenever possible. If you do not specify an absolute path, the file locations will be considered relative to the current working directory for the process. Because this is shared between all threads, it is possible for one thread to change the current working directory at any time and this can create inconsistent results. If you must use relative paths in a multithreaded application, use a mutex or critical section to ensure other threads cannot change the current working directory for the process while performing the file comparison.

This function will normalize the file names provided by the caller and perform checks to make sure the names do not contain illegal characters. If the name includes quotes, wildcard characters or other

invalid symbols the function will fail and return zero with the last error code set to `ST_ERROR_INVALID_FILE_NAME`. It is permitted to use forward slashes in path names and these will be converted to the standard backslash character used with Windows paths. This function cannot be used to compare the contents of NTFS alternate data streams.

This function is defined using an alias which automatically selects an ANSI or Unicode version based on the value of the `UNICODE` preprocessor macro. If you use the ANSI version of this function, the expanded file names will always be considered UTF-8 encoded strings, regardless of the current locale of the application. If your application uses file names which contain non-ASCII characters, you should always use the Unicode version of the function, even if your project is configured to use a multi-byte character set.

Example

```
// Compare the contents of two files
LPCTSTR lpszFile1 = _T("%USERPROFILE%\\AppName\\ProjectData.db");
LPCTSTR lpszFile2 = _T("%TEMP%\\BackupData.db");

BOOL bIdentical = CompareFile(lpszFile1, lpszFile2);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csncdv11.lib`

Unicode: Implemented as Unicode and ANSI versions

CompareFileEx Function

```
BOOL WINAPI CompareFileEx(  
    LPCTSTR lpszFile1,  
    LPCTSTR lpszFile2,  
    DWORD dwOptions,  
    LPCTSTR lpszDigest  
);
```

The **CompareFileEx** function compares the contents of two files with an optional message digest.

Parameters

lpszFile1

A pointer to a null-terminated string which specifies the name of the first file to compare. This parameter must specify the name of a file which exists and can be opened for read access by the current process. If the file name specifies a directory or device name, the function will fail. This parameter cannot be NULL or a zero-length string. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters after the variable expansion, they will be removed.

lpszFile2

A pointer to a null-terminated string which specifies the name of the second file to compare. If this parameter is NULL or a zero-length string, the *lpszDigest* parameter must specify a valid message digest and the contents of the first file will be compared against that digest. If this parameter specifies a file name, the file must exist and the current process must be able to open it for read access. If the file name specifies a directory or device name, the function will fail. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters after the variable expansion, they will be removed.

dwOptions

An unsigned integer value which specifies one or more option flags which will control how the files are compared. It may be one or more of the following values:

Value	Description
COMPARE_FILE_DEFAULT	Use the default comparison option, which is to perform a byte comparison of both files. If the <i>lpszDigest</i> parameter is not NULL or a zero-length string, the function will compare the message digest against the contents of the file. If the <i>lpszDigest</i> parameter has a value and no specific hash algorithm has been specified as one of the options, the hash type will be automatically determined based on its value
0x0001	COMPARE_FILE_CONTENTS
	Perform a byte comparison of the two files. This option

		requires both files be specified. The current process must be able to open both files for exclusive read access. If either file is opened for write access, the function will fail. The <i>lp szFile2</i> parameter must specify a valid file name if this option is used.
0x0002	COMPARE_FILE_TIME_CREATED	Compare the file creation times for both files and only consider them to be identical if the creation times are identical. If this option is specified and the creation times are different, the function will return zero even if the contents of the two files are identical. The <i>lp szFile2</i> parameter must specify a valid file name if this option is used.
0x0004	COMPARE_FILE_TIME_MODIFIED	Compare the file modification times for both files and only consider them to be identical if the modification times are identical. If this option is specified and the modification times are different, the function will return zero even if the contents of the two files are identical. The <i>lp szFile2</i> parameter must specify a valid file name if this option is used.
0x0100	COMPARE_FILE_DIGEST_MD5	Use the MD5 algorithm to compute 128-bit hash value for the contents of the first file and compare this against the specified digest string. This algorithm is the most efficient method to compute a hash to verify data integrity, however it is not considered cryptographically secure

		and hash collision is possible. When this option is used the <i>lpszDigest</i> parameter must specify a valid MD5 hash as a 32 digit hexadecimal string.
0x0200	COMPARE_FILE_DIGEST_SHA1	Use the SHA-1 algorithm to compute 160-bit hash value for the contents of the first file and compare this against the specified digest string. This algorithm is comparable to the MD5 algorithm and has a lower chance of hash collision; however, it is not considered cryptographically secure and hash collision is possible. When this option is used the <i>lpszDigest</i> parameter must specify a valid SHA-1 hash as a 40 digit hexadecimal string.
0x0400	COMPARE_FILE_DIGEST_SHA256	Use the SHA-256 algorithm to compute a 256-bit hash value for the contents of the first file and compare this against the specified digest string. This is a cryptographically secure algorithm which is more compute intensive than either MD5 or SHA-1, but the chance of a hash collision is extremely low and typically not a concern for most applications. When this option is used the <i>lpszDigest</i> parameter must specify a valid SHA-256 hash as a 64 digit hexadecimal string.

lpszDigest

A pointer to a null-terminated string which specifies a sequence of hexadecimal numbers which are used to compare against the computed hash value for the file. If this parameter is not NULL and no option is specified to indicate the hash type, it will be inferred from the length of the string. If this parameter is NULL or a zero-length string, it will be ignored. The case of the hexadecimal digits in

the string are ignored and it is permitted, but not required, to prefix the string with either "0x" or "&H" to indicate it is a hexadecimal value. If the string does not specify a valid hexadecimal number or is not a value computed using one of the supported hash algorithms, the function will fail.

Return Value

A non-zero value is returned if the files are identical using the specified criteria. A value of zero indicates the files are different or an error has occurred. Check the value returned by the **GetLastError** function to determine the reason the file comparison was not successful. If the files are identical, this function will clear the last error code for the current thread.

Remarks

The **CompareFileEx** function can be used to either compare the contents of two files or compare the contents of a file against a pre-computed hash value to determine if they match. In addition to comparing file contents, the function can also check the file creation and/or modification times to ensure they are the same. You can use the **GetMessageDigest** function to compute a hash value for a file.

In most cases, an application will specify either two files to compare or a message digest value. If you call the function using two file names and a message digest, the contents of both files must be identical and the computed hash value must match the specified message digest. If any of the requirements are not satisfied, the function will return zero (false). For example, if the actual contents of the two files are identical, but the value specified by *lpzdDigest* does not match the computed hash value of files, the function will still return zero.

This function performs the comparison in a way to minimize potential disk I/O whenever possible. First, the size of the two files are compared and if they are different, no further checks are performed. Next, if either the COMPARE_FILE_TIME_CREATED or COMPARE_FILE_TIME_MODIFIED options have been specified, the file timestamps are compared and no further checks are performed if they do not match. A byte comparison of both files will only be performed after the other comparison criteria has been satisfied.

Comparing the contents of a file against a message digest value is the most expensive operation in terms of memory and processor utilization. The larger the files are, and the more complex the hash algorithm, the more compute-intensive the operation will be. In most cases, the SHA-1 algorithm provides a good balance between resource utilization and minimizing the possibility of hash collisions where different files could potentially generate the same hash value.

If it is critically important to minimize the possibility of a hash collision, use the SHA-256 algorithm; however, be aware of the impact it can have on performance when used with very large files. The current thread will block while the hash is being computed and if a large amount of data is being processed, this may cause the application to become non-responsive. In that case, it is recommended you create a background worker thread and call this function from within that worker thread, rather than inside the main UI thread.

To avoid potential problems with relative pathing in multithreaded applications, it is recommended you use absolute paths whenever possible. If you do not specify an absolute path, the file locations will be considered relative to the current working directory for the process. Because this is shared between all threads, it is possible for one thread to change the current working directory at any time and this can create inconsistent results. If you must use relative paths in a multithreaded application, use a mutex or critical section to ensure other threads cannot change the current working directory for the process while performing the file comparison.

This function will normalize the file names provided by the caller and perform checks to make sure the names do not contain illegal characters. If the name includes quotes, wildcard characters or other

invalid symbols the function will fail and return zero with the last error code set to `ST_ERROR_INVALID_FILE_NAME`. It is permitted to use forward slashes in path names and these will be converted to the standard backslash character used with Windows paths. This function cannot be used to compare the contents of NTFS alternate data streams.

This function is defined using an alias which automatically selects an ANSI or Unicode version based on the value of the `UNICODE` preprocessor macro. If you use the ANSI version of this function, the expanded file names will always be considered UTF-8 encoded strings, regardless of the current locale of the application. If your application uses file names which contain non-ASCII characters, you should always use the Unicode version of the function, even if your project is configured to use a multi-byte character set.

Example

```
// Compare the contents of a file against an SHA-1 hash value
LPCTSTR lpszFile = _T("%USERPROFILE%\Documents\Projects\MyDocument.docx");
LPCTSTR lpszSHA1 = _T("541E43FDC612E41C02B770A2FD87EBB4A12EA800");
BOOL bIdentical;

bIdentical = CompareFileEx(
    lpszFile,
    NULL,
    COMPARE_FILE_DIGEST_SHA1,
    lpszSHA1);

// Compare the contents of two files
LPCTSTR lpszFile1 = _T("%USERPROFILE%\AppName\ProjectData.db");
LPCTSTR lpszFile2 = _T("%TEMP%\BackupData.db");

bIdentical = CompareFileEx(
    lpszFile1,
    lpszFile2,
    COMPARE_FILE_CONTENTS,
    NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csncdv11.lib`

Unicode: Implemented as Unicode and ANSI versions

CompressBuffer Function

```
BOOL WINAPI CompressBuffer(  
    LPVOID lpvInputBuffer,  
    DWORD cbInputBuffer  
    LPVOID lpvOutputBuffer,  
    LPDWORD lpcbOutputBuffer  
);
```

The **CompressBuffer** function compresses the contents of the specified buffer.

Parameters

lpvInputBuffer

A pointer to the buffer which contains the data to be compressed.

cbInputBuffer

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

A pointer to the buffer which will contain the compressed data. This parameter may be NULL, which can be used to determine the size of the of the resulting compressed data prior to allocating memory for it.

lpcbOutputBuffer

A pointer to the number of bytes that may be copied into the output buffer. If the *lpvOutputBuffer* parameter is not NULL, this must be initialized to a non-zero value. When the function returns, the actual number of bytes of compressed data is returned in this parameter.

Return Value

A non-zero value is returned if the data was successfully compressed. A zero value indicates that the data could not be compressed.

Remarks

This function will use the default Deflate algorithm to compress the contents of the buffer. This is a compression algorithm which combines the LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. It generally provides a good balance between the data compression ratio and system resources used. The compression ratio achieved by the **CompressBuffer** function will depend on the type of data being compressed.

The compressed data can be expanded to its original contents by calling the **ExpandBuffer** function.

Example

```
cbOutputBuffer = 0;  
bResult = CompressBuffer(lpInputBuffer,  
                          cbInputBuffer,  
                          NULL,  
                          &cbOutputBuffer);  
  
if (bResult)  
{  
    lpOutputBuffer = (LPBYTE)LocalAlloc(LPTR, cbOutputBuffer);  
    bResult = CompressBuffer(lpInputBuffer,  
                             cbInputBuffer,  
                             lpOutputBuffer,
```

```
}  
    &cbOutputBuffer);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csncdv11.lib

CompressFile Function

```
BOOL WINAPI CompressFile(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile  
);
```

The **CompressFile** function compresses the contents of the specified file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON:, is specified as the file name. An error will be returned if this parameter is NULL or a zero-length string.

lpszOutputFile

The name of the file that is to contain the compressed file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON:, is specified as the file name. If this parameter is NULL or a zero-length string, the compression is performed in-place.

Return Value

A non-zero value is returned if the file was successfully compressed. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The compression ratio achieved by the **CompressFile** function depends on the type of file that is being compressed. The compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

This function will use the default Deflate algorithm to compress the file. This is a compression algorithm which combines the LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. It generally provides a good balance between the data compression ratio and system resources used. You can use the **CompressFileEx** function to specify an alternate compression algorithm if you wish to perform more resource-intensive file compression.

If the output file already exists, it will be replaced with the compressed contents of the input file. If the compression fails for any reason, the output file will be deleted and the last error code will be updated indicating the cause of the failure. If you want to ensure an existing output file will be preserved if an error occurs, you should create a temporary file and use it as the output file. If this function succeeds, then you can rename or move the temporary file using a function like **MoveFileEx**.

It is possible to compress the input file in-place by specifying the *lpszOutputFile* parameter as a NULL pointer or zero-length string. In this case, the contents of the input file will be compressed to a temporary file and if the compression succeeds, the original input file will be replaced by the temporary file. If an error occurs, the input file will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[CompressFileEx](#), [DecodeFile](#), [EncodeFile](#), [ExpandFile](#), [ExpandFileEx](#)

CompressFileEx Function

```
BOOL WINAPI CompressFileEx(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile,  
    DWORD dwCompressionType,  
    DWORD dwCompressionLevel,  
    LPVOID lpvReserved,  
    DWORD dwReserved  
);
```

The **CompressFileEx** function compresses the contents of the specified file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name. An error will be returned if this parameter is NULL or a zero-length string.

lpszOutputFile

The name of the file that is to contain the compressed file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name. If this parameter is NULL or a zero-length string, the compression is performed in-place.

dwCompressionType

A numeric value which determines the algorithm that will be used to compress the data. One of the following values may be specified. By default, the Deflate algorithm is used.

Value	Description
COMPRESSION_TYPE_DEFLATE	A compression algorithm that combines the LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. Deflate is widely used by compression software and provides a good balance between the data compression ratio and system resources used. This is the default compression method.
COMPRESSION_TYPE_BZIP2	A compression algorithm that rearranges blocks of data in sorted order and then uses Huffman coding to process different frequencies of data within the block. Burrows-Wheeler compression provides a better compression ratio than the Deflate algorithm, however it requires more resources to perform the compression.
COMPRESSION_TYPE_LZMA	A compression algorithm that combines the LZ77 algorithm for dictionary-based compression with range encoding to efficiently

	represent repetitive patterns in the data. LZMA can achieve higher compression ratios than Deflate or the Burrows-Wheeler algorithms; however, it requires more memory and CPU resources due to the larger dictionary sizes and more complex encoding algorithm.
--	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

dwCompressionLevel

A numeric value which specifies the compression level to use. A value of zero specifies that the default compression level appropriate for the selected algorithm should be used, balancing resource usage and the compression ratio of the data. A value of 1 specifies that the compression should be performed using minimal memory resources, at the expense of the compression ratio. The maximum value of 9 specifies that the algorithm should use more memory to achieve the maximum compression ratio. It is recommended that most applications use the default value of zero.

lpvReserved

A reserved parameter which should always be NULL.

dwReserved

A reserved unsigned integer value which should always be zero.

Return Value

A non-zero value is returned if the file was successfully compressed. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The compression ratio achieved by the **CompressFileEx** function depends on the type of file that is being compressed. The compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

If the output file already exists, it will be replaced with the compressed contents of the input file. If the compression fails for any reason, the output file will be deleted and the last error code will be updated indicating the cause of the failure. If you want to ensure an existing output file will be preserved if an error occurs, you should create a temporary file and use it as the output file. If this function succeeds, then you can rename or move the temporary file using a function like **MoveFileEx**.

It is possible to compress the input file in-place by specifying the *lpvOutputFile* parameter as a NULL pointer or zero-length string. In this case, the contents of the input file will be compressed to a temporary file and if the compression succeeds, the original input file will be replaced by the temporary file. If an error occurs, the input file will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

DecodeBuffer Function

```
LONG WINAPI DecodeBuffer(  
    LPCTSTR lpszInput,  
    LPBYTE lpOutput,  
    LONG cbOutput,  
    DWORD dwOptions  
);
```

The **DecodeBuffer** function decodes an encoded string, and stores the result in the specified buffer.

Parameters

lpszInput

A pointer to a string which contains the base64 encoded text.

lpOutput

A pointer to a byte array buffer which is used to store the decoded data. It is recommended that the buffer be as large as the length of the encoded string.

cbOutput

A long integer which specifies the maximum number of bytes which may be stored in the buffer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
DATA_DECODE_BASE64	Decode a string that was created using the base64 encoding algorithm. This is the encoding method that is used by most modern email client software. Note that this option cannot be combined with other decoding methods.
DATA_DECODE_QUOTED	Decode a string that was created using the quoted-printable encoding algorithm. Note that this option cannot be combined with the other decoding methods.
DATA_DECODE_URL	Decode a string that was created using the URL encoding algorithm. Note that this option cannot be combined with the other decoding methods.
DATA_DECODE_UTF7	Decode a string that was created using the UTF-7 encoding algorithm. Note that this option cannot be combined with the other decoding methods.
DATA_DECODE_UTF8	Decode a string that was created using the UTF-8 encoding algorithm. Note that this option cannot be combined with the other decoding methods.
DATA_DECODE_COMPRESSED	The data was compressed prior to being encoded, and should be expanded after the decoding has completed successfully. This option is ignored if the encoding type is not base64. This should only be used if it was specified when the data was encoded.

Return Value

If the function succeeds, it will return the number of bytes decoded and stored in the buffer. If the function fails, it will return -1. Failure typically indicates that the encoded string was corrupted or the buffer is not large enough to store the decoded data.

Remarks

The **DecodeBuffer** function is used to decode a block of data that was previously encoded with the **EncodeBuffer** function. To decode the contents of a file, it is recommended that you use the **DecodeFile** function instead.

If you specify either UTF-7 or UTF-8 encoding, the *lpOutput* parameter must point to a Unicode string and the *cbOutput* parameter must specify the maximum number of characters, not bytes, that can be copied into the string. The return value will be the number of Unicode characters, not bytes, that were copied into the output buffer. The conversion is always performed using the default system code page.

It is recommended that you use the **UnicodeEncodeText** function to convert a string to UTF-8 encoded text, and the **UnicodeDecodeText** function to convert UTF-8 encoded text to a UTF-16 or localized multi-byte string.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[DecodeFile](#), [EncodeBuffer](#), [EncodeFile](#), [GetMessageDigest](#), [IsUnicodeText](#), [UnicodeDecodeText](#), [UnicodeEncodeText](#)

DecodeFile Function

```
BOOL WINAPI DecodeFile(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile,  
    DWORD dwOptions,  
    DWORD dwReserved  
);
```

The **DecodeFile** function opens and decodes an encoded file, storing the contents in the specified file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be decoded. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON:, is specified as the file name.

lpszOutputFile

The name of the file that is to contain the decoded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON:, is specified as the file name.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FILE_DECODE_BASE64	Use the base64 algorithm for decoding the file. This is the encoding method that is used by most modern email client software. Note that this option cannot be combined with other decoding methods.
FILE_DECODE_QUOTED	Use the quoted-printable algorithm for decoding the file. Note that this option cannot be combined with the other decoding methods.
FILE_DECODE_UUCODE	Use the uuencode algorithm for decoding the file. This is a common encoding method used in UNIX systems and older email client software. Note that this option cannot be combined with other decoding methods.
FILE_DECODE_YENC	Use the yEnc algorithm for decoding the file. Note that this option cannot be combined with other decoding methods.
FILE_DECODE_COMPRESSED	The file was compressed prior to being encoded, and should be expanded after the decoding has completed successfully. This option should only be used if it was specified when the file was encoded.

dwReserved

This parameter is reserved and should always be set to zero.

Return Value

A non-zero value is returned if the file was successfully decoded. A zero value indicates that the file does not exist, the encoded file was damaged or the output file could not be created.

Remarks

The **DecodeFile** function decodes files that were previously encoded through a call to the **EncodeFile** function or by a third-party application such as an email client. The option to expand a previously compressed file requires that the function be able to create a temporary file on the local system in the directory specified by the TEMP environment variable. This function can only expand a file that was previously compressed with the **EncodeFile** or **CompressFile** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

[CompressFile](#), [EncodeFile](#), [ExpandFile](#), [GetMessageDigest](#)

EncodeBuffer Function

```
LONG WINAPI EncodeBuffer(  
    LPBYTE lpInput,  
    LONG cbInput,  
    LPTSTR lpszOutput,  
    LONG cchOutput,  
    DWORD dwOptions  
);
```

The **EncodeBuffer** function encodes the contents of the specified byte array, converting the data into printable text.

Parameters

lpInput

A pointer to a buffer that contains the data to be encoded.

cbInput

A long integer which specifies the number of characters in the buffer which should be encoded.

lpszOutput

A pointer to a string that will be used to store the encoded text. The length of the string must be at least 33% larger than the number of bytes being encoded, and will be terminated with a null byte.

cchOutput

The maximum number of characters that may be stored in the string buffer. If this value is too small to store the encoded text, the function will fail.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
DATA_ENCODE_BASE64	Use the base64 algorithm for encoding the data. This is the encoding method that is used by most modern email client software. Note that this option cannot be combined with other encoding methods.
DATA_ENCODE_QUOTED	Use the quoted-printable algorithm for encoding the data. Most printable characters are left as-is, with control characters and 8-bit characters encoded as their hexadecimal value. Note that this option cannot be combined with the other encoding methods.
DATA_ENCODE_URL	Use the URL encoding algorithm for encoding the data. Letters and numbers are left as-is, with control characters, most punctuation and 8-bit characters encoded as their hexadecimal value. Note that this option cannot be combined with the other encoding methods.
DATA_ENCODE_UTF7	Encode the data using the Unicode Transformation Format. This converts Unicode text into 7-bit characters. Note that this option cannot be combined with the other encoding methods.

DATA_ENCODE_UTF8	Encode the data using the Unicode Transformation Format. This converts Unicode text into 8-bit characters. Note that this option cannot be combined with the other encoding methods.
DATA_ENCODE_COMPRESSED	The data should be compressed before it is encoded. To restore the original data, it must be expanded after it has been decoded. This option is ignored if the encoding type is not base64.
DATA_ENCODE_LINEBREAK	The encoded data should be broken into multiple lines of text if the resulting string is longer than 72 characters. This option is ignored if the encoding type is not base64 or quoted-printable. This option should be specified if the encoded data is going to be included in an email message.

Return Value

If the function succeeds, it will return the number of bytes encoded and stored in the string. If the function fails, it will return -1. Failure typically indicates that the buffer is not large enough to store the encoded data.

Remarks

The **EncodeBuffer** function is used to encode a block of data and store it in the specified string buffer as printable text. To encode the contents of a file it is recommended that you use the **EncodeFile** function instead.

A common use of this function is to use the Base64 algorithm to obscure a plain text string. This technique is used by some Internet application protocols when passing authentication information over a standard connection. Although it is not a secure method of encrypting data, it does prevent a casual observer from reading the encoded text.

If you specify either UTF-7 or UTF-8 encoding, the *lpInput* parameter must point to a Unicode string and the *cblInput* parameter must specify the number of characters, not bytes, that are to be encoded. The conversion is always performed using the default system code page.

It is recommended that you use the **UnicodeEncodeText** function to convert a string to UTF-8 encoded text, and the **UnicodeDecodeText** function to convert UTF-8 encoded text to a UTF-16 or localized multi-byte string.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

EncodeFile Function

```
BOOL WINAPI EncodeFile(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile,  
    DWORD dwOptions,  
    DWORD dwReserved  
);
```

The **EncodeFile** function opens and encodes a file, storing the contents as printable text in the specified file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be encoded. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON:, is specified as the file name.

lpszOutputFile

The name of the file that is to contain the encoded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON:, is specified as the file name.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FILE_ENCODE_BASE64	Use the base64 algorithm for encoding the file. This is the encoding method that is used by most modern email client software. Note that this option cannot be combined with the other encoding methods.
FILE_ENCODE_UUCODE	Use the uuencode algorithm for encoding the file. This is a common encoding method used UNIX systems and older email client software. Note that this option cannot be combined with the other encoding methods.
FILE_ENCODE_QUOTED	Use the quoted-printable algorithm for encoding the file. Note that this option cannot be combined with the other encoding methods.
FILE_ENCODE_YENCODE	Use the yEnc algorithm for encoding the file. This is an encoding method that is commonly used when posting files to Usenet newsgroups. Note that this option cannot be combined with other encoding methods.
FILE_ENCODE_COMPRESSED	The file should be compressed before it is encoded. To restore the original contents of the file, it must be expanded after it has been decoded.

dwReserved

This parameter is reserved and should always be set to zero.

Return Value

A non-zero value is returned if the file was successfully encoded. A zero value indicates that the input file does not exist or the output file could not be created.

Remarks

The **EncodeFile** function converts binary data files to a format that contains only printable ASCII characters. The option to compress the file requires that the function be able to create a temporary file on the local system in the directory specified by the TEMP environment variables. A compressed file must be expanded with the **DecodeFile** or **ExpandFile** functions. The compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

ExpandBuffer Function

```
BOOL WINAPI ExpandBuffer(  
    LPVOID lpvInputBuffer,  
    DWORD cbInputBuffer  
    LPVOID lpvOutputBuffer,  
    LPDWORD lpcbOutputBuffer  
);
```

The **ExpandBuffer** function expands the contents of the previously compressed buffer.

Parameters

lpvInputBuffer

A pointer to the buffer which contains the compressed data.

cbInputBuffer

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

A pointer to the buffer which will contain the expanded data. This parameter may be NULL, which can be used to determine the size of the of the resulting expanded data prior to allocating memory for it.

lpcbOutputBuffer

A pointer to the number of bytes that may be copied into the output buffer. If the *lpvOutputBuffer* parameter is not NULL, this must be initialized to a non-zero value. When the function returns, the actual number of bytes of expanded data is returned in this parameter.

Return Value

A non-zero value is returned if the data was successfully expanded. A zero value indicates that the data could not be expanded. Failure typically indicates that the compressed data was not in a recognized format.

Remarks

The compressed data buffer passed to the **ExpandBuffer** function must have been compressed by either the **CompressBuffer** or **CompressFile** functions. Data read from files that were compressed using third-party utilities such as WinZip will not be recognized by this function.

Example

```
cbOutputBuffer = 0;  
bResult = ExpandBuffer(lpInputBuffer,  
                        cbInputBuffer,  
                        NULL,  
                        &cbOutputBuffer);  
  
if (bResult)  
{  
    lpOutputBuffer = (LPBYTE)LocalAlloc(LPTR, cbOutputBuffer);  
    bResult = ExpandBuffer(lpInputBuffer,  
                           cbInputBuffer,  
                           lpOutputBuffer,  
                           &cbOutputBuffer);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csncdv11.lib

[CompressBuffer](#), [CompressFile](#), [DecodeFile](#), [EncodeFile](#), [ExpandFile](#)

ExpandFile Function

```
BOOL WINAPI ExpandFile(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile  
);
```

The **ExpandFile** function expands the contents of a previously compressed file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON:, is specified as the file name. An error will be returned if this parameter is NULL or a zero-length string.

lpszOutputFile

The name of the file that is to contain the expanded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON:, is specified as the file name. If this parameter is NULL or a zero-length string, the compression is performed in-place.

Return Value

A non-zero value is returned if the file was successfully expanded. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The **ExpandFile** function can only expand files that were previously compressed using the **CompressFile** function. It cannot expand the contents of a file stored in an archive format used by third-party applications such as PKZip or WinZip.

This function will use the default Deflate algorithm to expand the contents of the file. If the file was compressed using **CompressFileEx** using anything other than COMPRESSION_TYPE_DEFLATE, the file must be expanded using the **ExpandFileEx** function. This function will fail if a different compression algorithm was used to compress the file.

If the output file already exists, it will be replaced with the expanded contents of the compressed input file. If the input file cannot be expanded for any reason, the output file will be deleted and the last error code will be updated indicating the cause of the failure. If you want to ensure an existing output file will be preserved if an error occurs, you should create a temporary file and use it as the output file. If this function succeeds, then you can rename or move the temporary file using a function like **MoveFileEx**.

It is possible to expand the input file in-place by specifying the *lpszOutputFile* parameter as a NULL pointer or zero-length string. In this case, the contents of the input file will be expanded to a temporary file and if the operation is successful, the original compressed input file will be replaced by the temporary file. If an error occurs, the input file will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[CompressFile](#), [CompressFileEx](#), [DecodeFile](#), [EncodeFile](#), [ExpandFileEx](#)

ExpandFileEx Function

```
BOOL WINAPI ExpandFileEx(  
    LPCTSTR lpszInputFile,  
    LPCTSTR lpszOutputFile,  
    DWORD dwCompressionType,  
    LPVOID lpvReserved,  
    DWORD dwReserved  
);
```

The **ExpandFileEx** function expands the contents of the previously compressed file.

Parameters

lpszInputFile

A pointer to a string which specifies the name of the file which contains the compressed data. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name. An error will be returned if this parameter is NULL or a zero-length string.

lpszOutputFile

The name of the file that is to contain the expanded data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name. If this parameter is NULL or a zero-length string, the compression is performed in-place.

dwCompressionType

A numeric value which determines the algorithm that was used to compress the data. One of the following values may be specified. By default, the Deflate algorithm is used.

Value	Description
COMPRESSION_TYPE_UNKNOWN	The function should attempt to determine what compression algorithm was used when the data was compressed. This is done by examining the header block of the file and checking for certain signatures which can identify the algorithm. If the algorithm cannot be determined, the function will fail. It is recommended that most applications explicitly specify the compression algorithm.
COMPRESSION_TYPE_DEFLATE	A compression algorithm that combines the LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. Deflate is widely used by compression software and provides a good balance between the data compression ratio and system resources used. This is the default compression method.
COMPRESSION_TYPE_BZIP2	A compression algorithm that rearranges

	blocks of data in sorted order and then uses Huffman coding to process different frequencies of data within the block. Burrows-Wheeler compression provides a better compression ratio than the Deflate algorithm, however it requires more resources to perform the compression.
COMPRESSION_TYPE_LZMA	A compression algorithm that combines the LZ77 algorithm for dictionary-based compression with range encoding to efficiently represent repetitive patterns in the data. LZMA can achieve higher compression ratios than Deflate or the Burrows-Wheeler algorithms; however, it requires more memory and CPU resources due to the larger dictionary sizes and more complex encoding algorithm.

lpvReserved

A reserved parameter which should always be NULL.

dwReserved

A reserved unsigned integer value which should always be zero.

Return Value

A non-zero value is returned if the file was successfully expanded. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The **ExpandFileEx** function can only expand files that were previously compressed using the **CompressFile** or **CompressFileEx** functions. It cannot expand the contents of a file stored in an archive format used by third-party applications such as PKZip or WinZip.

The value of the *dwCompressionType* parameter must match the value which was used with the **CompressFileEx** function. This function will fail if you specify a different compression algorithm than what was used to compress the file. Although your application can use COMPRESSION_TYPE_UNKNOWN and attempt to automatically determine how the file was compressed, this is not always reliable.

If the output file already exists, it will be replaced with the expanded contents of the compressed input file. If the input file cannot be expanded for any reason, the output file will be deleted and the last error code will be updated indicating the cause of the failure. If you want to ensure an existing output file will be preserved if an error occurs, you should create a temporary file and use it as the output file. If this function succeeds, then you can rename or move the temporary file using a function like **MoveFileEx**.

It is possible to expand the input file in-place by specifying the *lpOutputFile* parameter as a NULL pointer or zero-length string. In this case, the contents of the input file will be expanded to a temporary file and if the operation is successful, the original compressed input file will be replaced by the temporary file. If an error occurs, the input file will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

GetMessageDigest Function

```
BOOL WINAPI GetMessageDigest(  
    LPVOID lpvBuffer,  
    DWORD cbBuffer,  
    DWORD dwDigestOptions,  
    LPTSTR lpszDigest,  
    INT nMaxLength  
);
```

The **GetMessageDigest** function computes a message digest for a buffer, string or data file.

Parameters

lpvBuffer

A pointer to the data that will be processed by the message digest algorithm. This parameter may be NULL, in which case the standard null hash value will be returned. Depending on the options specified, this may point to a block of memory, a null-terminated string or the name of a data file.

cbBuffer

The number of bytes of data that will be processed by the message digest algorithm. If this value is zero, then the standard null hash value will be returned. If the *lpvBuffer* parameter is NULL, this value must be zero. If this value is -1 then *lpvBuffer* is considered to be a pointer to a null-terminated string.

dwDigestOptions

A numeric value which specifies the algorithm that will be used to generate the message digest, and may be combined with other option flags. The algorithm may be one of the following values:

Value	Description
MESSAGE_DIGEST_DEFAULT	Use the default message digest algorithm, which is the same as specifying MESSAGE_DIGEST_SHA256
MESSAGE_DIGEST_MD5	Use the MD5 algorithm which generates a 128-bit hash value that is returned as as 32 digit hexadecimal string. This algorithm is typically used as a checksum to verify data integrity, however it is not considered cryptographically secure and hash collision is possible.
MESSAGE_DIGEST_SHA1	Use the SHA1 algorithm which generates a 160-bit hash value that is returned as a 40 digit hexadecimal string. This algorithm is typically used as a checksum to verify data integrity, however it is not considered cryptographically secure.
MESSAGE_DIGEST_SHA256	Use the SHA-256 algorithm which generates a 256-bit hash value that is returned as a 64 digit hexadecimal string. This algorithm is used for data integrity validation and various cryptographic uses, such as password storage and document signing.
MESSAGE_DIGEST_SHA384	Use the SHA-384 algorithm which generates a 384-bit hash value that is returned as a 96 digit hexadecimal string. This is a truncated version of the SHA-512 algorithm that uses different initial values.

MESSAGE_DIGEST_SHA512	Use the SHA-512 algorithm which generates a 512-bit hash value that is returned as a 128 digit hexadecimal string. This algorithm is used for data integrity validation and various cryptographic uses, such as password storage and document signing.
-----------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

The following values may be combined with the algorithm ID to specify options that determine how the message digest is computed and returned to the caller:

Value	Description	
0x10000	MESSAGE_DIGEST_MEMORY	The <i>lpvBuffer</i> parameter is a pointer to a block of memory and the <i>cbBuffer</i> parameter specifies how many bytes in the buffer should be used to compute the message digest. This is the default behavior if no other options are specified and the <i>cbBuffer</i> parameter is not -1.
0x20000	MESSAGE_DIGEST_STRING	The <i>lpvBuffer</i> parameter is a pointer to a null-terminated string and the <i>cbBuffer</i> parameter specifies how many characters in the string should be used to compute the message digest. If the <i>cbBuffer</i> parameter is -1 then all characters up to the terminating null byte will be used.
0x40000	MESSAGE_DIGEST_DATAFILE	The <i>lpvBuffer</i> parameter is a pointer to a null-terminated string that specifies the name of a data file, and the entire contents of the file will be used to compute the message digest. The <i>cbBuffer</i> parameter is ignored.
0x80000	MESSAGE_DIGEST_BASE64	The message digest will be returned in <i>lpszDigest</i> as a base64 encoded value rather than a string of hexadecimal digits. This can be useful for services that use HMAC message digests and require the hash to be in base64 format.

lpszDigest

A pointer to a string that will contain the message digest computed using the contents of the specified buffer. The digest value will consist of upper-case hexadecimal numbers, with the length varying based on the algorithm selected. The string buffer must be large enough to accommodate the entire message digest, including the terminating null character. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that may be copied into the *lpszDigest* string buffer, including the terminating null character. This value cannot be zero, and must be large enough to accommodate the complete message digest string value. It is recommended that the string buffer be at least MAX_DIGEST_STRING characters in size.

Return Value

A non-zero value is returned if the message digest was computed and returned in the string buffer provided by the caller. A zero value indicates that the digest could not be computed, or the string buffer provided by the caller was not large enough to contain the message digest value.

Remarks

The **GetMessageDigest** function accepts an arbitrary block of data, a null-terminated string or a data file and computes a fixed-length value (hash) that can be used to uniquely identify that content. These algorithms are designed to be one-way functions that are deterministic, have a low probability of collision and are difficult or infeasible to reverse. It should be noted that the MD5 and SHA1 algorithms are no longer considered cryptographically secure, however they are still widely used for data integrity validation to protect against accidental or unintended changes.

If the MESSAGE_DIGEST_STRING option is specified and the Unicode version of this function is called, the string will be automatically converted from UTF-16 to UTF-8 encoding, and the UTF-8 encoded text will be used to generate the message digest. If you need to generate a message digest using the UTF-16 encoded version of the string, use the MESSAGE_DIGEST_MEMORY option instead. Keep in mind that UTF-16 encoding represents each character with two bytes, so the buffer length should be twice the number of characters in the Unicode string.

If the MESSAGE_DIGEST_DATAFILE option is specified, the file contents will be processed as binary data with no special consideration given for the various end-of-line conventions used in text files, or any Unicode byte order marks in the file. It is permissible for the file to be empty (zero length), in which case the default null-hash value will be returned based on the algorithm selected by the caller.

The current thread will block while the message digest is being computed. If a large amount of data is being processed, this may cause the application to become non-responsive. In that case, it is recommended that you create a background worker thread and call this function from that worker thread, rather than from the main UI thread.

The length of the message digest string returned by this function will always be the same for a given algorithm, regardless of the size of the data buffer. For example, the length of the message digest for the SHA-256 algorithm will always be 64 characters long. Each byte of the message digest is represented by two upper-case hexadecimal numbers.

It is permitted to provide a NULL or zero-length data buffer to this function, in which case the standard null-hash value will be returned. The same null-hash value will also be returned for a zero-length string or an empty file.

Example

```
// Get a SHA-256 message digest for a string value
LPCTSTR lpszValue = _T("The quick brown fox jumps over the lazy dog");
TCHAR szDigest[MAX_DIGEST_STRING];
BOOL bSuccess;

bSuccess = GetMessageDigest(
    lpszValue,
    (DWORD)-1L,
    MESSAGE_DIGEST_SHA256 | MESSAGE_DIGEST_STRING,
    szDigest,
    MAX_DIGEST_STRING);

// Get an MD5 message digest for the contents of a data file
LPCTSTR lpszFileName = _T("testfile.zip");

bSuccess = GetMessageDigest(
    lpszFileName,
    0,
    MESSAGE_DIGEST_MD5 | MESSAGE_DIGEST_DATAFILE,
    szDigest,
```

MAX_DIGEST_STRING);

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

IsUnicodeText Function

```
BOOL WINAPI IsUnicodeText(  
    LPCTSTR lpString,  
    INT nLength  
);
```

The **IsUnicodeText** function checks if a string contains valid Unicode characters.

Parameters

lpString

A pointer to a null terminated string. This parameter cannot be NULL.

nLength

An integer value which specifies the number of characters to check. If this value is -1, the length of the string is determined by counting the number of characters up to the terminating null character. This parameter cannot be zero.

Return Value

A non-zero value is returned if the string contains valid Unicode characters. A zero value indicates the string contains characters that are not valid Unicode, or the string does not contain any Unicode characters.

Remarks

There are two versions of this function, **IsUnicodeTextA** which checks a multi-byte string to ensure that it contains valid UTF-8 encoded text, and **IsUnicodeTextW** which checks a wide string to ensure it contains valid UTF-16 text.

If the value of the *nLength* parameter is larger than the number of characters in the string, the function will not check beyond the terminating null character. If the length of the string is unknown, specify a length of -1 and the function will check the entire contents of the string up to the terminating null character.

If there is a byte order mark (BOM) sequence at the beginning of the string, this will be recognized by the function. A string that contains a valid BOM sequence with no corresponding text will be successfully validated by this function.

This function does not perform checks to ensure the string contains printable characters. It only validates that the Unicode string is structurally valid. The **IsUnicodeTextA** function will check to make sure there are no invalid UTF-8 encodings. The **IsUnicodeTextW** function will check to make sure the UTF-16 string does not contain any unpaired surrogates.

This function does not preserve state information and cannot be used to check the validity of a stream of text or binary data. It should only be used to validate complete Unicode strings that are terminated with a null character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

UnicodeDecodeText Function

```
INT WINAPI UnicodeDecodeText(  
    UINT nCodePage,  
    LPCSTR lpUtf8Text,  
    INT nLength,  
    LPTSTR lpString,  
    INT nMaxLength  
);
```

The **UnicodeDecodeText** function decodes UTF-8 encoded text and returns the contents in a string buffer.

Parameters

nCodePage

A value that specifies the code page used when decoding the text. This parameter can be set to the value of any code page that is available in the operating system. It is recommended that you use CP_ACP which specifies the system default ANSI code page. This parameter is only used when decoding UTF-8 encoded text to a multi-byte string.

lpUtf8Text

A pointer to a null terminated string that contains the UTF-8 encoded text to be decoded. This parameter must always specify a pointer to an 8-bit character string, regardless if the project is configured to use the Unicode or Multi-Byte character set. This parameter cannot be NULL.

nLength

The number of bytes in the UTF-8 encoded string to be decoded. If this parameter is -1, the length of the UTF-8 encoded text is determined by counting the number of characters up to the terminating null character.

lpString

A pointer to a string buffer that will contain the decoded UTF-8 text when the function returns. The string buffer must be large enough to contain all of the encoded text, and cannot be a NULL a pointer.

nMaxLength

The maximum number of characters that can be copied into the string buffer. The contents of the *lpString* buffer will always be null terminated, and the maximum size must be large enough to include the null character. This value must be greater than zero.

Return Value

If the UTF-8 encoded text is successfully decoded, the return value is the number of characters copied to the string buffer. If the text cannot be decoded, or the string buffer is not large enough to store all of the decoded text, the function will return zero. To get extended error information, call **GetLastError**.

Remarks

There are two versions of this function, **UnicodeDecodeTextA** which returns a localized multi-byte string and **UnicodeDecodeTextW** which converts the UTF-8 encoded text to UTF-16 text. Your project configuration typically determines which version of this function is used by default.

If the value of the *nLength* parameter is larger than the number of UTF-8 characters, the function will not check beyond the terminating null character. If the length of the *lpUtf8Text* string is unknown,

specify a length of -1 and the function will decode the entire contents of the string up to the terminating null character.

When calling **UnicodeDecodeTextA** to convert UTF-8 encoded text to a localized multi-byte string, it is recommended that you specify CP_ACP (zero) as the code page value unless you know it contains Unicode characters that cannot be represented using the default ANSI code page. Using CP_ACP will ensure the UTF-8 text is decoded using the current locale and language settings.

When calling **UnicodeDecodeTextW** to convert UTF-8 encoded text to UTF-16 text, the code page parameter is ignored and should always be a value of zero.

This function performs a strict check on the UTF-8 encoded text and will fail if the encoding is malformed, or in the case of being converted to a multi-byte string, if it cannot be decoded using the specified code page. It will not simply replace invalid character sequences with a default character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csncdv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[IsUnicodeText](#), [UnicodeEncodeText](#)

UnicodeEncodeText Function

```
INT WINAPI UnicodeEncodeText(  
    UINT nCodePage,  
    LPCTSTR lpString,  
    INT nLength,  
    LPSTR lpUtf8Text,  
    INT nMaxLength  
);
```

The **UnicodeEncodeText** function encodes a string and returns UTF-8 encoded text.

Parameters

nCodePage

A value that specifies the code page used when encoding the text. This parameter can be set to the value of any code page that is available in the operating system. It is recommended that you use CP_ACP which specifies the system default ANSI code page. This parameter is only used when encoding a multi-byte string.

lpString

A pointer to a null terminated string that contains the text to be encoded. This parameter cannot be NULL.

nLength

The number of characters in the string to be encoded. If this parameter is -1, the length of the string is determined by counting the number of characters up to the terminating null character.

lpUtf8Text

A pointer to a character buffer which will contain the UTF-8 encoded text when the function returns. This parameter must always specify a pointer to an 8-bit character string, regardless if the project is configured to use the Unicode or Multi-Byte character set. This parameter cannot be NULL.

nMaxLength

The maximum number of bytes that can be copied into the UTF-8 text buffer. The contents of the *lpUtf8Text* buffer will always be null terminated, and the maximum size must be large enough to include the null byte. This value must be greater than zero.

Return Value

If the string is successfully encoded, the return value is the number of characters copied to the output buffer. If the text cannot be encoded, or the output buffer is not large enough to store all of the encoded text, the function will return zero. To get extended error information, call **GetLastError**.

Remarks

There are two versions of this function, **UnicodeEncodeTextA** which converts a multi-byte string to UTF-8 encoded text, and **UnicodeEncodeTextW** which converts a UTF-16 string to a UTF-8 string. Your project configuration typically determines which version of this function is used by default.

If the value of the *nLength* parameter is larger than the number of characters in *lpString*, the function will not check beyond the terminating null character. If the length of *lpString* is unknown, specify a length of -1 and the function will encode the entire contents of the string up to the terminating null character.

When calling **UnicodeEncodeTextA** to convert a multi-byte string to UTF-8 encoding, it is recommended that you specify CP_ACP (zero) as the code page value unless you know it contains

ANSI characters from a different code page. Using CP_ACP will ensure the string is encoded using the current locale and language settings.

This function performs a strict check on the multi-byte input string and will fail if it contains a malformed multi-byte sequence or characters that cannot be converted to UTF-8 using the specified code page. It will not simply replace invalid character sequences with a default character.

When calling **UnicodeEncodeTextW** to convert UTF-16 text to UTF-8 encoded text, the code page parameter is ignored and should always be a value of zero. The text will be normalized prior to being converted to UTF-8 using canonical composition, where decomposed characters are combined to create their canonical precomposed equivalent.

Library Information

File Name	CSFTPV11.DLL
Version	11.0.2218.1855
LibID	22D6A6CD-4877-4CB9-B223-7149A9040534
Import Library	CSFTPV11.LIB
Dependencies	None
Standards	RFC 959, RFC 1579, RFC 2228

Overview

The File Transfer Protocol (FTP) library provides a comprehensive API which supports both high level operations, such as uploading or downloading files, as well as a collection of lower-level file I/O functions. In addition to file transfers, an application can create, rename and delete files and directories, search for files using wildcards and perform other common file management functions.

Files can be stored on the local file system or in memory, depending on the needs of your application and multiple file transfers be performed using a single function call. The library can also be used to manage files on the server and supports many of the common protocol extensions that can be used to access the remote file system. It understands a number of different directory listing formats, including those typically used with UNIX and Linux based systems, Windows server platforms, NetWare servers and VMS systems.

This library supports active and passive mode file transfers, firewall compatibility options, proxy servers and secure file transfers using the standard TLS 1.2 and SFTP protocols. Secure file transfers support implicit and explicit TLS sessions, client certificates and up to 256-bit AES encryption.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit

version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

File Transfer Protocol Functions

Function	Description
FtpAddQueuedFile	Add a new file to the queue to be uploaded or downloaded
FtpAddQueuedFileEx	Add a new file to the queue with additional transfer options
FtpAllocate	Allocate the specified number of bytes on the server
FtpAsyncConnect	Connect asynchronously to the specified server
FtpAsyncFileList	Return an unparsed list of files in the specified directory
FtpAsyncGetData	Copy the contents of a remote file to a local buffer
FtpAsyncGetFile	Copy a file from the server to the local system
FtpAsyncGetFileEx	Copy a file from the server to the local system, supporting files larger than 4GB
FtpAsyncProxyConnect	Connect asynchronously to the specified proxy server
FtpAsyncPutData	Create a file on the server using the contents of a local buffer
FtpAsyncPutFile	Copy a file from the local system to the server
FtpAsyncPutFileEx	Copy a file from the local system to the server, supporting files larger than 4GB
FtpAttachThread	Attach the specified client handle to another thread
FtpCancel	Cancel the current blocking operation
FtpCancelQueuedFile	Cancel the queued file transfer
FtpChangeDirectory	Change the current working directory on the server
FtpChangeDirectoryUp	Change the current working directory on the server
FtpClearQueue	Remove all files from the current transfer queue
FtpCloseDirectory	Close the open directory on the server
FtpCloseFile	Close the current file on the server
FtpCommand	Send a command to the server
FtpConnect	Establish a client connection with a server
FtpConnectUrl	Establish a client connection using the specified URL
FtpCreateDirectory	Create the specified directory on the server
FtpCreateQueue	Create a new file transfer queue
FtpCreateSecurityCredentials	Create a new security credentials structure
FtpDeleteFile	Delete a file from the server
FtpDeleteQueue	Delete a previously created file transfer queue
FtpDeleteSecurityCredentials	Delete a previously created security credentials structure
FtpDisableEvents	Disable event notification
FtpDisableTrace	Disable logging of network function calls to the trace log
FtpDisconnect	Disconnect the client session from the server
FtpDownloadFile	Download a file from the server to the local system
FtpEnableEvents	Enable event notification
FtpEnableFeature	Enable the specified feature in the client

FtpEnableTrace	Enable logging of network function calls to a file
FtpEndOfFile	Determine if the end-of-file has been reached
FtpEnumFiles	Return a list of files in a directory on the server
FtpEnumFilesEx	Return a list of files in a directory on the server, supporting files larger than 4GB
FtpEnumQueuedFiles	Return a list of files in the transfer queue
FtpEnumTasks	Return a list of asynchronous tasks
FtpEventProc	Callback function that processes events generated by the client
FtpFindQueuedFile	Find a file in the transfer queue which matches the search criteria
FtpFreezeEvents	Suspend and resume event handling by the client
FtpGetActivePorts	Return the range of local port numbers used for active transfers
FtpGetAutoFileType	Return the file transfer type based on the file extension or content
FtpGetBufferSize	Return the size of an internal buffer used during data transfers
FtpGetChannelMode	Return the mode for the specified communication channel
FtpGetClientQuota	Return quota information for the current client session
FtpGetData	Copy the contents of a remote file to a local buffer
FtpGetDirectory	Get the current working directory on the server
FtpGetDirectoryFormat	Get the format which is used by the server to list files
FtpGetErrorString	Return a description for the specified error code
FtpGetFeatures	Return the features available to the client
FtpGetFile	Copy a file from the server to the local system
FtpGetFileEx	Copy a file from the server to the local system, supporting files larger than 4GiB
FtpGetFileList	Return an unparsed list of files in the specified directory
FtpGetFileNameEncoding	Return the character encoding used when sending a file name to the server
FtpGetFilePermissions	Return the access permissions for the specified file
FtpGetFileSize	Return the size of a file on the server
FtpGetFileStatus	Return file status information from the server
FtpGetFileStatusEx	Return file status information from the server, supporting files larger than 4GiB
FtpGetFileTime	Return the modification time for the specified file on the server
FtpGetFileType	Return the default file type for the current session
FtpGetFirstFile	Return the first file from the file list returned by the server
FtpGetFirstFileEx	Return the first file from the file list returned by the server, supporting files larger than 4GiB
FtpGetFirstQueuedFile	Return information about the first file in the transfer queue
FtpGetLastError	Return the last error code
FtpGetMultipleFiles	Copy multiple files from the server to the local system
FtpGetNextFile	Return the next file from the file list returned by the server
FtpGetNextFileEx	Return the next file from the file list returned by the server, supporting files larger than 4GiB
FtpGetNextQueuedFile	Return information about the next file in the transfer queue
FtpGetPriority	Return the current priority for file transfers
FtpGetProxyType	Return the proxy type selected by the client

FtpGetQueueClient	Return the handle to the current client session
FtpGetQueuedFile	Return information about a file queued for transfer
FtpGetQueueStatus	Return the status of the current file transfer queue
FtpGetQueueThread	Return a value which uniquely identifies the queue manager thread
FtpGetResultCode	Return the result code from the previous command
FtpGetResultString	Return the result string from the previous command
FtpGetSecurityInformation	Return security information about the current client connection
FtpGetServerInformation	Get system information about the server
FtpGetServerStatus	Return system status of server
FtpGetServerTimeZone	Return the timezone offset in seconds for the current server
FtpGetServerType	Return the type of operating system the server is running on
FtpGetStatus	Return the current client status
FtpGetTaskError	Return the last error code for the specified asynchronous task
FtpGetTaskId	Return the unique task identifier associated with the specified client session
FtpGetText	Download the contents of a text file to a string buffer
FtpGetThreadQueue	Return the handle to a queue associated with the specified thread
FtpGetTimeout	Return the number of seconds until an operation times out
FtpGetTransferStatus	Return current file transfer statistics
FtpGetTransferStatusEx	Return current file transfer statistics, supporting files larger than 4GB
FtpInitialize	Initialize the library and validate the specified runtime license key
FtpIsBlocking	Determine if the current operation is blocked
FtpIsConnected	Determine if the client is connected to the server
FtpIsReadable	Determine if the client can read data from the data channel
FtpIsWritable	Determine if the client can write data to the data channel
FtpLogin	Login to the server
FtpLogout	Logout from the server
FtpMountStructure	Mount a structure (filesystem) on the server
FtpOpenDirectory	Open the specified directory for reading
FtpOpenFile	Open the specified file for reading or writing
FtpProxyConnect	Establish a connection with a proxy server
FtpPutData	Create a file on the server using the contents of a local buffer
FtpPutFile	Copy a file from the local system to the server
FtpPutFileEx	Copy a file from the local system to the server, supporting files larger than 4GiB
FtpPutMultipleFiles	Copy multiple files from the local system to the server
FtpPutText	Create a text file on the server from the contents of a string buffer
FtpRead	Read data from the server
FtpRegisterEvent	Register an event handler for the specified event
FtpRegisterFileType	Associate a file name extension with a specific file type

FtpRemoveDirectory	Remove a directory from the server
FtpRemoveQueuedFile	Remove a file from the transfer queue
FtpRenameFile	Rename a file on the server
FtpReset	Reset the client connection
FtpResetQueue	Reset the internal state of file transfers in the specified queue
FtpResumeQueue	Resume the transfer of files after queue processing has been paused
FtpSetActivePorts	Set the range of local port numbers used for active transfers
FtpSetBufferSize	Set the size of an internal buffer used during data transfers
FtpSetChannelMode	Change the security mode for the specified channel
FtpSetDirectoryFormat	Set the format which is used by the server to list files
FtpSetFeatures	Set the features which can be used by the client
FtpSetFileMode	Set the current file mode
FtpSetFileNameEncoding	Set the character encoding type used when sending a file name to the server
FtpSetFilePermissions	Set the access permissions for the specified file
FtpSetFileStructure	Set the current file data structure
FtpSetFileTime	Set the modification time for the specified file on the server
FtpSetFileType	Set the default file type for the current session
FtpSetLastError	Set the last error code
FtpSetPassiveMode	Set the server in passive mode
FtpSetPriority	Set the priority for file transfers
FtpSetTimeout	Set the number of seconds until an operation times out
FtpStartQueue	Begin transferring the files in the specified queue
FtpStopQueue	Stop transferring the files in the specified queue
FtpSuspendQueue	Pause the transfer of files in the specified queue
FtpTaskAbort	Abort the specified asynchronous task
FtpTaskDone	Determine if an asynchronous task has completed
FtpTaskResume	Resume execution of an asynchronous task
FtpTaskSuspend	Suspend execution of an asynchronous task
FtpTaskWait	Wait for an asynchronous task to complete
FtpUninitialize	Terminate use of the library by the calling process
FtpUploadFile	Upload a file from the local system to the server
FtpValidateHostName	Validate the specified host name and return the resolved IP address
FtpValidateUrl	Check the contents of a string to ensure it represents a valid URL
FtpVerifyFile	Compare the contents of a local file against a file stored on the server
FtpWaitForQueue	Wait for the transfer of all queued files to complete
FtpWrite	Write data to the server

FtpAddQueuedFile Function

```
DWORD WINAPI FtpAddQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwQueueMode,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    UINT nFileType,  
    UINT nTimeout  
);
```

The **FtpAddQueuedFile** function adds a new file to the queue with additional transfer options.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An integer value which specifies if the file should be downloaded from the server or uploaded to the server. This parameter must be one of the following options and cannot have a value of zero.

Constant	Description
FTP_QUEUE_DOWNLOAD	The file should be queued for downloading from the server to the local system.
FTP_QUEUE_UPLOAD	The file should be queued for uploading from the local system to the server.

lpszLocalFile

A pointer to a null terminated string which specifies the name of the local file to be queued for transfer. This parameter cannot be NULL or point to an empty string. If the file is being queued for an upload, the file must exist on the local system or the function will fail. If the file is being downloaded, it will be created or replaced on the local system.

lpszRemoteFile

A pointer to a null terminated string which specifies the URL to the location of the file on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator and can be any of the options used with the **FtpConnect** function. If this value is zero, the default options for the queue will be used. The most common options are:

Value	Description
FTP_OPTION_PASSIVE	This option specifies the file transfer should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the

	server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the file transfer should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the file transfer should attempt to establish a secure connection with the server by default. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the file transfer should attempt to immediately establish secure TLS connection with the server by default. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the file transfer should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the file transfer should use the Secure Shell (SSH) protocol to establish the connection by default. This option will automatically be selected if the connection is established using port 22, the default port for SSH.

nFileType

An integer value which specifies the type of file being transferred. It can be one of the following values:

Value	Description
FILE_TYPE_AUTO	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the FtpRegisterFileType function.
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.

FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executable programs. If the type of file cannot be automatically determined, it will always be considered a binary file. If this file type is specified when uploading or downloading text files, the native end-of-line character sequences will be preserved.
FILE_TYPE_LOCAL	The file is a binary file that uses the local byte size for the server platform. On most servers, this file type is considered to be the same as FILE_TYPE_IMAGE. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.

nTimeout

The number of seconds to wait for a response from the server before failing the file transfer. If this value is zero, the default timeout period for the queue will be used.

Return Value

If the function succeeds, the return value is a unique identifier which corresponds to the queued file. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function will add a file to the current transfer queue. If successful, the value returned is a unique integer which identifies that file in the queue. To obtain information about the queued file, you can call the **FtpGetQueuedFile** function and provide this return value as the *dwFileId* parameter. To remove a file from the queue, use the **FtpRemoveQueuedFile** function.

Files can only be added to the queue when in an idle or paused state. If you attempt to add a file to the queue while the queue manager is transferring files, the function will fail. To determine the current state of the queue, call the **FtpGetQueueStatus** function.

There are no fixed limits to the number of files which can be queued for transfer. To release the memory allocated for the queue, call the **FtpClearQueue** function. To determine the current status of the queue, including how many file transfers have been queued and how many are pending completion, call the **FtpGetQueueStatus** function.

If the local file name includes environment variables enclosed in percentage (%) symbols, those values will automatically be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

This function will not immediately begin the process of uploading or downloading the file. It will only add the transfer request to the current queue. The file transfers are managed by a background worker thread which is created when the **FtpStartQueue** function is called.

The **FtpAddQueuedFileEx** function is an extended version of this function with additional parameters to specify a hostname, port number, user name and password. Because most file uploads require authentication, using the extended function may be preferred to composing a URL which includes the

account credentials.

Example

```
// Create a new queue
HQUEUE hQueue = FtpCreateQueue(INFINITE, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = FtpAddQueuedFile(
    hQueue,
    lpzLocalFile,
    lpzRemoteFile,
    FTP_OPTION_DEFAULT,
    FILE_TYPE_AUTO,
    FTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case FTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case FTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szLocalFile,
                    queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (FtpStartQueue(hQueue, FTP_QUEUE_ALL, 0, NULL, 0))
{
    FtpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    FtpStopQueue(hQueue);
}

// Remove all files from the queue
FtpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpAddQueuedFileEx Function

```
DWORD WINAPI FtpAddQueuedFileEx(  
    HQUEUE hQueue,  
    DWORD dwQueueMode,  
    LPCTSTR lpszHostName,  
    UINT nHostPort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    UINT nFileType,  
    UINT nTimeout,  
    LPVOID lpvReserved  
);
```

The **FtpAddQueuedFileEx** function adds a new file to the queue with additional transfer options.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An integer value which specifies if the file should be downloaded from the server or uploaded to the server. This parameter must be one of the following options and cannot have a value of zero.

Constant	Description
FTP_QUEUE_DOWNLOAD	The file should be queued for downloading from the server to the local system.
FTP_QUEUE_UPLOAD	The file should be queued for uploading from the local system to the server.

lpszHostName

A pointer to the name of the server to establish a connection with. This may be a fully-qualified domain name or an IP address. If this parameter is NULL or points to an empty string, the ***lpszRemoteFile*** parameter must specify a complete URL which identifies the server as well as the path to the remote file.

nHostPort

The port number which should be used when establishing the connection. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990. If this parameter is zero and a URL is specified with the ***lpszRemoteFile*** parameter, the port number included in the URL will be used as the default value.

lpszUserName

Points to a null terminated string which specifies the user name to be used to authenticate the connection. If this parameter is NULL or an empty string, then the login is considered to be anonymous. Note that anonymous logins are not supported for secure connections using the SSH protocol.

lpszPassword

Points to a null terminated string which specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

lpszLocalFile

A pointer to a null terminated string which specifies the name of the local file to be queued for transfer. This parameter cannot be NULL or point to an empty string. If the file is being queued for an upload, the file must exist on the local system or the function will fail. If the file is being downloaded, it will be created or replaced on the local system.

lpszRemoteFile

A pointer to a null terminated string which specifies the name of the file on the server. If the file is being downloaded, the file must exist on the server or the transfer will fail. If the file is being uploaded, the file will be created or replaced on the server. This parameter may specify a complete URL. Note that any values you specify as arguments to this function will override the values specified in the URL. If you want to use a URL as the remote file name, the *lpszHostName* parameter should be NULL and the *nHostPort* parameter should be zero.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator and can be any of the options used with the **FtpConnect** function. If this value is zero, the default options for the queue will be used. The most common options are:

Value	Description
FTP_OPTION_PASSIVE	This option specifies the file transfer should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the file transfer should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the file transfer should attempt to establish a secure connection with the server by default. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the file transfer should attempt to immediately establish secure TLS connection with the server by default. This option is typically used when

	connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the file transfer should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the file transfer should use the Secure Shell (SSH) protocol to establish the connection by default. This option will automatically be selected if the connection is established using port 22, the default port for SSH.

nFileType

An integer value which specifies the type of file being transferred. It can be one of the following values:

Value	Description
FILE_TYPE_AUTO	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the FtpRegisterFileType function.
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executable programs. If the type of file cannot be automatically determined, it will always be considered a binary file. If this file type is specified when uploading or downloading text files, the native end-of-line character sequences will be preserved.
FILE_TYPE_LOCAL	The file is a binary file that uses the local byte size for the server platform. On most servers, this file type is considered to be the same as FILE_TYPE_IMAGE. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.

nTimeout

The number of seconds to wait for a response from the server before failing the file transfer. If this

value is zero, the default timeout period for the queue will be used.

lpvReserved

A reserved parameter which should always be NULL.

Return Value

If the function succeeds, the return value is a unique identifier which corresponds to the queued file. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function will add a file to the current transfer queue. If successful, the value returned is a unique integer which identifies that file in the queue. To obtain information about the queued file, you can call the **FtpGetQueuedFile** function and provide this return value as the *dwFileId* parameter. To remove a file from the queue, use the **FtpRemoveQueuedFile** function.

Files can only be added to the queue when in an idle or paused state. If you attempt to add a file to the queue while the queue manager is transferring files, the function will fail. To determine the current state of the queue, call the **FtpGetQueueStatus** function.

There are no fixed limits to the number of files which can be queued for transfer. To release the memory allocated for the queue, call the **FtpClearQueue** function. To determine the current status of the queue, including how many file transfers have been queued and how many are pending completion, call the **FtpGetQueueStatus** function.

If the local file name includes environment variables enclosed in percentage (%) symbols, those values will automatically be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

This function will not immediately begin the process of uploading or downloading the file. It will only add the transfer request to the current queue. The file transfers are managed by a background worker thread which is created when the **FtpStartQueue** function is called.

Example

```
// Create a new queue
HQUEUE hQueue = FtpCreateQueue(INFINITE, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = FtpAddQueuedFileEx(
    hQueue,
    FTP_QUEUE_DOWNLOAD,
    lpszHostName,
    FTP_PORT_DEFAULT,
    lpszUserName,
    lpszPassword,
    lpszLocalFile,
    lpszRemoteFile,
    FTP_OPTION_DEFAULT,
    FILE_TYPE_AUTO,
    FTP_TIMEOUT,
    NULL);

// Display information about the queued file
if (dwFileId != 0)
```

```

{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case FTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case FTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\\n"),
                    dwFileId,
                    queuedFile.szLocalFile,
                    queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (FtpStartQueue(hQueue, FTP_QUEUE_ALL, 0, NULL, 0))
{
    FtpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    FtpStopQueue(hQueue);
}

// Remove all files from the queue
FtpDeleteQueue(hQueue);

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpAllocate Function

```
INT WINAPI FtpAllocate(  
    HCLIENT hClient,  
    DWORD dwFileLength,  
    DWORD dwRecSize  
);
```

The **FtpAllocate** function instructs the server to reserve sufficient storage to accommodate the new file being transferred.

Parameters

hClient

Handle to the client session.

dwFileLength

The number of bytes to allocate storage for on the server.

dwRecSize

The maximum record or page size for the file. A value of zero indicates that the file does not have a record or page structure, and the parameter is ignored.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should be called immediately before the **FtpOpenFile** function.

This function is ignored by those servers which do not require that the maximum size of the file be declared beforehand. The most common FTP servers running under UNIX and Windows do not require that file space be pre-allocated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

FtpAsyncConnect Function

```
HCLIENT WINAPI FtpAsyncConnect(
    LPCTSTR lpszRemoteHost,
    UINT nRemotePort,
    LPCTSTR lpszUserName,
    LPCTSTR lpszPassword,
    UINT nTimeout,
    DWORD dwOptions,
    LPSECURITYCREDENTIALS lpCredentials,
    HWND hEventWnd,
    UINT uEventMsg
);
```

The **FtpAsyncConnect** function establishes a connection with the specified server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **FtpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990. If the secure port number is specified, an implicit TLS connection will be established by default.

lpszUserName

Points to a string that specifies the user name to be used to authenticate the current client session. If this parameter is NULL or an empty string, then the login is considered to be anonymous. Note that anonymous logins are not supported for secure connections using the SSH protocol.

lpszPassword

Points to a string that specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
-------	-------------

FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.
FTP_OPTION_KEEPAIVE	This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.
FTP_OPTION_NOAUTHRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using TLS.
FTP_OPTION_NOPWDNUL	This option specifies the user password cannot be

	terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using TLS.
FTP_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour. This option has no effect on standard or secure connections using TLS.
FTP_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.
FTP_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using TLS.
FTP_OPTION_VIRTUALHOST	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying

	FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the client should use the Secure Shell (SSH) protocol to establish the connection. This option will automatically be selected if the connection is established using port 22, the default port for SSH.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPA_LIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPA_LIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6

	address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members *dwSize*, *lpzCertStore* and *lpzCertName* must be defined. Undefined structure members must be initialized to a value of zero or NULL and the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
FTP_EVENT_CONNECT	The control connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification

	message will be posted if an error has occurred.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event is generated when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event is generated when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.

To cancel asynchronous notification and return the client to a blocking mode, use the **FtpDisableEvents** function.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the `FTP_OPTION_SECURE_EXPLICIT` option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit TLS session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the `FTP_OPTION_FREETHREAD` option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
// The Ipswitch WS_FTP server accepts the AUTH command to establish
// an explicit TLS session on the default FTP port
hClient = FtpAsyncConnect(lpszRemoteHost,
                        FTP_PORT_DEFAULT,
                        FTP_TIMEOUT,
                        FTP_OPTION_SECURE_EXPLICIT,
                        NULL,
                        hEventWnd,
                        uEventMsg);

// When the GlobalSCAPE Secure FTP server is configured in implicit
// authorization mode, it negotiates a secure session as soon as the
// connection is established and does not require a command
hClient = FtpAsyncConnect(lpszRemoteHost,
                        FTP_PORT_SECURE,
                        FTP_TIMEOUT,
                        FTP_OPTION_SECURE_IMPLICIT,
                        NULL,
                        hEventWnd,
                        uEventMsg);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftpv11.lib`

Unicode: Implemented as Unicode and ANSI versions

FtpAsyncFileList Function

```
UINT WINAPI FtpAsyncFileList(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory,  
    DWORD dwOptions,  
    LPTSTR lpszBuffer,  
    INT nMaxLength,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Return an unparsed list of files in the specified directory.

Parameters

hClient

Handle to the client session.

lpszDirectory

A pointer to a string that specifies the name of a directory and/or a wildcard file mask. The format of the directory name must match the file naming conventions of the server. If this parameter is NULL or points to an empty string, the current working directory will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_LIST_DEFAULT	This option specifies the server should return a complete listing of files in the specified directory with as much detail as possible. This typically means that the file size, date, ownership and access rights will be returned to the client. Information about the files are returned in lines of text, with each line terminated by carriage return and linefeed (CRLF) characters. The exact format of the data returned is specific to the server operating system.
FTP_LIST_NAMEONLY	This option specifies the server should only return a list of file names, with no additional information about the file. Each file name is terminated by carriage return and linefeed (CRLF) characters.

lpszBuffer

A pointer to a string buffer that will contain the list of files when the function returns. This buffer should be large enough to store the complete file listing and a terminating null character. If the buffer is smaller than the total amount of data returned by the server, the data will be truncated. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more

information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the ***lpEventProc*** parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpAsyncFileList** function returns a list of files in the specified directory, copying the data to a string buffer. This function is similar to the **FtpGetFileList** function, however it retrieves the list of files asynchronously using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file listing is being returned by the server.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, such as with the example listed below, then you must ensure that your code does not return from the function while the directory listing is being retrieved. In the example, this is achieved by calling the **FtpTaskWait** function. You can also perform other operation and poll the status of the task by calling the **FtpTaskDone** function. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the ***lpSzBuffer*** parameter on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the directory listing has completed. This enables your application to know when the directory listing is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

This function can be particularly useful when the client is connected to a server that returns file listings in a format that is not recognized by the library. The application can retrieve the unparsed file listing from the server and parse the contents. Note that if you specify the FTP_LIST_NAMEONLY option, the data will only contain a list of file names and there will be no way for the application to know if they represent a regular file or a subdirectory.

This function is supported for both FTP and SFTP (SSH) connections, however the format of the data may differ depending on which protocol is used. Most UNIX based FTP servers will not list files and subdirectories that begin with a period, however most SFTP servers will return a list of all files, even those that begin with a period.

Example

```
TCHAR szFileList[MAXFILELISTSIZE];
UINT nTaskId;

nTaskId = FtpAsyncFileList(hClient,
                          NULL,
```

```

        FTP_LIST_DEFAULT,
        szFileList,
        MAXFILELISTSIZE,
        NULL, 0);

if (nTaskId == 0)
{
    _tprintf(_T("Unable to list files (error 0x%08lx)\n"), FtpGetLastError());
    return;
}
else
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    FtpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);
    _tprintf(_T("Asynchronous file listing returned in %lu milliseconds\n"),
dwElapsed);
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpAsyncGetData Function

```
UINT WINAPI FtpAsyncGetData(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Copies the contents of a file on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncGetData** function is used to download the contents of a remote file into a local buffer. This function is similar to the **FtpGetData** function, however it retrieves the contents of the file using a

background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being copied to the local system.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, such as with the example listed below, then you must ensure that your code does not return from the function while the data is being downloaded. In the example, this is achieved by calling the **FtpTaskWait** function. You can also perform other operation and poll the status of the task by calling the **FtpTaskDone** function. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvBuffer* and *lpdwLength* parameters on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

The *lpBuffer* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the file or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpdwLength* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpdwLength* must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hgblBuffer = NULL;
DWORD dwLength = 0;
UINT nTaskId;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter

nTaskId = FtpAsyncGetData(hClient,
                          lpzFileName,
                          &hgblBuffer,
                          &dwLength,
                          0, NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    FtpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // contents of the file data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
```

```
// and freed, otherwise a memory leak will occur  
GlobalUnlock(hgblBuffer);  
GlobalFree(hgblBuffer);  
}
```

FtpAsyncGetFile Function

```
UINT WINAPI FtpAsyncGetFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Downloads the specified file from the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncGetFile** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **FtpGetFile** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the FTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = FtpAsyncGetFile(hClient,
                          lpszLocalFile,
                          lpszRemoteFile,
                          FTP_TRANSFER_DEFAULT,
                          0,
                          NULL,
                          0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;
```

```
// Wait for the transfer to complete
FtpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpAsyncGetFileEx Function

```
UINT WINAPI FtpAsyncGetFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncGetFileEx** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **FtpGetFileEx** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the FTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

FtpAsyncProxyConnect Function

```
HCLIENT WINAPI FtpAsyncProxyConnect(  
    UINT nProxyType,  
    LPCTSTR LpszProxyHost,  
    UINT nProxyPort,  
    LPCTSTR LpszProxyUser,  
    LPCTSTR LpszProxyPassword,  
    LPCTSTR LpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **FtpAsyncProxyConnect** function establishes a connection through a proxy server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **FtpProxyConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

nProxyType

An identifier which specifies the type of proxy server that is being connected to. This value must be defined as one of the following values:

Value	Description
FTP_PROXY_NONE	This value specifies that no proxy server is being used. In this case, the FtpConnect function is called directly, ignoring the proxy parameters.
FTP_PROXY_USER	This value specifies that the client is not logged into the proxy server. The USER command is sent in the format username@ftpsite followed by the password. This is the format used with the Gauntlet proxy server.
FTP_PROXY_LOGIN	This value specifies that the client is logged into the proxy server. The USER command is then sent in the format username@ftpsite followed by the password. This is the format used by the InterLock proxy server.
FTP_PROXY_OPEN	This value specifies that the client is not logged into the proxy server. The OPEN command is sent specifying the host name, followed by the username and password.
FTP_PROXY_SITE	This value specifies that the client is logged into the server. The SITE command is sent, specifying the host name, followed by the

	username and the password.
FTP_PROXY_OTHER	This special proxy type specifies that another, undefined proxy server is being used. The client connects to the proxy host, but does not attempt to authenticate the client. The application is responsible for negotiating with the proxy server, typically using the FtpCommand function to send specific command sequences.

lpszProxyHost

A pointer to the name of the proxy server to connect through; this may be a fully-qualified domain name or an IP address.

nProxyPort

The port number the proxy server is listening on; a value of zero specifies that the default port number should be used.

lpszProxyUser

A pointer to the user name used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a username is required.

lpszProxyPassword

A pointer to the password used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a password is required.

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the

	<p>local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.</p>
FTP_OPTION_FIREWALL	<p>This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.</p>
FTP_OPTION_NOAUTH	<p>This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.</p>
FTP_OPTION_KEEPAIVE	<p>This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.</p>
FTP_OPTION_VIRTUALHOST	<p>This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.</p>
FTP_OPTION_VERIFY	<p>This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers</p>

	because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).

FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members *dwSize*, *lpzCertStore* and *lpzCertName* must be defined. Undefined structure members must be initialized to a value of zero or NULL and the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

The username and password that is used to authenticate the client with the proxy server are not the same as those used to login to the target server. Once a connection has been established with the

proxy server, the client must call the **FtpLogin** function to actually login to the server and begin a file transfer.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
FTP_EVENT_CONNECT	The control connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event is generated when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event is generated when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.

To cancel asynchronous notification and return the client to a blocking mode, use the **FtpDisableEvents** function.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit TLS session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpAsyncPutData Function

```
UINT WINAPI FtpAsyncPutData(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPVOID lpvBuffer,  
    DWORD dwLength,  
    DWORD dwReserved,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Copies the contents of the specified buffer to a file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to the data that will be copied to the server and stored in the specified file.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncPutData** function is used to upload the contents of a local buffer to the server. This function is similar to the **FtpPutData** function, however it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent to the server.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the

stack, ensure that your code does not return from the function while the data is being uploaded. This can be achieved by calling the **FtpTaskWait** function or periodically calling the **FtpTaskDone** function to determine if the transfer has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvBuffer* parameter on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

If the *lpvBuffer* parameter is pointing to a Unicode string, it is important to note that the value of the *dwLength* parameter should specify the number of bytes, not the number of characters. When using UTF-16, each character is two bytes long and therefore the length of the buffer is effectively double the length of the string. Because Unicode strings can contain null characters, you must also set the current file type to FILE_TYPE_IMAGE prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpAsyncPutFile Function

```
UINT WINAPI FtpAsyncPutFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Uploads the specified file from the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncPutFile** function is used to upload the contents of a local file to the server. This function is similar to the **FtpPutFile** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the FTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpAsyncGetData](#), [FtpAsyncGetFile](#), [FtpAsyncPutData](#), [FtpEventProc](#), [FtpPutFile](#), [FtpTaskDone](#), [FtpTaskWait](#)

FtpAsyncPutFileEx Function

```
UINT WINAPI FtpAsyncPutFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset,  
    FTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Uploads the specified file from the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncPutFileEx** function is used to upload the contents of a local file to the server. This function is similar to the **FtpPutFileEx** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the FTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

FtpAttachThread Function

```
DWORD WINAPI FtpAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **FtpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **FtpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **FtpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **FtpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **FtpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftpv11.lib`

See Also

[FtpConnect](#), [FtpDisconnect](#), [FtpUninitialize](#)

FtpCancel Function

```
INT WINAPI FtpCancel(  
    HCLIENT hClient  
);
```

The **FtpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

When the **FtpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

This function may be called during a blocking file transfer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpIsBlocking](#)

FtpCancelQueuedFile Function

```
BOOL WINAPI FtpCancelQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwFileId  
);
```

The **FtpCancelQueuedFile** function cancels the queued file transfer.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. If this value is zero, the function will cancel the current file transfer in progress. If queue transfers have been suspended, this parameter cannot be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

When this function is called, the queued file transfer may not immediately stop. An internal flag is set which causes the file transfer to exit with an error and the queue manager will begin processing the next file in the queue. If the queue is in an idle state, this function will fail.

It is permitted to call **FtpCancelQueuedFile** from within a queue event handler to cancel the current file transfer. In this case, the *dwFileId* parameter should be zero. If you specify a file which has not been transferred, it will be flagged as canceled and skipped by the queue manager when processing the queue. If you specify a file which has already been processed, this function will fail.

A canceled file transfer is also considered a failed transfer. When you call **FtpGetQueueStatus** after a queued file transfer is canceled, the *dwFailedFiles* member of the [FTPQUEUESTATUS](#) structure will be incremented to reflect this change. You can determine the status of an individual file transfer by calling the **FtpGetQueuedFile** function and checking the value of the *dwQueueFlags* member of the [FTPQUEUEDFILE](#) structure.

The **FtpResetQueue** function can be used to reset the state of previously canceled transfers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib.h

FtpChangeDirectory Function

```
INT WINAPI FtpChangeDirectory(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory  
);
```

The **FtpChangeDirectory** function changes the current working directory for the client session.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a string that specifies the name of the directory. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the CWD command to change the current working directory. The user must have the appropriate permission to access the specified directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpChangeDirectoryUp Function

```
INT WINAPI FtpChangeDirectoryUp(  
    HCLIENT hClient  
);
```

The **FtpChangeDirectoryUp** function changes directory to the parent of the current working directory.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the CDUP command to the server. This command is a special case of the CWD command, and is included to simplify transferring between directory trees on those operating systems which have different syntaxes for naming the parent directory. The current user must have the appropriate permission to access the specified directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

FtpClearQueue Function

```
BOOL WINAPI FtpClearQueue(  
    HQUEUE hQueue  
);
```

The **FtpClearQueue** function removes all files from the queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function can only be called when the queue is in an idle state. An error will be returned if the function is called while the queue manager is paused or actively transferring files in the queue. To determine the current state of the queue, call the **FtpGetQueueStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

FtpCloseDirectory Function

```
INT WINAPI FtpCloseDirectory(  
    HCLIENT hClient  
);
```

The **FtpCloseDirectory** function closes the data socket connection to the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function must be called after all of the file information from the server has been returned. Because directory information is returned on the data channel, no file transfers can take place while a directory is being read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

[FtpGetDirectoryFormat](#), [FtpGetFileStatus](#), [FtpGetFirstFile](#), [FtpGetNextFile](#), [FtpOpenDirectory](#), [FtpSetDirectoryFormat](#)

FtpCloseFile Function

```
INT WINAPI FtpCloseFile(  
    HCLIENT hClient  
);
```

The **FtpCloseFile** function flushes the internal client buffers and closes the data socket connection to the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If the file is opened for writing, all buffered data is written to the server before the socket is closed. This may cause the client to block until all of the data can be written. The client application should not perform any other action until the function returns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

[FtpOpenFile](#), [FtpRead](#), [FtpWrite](#)

FtpCommand Function

```
INT WINAPI FtpCommand(  
    HCLIENT hClient,  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszParameter  
);
```

The **FtpCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the function succeeds, the return value is the result code returned by the server. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should only be used when the application needs to send a custom, site-specific command or send a command that is not directly supported by this API. This function should never be used to issue a command that opens a data channel. If the application needs to transform data as it is being sent or received, and cannot use the **FtpGetFile** or **FtpPutFile** functions, then use the **FtpOpenFile** function to open a data channel with the server.

By default, file names which are sent to the server using the **FtpCommand** function are sent as ANSI characters. If the Unicode version of the function is used, the file name will be converted from Unicode to ANSI using the current codepage. If the server supports UTF-8 encoded file names, the **FtpSetFileNameEncoding** function can be used to specify that file names with non-ASCII characters should be sent as UTF-8 encoded values. It is important to note that this option is only available if the server advertises support for UTF-8 and permits that encoding type.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpConnect Function

```
HCLIENT WINAPI FtpConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **FtpConnect** function establishes a connection with the specified server.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990.

lpszUserName

Points to a string that specifies the user name to be used to authenticate the current client session. If this parameter is NULL or an empty string, then the login is considered to be anonymous. Note that anonymous logins are not supported for secure connections using the SSH protocol.

lpszPassword

Points to a string that specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the

	server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.
FTP_OPTION_KEEPAIVE	This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.
FTP_OPTION_NOAUTHRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using TLS.
FTP_OPTION_NOPWDNUL	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using TLS.
FTP_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour. This option has no effect on standard or secure connections

	using TLS.
FTP_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.
FTP_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using TLS.
FTP_OPTION_VIRTUALHOST	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a

	standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the client should use the Secure Shell (SSH) protocol to establish the connection. This option will automatically be selected if the connection is established using port 22, the default port for SSH.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds.

	This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members *dwSize*, *lpzCertStore* and *lpzCertName* must be defined. Undefined structure members must be initialized to a value of zero or NULL and the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **FtpConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit TLS session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
// Connect to a server using a standard (non-secure) connection on
// the default port. The username and password are not encrypted.

hClient = FtpConnect(lpszRemoteHost,
                    FTP_PORT_DEFAULT,
                    lpszUserName,
                    lpszPassword,
                    FTP_TIMEOUT,
                    FTP_OPTION_DEFAULT,
                    NULL);

// Connect to a server using the default port and then initiate a
// secure connection using the AUTH TLS command

hClient = FtpConnect(lpszRemoteHost,
                    FTP_PORT_DEFAULT,
                    lpszUserName,
                    lpszPassword,
                    FTP_TIMEOUT,
                    FTP_OPTION_PASSIVE | FTP_OPTION_SECURE_EXPLICIT,
                    NULL);

// Connect to a server on port 990 and immediately initiate a
// secure connection as soon as the connection is established

hClient = FtpConnect(lpszRemoteHost,
                    FTP_PORT_SECURE,
                    lpszUserName,
                    lpszPassword,
                    FTP_TIMEOUT,
                    FTP_OPTION_PASSIVE | FTP_OPTION_SECURE_IMPLICIT,
                    NULL);

// Connect to a server on port 22 using the Secure Shell (SFTP)
// protocol to transfer files

hClient = FtpConnect(lpszRemoteHost,
                    FTP_PORT_SSH,
                    lpszUserName,
                    lpszPassword,
                    FTP_TIMEOUT,
                    FTP_OPTION_SECURE_SHELL,
                    NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpConnectUrl Function

```
HCLIENT WINAPI FtpConnectUrl(  
    LPCTSTR lpszUrl,  
    UINT nTimeout,  
    DWORD dwOptions  
);
```

The **FtpConnectUrl** function establishes a connection with the specified server using a URL.

Parameters

lpszUrl

A pointer to a string which specifies the URL for the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require

	<p>authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.</p>
FTP_OPTION_KEEPAIVE	<p>This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.</p>
FTP_OPTION_NOAUTHRSA	<p>This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using TLS.</p>
FTP_OPTION_NOPWDNUL	<p>This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server. This option has no effect on standard or secure connections using TLS.</p>
FTP_OPTION_NOREKEY	<p>This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour. This option has no effect on standard or secure connections using TLS.</p>
FTP_OPTION_COMPATSID	<p>This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using SSL.</p>
FTP_OPTION_COMPATHMAC	<p>This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions. This option has no effect on standard or secure connections using TLS.</p>
FTP_OPTION_VIRTUALHOST	<p>This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled,</p>

	the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the client should use the Secure Shell (SSH) protocol to establish the connection. This option will automatically be selected if the connection is established using port 22, the default port for SSH.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the

	connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpConnectUrl** function is a high-level function that uses an FTP URL to establish a connection with a server. Unlike the other connection related functions such as **FtpConnect**, this function does more than simply connect to the server. It will also authenticate the client session, change the current working directory and set the default file transfer mode. By default, this function will always place the client in passive mode, ensuring the broadest compatibility with most servers.

The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @[hostname [:port] / [path / ...]  
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. The paths in an FTP URL are relative to the home directory of the user account and are not absolute paths starting at the root directory on the server. If a file name is also specified in the URL, it will be ignored and only the file path will be used. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The **FtpConnectUrl** function is designed to provide a simpler, more convenient interface to establishing a connection with a server. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to use the lower-level connection functions. If you only need to upload or download a file using a URL, then refer to the **FtpUploadFile** and **FtpDownloadFile** functions.

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **FtpConnectUrl** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
HCLIENT hClient;  
LPCTSTR lpszUrl = _T("ftp://ftp.sockettools.com/");  
  
// Connect to the site specified by the URL  
hClient = FtpConnectUrl(lpszUrl, FTP_TIMEOUT, FTP_OPTION_DEFAULT);  
  
if (hClient == INVALID_CLIENT)  
{  
    TCHAR szError[128];
```

```
// Display a message box that describes the error
FtpGetErrorString(FtpGetLastError(), szError, 128);
MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpCreateDirectory Function

```
INT WINAPI FtpCreateDirectory(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory  
);
```

The **FtpCreateDirectory** function creates the specified directory on the server.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a string that specifies the name of the directory. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the MKD command to create the directory. The user must have the appropriate permission to create the specified directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpCreateQueue Function

```
HQUEUE WINAPI FtpCreateQueue(  
    UINT nMaxFiles,  
    UINT nTimeout,  
    DWORD dwOptions  
);
```

The **FtpCreateQueue** function creates new file transfer queue.

Parameters

nMaxFiles

An unsigned integer which specifies the maximum number of files which can be added to the queue. The constant INFINITE can be used to specify that there is no fixed limit to the number of files in the queue.

nTimeout

An unsigned integer which specifies the default timeout for all queued file transfers. If this value is zero, a reasonable default timeout period will be used. This timeout period is used when a file is added to the queue without providing a timeout period for that specific file transfer. If a timeout period is specified for a particular file, it will override this value.

dwOptions

An unsigned integer value which specifies one or more default options for all queued files. This parameter is constructed by using a bitwise operator and can be any of the options used with the **FtpConnect** function. If transfer options are specified for a particular file, it will override this value. The most common options are:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for queued file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies queued transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies queued transfers should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an

	unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies queued file transfers should attempt to establish a secure connection with the server by default. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies queued file transfers should attempt to immediately establish secure TLS connection with the server by default. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies queued file transfers should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies queued file transfers should use the Secure Shell (SSH) protocol to establish the connection by default. This option will automatically be selected if the connection is established using port 22, the default port for SSH.

Return Value

If the function succeeds, the return value is a handle to the queue which can be used with subsequent function calls. If the function fails, the return value is INVALID_QUEUE. To get extended error information, call **FtpGetLastError**.

Remarks

If the *nMaxFiles* parameter is INFINITE, memory will be dynamically allocated on the process heap with no limit to the number of files which can be queued. If there is a logic error which causes the application to recursively add files to the queue, or repeatedly queue the same file, this can result in virtual memory being exhausted for the process. You can avoid this by specifying a reasonable maximum queue size, which will cause the **FtpAddQueuedFile** function to fail if that limit is exceeded.

The memory allocated for the queue will be released when the **FtpDeleteQueue** function is called.

Example

```
// Create a new queue
HQUEUE hQueue = FtpCreateQueue(INFINITE, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = FtpAddQueuedFile(
    hQueue,
    lpszLocalFile,
    lpszRemoteFile,
```

```

        FTP_OPTION_DEFAULT,
        FILE_TYPE_AUTO,
        FTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case FTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case FTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\\n"),
                    dwFileId,
                    queuedFile.szLocalFile,
                    queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (FtpStartQueue(hQueue, FTP_QUEUE_ALL, 0, NULL, 0))
{
    FtpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    FtpStopQueue(hQueue);
}

// Remove all files from the queue
FtpDeleteQueue(hQueue);

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

FtpCreateSecurityCredentials Function

```
BOOL WINAPI FtpCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **FtpCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol should be used when establishing the connection. This is the default version of the protocol that is supported by most SSH servers.

dwOptions

A value which specifies one or more options. This value should always be zero for connections using SSH. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpzUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpzPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpzCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpzCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **FtpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **FtpConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you

can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpzPassword* parameter or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPCTSTR lpzCertStore = _T("HKCU:MY"); // The current user's personal certificate
store
LPCTSTR lpzCertName = _T("ClientCert"); // The client certificate name
LPSECURITYCREDENTIALS lpSecCred = NULL;

FtpCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                             CREDENTIAL_STORE_CURRENT_USER,
                             NULL,
                             NULL,
                             lpzCertStore,
                             lpzCertName,
                             NULL,
                             &lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csWSKV11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpDeleteFile Function

```
INT WINAPI FtpDeleteFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName  
);
```

The **FtpDeleteFile** function deletes the specified file from the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to delete. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The current user must have the appropriate permission to delete the file, or an error will be returned by the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpGetFile](#), [FtpPutFile](#), [FtpRenameFile](#)

FtpDeleteQueue Function

```
BOOL WINAPI FtpDeleteQueue(  
    HQUEUE hQueue  
);
```

The **FtpDeleteQueue** function deletes the specified file transfer queue, releasing all memory allocated for the queued files.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function can only be called when the queue is in an idle state. If the queue manager is in the process of uploading or downloading files, the function will fail and return a value of zero. You can determine the current state of the queue by calling the **FtpGetQueueStatus** function. It is not necessary to explicitly clear the queue prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

FtpDeleteSecurityCredentials Function

```
VOID WINAPI FtpDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **FtpDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)  
    FtpDeleteSecurityCredentials(&lpSecCred);  
  
FtpUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpDisableEvents Function

```
INT WINAPI FtpDisableEvents(  
    HCLIENT hClient  
);
```

The **FtpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpDisableEvents** function is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this function has been called.

This function is automatically called if the client has event notification enabled, and the **FtpDisconnect** function is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

[FtpEnableTrace](#)

FtpDisconnect Function

```
INT WINAPI FtpDisconnect(  
    HCLIENT hClient  
);
```

The **FtpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpDownloadFile Function

```
BOOL WINAPI FtpDownloadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    UINT nTimeout  
    DWORD dwOptions  
    LPFTPTRANSFERSTATUS lpStatus  
    FTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **FtpDownloadFile** function downloads the specified file from the server to the local system.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in

	response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpDownloadFile** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then download the file to the local system. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @[hostname [:port] / [path / ...]
[filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be downloaded as a text or binary file. A value of "a" specifies that the file should be downloaded as a text file. A value of "i" specifies that the file should be downloaded as a binary file. If the type is not explicitly specified, the

file will be downloaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling

FtpGetTransferStatus and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpDownloadFile** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpGetFile** to download the file.

Example

```
FTPTRANSFERSTATUS ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile = _T("ftp://ftp.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = FtpDownloadFile(lpszLocalFile,
                          lpszRemoteFile,
                          FTP_OPTION_PASSIVE,
                          &ftpStatus,
                          NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

FtpDownloadFileEx Function

```
BOOL WINAPI FtpDownloadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    UINT nTimeout  
    DWORD dwOptions  
    LPFTPTRANSFERSTATUSEX lpStatus  
    FTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **FtpDownloadFileEx** function downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this

	option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpDownloadFileEx** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then download the file to the local system. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @[hostname [:port] / [path / ...]
[filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be downloaded as a text or binary file. A value of "a" specifies that the file should be downloaded as a text file. A value of "i" specifies that the file should be downloaded as a binary file. If the type is not explicitly specified, the file will be downloaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related

to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling

FtpGetTransferStatusEx and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpDownloadFileEx** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpGetFileEx** to download the file.

Example

```
FTPTRANSFERSTATUSEX ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile = _T("ftp://ftp.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = FtpDownloadFileEx(lpszLocalFile,
                           lpszRemoteFile,
                           FTP_OPTION_PASSIVE,
                           &ftpStatus,
                           NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

FtpEnableEvents Function

```
INT WINAPI FtpEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **FtpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **FtpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpEnableEvents** function is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
FTP_EVENT_CONNECT	The control connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client

	should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event is generated when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event is generated when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **FtpDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

FtpEnableFeature Function

```
BOOL WINAPI FtpEnableFeature(  
    HCLIENT hClient,  
    DWORD dwFeature,  
    BOOL bEnable  
);
```

The **FtpEnableFeature** function enables or disables a specific server feature available to the client.

Parameters

hClient

Handle to the client session.

dwFeature

An unsigned integer which specifies the feature to be enabled to disabled for the current client session. Refer to the documentation for the **FtpGetFeatures** function for a list of available features.

bEnable

A boolean flag which specifies if the feature should be enabled or disabled. If the value is non-zero, the library will attempt to use that feature on the server. If the value is zero, the feature is disabled. If an application calls a function which requires a specific feature and that feature is disabled, the function will fail with an error indicating the feature is not supported.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return a value of zero. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpEnableFeature** function is used to enable or disable a specific feature for the current session. When a client connection is first established, features are enabled based on the server type and the server's response to the FEAT command. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client. An application can use the **FtpEnableFeature** function to control what commands will be sent to the server, or re-enable a command that was previously disabled.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

[FtpGetFeatures](#), [FtpSetFeatures](#)

FtpEnableTrace Function

```
BOOL WINAPI FtpEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **FtpEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv11.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpEndOfFile Function

```
BOOL WINAPI FtpEndOfFile(  
    HCLIENT hClient  
);
```

The **FtpEndOfFile** function is used to determine if the end-of-file has been reached while reading the contents of a remote file.

Parameters

hClient

Handle to the client session.

Return Value

If the end-of-file has been reached, the function returns a non-zero value. If the client handle is invalid, or the end-of-file has not been reached, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

FtpEnumFiles Function

```
INT WINAPI FtpEnumFiles(
    HCLIENT hClient,
    LPCTSTR lpszDirectory,
    LPCTSTR lpszFileMask,
    DWORD dwOptions,
    LPFTPFILESTATUS lpFileList,
    INT nMaxFiles
);
```

The **FtpEnumFilesEx** function populates an array of structures that contain information about the files in a directory.

Parameters

- hClient***
- Handle to the client session.
- lpszDirectory***
- A pointer to a string that specifies the name of a directory on the server. If this parameter is NULL or points to an empty string, the function will return the files in the current working directory. This string cannot contain wildcard characters and must specify a valid directory name that exists on the server.
- lpszFileMask***
- A pointer to a string that specifies a wildcard file mask that is used to return a subset of files in the directory. If this parameter is NULL or an empty string then all of the files in the directory will be returned.
- dwOptions***
- An unsigned integer value that specifies one or more options. This parameter can be a combination of one or more of the following values:
- | Value | Description |
|--------------------|---------------------------------------------------------------------|
| FTP_ENUM_DEFAULT | The function will return both regular files and subdirectories. |
| FTP_ENUM_FILE | The function will return only regular files. |
| FTP_ENUM_DIRECTORY | The function will return only subdirectories. |
| FTP_ENUM_FULLPATH | The function will return the full path of the file or subdirectory. |
- lpFileList***
- A pointer to an array of [FTPFILESTATUS](#) structures which contains information about each of the files in the specified directory. This parameter cannot be NULL, and the array must be large enough to store the number of files specified by the ***nMaxFiles*** parameter.
- nMaxFiles***
- An integer value that specifies the maximum number of files that should be returned. This value must be greater than zero and the ***lpFileList*** parameter must provide an array that is large enough to store information about each file.

Return Value

If the function succeeds, the return value is the number of files returned by the function. If the

directory is empty or there are no files that match the specified wildcard file mask, the function will return zero. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpEnumFiles** function provides a high-level interface for obtaining a list of available files in a directory on the server in a single function call. This is an alternative to opening a directory and returning information about each file by calling the **FtpGetNextFile** function in a loop.

This function temporarily changes the current working directory to the directory specified by the *lpSzDirectory* parameter. The current working directory will be restored to its original value when the function returns. The user must have the appropriate permissions to access the directory or this function will fail.

To obtain information on a subset of files in the directory, you can specify a wildcard file mask. For FTP and FTPS (TLS) sessions, this value is passed as a parameter to the LIST command and the server performs the wildcard matching. For SFTP (SSH) sessions the wildcard matching is performed by the library, and the standard conventions for Windows file wildcards are used.

By default, the *szFileName* member for each **FTPFILESTATUS** structure will contain the base file name. If the `FTP_ENUM_FULLPATH` option is specified, the function will return the full path name to the file. The library must be able to automatically determine the path delimiter that is used by the server. This is done by examining how the server identifies itself, the current directory format and the path the server returns for the current working directory. For example, UNIX based servers use the forward slash as a path delimiter. If the function cannot determine what the appropriate path delimiter is, it will ignore this option and return only the base file name.

This function will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled. If the directory contains files that are larger than 4GB, the **FtpEnumFilesEx** function should be used to obtain the correct file size.

Example

```
LPFTPFILESTATUS lpFileList = new FTPFILESTATUS[MAXFILECOUNT];

// Return all of the regular files in the current working directory
INT nResult = FtpEnumFiles(hClient, NULL, NULL, FTP_ENUM_FILE,
                           lpFileList, MAXFILECOUNT);

if (nResult == FTP_ERROR)
{
    DWORD dwError = FtpGetLastError();
    _tprintf(_T("FtpEnumFiles failed, error 0x%08lx\n"), dwError);
    return;
}

_tprintf(_T("FtpEnumFiles returned %d files\n"), nResult);
for (INT nIndex = 0; nIndex < nResult; nIndex++)
{
    _tprintf(_T("file=\"%s\" size=%lu\n"), lpFileList[nIndex].szFileName,
            lpFileList[nIndex].dwFileSize);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpEnumFilesEx Function

```
INT WINAPI FtpEnumFilesEx(
    HCLIENT hClient,
    LPCTSTR lpszDirectory,
    LPCTSTR lpszFileMask,
    DWORD dwOptions,
    LPFTPFILESTATUSEX lpFileList,
    INT nMaxFiles
);
```

The **FtpEnumFilesEx** function populates an array of structures that contain information about the files in a directory. This version of the function is designed to support files that are larger than 4GB.

Parameters

- hClient***
Handle to the client session.
- lpszDirectory***
A pointer to a string that specifies the name of a directory on the server. If this parameter is NULL or points to an empty string, the function will return the files in the current working directory. This string cannot contain wildcard characters and must specify a valid directory name that exists on the server.
- lpszFileMask***
A pointer to a string that specifies a wildcard file mask that is used to return a subset of files in the directory. If this parameter is NULL or an empty string then all of the files in the directory will be returned.
- dwOptions***
An unsigned integer value that specifies one or more options. This parameter can be a combination of one or more of the following values:
- | Value | Description |
|--------------------|---------------------------------------------------------------------|
| FTP_ENUM_DEFAULT | The function will return both regular files and subdirectories. |
| FTP_ENUM_FILE | The function will return only regular files. |
| FTP_ENUM_DIRECTORY | The function will return only subdirectories. |
| FTP_ENUM_FULLPATH | The function will return the full path of the file or subdirectory. |
- lpFileList***
A pointer to an array of [FTPFILESTATUSEX](#) structures which contains information about each of the files in the specified directory. This parameter cannot be NULL, and the array must be large enough to store the number of files specified by the ***nMaxFiles*** parameter.
- nMaxFiles***
An integer value that specifies the maximum number of files that should be returned. This value must be greater than zero and the ***lpFileList*** parameter must provide an array that is large enough to store information about each file.

Return Value

If the function succeeds, the return value is the number of files returned by the function. If the

directory is empty or there are no files that match the specified wildcard file mask, the function will return zero. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpEnumFilesEx** function provides a high-level interface for obtaining a list of available files in a directory on the server in a single function call. This is an alternative to opening a directory and returning information about each file by calling the **FtpGetNextFileEx** function in a loop.

This function temporarily changes the current working directory to the directory specified by the *lpSzDirectory* parameter. The current working directory will be restored to its original value when the function returns. The user must have the appropriate permissions to access the directory or this function will fail.

To obtain information on a subset of files in the directory, you can specify a wildcard file mask. For FTP and FTPS (TLS) sessions, this value is passed as a parameter to the LIST command and the server performs the wildcard matching. For SFTP (SSH) sessions the wildcard matching is performed by the library, and the standard conventions for Windows file wildcards are used.

By default, the *szFileName* member for each **FTPFILESTATUSEX** structure will contain the base file name. If the `FTP_ENUM_FULLPATH` option is specified, the function will return the full path name to the file. The library must be able to automatically determine the path delimiter that is used by the server. This is done by examining how the server identifies itself, the current directory format and the path the server returns for the current working directory. For example, UNIX based servers use the forward slash as a path delimiter. If the function cannot determine what the appropriate path delimiter is, it will ignore this option and return only the base file name.

This function will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled.

Example

```
LPFTPFILESTATUSEX lpFileList = new FTPFILESTATUSEX[MAXFILECOUNT];

// Return all of the regular files in the current working directory
INT nResult = FtpEnumFilesEx(hClient, NULL, NULL, FTP_ENUM_FILE,
                             lpFileList, MAXFILECOUNT);

if (nResult == FTP_ERROR)
{
    DWORD dwError = FtpGetLastError();
    _tprintf(_T("FtpEnumFilesEx failed, error 0x%08lx\n"), dwError);
    return;
}

_tprintf(_T("FtpEnumFilesEx returned %d files\n"), nResult);
for (INT nIndex = 0; nIndex < nResult; nIndex++)
{
    _tprintf(_T("file=\"%s\" size=%I64d\n"), lpFileList[nIndex].szFileName,
            lpFileList[nIndex].uiFileSize);
}
```

Requirements

FtpEnumQueuedFiles Function

```
LONG WINAPI FtpEnumQueuedFiles(  
    HQUEUE hQueue,  
    LPCTSTR lpszFileMask,  
    DWORD dwQueueMode,  
    DWORD dwExcludeFiles,  
    LPDWORD lpFileList,  
    LONG nMaxFiles  
);
```

The **FtpEnumQueuedFiles** function returns a list of files in the current transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpszFileMask

A pointer to a null terminated string which specifies a file name which can include wildcards. Only those files which match this value will be enumerated. The character '?' will match against any single character, and '*' will match any number of characters. If this parameter is NULL or points to an empty string, all eligible files in the queue will be matched.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. Only those files which match the queue mode will be enumerated. This is a bitmask which may be one or more of the following values:

Constant	Description
FTP_QUEUE_ALL	Match the file name to all files in the queue.
FTP_QUEUE_DOWNLOAD	Match file names which are queued for download.
FTP_QUEUE_UPLOAD	Match file names which are queued for upload.
FTP_QUEUE_LOCAL	Match against the local file name instead of the remote file name.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the enumeration. If this value is zero, no files will be excluded; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_QUEUE_FLAG_NONE	No files should be excluded.
FTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
FTP_QUEUE_FLAG_FAILED	Exclude files which were not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.

FTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the FtpCancelQueuedFile function has been called and a queued file is in the process of being uploaded or downloaded.
-------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

lpFileList

A pointer to an array of unsigned integer values which will contain the unique file identifiers for each matching file in the queue. This parameter must specify an array large enough to store all of the file identifiers, otherwise the function will fail with a ST_ERROR_BUFFER_TOO_SMALL error. If this parameter is NULL, the function will return the number of matching files.

nMaxFiles

An integer value which specifies the maximum number of file identifiers which can be copied into the *lpFileList* array. If the *lpFileList* parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of matching files. If the queue is empty or there are no matching files, this function will return zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function populates an array of unique file identifiers which can be used to obtain information about the files in the current queue. The values returned in the *lpFileList* array can be used in conjunction with the **FtpGetQueuedFile** function. This provides an alternative to using the **FtpGetFirstQueuedFile** and **FtpGetNextQueuedFile** functions.

The application should not make any assumptions about the value of the file identifiers returned by this function. They should be considered opaque values which are only guaranteed to uniquely identify a file in the transfer queue. In particular, there is no guarantee that the file identifiers will be sequential and they should not be used as index values into an array.

Example

```
// Get the total number of files in the queue
LONG nFiles = FtpEnumQueuedFiles(hQueue, NULL, FTP_QUEUE_ALL, FTP_QUEUE_FLAG_NONE,
NULL, 0)

// Display information about the queued files
if (nFiles > 0)
{
    DWORD *pdwFileList = new DWORD[nFiles];

    nFiles = FtpEnumQueuedFiles(hQueue, NULL, FTP_QUEUE_ALL, FTP_QUEUE_FLAG_NONE,
pdwFileList, nFiles);

    for (LONG nIndex = 0; nIndex < nFiles; nIndex++)
    {
        FTPQUEUEDFILE queuedFile;

        if (FtpGetQueuedFile(hQueue, pdwFileList[nIndex], &queuedFile) == FALSE)
            break;

        switch (queuedFile.dwMode)
        {
        case FTP_QUEUE_DOWNLOAD:
            _tprintf(_T("%u: Download \"%s\" to \"%s\"\\n"),
```

```

        queuedFile.dwFileId,
        queuedFile.szRemoteFile,
        queuedFile.szLocalFile);
    break;

case FTP_QUEUE_UPLOAD:
    _tprintf(_T("%u: Upload \"%s\" to \"%s\"\\n"),
        queuedFile.dwFileId,
        queuedFile.szLocalFile,
        queuedFile.szRemoteFile);
    break;
}
}

delete pdwFileList;
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpEnumTasks Function

```
INT WINAPI FtpEnumTasks(  
    UINT *lpTasks,  
    INT nMaxTasks,  
    DWORD dwOptions  
);
```

Return a list of active, suspended or finished asynchronous tasks.

Parameters

lpTasks

A pointer to an array of unsigned integer values that will contain unique task identifiers when the function returns. If this parameter is NULL, the function will return the number of tasks.

nMaxTasks

An integer value that specifies the maximum number of task identifiers that may be copied into the *lpTasks* array. If the *lpTasks* parameter is NULL, this value must be zero.

dwOptions

An unsigned integer that specifies the type of asynchronous tasks that may be returned by this function. It may be a combination of the following values:

Value	Description
FTP_TASK_DEFAULT	The list of asynchronous task IDs should include both active and suspended tasks. This option is the same as specifying both the FTP_TASK_ACTIVE and FTP_TASK_SUSPENDED options.
FTP_TASK_ACTIVE	The list of asynchronous task IDs should include those tasks which are currently active. An active task represents a background connection to a server that is in the process of performing the requested action, such as uploading or downloading a file.
FTP_TASK_SUSPENDED	The list of asynchronous task IDs should include those tasks which have been suspended. A suspended task represents a background connection that has been established, but the worker thread is not scheduled for execution.
FTP_TASK_FINISHED	The list of asynchronous task IDs should include those tasks which have completed recently.

Return Value

If the function is successful, the return value is the number of task identifiers copied into the provided array. If there are no tasks which match the requested criteria, the return value is zero. A return value of FTP_ERROR indicates an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpEnumTasks** function can be used to obtain a list of numeric identifiers that represent the asynchronous tasks that have been started or those that have completed. These task IDs are used by other functions to reference the background worker thread that has been created and obtain status information for the task. For example, the **FtpTaskDone** function can be used to determine if a particular task has completed, and the **FtpTaskWait** function can be used to wait for a task to

complete and return an error status code if the background operation failed.

There is an internal limit of 128 asynchronous tasks per process that may be active at any one time. When a task completes, the status information about that task is maintained for period of time after the task has completed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

FtpEventProc Function

```
VOID CALLBACK FtpEventProc(  
    HCLIENT hClient,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **FtpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEventId

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **FtpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **FtpRegisterEvent** function. This callback function is also used by asynchronous tasks to notify the application when the task has started and completed. The **FtpEventProc** function is a placeholder for the application-defined function name. Other functions, such as **FtpStartQueue** can also use event callbacks.

If the callback function is invoked by an asynchronous task, it will execute in the context of the worker thread that is managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself, and you should avoid calling any functions which could cause the thread to block. For example, you should not attempt to establish other network connections from within the event handler.

If your application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function for an asynchronous task. Controls should only be modified by the same UI thread that created their window. One common approach to resolve this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

FtpFindQueuedFile Function

```
DWORD WINAPI FtpFindQueuedFile(  
    HQUEUE hQueue,  
    LPCTSTR lpszFileName,  
    DWORD dwQueueMode,  
    DWORD dwExcludeFiles  
);
```

The **FtpFindQueuedFile** function finds a file in the transfer queue which matches the search criteria.

Parameters

hQueue

A handle to a file transfer queue.

lpszFileName

A pointer to a null terminated string which specifies the name of the file to search for. The string may contain the wildcard character '?' to match against any single character, and '*' will match any number of characters. This parameter cannot be NULL or point to an empty string.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. This is a bitmask which may be one or more of the following values:

Constant	Description
FTP_QUEUE_ALL	Match the file name to all files in the queue.
FTP_QUEUE_DOWNLOAD	Match file names which are queued for download.
FTP_QUEUE_UPLOAD	Match file names which are queued for upload.
FTP_QUEUE_LOCAL	Match against the local file name instead of the remote file name.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the search. If this value is zero, no files will be excluded from the search; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_QUEUE_FLAG_NONE	No files should be excluded from the search.
FTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
FTP_QUEUE_FLAG_FAILED	Exclude files which were not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.
FTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the FtpCancelQueuedFile function has been called and a queued file is in the

	process of being uploaded or downloaded.
--	------------------------------------------

Return Value

If the function succeeds, the return value is a unique identifier for the file. To obtain information about the file, call the **FtpGetQueuedFile** function. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function returns a unique file identifier for the first file which matches the specified file name in the queue. If the *lpzFileName* parameter includes wildcard characters, this function will return the first file in the queue which matches the name. File name matches are not case-sensitive, even when matching against remote file names on servers which use case-sensitive naming, such as UNIX based servers.

To perform more complex searches based on the file name, or to find multiple files, you can use the **FtpGetFirstQueuedFile** and **FtpGetNextQueuedFile** functions to iterate through all queued files.

Example

```
// Find a local file in the download queue
DWORD dwFileId = FtpFindQueuedFile(
    hQueue,
    lpzFileName,
    FTP_QUEUE_DOWNLOAD | FTP_QUEUE_LOCAL,
    FTP_QUEUE_FLAG_NONE);

// Display information about the queued file
if (dwFileId != 0)
{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case FTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case FTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szLocalFile,
                    queuedFile.szRemoteFile);
                break;
        }
    }
}
```

FtpFreezeEvents Function

```
INT WINAPI FtpFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **FtpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

FtpGetActivePorts Function

```
INT WINAPI FtpGetActivePorts(  
    HCLIENT hClient,  
    UINT *lpnLowPort,  
    UINT *lpnHighPort  
);
```

The **FtpGetActivePorts** function returns the local port numbers used for active mode file transfers.

Parameters

hClient

Handle to the client session.

lpnLowPort

Points to an unsigned integer that will contain the low port number when the function returns.

lpnHighPort

Points to an unsigned integer that will contain the high port number when the function returns.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to determine the default port numbers being used for active mode file transfers. When using active mode, the client listens for an inbound connection from the server rather than establishing an outbound connection for the data transfer. In most cases, passive mode transfers are preferred because they mitigate potential compatibility issues with firewalls and NAT routers.

If active mode transfers are required, the default port range used when listening for the server connection is between 1024 and 5000. This is the standard range of ephemeral ports used by the Windows operating system. However, under some circumstances that range of ports may be too small, or a firewall may be configured to deny inbound connections on ephemeral ports. In that case, the **FtpSetActivePorts** function can be used to specify a different range of port numbers.

While it is technically permissible to assign the low and high port numbers to the same value, effectively specifying a single active port number, this is not recommended as it can cause the transfer to fail unexpectedly if multiple file transfers are performed. A minimum range of at least 1000 ports is recommended. For example, if you specify a low port value of 40000 then it is recommended that the high port value be at least 41000. The maximum port value is 65535.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpGetAutoFileType Function

```
UINT WINAPI FtpGetAutoFileType(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    BOOL bScanFile  
);
```

The **FtpGetAutoFileType** function returns the file transfer type based on the file extension or content.

Parameters

hClient

Handle to the client session. If this parameter is INVALID_CLIENT the function will only check against the global list of default text file extensions. If the handle is valid, it will also check for any application defined file extensions.

lpszFileName

A pointer to a null-terminated string which specifies the local path to the file. This parameter cannot be NULL and cannot specify a local device name or directory.

bScanFile

Specifies if the contents of the file should be scanned. A value of zero indicates that only the file extension should be used to determine the file type, while a non-zero value specifies the contents of the file should be examined if the file type cannot be determined based on its extension.

Return Value

If the function succeeds, the return value is the file transfer type. If the function fails, the return value is INVALID_FILE_TYPE. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to determine the file transfer type to be used when uploading or downloading files. This function is called internally when FILE_TYPE_AUTO is specified as the default file type. The return value may be one of the following:

Value	Description
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executable programs. If the type of file cannot be automatically determined, it will always be considered a binary file. If this file type is specified when uploading or downloading text files, the native end-of-line character sequences will be preserved.

If the file extension or contents are not recognized, the default file transfer type for the client session will be returned. This will usually be `FILE_TYPE_IMAGE`, however this can be changed by calling the **FtpRegisterFileType** function. The file type for the current client session can be explicitly set using the **FtpSetFileType** function.

If the **bScanFile** parameter is non-zero, the local file will be opened in a shared reading mode and up to 4,096 bytes will be examined to determine if it contains binary data. If the file is currently locked or has been opened exclusively by another process, the file type associated with the file extension will be returned instead. Text files which contain UTF-16 text will always return a file type of `FILE_TYPE_IMAGE` because they can contain non-ASCII characters and/or embedded null characters.

If the **bScanFile** parameter is non-zero and the file type cannot be determined based on the file name extension, the file specified by **lpzFileName** must exist and be a regular file. If the file does not exist, an error will be returned and the last error code will be set to `ST_ERROR_FILE_NOT_FOUND`. If the **bScanFile** parameter is zero, no errors will be returned if the file does not exist, the function will only check the file name extension to determine the file type. When downloading a file, the **bScanFile** parameter should normally be zero because the local file may not exist yet.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftpv11.lib`

Unicode: Implemented as Unicode and ANSI versions

FtpGetBufferSize Function

```
INT WINAPI FtpGetBufferSize(  
    HCLIENT hClient  
);
```

The **FtpGetBufferSize** function returns the size in bytes of an internal buffer that will be used during data transfers.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the size of the internal buffer that will be used in data transfers. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The speed of data transfers, particularly on uploads, may be sensitive to network type and configuration, and the size of the internal buffer used for data transfers. The default size of this buffer will result in good performance for a wide range of network characteristics. A larger buffer will not necessarily result in better performance. For example, a value of 1460, which is the typical Maximum Transmission Unit (MTU), may be optimal in many situations.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

FtpGetChannelMode Function

```
INT WINAPI FtpGetChannelMode(  
    HCLIENT hClient,  
    INT nChannel  
);
```

The **FtpGetChannelMode** function returns the mode of the specified communications channel.

Parameters

hClient

Handle to the client session.

nChannel

An integer value which specifies which channel to return information for. It may be one of the following values:

Value	Description
FTP_CHANNEL_COMMAND	Return information about the command channel. This is the communication channel used to send commands to the server and receive command result and status information from the server.
FTP_CHANNEL_DATA	Return information about the data channel. This is the communication channel used to send or receive data during a file transfer.

Return Value

If the function succeeds, the return value is the mode for the specified channel. If the function fails, it will return FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetChannelMode** function returns a integer which may be one of the following values:

Value	Description
FTP_CHANNEL_CLEAR	The channel is not encrypted. This is the default mode for both channels when a standard, non-secure connection is established with the server.
FTP_CHANNEL_SECURE	The channel is encrypted. This is the default mode for both channels when a secure connection is established with the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpGetClientQuota Function

```
INT WINAPI FtpGetClientQuota(  
    HCLIENT hClient,  
    LPFTPCLIENTQUOTA lpClientQuota  
);
```

The **GetClientQuota** function returns information about file quotas for the current client session.

Parameters

hClient

Handle to the client session.

lpClientQuota

A pointer to an [FTPCLIENTQUOTA](#) structure which contains the quota information returned by the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method uses the XQUOTA command to obtain information for the current client session. If the server does not support this command, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

FtpGetData Function

```
INT WINAPI FtpGetData(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwReserved  
);
```

The **FtpGetData** function transfers the contents of a file on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetData** function is used to download the contents of a remote file into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpdwLength* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when downloading the file, the variable passed to this function may have a value of zero when the function returns, indicating no data has

been returned to the caller.

The **FtpGetText** function can be used to download a text file and store the contents in a string.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = FtpGetData(hClient,
                    lpszRemoteFile,
                    &hgblBuffer,
                    &cbBuffer,
                    0);

if (nResult != FTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // contents of the file data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

FtpGetDirectory Function

```
INT WINAPI FtpGetDirectory(  
    HCLIENT hClient,  
    LPTSTR lpszDirectory,  
    INT cbDirectory  
);
```

The **FtpGetDirectory** function copies the current working directory on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a buffer that will contain the name of the current working directory on the server. The file pathing and name conventions must be that of the server.

cbDirectory

The maximum number of characters that may be copied into the buffer, including the terminating null-character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the PWD command to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetDirectoryFormat Function

```
INT WINAPI FtpGetDirectoryFormat(  
    HCLIENT hClient  
);
```

The **FtpGetDirectoryFormat** function returns an identifier which specifies what format is being used by the server to list files. By default, the library will automatically determine the appropriate format, but this value may be overridden by the **FtpSetDirectoryFormat** function.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the currently selected directory format. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Refer to the **FtpSetDirectoryFormat** function for a list of directory format types that are supported by the library. This function can be used to determine which format was selected by the library after a file listing has been retrieved.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

FtpGetErrorString Function

```
INT WINAPI FtpGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **FtpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **FtpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetLastError](#), [FtpSetLastError](#)

FtpGetFeatures Function

```
DWORD WINAPI FtpGetFeatures(  
    HCLIENT hClient  
);
```

The **FtpGetFeatures** function returns the server features available to the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is one or more bit flags which specify the features that are available to the client. If the function fails, it will return zero. Because it is possible that no features would be enabled, a return value of zero does not always indicate an error. An application should call **FtpGetLastError** to determine if an error code has been set.

Remarks

The **FtpGetFeatures** function returns a value which may be a combination of one or more of the following bit flags:

Value	Description
FTP_FEATURE_SIZE	The server supports the SIZE command to determine the size of a file. If this feature is not enabled, the library will attempt to use the MLST or STAT command to determine the file size.
FTP_FEATURE_STAT	The server supports using the STAT command to return information about a specific file. If this feature is not enabled, the client may not be able to obtain information about a specific file such as its size, permissions or modification time.
FTP_FEATURE_MDTM	The server supports the MDTM command to obtain information about the modification time for a specific file. This command may also be used to set the file time on the server.
FTP_FEATURE_REST	The server supports restarting file transfers using the REST command. If this feature is not enabled, the client will not be able to restart file transfers and must upload or download the complete file.
FTP_FEATURE_SITE	The server supports site specific commands using the SITE command. If this feature is not enabled, no site specific commands will be sent to the server.
FTP_FEATURE_IDLE	The server supports setting the idle timeout period using the SITE IDLE command to specify the number of seconds that the client may idle before the server terminates the connection.
FTP_FEATURE_CHMOD	The server supports modifying the permissions of a specific file using the SITE CHMOD command. If this feature is not enabled, the client will not be able to set the permissions for a file.
FTP_FEATURE_AUTH	The server supports explicit TLS sessions using the AUTH

	command. If this feature is not enabled, the client will only be able to connect to a secure server that uses implicit TLS connections. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_PBSZ	The server supports the PBSZ command which specifies the buffer size used with secure data connections. If this feature is disabled, it may prevent the client from changing the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_PROT	The server supports the PROT command which specifies the protection level for the data channel. If this feature is disabled, the client will be unable to change the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_CCC	The server supports the CCC command which returns the command channel to a non-secure mode. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_HOST	The server supports the HOST command which enables a client to specify the hostname after establishing a connection with a server that supports virtual hosting.
FTP_FEATURE_MLST	The server supports the MLST command which returns status information for files. If this feature is enabled, the MLST command will be used instead of the STAT command.
FTP_FEATURE_MFMT	The server supports the MFMT command which is used to change the last modification time for a file. If this command is supported, it is used instead of the MDTM command to change the modification time for a file.
FTP_FEATURE_XCRC	The server supports the XCRC command which returns the CRC-32 checksum for the contents of a specified file. This command is used for file verification.
FTP_FEATURE_XMD5	The server supports the XMD5 command which returns an MD5 hash for the contents of a specified file. This command is used for file verification.
FTP_FEATURE_LANG	The server supports the LANG command which sets the language used for the current client session. Command responses and file naming conventions will use the specified language.
FTP_FEATURE_UTF8	The server supports the OPTS UTF-8 command which specifies UTF-8 encoding when specifying filenames. This feature is typically used in conjunction with setting the default language for the client session.
FTP_FEATURE_XQUOTA	The server supports the XQUOTA command which returns quota information for the current client session.
FTP_FEATURE_UTIME	The server supports the UTIME command which is used to change the last modification time for a specified file.

When a client connection is first established, features are enabled based on the server type and the server's response to the FEAT command. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client.

For example, the first time an application calls the **FtpGetFileSize** function to determine the size of a file, the library will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the library will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the library from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpGetFile Function

```
INT WINAPI FtpGetFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset  
);
```

The **FtpGetFile** function transfers the specified file on the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetFileEx Function

```
INT WINAPI FtpGetFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset  
);
```

The **FtpGetFileEx** function transfers the specified file on the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

- hClient***
Handle to the client session.
- lpszLocalFile***
A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.
- lpszRemoteFile***
A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.
- dwOptions***
An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

- uiOffset***
A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent**

function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetFileList Function

```
INT WINAPI FtpGetFileList(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory,  
    DWORD dwOptions,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **FtpGetFileList** function returns an unparsed list of files in the specified directory.

Parameters

hClient

Handle to the client session.

lpszDirectory

A pointer to a string that specifies the name of a directory and/or a wildcard file mask. The format of the directory name must match the file naming conventions of the server. If this parameter is NULL or points to an empty string, the current working directory will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_LIST_DEFAULT	This option specifies the server should return a complete listing of files in the specified directory with as much detail as possible. This typically means that the file size, date, ownership and access rights will be returned to the client. Information about the files are returned in lines of text, with each line terminated by carriage return and linefeed (CRLF) characters. The exact format of the data returned is specific to the server operating system.
FTP_LIST_NAMEONLY	This option specifies the server should only return a list of file names, with no additional information about the file. Each file name is terminated by carriage return and linefeed (CRLF) characters.

lpszBuffer

A pointer to a string buffer that will contain the list of files when the function returns. This buffer should be large enough to store the complete file listing and a terminating null character. If the buffer is smaller than the total amount of data returned by the server, the data will be truncated. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the number of bytes copied into the string buffer, not including the terminating null character. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetFileList** function returns a list of files in the specified directory, copying the data to a string buffer. Unlike the other functions like **FtpEnumFiles** that parse a directory listing and return information in an **FTPFILESTATUS** structure, this function returns the unparsed file list data. The actual format of the data that is returned depends on the operating system and how the server implements file listings. For example, UNIX servers typically return the output from the **/bin/ls** command.

Some servers may not support file listings for any directory other than the current working directory. If an error is returned when specifying a directory name, try changing the current working directory using the **FtpChangeDirectory** function and then call this function again, passing NULL or an empty string as the *lpzDirectory* parameter.

This function can be particularly useful when the client is connected to a server that returns file listings in a format that is not recognized by the library. The application can retrieve the unparsed file listing from the server and parse the contents. Note that if you specify the **FTP_LIST_NAMEONLY** option, the data will only contain a list of file names and there will be no way for the application to know if they represent a regular file or a subdirectory.

This function is supported for both FTP and SFTP (SSH) connections, however the format of the data may differ depending on which protocol is used. Most UNIX based FTP servers will not list files and subdirectories that begin with a period, however most SFTP servers will return a list of all files, even those that begin with a period.

This function will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled.

Example

```
TCHAR szFileList[MAXFILELISTSIZE];

nResult = FtpGetFileList(hClient, NULL, FTP_LIST_NAMEONLY,
                        szFileList, MAXFILELISTSIZE);

if (nResult != FTP_ERROR)
    _tprintf(_T("%s\n"), szFileList);
else
{
    DWORD dwError = FtpGetLastError();
    _tprintf(_T("Unable to list files (error 0x%08lx)\n"), dwError);
    return;
}
```

Requirements

FtpGetFileNameEncoding Function

```
INT WINAPI FtpGetFileNameEncoding(  
    HCLIENT hClient  
);
```

The **FtpGetFileNameEncoding** function returns an identifier which specifies what type of encoding is being used when file names are sent to the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the type of encoding that is used. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Refer to the **FtpSetFileNameEncoding** function for a list of encoding types that are supported by the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

FtpGetFilePermissions Function

```
INT WINAPI FtpGetFilePermissions(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPDWORD lpdwPermissions  
);
```

The **FtpGetFilePermissions** function returns information about the access permissions for a specific file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string which contains the name of the file that the access permissions are to be returned for. The filename cannot contain any wildcard characters.

lpdwPermissions

A pointer to an unsigned integer which will contain the access permissions for the file when the function returns. The file permissions are represented as bit flags, and may be one or more of the following values:

Value	Description
FILE_OWNER_READ	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.
FILE_OWNER_WRITE	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_OWNER_EXECUTE	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_GROUP_READ	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.
FILE_GROUP_WRITE	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_GROUP_EXECUTE	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.

FILE_WORLD_READ	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.
FILE_WORLD_WRITE	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.
FILE_WORLD_EXECUTE	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.

Return Value

If the function succeeds, the return value is a result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the STAT command to retrieve information about the specified file. On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the function will fail and value pointed to by the *lpdwPermissions* parameter will be zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetFileSize Function

```
INT WINAPI FtpGetFileSize(  
    HCLIENT hClient,  
    LPCTSTR lpzFileName,  
    LPDWORD lpdwFileSize  
);
```

The **FtpGetFileSize** function returns the size of the specified file on the server.

Parameters

hClient

Handle to the client session.

lpzFileName

Points to a string that specifies the name of the remote file.

lpdwFileSize

Points to an unsigned integer that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the SIZE command to determine the length of the specified file. Not all servers implement this command, in which case the function call will fail, and the *lpdwFileSize* parameter will be set to zero.

Note that if the file on the server is a text file, it is possible that the value returned by this method will not match the size of the file when it is downloaded to the local system. This is because different operating systems use different sequences of characters to mark the end of a line of text, and when a file is transferred in text mode, the end of line character sequence is automatically converted to a carriage return-linefeed, which is the convention used by the Windows platform.

Some FTP servers will refuse to return the size of a file if the current file type is set to FILE_TYPE_ASCII because the size of a text file on the server may not accurately reflect what the size of the file will be on the local system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetFileSizeEx Function

```
INT WINAPI FtpGetFileSizeEx(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    ULARGE_INTEGER *lpuiFileSize  
);
```

The **FtpGetFileSizeEx** function returns the size of the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpuiFileSize

Points to a ULARGE_INTEGER structure that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the SIZE command to determine the length of the specified file. Not all servers implement this command, in which case the function call will fail, and the *lpdwFileSize* parameter will be set to zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetFileStatusEx](#), [FtpOpenDirectory](#)

FtpGetFileStatus Function

```
BOOL WINAPI FtpGetFileStatus(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPFTPFILESTATUS lpFileStatus  
);
```

The **FtpGetFileStatus** function returns information about a specific file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string which contains the name of the file that status information will be returned on. The file name cannot contain any wildcard characters.

lpFileStatus

A pointer to an [FTPFILESTATUS](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the STAT command to retrieve information about the specified file. Unlike the **FtpGetFirstFile** and **FtpGetNextFile** functions, which read through a file list returned on the data channel, this function reads the result of a command string. For applications that need information about a specific file, using this function can be considerably faster than iterating through all of the files in a given directory. Note that not all servers support using the command in this way.

On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the FTPFILESTATUS structure members will be empty strings and zero values.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetFileStatusEx Function

```
BOOL WINAPI FtpGetFileStatusEx(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPFTPFILESTATUSEX lpFileStatus  
);
```

The **FtpGetFileStatusEx** function returns information about a specific file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string which contains the name of the file that status information will be returned on. The file name cannot contain any wildcard characters.

lpFileStatus

A pointer to an [FTPFILESTATUSEX](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the STAT command to retrieve information about the specified file. Unlike the **FtpGetFirstFileEx** and **FtpGetNextFileEx** functions, which read through a file list returned on the data channel, this function reads the result of a command string. For applications that need information about a specific file, using this function can be considerably faster than iterating through all of the files in a given directory. Note that not all servers support using the command in this way.

On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the FTPFILESTATUSEX structure members will be empty strings and zero values.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetFileTime Function

```
INT WINAPI FtpGetFileTime(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPSYSTEMTIME lpFileTime,  
    BOOL bLocalize  
);
```

The **FtpGetFileTime** function returns the modification time for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileTime

Points to a [SYSTEMTIME](#) structure that will be set to the current modification time for the remote file.

bLocalize

A boolean flag which specifies if the file time is localized to the current timezone. If this value is non-zero, then the file time is adjusted to that the time is local to the current system. If this value is zero, the file time is returned in UTC time.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetFileTime** function can be used to determine the date and time that a file was last modified on the server. The time may either be localized to the current system, or it may be returned as UTC time. If you plan on changing the values returned in the SYSTEMTIME structure and then calling **FtpSetFileTime** function to modify the file time on the server, you should do not localize the time.

This function uses the MDTM command to determine the modification time of the specified file. If the server does not support this command, the function will attempt to use the STAT command to determine the file modification time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetFileType Function

```
INT WINAPI FtpGetFileType(  
    HCLIENT hClient,  
    UINT *lpnFileType  
);
```

The **FtpGetFileType** function returns the default file type for the current client session.

Parameters

hClient

Handle to the client session.

lpnFileType

A pointer to an unsigned integer that will identify the current file type. This parameter cannot be NULL. When the function returns it will contain one of the following values:

Value	Description
FILE_TYPE_AUTO	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the FtpRegisterFileType function.
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executables. If the type of file cannot be automatically determined, it will always be considered a binary file.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If this function is called when connected to an SFTP (SSH) server, the default file type will always be FILE_TYPE_IMAGE because SFTP does not differentiate between text files and binary files.

The **FtpSetFileType** function can be used to change the default file type. To determine the automatic file type for a specific file based on its extension or contents, use the **FtpGetAutoFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

FtpGetFirstFile Function

```
BOOL WINAPI FtpGetFirstFile(  
    HCLIENT hClient,  
    LPFTPFILESTATUS lpFileStatus  
);
```

The **FtpGetFirstFile** function returns the first file in the directory listing returned by the server after a call to the **FtpOpenDirectory** function.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an [FTPFILESTATUS](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This file list information returned by the server is cached by the library, allowing you to use this function to reposition back to the beginning of the file list.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)  
{  
    FTPFILESTATUS ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFile(hClient, &ftpFile);  
    while (bResult)  
    {  
        // The ftpFile structure contains information about the file  
        bResult = FtpGetNextFile(hClient, &ftpFile);  
    }  
  
    FtpCloseDirectory(hClient);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: csutils11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpCloseDirectory](#), [FtpGetDirectoryFormat](#), [FtpGetFileStatus](#), [FtpGetNextFile](#), [FtpOpenDirectory](#), [FtpSetDirectoryFormat](#)

FtpGetFirstFileEx Function

```
BOOL WINAPI FtpGetFirstFileEx(  
    HCLIENT hClient,  
    LPFTPFILESTATUSEX lpFileStatus  
);
```

The **FtpGetFirstFileEx** function returns the first file in the directory listing returned by the server after a call to the **FtpOpenDirectory** function. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an [FTPFILESTATUSEX](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This file list information returned by the server is cached by the library, allowing you to use this function to reposition back to the beginning of the file list.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)  
{  
    FTPFILESTATUSEX ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFileEx(hClient, &ftpFile);  
    while (bResult)  
    {  
        // The ftpFile structure contains information about the file  
        bResult = FtpGetNextFileEx(hClient, &ftpFile);  
    }  
  
    FtpCloseDirectory(hClient);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetFirstQueuedFile Function

```
DWORD WINAPI FtpGetFirstQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwQueueMode,  
    DWORD dwExcludeFiles,  
    LPFTPQUEUEDFILE lpFileInfo  
);
```

The **FtpGetFirstQueuedFile** function returns information about the first file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. It may be one of the following values:

Constant	Description
FTP_QUEUE_ALL	Return information about all files in the queue.
FTP_QUEUE_DOWNLOAD	Return information for files which are queued for download.
FTP_QUEUE_UPLOAD	Return information for files which are queued for upload.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the search. If this value is zero, no files will be excluded from the search; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_QUEUE_FLAG_NONE	No files should be excluded.
FTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
FTP_QUEUE_FLAG_FAILED	Exclude files which were not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.
FTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the FtpCancelQueuedFile function has been called and a queued file is in the process of being uploaded or downloaded.

lpFileInfo

A pointer to a [FTPQUEUEDFILE](#) structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is an unsigned integer with a non-zero value which uniquely identifies the file in the queue. If there are no queued files which match the specified parameters, or the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function returns information about the first file in the current transfer queue. It is used in conjunction with the **FtpGetNextQueuedFile** function to obtain information about all queued files.

Example

```
// List all files in a file transfer queue
FTPQUEUEDFILE queuedFile;
DWORD dwFileId;

dwFileId = FtpGetFirstQueuedFile(hQueue, FTP_QUEUE_ALL, FTP_QUEUE_FLAG_NONE,
&queuedFile);

while (dwFileId != 0)
{
    switch (queuedFile.dwQueueMode)
    {
    case FTP_QUEUE_DOWNLOAD:
        _tprintf(_T("%u: download \"%s\" to \"%s\"\n"),
            queuedFile.dwFileId,
            queuedFile.szRemoteFile,
            queuedFile.szLocalFile);
        break;

    case FTP_QUEUE_UPLOAD:
        _tprintf(_T("%u: upload \"%s\" to \"%s\"\n"),
            queuedFile.dwFileId,
            queuedFile.szRemoteFile,
            queuedFile.szLocalFile);
        break;
    }

    dwFileId = FtpGetNextQueuedFile(hQueue, &queuedFile);
}
```

FtpGetLastError Function

DWORD WINAPI FtpGetLastError();

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **FtpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **FtpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **FtpSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or FTP_ERROR. Those functions which call **FtpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

FtpGetMultipleFiles Function

```
INT WINAPI FtpGetMultipleFiles(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalDirectory,  
    LPCTSTR lpszRemoteDirectory,  
    LPCTSTR lpszFileMask,  
    DWORD dwReserved  
);
```

The **FtpGetMultipleFiles** function copies one or more files from the server to the local host, using the specified wildcard.

Parameters

hClient

Handle to the client session.

lpszLocalDirectory

Pointer to a string which specifies the local directory where the files will be copied to. A NULL pointer or empty string specifies that files should be copied to the current working directory.

lpszRemoteDirectory

Pointer to a string which specifies the remote directory where the files will be copied from. A NULL pointer or empty string specifies that the files should be copied from the current working directory on the server.

lpszFileMask

Pointer to a string which specifies the files that are to be copied from the server to the local system. The file mask should follow the native conventions used for wildcard file matches on the server.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetMultipleFiles** function is used to transfer files from the server to the local host which match a specified wildcard file mask. This function requires that the client be able to automatically list and parse directory listings from the server, otherwise an error will be returned. All files will be transferred using the current file type as specified by the **FtpSetFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetNextFile Function

```
BOOL WINAPI FtpGetNextFile(  
    HCLIENT hClient,  
    LPFTPFILESTATUS lpFileStatus  
);
```

The **FtpGetNextFile** function returns the next file in the directory listing returned by the server.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an [FTPFILESTATUS](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetNextFile** function returns the next file in the directory listing. If the last file has been returned, the function will return zero and the client should call the **FtpCloseDirectory** function to close the directory.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)  
{  
    FTPFILESTATUS ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFile(hClient, &ftpFile);  
    while (bResult)  
    {  
        // The ftpFile structure contains information about the file  
        bResult = FtpGetNextFile(hClient, &ftpFile);  
    }  
  
    FtpCloseDirectory(hClient);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetNextFileEx Function

```
BOOL WINAPI FtpGetNextFileEx(  
    HCLIENT hClient,  
    LPFTPFILESTATUSEX lpFileStatus  
);
```

The **FtpGetNextFileEx** function returns the next file in the directory listing returned by the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an [FTPFILESTATUSEX](#) structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetNextFileEx** function returns the next file in the directory listing. If the last file has been returned, the function will return zero and the client should call the **FtpCloseDirectory** function to close the directory.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)  
{  
    FTPFILESTATUSEX ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFileEx(hClient, &ftpFile);  
    while (bResult)  
    {  
        // The ftpFile structure contains information about the file  
        bResult = FtpGetNextFileEx(hClient, &ftpFile);  
    }  
  
    FtpCloseDirectory(hClient);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetNextQueuedFile Function

```
DWORD WINAPI FtpGetNextQueuedFile(  
    HQUEUE hQueue,  
    LPFTPQUEUEDFILE lpFileInfo  
);
```

The **FtpGetNextQueuedFile** function returns information about the next file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpFileInfo

A pointer to a [FTPQUEUEDFILE](#) structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is an unsigned integer with a non-zero value which uniquely identifies the file in the queue. If there are no additional queued files which match the exclusion criteria specified with the call to **FtpGetFirstQueuedFile**, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function returns information about the next file in the current transfer queue after an initial call to **FtpGetFirstQueuedFile**. To obtain a list of all matching files in the queue, call this function repeatedly until it returns a value of zero. When information about the last file in the queue has been returned, the last error code will be set to **ST_ERROR_END_OF_QUEUE**.

Example

```
// List all files in a file transfer queue  
FTPQUEUEDFILE queuedFile;  
DWORD dwFileId;  
  
dwFileId = FtpGetFirstQueuedFile(hQueue, FTP_QUEUE_ALL, FTP_QUEUE_FLAG_NONE,  
&queuedFile);  
  
while (dwFileId != 0)  
{  
    switch (queuedFile.dwQueueMode)  
    {  
        case FTP_QUEUE_DOWNLOAD:  
            _tprintf(_T("%u: download \"%s\" to \"%s\"\\n"),  
                    queuedFile.dwFileId,  
                    queuedFile.szRemoteFile,  
                    queuedFile.szLocalFile);  
            break;  
  
        case FTP_QUEUE_UPLOAD:  
            _tprintf(_T("%u: upload \"%s\" to \"%s\"\\n"),  
                    queuedFile.dwFileId,  
                    queuedFile.szRemoteFile,  
                    queuedFile.szLocalFile);  
            break;  
    }  
}
```

```
    dwFileId = FtpGetNextQueuedFile(hQueue, &queuedFile);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetQueuedFile](#)

FtpGetPriority Function

```
INT WINAPI FtpGetPriority(  
    HCLIENT hClient  
);
```

The **FtpGetPriority** function returns a value which specifies the priority of file transfers.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the current file transfer priority. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetPriority** function can be used to determine the current priority assigned to file transfers performed by the client. It may be one of the following values:

Value	Description
FTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpSetPriority](#)

FtpGetProxyType Function

```
INT WINAPI FtpGetProxyType(  
    HCLIENT hClient  
);
```

The **FtpGetProxyType** function returns the type of proxy that the client is connected to. By default, no proxy server is specified and this function returns a value of FTP_PROXY_NONE. For a list of possible proxy server types, refer to the **FtpProxyConnect** function.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value identifies the type of proxy that the client is connected to. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpConnect](#), [FtpProxyConnect](#)

FtpGetQueueClient Function

```
HCLIENT WINAPI FtpGetQueueClient(  
    HQUEUE hQueue  
);
```

The **FtpGetQueueClient** function returns a handle to the current client session.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, it will return `INVALID_CLIENT`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetQueueClient** function returns the handle to a client session which may be used with other functions, such as **FtpGetTransferStatus**. A valid handle will only be returned if the queue manager is currently uploading or downloading a file. If the queue is active but there are no file transfers in progress at the time this function is called, it will fail and set the last error code to `ST_ERROR_NO_QUEUED_TRANSFER`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftpv11.lib`

See Also

FtpGetQueuedFile Function

```
BOOL WINAPI FtpGetQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwFileId,  
    LPFTPQUEUEDFILE lpFileInfo  
);
```

The **FtpGetQueuedFile** function returns information about the specified file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. This value cannot be zero.

lpFileInfo

A pointer to a [FTPQUEUEDFILE](#) structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the file identifier is not valid or the file has been removed from the queue, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The file identifier can be obtained by several different functions, including **FtpEnumQueuedFiles** and **FtpGetQueueStatus**, which provides information about the current file being processed in the queue. Do not make any assumptions about the value of the identifier. Although the value is guaranteed to be unique for the specified queue, it is not guaranteed that file identifiers will be assigned in sequential order.

Example

```
// Get the number of files in the queue  
LONG nFiles = FtpEnumQueuedFiles(hQueue, NULL, 0)  
  
// Display information about the queued files  
if (nFiles > 0)  
{  
    DWORD *pdwFileList = new DWORD[nFiles];  
  
    nFiles = FtpEnumQueuedFiles(hQueue, pdwFileList, nFiles);  
  
    for (LONG nIndex = 0; nIndex < nFiles; nIndex++)  
    {  
        FTPQUEUEDFILE queuedFile;  
  
        if (FtpGetQueuedFile(hQueue, pdwFileList[nIndex], &queuedFile) == FALSE)  
            break;  
  
        switch (queuedFile.dwMode)  
        {  
            case FTP_QUEUE_DOWNLOAD:  
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\\n"),
```

```

        queuedFile.dwFileId,
        queuedFile.szRemoteFile,
        queuedFile.szLocalFile);
    break;

case FTP_QUEUE_UPLOAD:
    _tprintf(_T("%u: Upload \"%s\" to \"%s\"\\n"),
        queuedFile.dwFileId,
        queuedFile.szLocalFile,
        queuedFile.szRemoteFile);
    break;
}
}

delete pdwFileList;
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

[FtpAddQueuedFile](#), [FtpEnumQueuedFiles](#), [FtpFindQueuedFile](#), [FtpGetFirstQueuedFile](#),
[FtpGetNextQueuedFile](#), [FtpGetQueueStatus](#)

FtpGetQueueStatus Function

```
INT WINAPI FtpGetQueueStatus(  
    HQUEUE hQueue,  
    LPFTPQUEUESTATUS lpQueueStatus  
);
```

The **FtpGetQueuedFile** function returns information about the specified file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpQueueStatus

A pointer to a [FTPQUEUESTATUS](#) structure which will contain information about the current state of the file transfer queue. If this parameter is NULL, the function will ignore the parameter and only return the current status of the queue.

Return Value

If the function succeeds, the return value is the current queue status. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**. The following status values may be returned:

Value	Description
FTP_QUEUE_STATUS_IDLE	The file transfer queue is idle and no files are being uploaded or downloaded. This state is returned before FtpStartQueue has been called or after FtpStopQueue has been called. The queue will also automatically enter an idle state after the last file transfer has completed and the queue manager thread exits.
FTP_QUEUE_STATUS_ACTIVE	The queue manager is active and files are currently being uploaded or downloaded.
FTP_QUEUE_STATUS_PAUSED	The queue manager is active although file transfers are currently paused. The queue enters this state after the FtpSuspendQueue function is called and resumes file transfers after the FtpResumeQueue function is called.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
- Minimum Server Platform:** Windows Server 2008 R2 Service Pack 1
- Header File:** cstdlib11.h
- Import Library:** csftpv11.lib

See Also

[FtpCancelQueuedFile](#), [FtpResetQueue](#), [FtpResumeQueue](#), [FtpStartQueue](#), [FtpSuspendQueue](#), [FtpStopQueue](#)

FtpGetQueueThread Function

```
DWORD WINAPI FtpGetQueueThread(  
    HQUEUE hQueue  
);
```

The **FtpGetQueueThread** function returns a value which uniquely identifies the queue manager thread.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero and specifies a unique identifier for the queue manager thread. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetQueueThread** function can be used to obtain a unique identifier for the queue manager thread which is responsible for performing the file transfers. If the function returns zero, this indicates that either the queue handle is no longer valid, or the queue is idle and no files are currently being processed. To obtain the handle to a queue associated with a particular thread, call the **FtpGetThreadQueue** function.

You should not store the thread ID or consider it a persistent value, even during the lifetime of the process. It is only valid while the queue manager is actively processing files in the queue. The thread ID value will change every time the **FtpStartQueue** function is called.

Never use the thread ID to obtain a handle to the thread and call Windows API functions such as **SuspendThread** or **TerminateThread**. This can result in inconsistency within the internal state of the queue manager and may result in incomplete or corrupted file transfers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

FtpGetResultCode Function

```
INT WINAPI FtpGetResultCode(  
    HCLIENT hClient  
);
```

The **FtpGetResultCode** function reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

hClient
Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
- Minimum Server Platform:** Windows Server 2008 R2 Service Pack 1
- Header File:** cstdlib11.h
- Import Library:** csftpv11.lib

[FtpCommand](#), [FtpGetResultString](#)

FtpGetResultString Function

```
INT WINAPI FtpGetResultString(  
    HCLIENT hClient,  
    LPTSTR lpszResult,  
    INT cbResult  
);
```

The **FtpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

A pointer to the buffer that will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server.

If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **FtpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

FtpGetSecurityInformation Function

```
BOOL WINAPI FtpGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **FtpGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;  
  
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (FtpGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpConnect](#), [FtpCreateSecurityCredentials](#), [FtpDeleteSecurityCredentials](#), [FtpDisconnect](#),
[FtpProxyConnect](#), [SECURITYINFO](#)

FtpGetServerInformation Function

```
INT WINAPI FtpGetServerInformation(  
    HCLIENT hClient,  
    LPTSTR lpszSystemInfo,  
    INT nMaxLength  
);
```

The **FtpGetServerInformation** function returns information about the server, typically including the operating system type, version and platform.

Parameters

- hClient**
Handle to the client session.
- lpszSystemInfo**
A pointer to the buffer that will contain the system information returned by the server.
- nMaxLength**
The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SYST command to the server. The first word will identify the type of operating system. The format for the remaining information depends on the server type. Typically it is a description of the operating system version and hardware platform. For example, here are some strings commonly returned by various FTP servers:

Example	Description
UNIX Type: L8	A standard UNIX based server. This is the most common value returned by servers, and this indicates that the server supports UNIX file naming and directory listing conventions. This string may also include additional information such as the specific variant of UNIX and its version. The L8 portion of the string is a convention that lets the client know that a byte consists of 8 bits.
Windows_NT Version 5.0	A standard Windows based server, typically part of Internet Information Services (ISS). The server will use Windows file naming and directory listing conventions. The version identifies the specific release of Windows. For example, version 4.0 specifies Windows NT 4.0 and 5.0 specifies Windows 2000.
VMS V7.1 AlphaServer	A server running the VMS operating system. The server will use the standard file naming and directory listing conventions for that platform. Note that it is possible that a VMS system may also be configured to operate in a UNIX emulation mode, in which case it will return UNIX instead of VMS.
NetWare	A server running the NetWare operating system. The server will use the

system type	standard file naming and directory listing conventions for that platform. Note that it is possible that a NetWare system may be configured to operate in a UNIX emulation mode, in which case it return UNIX instead of NetWare.
WORLDGROUP Type: L8	A server running the WorldGroup software on the Windows platform. This server supports UNIX file naming and directory listing conventions. WorldGroup is a collaborative workgroup, email and file sharing service which includes an FTP server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetServerStatus Function

```
INT WINAPI FtpGetServerStatus(  
    HCLIENT hClient,  
    LPTSTR lpszStatus,  
    INT nMaxLength  
);
```

The **FtpGetServerStatus** function requests that the server return status information about itself.

Parameters

hClient

Handle to the client session.

lpszStatus

A pointer to the buffer that will contain the system status returned by the server.

nMaxLength

The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the STAT command to the server. The format for the information returned depends on the server type. Typically it is a description of the server platform, version, current user and file transfer options.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpGetServerInformation](#), [FtpGetServerType](#)

FtpGetServerTimeZone Function

```
INT WINAPI FtpGetServerTimeZone(  
    HCLIENT hClient,  
    LPLONG lpnTimeZone  
);
```

The **FtpGetServerTimeZone** function returns the timezone for the current server.

Parameters

hClient

Handle to the client session.

lpnTimeZone

A pointer to a signed long integer which will contain the timezone offset in seconds.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SITE ZONE command to the server to determine its timezone. The value returned is expressed as the number of seconds offset from Coordinated Universal Time (UTC). A positive value specifies a time west of UTC, while a negative value specifies a time east of UTC. For example, a value of 28800 would specify an offset of 8 hours west of UTC, which is the Pacific timezone.

The SIZE ZONE command is an extension that is not supported by all servers. If the server timezone cannot be determined, the function will fail and the value pointed to by the *lpnTimeZone* parameter will be zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

FtpGetServerType Function

```
INT WINAPI FtpGetServerType(  
    HCLIENT hClient  
);
```

The **FtpGetServerType** function returns the type of server the client has connected to.

Parameters

hClient
Handle to the client session.

Return Value

If the function succeeds, the return value is a numeric value which indicates the server type. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SYST command to the server to determine the server type. The following server types are recognized by the library:

Value	Description
FTP_SERVER_UNKNOWN	The server type could not be determined by issuing the SYST command. The server may not support the command, or the command may only be allowed when issued by an authenticated user.
FTP_SERVER_UNIX	The server is running on a UNIX based operating system. This can include Linux and other variants, as well as operating systems which emulate UNIX style file pathing and directory listings.
FTP_SERVER_MSDOS	The server is running on an MS-DOS based operating system. The server expects file pathing and naming conventions according to the standard MS-DOS format and returns directory listings similar to the output of the DIR command.
FTP_SERVER_WINDOWS	The server is running on a Windows based operating system. The server expects file pathing and naming conventions according to the standard Windows long filename format, and returns directory listings similar to the output of the DIR command. Note that Windows servers may be configured to return file and directory information in a format similar to UNIX systems, in which case the system may be identified as UNIX even though it is actually running on a Windows platform.
FTP_SERVER_VMS	The server is running on a DEC VMS based operating system. The server expects file pathing and naming conventions specific to that operating system. Note that VMS servers may be configured to return file and directory information in a format similar to UNIX systems, in which case the system may be identified as UNIX even though it is actually running on a VMS platform.

FTP_SERVER_NETWARE	The server is running on a NetWare based operating system. The server expects file pathing and naming conventions similar to the standard Windows long filename format, and returns directory listings that are similar to UNIX systems with the exception of the access and permissions flags for the file. Note that a NetWare system may return listings in different formats based on the filesystem and site specific options specified.
FTP_SERVER_OTHER	The server type was not recognized. An attempt will be made to automatically determine the correct file pathing and naming conventions used by the server. To obtain a list of files on the server, it may be necessary to use the FtpSetDirectoryFormat function to specify the directory listing format.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

FtpGetStatus Function

```
INT WINAPI FtpGetStatus(  
    HCLIENT hClient  
);
```

The **FtpGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
FTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
FTP_STATUS_CONNECT	The client is establishing a connection with the server.
FTP_STATUS_READ	The client is reading data from the server.
FTP_STATUS_WRITE	The client is writing data to the server.
FTP_STATUS_DISCONNECT	The client is disconnecting from the server.
FTP_STATUS_OPENFILE	The client is opening a data connection to the server.
FTP_STATUS_CLOSEFILE	The client is closing the data connection to the server.
FTP_STATUS_GETFILE	The client is downloading a file from the server.
FTP_STATUS_PUTFILE	The client is uploading a file to the server.
FTP_STATUS_FILELIST	The client is retrieving a file listing from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session. To obtain status information about a file transfer, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpGetTaskError Function

```
DWORD WINAPI FtpGetTaskError(  
    UINT nTaskId  
);
```

Return the last error code for the specified asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed successfully, this function returns a value of zero. A non-zero return value indicates an error has occurred.

Remarks

The **FtpGetTaskError** function returns the last error code associated with the specified asynchronous task. If the task completed successfully, the return value will be zero. If the task is still active, the function will return the error ST_ERROR_TASK_ACTIVE. If the task has been suspended, the function will return ST_ERROR_TASK_SUSPENDED. Any other value indicates that the task completed, but the operation has failed and the error code will specify the cause of the failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpTaskAbort](#), [FtpTaskResume](#), [FtpTaskSuspend](#), [FtpTaskWait](#)

FtpGetTaskId Function

```
UINT WINAPI FtpGetTaskId(  
    HCLIENT hClient  
);
```

Return the asynchronous task identifier associated with the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the client handle is not associated with an asynchronous task, the function will return a value of zero.

Remarks

The **FtpGetTaskId** function will return the task ID that is associated with a client session. This is a unique unsigned integer value that references the worker thread that was created to manage the asynchronous client session. This function should only be called within an event handler that is invoked by a background task that has been started using a function such as **FtpAsyncGetFile**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

FtpGetText Function

```
INT WINAPI FtpGetText(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **FtpGetText** function copies the contents of a text file on the server to the specified string buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies a text file on the server. The file pathing and naming conventions must be that of the host operating system.

lpszBuffer

A pointer to a string buffer which will contain the contents of the text file when the function returns. This buffer should be large enough to store the contents of the file, including a terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. This value must be larger than zero. If this value is smaller than the actual size of the text file, the data returned will be truncated.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetText** function is used to download a text file and store the contents in a string buffer. This function will always set the file type to FILE_TYPE_ASCII before downloading the file, and will restore the default file type before the method returns. Because binary files can include embedded null characters, this function should only be used with known text files.

This function has been included as a convenience for applications that need to retrieve relatively small text files and manipulate the contents as a string. If the Unicode version of this function is called, the contents of the text file is automatically converted to a Unicode string. If the size of the file is unknown or the text file is very large, it is recommended that you use the **FtpGetData** or **FtpGetFile** functions.

If you use the **FtpGetFileSize** function to determine how large the string buffer should be prior to calling this function, it is important to be aware that the actual number of characters may differ based on the end-of-line conventions used by the host operating system. For example, if you call **FtpGetFileSize** to obtain the size of a text file on a UNIX system, the value will not be large enough to store the complete file because UNIX uses a single linefeed (LF) character to indicate the end-of-line, while a Windows system will use a carriage-return and linefeed (CRLF) pair. To accommodate this difference, you should always allocate extra memory for the string buffer to store the additional end-of-line characters.

FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user

interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Example

```
LPTSTR lpszBuffer = (LPTSTR)calloc(MAXFILESIZE, sizeof(TCHAR));

if (lpszBuffer == NULL)
    return;

nResult = FtpGetText(hClient, lpszRemoteFile, lpszBuffer, MAXFILESIZE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetThreadQueue Function

```
HQUEUE WINAPI FtpGetThreadQueue(  
    DWORD dwThreadId  
);
```

The **FtpGetThreadQueue** function returns a handle to the queue associated with the specified thread.

Parameters

dwThreadId

An unsigned integer value which specifies a unique identifier for the queue manager thread. If this value is zero, it will return the handle associated with the current thread.

Return Value

If the function succeeds, the return value is the handle to the queue. If the function fails, it will return INVALID_QUEUE. To get extended error information, call **FtpGetLastError**.

Remarks

All queued file transfers are handled by a queue manager which executes asynchronously in a background worker thread. This worker thread is created when the **FtpStartQueue** function is called and terminates when all files in the queue have been processed, or when the **FtpStopQueue** function is called. This function will return the queue handle associated with that worker thread.

The most common use of this function would be to obtain the handle for the queue from within a queue event handler. The application would pass in a value of zero as the thread ID and the function will return the handle to the queue which invoked the event notification.

If you call this function outside of an event handler and the *dwThreadId* parameter is zero, or if the queue is idle and not transferring files, this function will return INVALID_QUEUE. The thread ID is only valid while the queue manager is actively processing files in the queue.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpGetQueueStatus](#), [FtpGetQueueThread](#), [FtpStartQueue](#), [FtpStopQueue](#)

FtpGetTimeout Function

```
INT WINAPI FtpGetTimeout(  
    HCLIENT hClient  
);
```

The **FtpGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

[FtpConnect](#), [FtpIsReadable](#), [FtpIsWritable](#), [FtpProxyConnect](#), [FtpRead](#), [FtpSetTimeout](#), [FtpWrite](#)

FtpGetTransferStatus Function

```
INT WINAPI FtpGetTransferStatus(  
    HCLIENT hClient,  
    LPFTPTRANSFERSTATUS lpStatus  
);
```

The **FtpGetTransferStatus** function returns information about the current file transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an **FTPTRANSFERSTATUS** structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetTransferStatus** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option FTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the **FTPTRANSFERSTATUS** structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small files over a fast network connection.

If you are uploading or downloading large files which exceed 4GB, you should use the **FtpGetTransferStatusEx** function which returns the size as a 64-bit value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetTransferStatusEx Function

```
INT WINAPI FtpGetTransferStatusEx(  
    HCLIENT hClient,  
    LPFTPTRANSFERSTATUS lpStatus  
);
```

The **FtpGetTransferStatusEx** function returns information about the current file transfer in progress. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [FTPTRANSFERSTATUSEX](#) structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `FTP_ERROR`. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetTransferStatusEx** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option `FTP_OPTION_HIRES_TIMER` has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the **FTPTRANSFERSTATUSEX** structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small files over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftpv11.lib`

Unicode: Implemented as Unicode and ANSI versions

See Also

FtpInitialize Function

```
BOOL WINAPI FtpInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **FtpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **FtpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **FtpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **FtpInitialize** or **FtpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpConnect](#), [FtpDisconnect](#), [FtpUninitialize](#)

FtpIsBlocking Function

```
BOOL WINAPI FtpIsBlocking(  
    HCLIENT hClient  
);
```

The **FtpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **FtpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

[FtpCancel](#), [FtpGetStatus](#), [FtpIsConnected](#), [FtpIsReadable](#), [FtpIsWritable](#), [FtpRead](#), [FtpWrite](#)

FtpIsConnected Function

```
BOOL WINAPI FtpIsConnected(  
    HCLIENT hClient  
);
```

The **FtpIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

[FtpGetStatus](#), [FtpIsBlocking](#), [FtpIsReadable](#), [FtpIsWritable](#)

FtpIsReadable Function

```
BOOL WINAPI FtpIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **FtpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpGetStatus](#), [FtpIsBlocking](#), [FtpIsConnected](#), [FtpIsWritable](#), [FtpRead](#)

FtpIsWritable Function

```
BOOL WINAPI FtpIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **FtpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpGetStatus](#), [FtpIsBlocking](#), [FtpIsConnected](#), [FtpIsReadable](#), [FtpWrite](#)

FtpLogin Function

```
INT WINAPI FtpLogin(  
    HCLIENT hClient,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszAccount  
);
```

The **FtpLogin** function authenticates the specified user in on the server. This function must be called after the connection has been established, and before attempting to transfer files or perform any other function on the server.

Parameters

hClient

Handle to the client session.

lpszUserName

Points to a string that specifies the user name to be used to authenticate the current client session. If this parameter is NULL or an empty string, then the login is considered to be anonymous.

lpszPassword

Points to a string that specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

lpszAccount

Points to a string that specifies the account name to be used to authenticate the current client session. This parameter may be NULL or an empty string if no account name is required for the specified user.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Some public FTP servers support anonymous logins, where a username and password are not required to access the server. In this case, both the *lpszUserName* and *lpszPassword* parameters can be NULL or specify empty strings. In most cases, access to the server using an anonymous login is restricted, with clients only having permission to download files. Servers may also restrict the maximum number of anonymous sessions that may be logged in at one time.

This function should only be used after calling the **FtpLogout** function, enabling you to log in as another user during the same session. Not all servers will permit a client to change user credentials during the same session. In most cases, it is preferable to disconnect from the server and re-connect using the new credentials rather than using this function.

This function is not supported with secure connections using the SSH protocol.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpConnect](#), [FtpLogout](#), [FtpProxyConnect](#)

FtpLogout Function

```
INT WINAPI FtpLogout(  
    HCLIENT hClient  
);
```

The **FtpLogout** function logs out the user associated with the current client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpLogout** function is used when the client wants to re-authenticate using a new username and password. Before any further action may be taken, other than disconnecting from the server, the **FtpLogin** function must be called to re-authenticate the client.

It is not necessary to call this function prior to disconnecting from the server because the user current user is automatically logged out when the **FtpDisconnect** function is called.

This function is not supported with secure connections using the SSH protocol.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

FtpMountStructure Function

```
INT WINAPI FtpMountStructure(  
    HCLIENT hClient,  
    LPCTSTR lpszFileSystem  
);
```

The **FtpMountStructure** function mounts a different file system or other directory data structure on the server.

Parameters

hClient

Handle to the client session.

lpszFileSystem

A pointer to a string which specifies the file system to mount on the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SMNT command to the server, which may not be supported on some platforms. Use of this command typically requires that the user have administrator privileges on the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpCreateDirectory](#), [FtpRemoveDirectory](#)

FtpOpenDirectory Function

```
INT WINAPI FtpOpenDirectory(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory  
);
```

The **FtpOpenDirectory** function opens the specified directory on the server.

Parameters

hClient

Handle to the client session.

lpszDirectory

Pointer to the name of the directory that will be opened. The format of the directory name must match the filename conventions used by the server. If a NULL pointer or an empty string is specified, then the current working directory is opened.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpOpenDirectory** function opens the specified directory on the server using the LIST command. The contents of the directory can be read using the **FtpGetFirstFile** and **FtpGetNextFile** functions. The directory listing is returned on the data channel in one of several different formats. The library can recognize listing formats generated by UNIX, VMS and Windows servers, as well as those of other servers which emulate one of those common formats. Once the complete directory listing has been read, the directory must be closed by calling the **FtpCloseDirectory** function.

Because the directory listing is returned on the data channel, a file transfer cannot be performed while the directory is in the process of being read by the client. Applications which need to collect a list of files to download should first open the directory, read the contents and store the file names in an array. After the directory has been closed, the application can then start transferring the files to the local system.

Some servers may not support file listings for any directory other than the current working directory. If an error is returned when specifying a directory name, try changing the current working directory using the **FtpChangeDirectory** function and then call this function again, passing NULL or an empty string as the *lpszDirectory* parameter.

To obtain a list of all files in a directory using a single function call, use the **FtpEnumFiles** function. If the server lists files in a format that is not recognized by the library, the **FtpGetFileList** function can be used to obtain an unparsed file listing from the server.

Example

```
if (FtpOpenDirectory(hClient, NULL) != FTP_ERROR)  
{  
    FTPFILESTATUS ftpFile;  
    BOOL bResult;  
  
    bResult = FtpGetFirstFile(hClient, &ftpFile);  
    while (bResult)  
    {
```

```
        // The ftpFile structure contains information about the file
        bResult = FtpGetNextFile(hClient, &ftpFile);
    }

    FtpCloseDirectory(hClient);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

FtpOpenFile Function

```
INT WINAPI FtpOpenFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    DWORD dwOpenMode,  
    DWORD dwOffset  
);
```

The **FtpOpenFile** function creates or opens the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to create or open. The file pathing and name conventions must be that of the server.

dwOpenMode

Specifies the type of access to the file. An application can open a file for reading, create a new file or append data to an existing file. This parameter should be one of the following values.

Value	Description
FTP_FILE_READ	The file is opened for reading on the server. A data channel is created and the contents of the file are returned to the client.
FTP_FILE_WRITE	The file is opened for writing on the server. If the file does not exist, it will be created. If it does exist, it will be overwritten.
FTP_FILE_APPEND	The file is opened for writing on the server. All data will be appended to the end of the file.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset using FTP requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Attempting to perform an action such as uploading or downloading another file while a file is currently open will result in an error. Typically this indicates that the application failed to call the **FtpCloseFile** function.

It is strongly recommended that most applications use the **FtpGetFile** or **FtpPutFile** functions to perform file transfers. These functions are easier to use, and have internal optimizations that improves the overall data transfer rate when compared to implementing the file transfer code in your own application.

When a file is created on the server, the file ownership and access rights are determined by the server.

Some servers may provide a method to change these attributes through site-specific commands. Refer to the server's operating system documentation for more information about what commands may be available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

FtpOpenFileEx Function

```
INT WINAPI FtpOpenFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    DWORD dwOpenMode,  
    DWORD dwReserved,  
    ULARGE_INTEGER uiOffset  
);
```

The **FtpOpenFileEx** function creates or opens the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to create or open. The file pathing and name conventions must be that of the server.

dwOpenMode

Specifies the type of access to the file. An application can open a file for reading, create a new file or append data to an existing file. This parameter should be one of the following values.

Value	Description
FTP_FILE_READ	The file is opened for reading on the server. A data channel is created and the contents of the file are returned to the client.
FTP_FILE_WRITE	The file is opened for writing on the server. If the file does not exist, it will be created. If it does exist, it will be overwritten.
FTP_FILE_APPEND	The file is opened for writing on the server. All data will be appended to the end of the file.

dwReserved

An unsigned integer value that is reserved for future use. This parameter should always have a value of zero.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset using FTP requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Attempting to perform an action such as uploading or downloading another file while a file is currently open will result in an error. Typically this indicates that the application failed to call the **FtpCloseFile** function.

It is strongly recommended that most applications use the **FtpGetFileEx** or **FtpPutFileEx** functions to perform file transfers. These functions are easier to use, and have internal optimizations that improves the overall data transfer rate when compared to implementing the file transfer code in your own application.

When a file is created on the server, the file ownership and access rights are determined by the server. Some servers may provide a method to change these attributes through site-specific commands. Refer to the server's operating system documentation for more information about what commands may be available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpProxyConnect Function

```
HCLIENT WINAPI FtpProxyConnect(  
    UINT nProxyType,  
    LPCTSTR lpszProxyHost,  
    UINT nProxyPort,  
    LPCTSTR lpszProxyUser,  
    LPCTSTR lpszProxyPassword,  
    LPCTSTR lpszRemoteHost,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **FtpProxyConnect** function establishes a connection through a proxy server.

Parameters

nProxyType

An identifier which specifies the type of proxy server that is being connected to. This value must be defined as one of the following values:

Value	Description
FTP_PROXY_NONE	This value specifies that no proxy server is being used. In this case, the FtpConnect function is called directly, ignoring the proxy parameters.
FTP_PROXY_USER	This value specifies that the client is not logged into the proxy server. The USER command is sent in the format username@ftpsite followed by the password. This is the format used with the Gauntlet proxy server.
FTP_PROXY_LOGIN	This value specifies that the client is logged into the proxy server. The USER command is then sent in the format username@ftpsite followed by the password. This is the format used by the InterLock proxy server.
FTP_PROXY_OPEN	This value specifies that the client is not logged into the proxy server. The OPEN command is sent specifying the host name, followed by the username and password.
FTP_PROXY_SITE	This value specifies that the client is logged into the server. The SITE command is sent, specifying the host name, followed by the username and the password.
FTP_PROXY_OTHER	This special proxy type specifies that another, undefined proxy server is being used. The client connects to the proxy host, but does not attempt to authenticate the client. The application is responsible for negotiating with the proxy server, typically using the FtpCommand function to send specific command sequences.

lpszProxyHost

A pointer to the name of the proxy server to connect through; this may be a fully-qualified domain name or an IP address.

nProxyPort

The port number the proxy server is listening on; a value of zero specifies that the default port number should be used.

lpszProxyUser

A pointer to the user name used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a username is required.

lpszProxyPassword

A pointer to the password used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a password is required.

lpszRemoteHost

A pointer to the name of the server that you want to connect to, through the proxy server.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require

	<p>authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.</p>
FTP_OPTION_KEEPALIVE	<p>This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.</p>
FTP_OPTION_VIRTUALHOST	<p>This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.</p>
FTP_OPTION_VERIFY	<p>This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.</p>
FTP_OPTION_TRUSTEDSITE	<p>This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.</p>
FTP_OPTION_SECURE	<p>This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.</p>
FTP_OPTION_SECURE_IMPLICIT	<p>This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to</p>

	a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller

	files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members *dwSize*, *lpzCertStore* and *lpzCertName* must be defined. Undefined structure members must be initialized to a value of zero or NULL and the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **FtpProxyConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The username and password that is used to authenticate the client with the proxy server are not the same as those used to login to the target server. Once a connection has been established with the proxy server, the client must call the **FtpLogin** function to actually login to the server and begin a file transfer.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit TLS session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it.

From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpPutData Function

```
INT WINAPI FtpPutData(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPVOID lpvBuffer,  
    DWORD dwLength,  
    DWORD dwReserved  
);
```

The **FtpPutData** function transfers the contents of the specified buffer to a file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to the data that will be copied to the server and stored in the specified file.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If the *lpvBuffer* parameter is pointing to a Unicode string, it is important to note that the value of the *dwLength* parameter should specify the number of bytes, not the number of characters. When using UTF-16, each character is two bytes long and therefore the length of the buffer is effectively double the length of the string. Because Unicode strings can contain null characters, you must also set the current file type to FILE_TYPE_IMAGE prior to calling this function.

The **FtpPutText** function can be used to create a text file from the contents of a string.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpChangeDirectory](#), [FtpEnableEvents](#), [FtpGetData](#), [FtpGetFile](#), [FtpGetTransferStatus](#), [FtpPutFile](#),
[FtpRegisterEvent](#), [FtpSetBufferSize](#)

FtpPutFile Function

```
INT WINAPI FtpPutFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset  
);
```

The **FtpPutFile** function transfers the specified file on the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpGetTransferStatus](#), [FtpPutData](#), [FtpPutMultipleFiles](#), [FtpRegisterEvent](#), [FtpSetBufferSize](#), [FtpVerifyFile](#)

FtpPutFileEx Function

```
INT WINAPI FtpPutFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset  
);
```

The **FtpPutFileEx** function transfers the specified file on the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

- hClient***
Handle to the client session.
- lpszLocalFile***
A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.
- lpszRemoteFile***
A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.
- dwOptions***
An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

- uiOffset***
A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent**

function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpChangeDirectory](#), [FtpEnableEvents](#), [FtpGetData](#), [FtpGetFileEx](#), [FtpGetMultipleFiles](#), [FtpGetTransferStatusEx](#), [FtpPutData](#), [FtpPutMultipleFiles](#), [FtpRegisterEvent](#), [FtpSetBufferSize](#), [FtpVerifyFile](#)

FtpPutMultipleFiles Function

```
INT WINAPI FtpPutMultipleFiles(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalDirectory,  
    LPCTSTR lpszRemoteDirectory,  
    LPCTSTR lpszFileMask,  
    DWORD dwReserved  
);
```

The **FtpPutMultipleFiles** function copies one or more files from the local host to the server, using the specified wildcard.

Parameters

hClient

Handle to the client session.

lpszLocalDirectory

Pointer to a string which specifies the local directory where the files will be copied from. A NULL pointer or empty string specifies that files should be copied from the current working directory.

lpszRemoteDirectory

Pointer to a string which specifies the remote directory where the files will be copied to. A NULL pointer or empty string specifies that the files should be copied to the current working directory on the server.

lpszFileMask

Pointer to a string which specifies the files that are to be copied from the local system to the server. The file mask should follow the Windows conventions used for wildcard file matches.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpPutMultipleFiles** function is used to transfer files from the local host to the server which match a specified wildcard file mask. All files will be transferred using the current file type as specified by the **FtpSetFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpChangeDirectory](#), [FtpGetFile](#), [FtpGetMultipleFiles](#), [FtpPutFile](#)

FtpPutText Function

```
INT WINAPI FtpPutText(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPCTSTR lpszBuffer  
);
```

The **FtpPutText** function creates a text file on the server using the contents of a string buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies the text file on the server that will be created or overwritten. The file pathing and name conventions must be that of the server.

lpszBuffer

A pointer to a string that contains the text that will be stored in the file.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpPutText** function is used to create a text file on the server from the contents of a string. If the specified file already exists on the server, its contents will be overwritten. This function will always set the file type to FILE_TYPE_ASCII before creating the file, and will restore the default file type before the method returns.

If the Unicode version of this function is called, the string will be converted to UTF-8 and then uploaded to the server. If you wish to store the contents of the string as UTF-16 Unicode on the server, you must set the current file type to FILE_TYPE_IMAGE and use the **FtpPutData** function. This function should never be used to upload binary data.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpChangeDirectory](#), [FtpEnableEvents](#), [FtpGetText](#), [FtpGetTransferStatus](#), [FtpPutData](#), [FtpPutFile](#),

FtpRead Function

```
INT WINAPI FtpRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **FtpRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

When **FtpRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpEnableEvents](#), [FtpGetData](#), [FtpGetFile](#), [FtpIsBlocking](#), [FtpIsReadable](#), [FtpIsWritable](#), [FtpRegisterEvent](#), [FtpWrite](#)

FtpRegisterEvent Function

```
INT WINAPI FtpRegisterEvent(  
    HCLIENT hClient,  
    UINT nEventId,  
    FTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **FtpRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
FTP_EVENT_CONNECT	The control connection to the server has completed.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be

	used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event is generated when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event is generated when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.
FTP_EVENT_QUEUE	This event is generated during a queued file transfer. It only occurs when a file is being transferred using the queue management APIs and the internal state of the queue has changed. The handle passed to this event will be a handle to the queue, not a client connection to the server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpRegisterEvent** function associates a callback function with a specific event. The event handler is an **FtpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a file is being uploaded or downloaded. The FTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one FTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

FtpRegisterFileType Function

```
BOOL WINAPI FtpRegisterFileType(  
    HCLIENT hClient,  
    LPCTSTR lpszExtension,  
    UINT nFileType  
);
```

The **FtpRegisterFileType** function associates a file name extension with a specific file type.

Parameters

hClient

Handle to the client session. If this parameter is `INVALID_CLIENT`, the file type is registered for all client sessions in the current process. If the parameter specifies a valid client session, then the association is made only for that specific session.

lpszExtension

A pointer to a null terminated string which specifies the file name extension. If this parameter is `NULL` or points to an empty string, the default file type will be changed for the client session.

nFileType

Specifies the type of file associated with the file extension. This parameter can be one of the following values.

Value	Description
<code>FILE_TYPE_ASCII</code>	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
<code>FILE_TYPE_EBCDIC</code>	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server.
<code>FILE_TYPE_IMAGE</code>	The file is a binary image and no data conversion of any type is performed on the file. This is typically the default file type for data file transfers. If the type of file that is being transferred is unknown, this file type should always be used.

Return Value

If the function succeeds, the return value non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpRegisterFileType** function is used to associate specific file types with file name extensions. The library has an internal list of standard text file extensions which it automatically recognizes. This method can be used to extend or modify that list for the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpRemoveDirectory Function

```
INT WINAPI FtpRemoveDirectory(  
    HCLIENT hClient,  
    LPCTSTR lpszDirectory  
);
```

The **FtpRemoveDirectory** function removes the specified directory on the server.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a string that specifies the name of the directory. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the RMD command to create the directory. The user must have the appropriate permission to remove the specified directory. Most servers will not permit you to remove a directory if it contains one or more files.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpRemoveQueuedFile Function

```
BOOL WINAPI FtpRemoveQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwFileId  
);
```

The **FtpRemoveQueuedFile** removes the specified file from the queue.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. This value cannot be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

Files can only be removed from the queue when in an idle or paused state. If you attempt to remove a file while the queue manager is in the process of uploading or download files, the function will fail.

The file identifier can be obtained by several different functions, including **FtpEnumQueuedFiles** and **FtpGetQueueStatus**, which provides information about the current file being processed in the queue. Do not make any assumptions about the value of the identifier. Although the value is guaranteed to be unique for the specified queue, it is not guaranteed that file identifiers will be assigned in sequential order.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

FtpRenameFile Function

```
INT WINAPI FtpRenameFile(  
    HCLIENT hClient,  
    LPCTSTR lpszOldFileName,  
    LPCTSTR lpszNewFileName  
);
```

The **FtpRenameFile** function renames or moves the specified file on the server. The original file must exist and the current user must have the appropriate permissions to change the file name.

Parameters

hClient

Handle to the client session.

lpszOldFileName

A null-terminated string which specifies the name of the remote file to rename or move. This parameter cannot be NULL or a zero-length string and the file must exist on the server. The file path and name must match the conventions used on the server.

lpszNewFileName

A null-terminated string which specifies the new name for the file. This parameter cannot be NULL or a zero-length string. The file path and name must match the conventions used on the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If the *lpszNewFileName* parameter specifies a file which already exists on the server, the contents of that file will be deleted and replaced by the contents of the file specified by *lpszOldFileName*. If you want to prevent this from occurring, your application can check if a file with the new name exists by calling the **FtpGetFileStatus** function. If successful, you can warn the user the rename operation would delete the contents of the new file as a consequence of renaming the original file.

If the connection was established using the standard FTP or FTPS protocols, this function causes two separate commands to be sent to the server, RNFR and RNT0. If either command fails, the function will fail and return an error code. If the connection was established using SFTP (SSH) the client will request the server rename the file atomically by specifying the internal SSH_FXF_RENAME_ATOMIC option. If the server does not support this option and *lpszNewFileName* already exists on the server, this function will attempt to delete the file and retry the rename operation.

This function can be used to move a file from one folder to another on the server, as long as the user has the appropriate permissions required to perform the operation. If the new file name includes a path, that path must already exist on the server or the function will fail.

If the old and new file names specify folders instead of regular files, the server may or may not allow the operation, depending on the access rights for those folders and the server's configuration. Some servers may allow a simple rename operation within the same parent folder, but may not permit you to move the folder to another location in the filesystem.

There is no guarantee the rename operation will be performed in an atomic fashion if multiple client sessions attempt to rename the same file at the same time. For example, it is possible that one client could attempt to rename a file while another client is already in the process of moving the file to a

new folder. In this case, the server may respond with an error indicating the file cannot be found, an access denied error or a general failure error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpReset Function

```
INT WINAPI FtpReset(  
    HCLIENT hClient  
);
```

The **FtpReset** function resets the client state and resynchronizes with the server. This function is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The client cannot be reset while a file transfer is in progress or if the client is in a blocked state. To abort a file transfer, use the **FtpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

[FtpCancel](#)

FtpResetQueue Function

```
BOOL WINAPI FtpResetQueue(  
    HQUEUE hQueue,  
    DWORD dwOptions  
);
```

The **FtpResetQueue** function resets the state of all file transfers in the current queue.

Parameters

hQueue

A handle to a file transfer queue.

dwOptions

An unsigned integer value which specifies which files should be reset in the queue. It may be one of the following values:

Value	Description
FTP_QUEUE_RESET_ALL	All files in the queue should be reset to their initial state.
FTP_QUEUE_RESET_COMPLETED	All files in the queue which have been successfully transferred will be reset to their initial state.
FTP_QUEUE_RESET_FAILED	All files in the queue which were not transferred will be reset to their initial state.
FTP_QUEUE_RESET_CANCELED	All files in the queue which were canceled will be reset to their initial state.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

When the **FtpStartQueue** function is called multiple times using the same queue handle, it will not attempt to transfer files which have already been successfully copied, and it will not attempt to re-transfer files if the previous transfer failed. This function resets queued files back to their initial state, prior to when the queue manager attempted to perform the transfer. The most common use would be to call the function with the FTP_QUEUE_RESET_FAILED mode and then call **FtpStartQueue** to retry failed or canceled file transfers.

Because canceled file transfers are also considered failed transfers, specifying FTP_QUEUE_RESET_FAILED will reset queued files which either encountered an error during the transfer or were explicitly canceled by calling the **FtpCancelQueuedFile** function. The FTP_QUEUE_RESET_CANCELED option will only reset the state of queued file transfers which were canceled.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

[FtpCancelQueuedFile](#), [FtpGetQueuedFile](#), [FtpResumeQueue](#), [FtpStartQueue](#), [FtpStopQueue](#),
[FtpSuspendQueue](#)

FtpResumeQueue Function

```
BOOL WINAPI FtpResumeQueue(  
    HQUEUE hQueue  
);
```

The **FtpResumeQueue** function resumes transfers in the queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function signals the queue manager to resume processing files in the transfer queue after the **FtpSuspendQueue** function has been called. This function will fail if the queue is in an idle (stopped) state, and will be ignored if the queue manager is already transferring files. The **FtpGetQueueStatus** function can be called to obtain the current status of the queue.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

FtpSetActivePorts Function

```
INT WINAPI FtpSetActivePorts(  
    HCLIENT hClient,  
    UINT nLowPort,  
    UINT nHighPort  
);
```

The **FtpSetActivePorts** function changes the range of local port numbers used for active mode file transfers.

Parameters

hClient

Handle to the client session.

nLowPort

An unsigned integer that specifies the low port number.

nHighPort

An unsigned integer that specifies the high port number.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to modify the range of local port numbers used for active mode file transfers. When using active mode, the client listens for an inbound connection from the server rather than establishing an outbound connection for the data transfer. In most cases, passive mode transfers are preferred because they mitigate potential compatibility issues with firewalls and NAT routers.

If active mode transfers are required, the default port range used when listening for the server connection is between 1024 and 5000. This is the standard range of ephemeral ports used by the Windows operating system. However, under some circumstances that range of ports may be too small, or a firewall may be configured to deny inbound connections on ephemeral ports. In that case, the **FtpSetActivePorts** function can be used to specify a different range of port numbers.

While it is technically permissible to assign the low and high port numbers to the same value, effectively specifying a single active port number, this is not recommended as it can cause the transfer to fail unexpectedly if multiple file transfers are performed. A minimum range of at least 1000 ports is recommended. For example, if you specify a low port value of 40000 then it is recommended that the high port value be at least 41000. The maximum port value is 65535.

To determine the current range of active port numbers being used, call the **FtpGetActivePorts** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

FtpSetBufferSize Function

```
INT WINAPI FtpSetBufferSize(  
    HCLIENT hClient,  
    INT nBufferSize  
);
```

The **FtpSetBufferSize** function sets the size in bytes of an internal buffer that will be used during data transfers.

Parameters

hClient

Handle to the client session.

nBufferSize

The size of an internal buffer, in bytes. Any value greater than or equal to zero is acceptable. If *nBufferSize* is zero, then the default value of 4096 will be used. If *nBufferSize* is less than 256 bytes, the buffer size will be set to 256. The maximum value of *nBufferSize* is 1048576 (1Mb).

Return Value

If the function succeeds, the return value is the size of the internal buffer that will be used. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The speed of data transfers, particularly on uploads, may be sensitive to network type and configuration, and the size of the internal buffer used for data transfers. The default size of this buffer will result in good performance for a wide range of network characteristics. A larger buffer will not necessarily result in better performance. For example, a multiple of 1460, which is the typical Maximum Transmission Unit (MTU), may be optimal in many situations.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

FtpSetChannelMode Function

```
INT WINAPI FtpSetChannelMode(  
    HCLIENT hClient,  
    INT nChannel,  
    INT nMode  
);
```

The **FtpSetChannelMode** function changes the security mode for the specified communication channel.

Parameters

hClient

Handle to the client session.

nChannel

An integer value which specifies which channel to return information for. It may be one of the following values:

Value	Description
FTP_CHANNEL_COMMAND	Change information for the command channel. This is the communication channel used to send commands to the server and receive command result and status information from the server.
FTP_CHANNEL_DATA	Change information for the data channel. This is the communication channel used to send or receive data during a file transfer.

nMode

An integer value which specifies the new mode for the specified channel. It may be one of the following values:

Value	Description
FTP_CHANNEL_CLEAR	Data sent and received on this channel should not be encrypted.
FTP_CHANNEL_SECURE	Data sent and received on this channel should be encrypted. Specifying this option requires that a secure connection has already been established with the server.

Return Value

If the function succeeds, the return value is the previous mode for the specified channel. If the function fails, it will return FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetChannelMode** function is used to change the default mode for the specified channel, and is typically used to control whether or not data is encrypted during a file transfer. If a standard, non-secure connection has been established with the server, an error will be returned if you specify the FTP_CHANNEL_SECURE mode for either channel.

If you have established a secure connection and then specify the FTP_CHANNEL_CLEAR mode for the command channel, the client will send the CCC command to the server to indicate that commands

should no longer be encrypted. If the server does not support this command, an error will be returned and the channel mode will remain unchanged. Once the command channel has been changed to clear mode, it cannot be changed back to secure mode. You must disconnect and re-connect to the server if you want to resume sending commands over an encrypted channel.

Changing the mode for the data channel requires that the server support the PROT command. If this command is not supported by the server, the function will fail and the channel mode will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

See Also

[FtpGetChannelMode](#)

FtpSetDirectoryFormat Function

```
INT WINAPI FtpSetDirectoryFormat(  
    HCLIENT hClient,  
    INT nFormatId  
);
```

The **FtpSetDirectoryFormat** function is used to specify the format used by the server when returning a list of files. The format type is used internally by the library when parsing the file list returned by the server.

Parameters

hClient

Handle to the client session.

nFormatId

An identifier used to specify the format of the file list returned by the server. The following values are recognized:

Value	Description
FTP_DIRECTORY_AUTO	This value specifies that the library should automatically determine the format of the file lists returned by the server. It is recommended that most applications use this value and allow the library to automatically determine the appropriate file listing format used by the server.
FTP_DIRECTORY_UNIX	This value specifies that the server returns file lists in the format commonly used by UNIX servers. Note that many servers can be configured to return file listings in this format, even if they are not actually a UNIX based platform. Consult the technical reference documentation for your server for more information.
FTP_DIRECTORY_MSDOS	This value specifies that the server returns file lists in the format commonly used by MS-DOS based systems. This includes Windows IIS servers. Long file names will be returned if supported by the underlying filesystem, such as NTFS or FAT32.
FTP_DIRECTORY_VMS	This value specifies that the server returns file lists in the format commonly used by VMS servers. Note that VMS servers can be configured to return a standard UNIX style listing in addition to the default VMS format.
FTP_DIRECTORY_STERLING_1	This value specifies that the server returns file listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange) applications. This format uses a 13 byte status code.
FTP_DIRECTORY_STERLING_2	This value specifies that the server returns file listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange) applications. This format uses a 10 byte status code.

FTP_DIRECTORY_NETWARE	This value specifies that the server returns file listings in a proprietary format used by NetWare servers. The format is similar to UNIX style listings except that file access and permissions are indicated by letter codes enclosed in brackets. This is the default format selected if the server identifies itself as a NetWare system.
FTP_DIRECTORY_MLSD	This value specifies that the server should return file listings in a machine-independent format as defined by RFC 3659. This format specifies file information as a sequence of name/value pairs, with the same format being used regardless of the operating system that the server is hosted on. Note that not all servers support this format, and some proxy servers may reject the command even if the remote server supports its use.

Return Value

If the function succeeds, the return value identifies the file list format used by the server. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should only be used when the library cannot automatically determine the directory format returned by the server. To determine the format used by a server after a file list has been retrieved, use the **FtpGetDirectoryFormat** function.

The default directory format is determined both by the server's operating system and by analyzing the format of the data returned by the server. If the library is unable to automatically determine the format, it will attempt to parse the list of files as though it is a UNIX style listing.

If the FTP_DIRECTORY_MLSD format is specified, the file information returned by the server may differ from the default output of the LIST command. For example, on a UNIX based FTP server, the output of the LIST command is typically the same format that is used by the /bin/lis command, where file names are sorted and hidden files are not listed. However, the MLSD command may return an unsorted list of files that includes hidden files and directories.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

FtpSetFeatures Function

```
DWORD WINAPI FtpSetFeatures(  
    HCLIENT hClient,  
    DWORD dwFeatures  
);
```

The **FtpSetFeatures** function specifies the server features available to the client.

Parameters

hClient

Handle to the client session.

dwFeatures

An unsigned integer that specifies one or more features. Refer to the documentation for the **FtpGetFeatures** function for a list of available features.

Return Value

If the function succeeds, the return value specifies the features that were previously enabled. If the function fails, it will return zero. Because it is possible that no features were enabled, a return value of zero does not always indicate an error. An application should call **FtpGetLastError** to determine if an error code has been set.

Remarks

The **FtpSetFeatures** function is used to enable a specific set of features for the current session. When a client connection is first established, features are enabled based on the server type and the server's response to the FEAT command. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client. To enable or disable a specific feature, an application can use the **FtpEnableFeature** function.

For example, the first time an application calls the **FtpGetFileSize** function to determine the size of a file, the library will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the library will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the library from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

FtpSetFileMode Function

```
INT WINAPI FtpSetFileMode(  
    HCLIENT hClient,  
    UINT nMode  
);
```

The **FtpSetFileMode** function sets the default file transfer mode for the current client session.

Parameters

hClient

Handle to the client session.

nMode

Specifies the default type of data transfer mode for files being opened or created on the server. This parameter can be one of the following values.

Value	Description
FILE_MODE_STREAM	The data is transmitted as a stream of bytes. This is the default client transfer mode.
FILE_MODE_BLOCK	The data is transmitted as a series of data blocks preceded by one or more header bytes. This transfer mode is currently not supported.
FILE_MODE_COMPRESSED	The data is transmitted in compressed form. This transfer mode is currently not supported.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The file transfer mode should be set before a file is opened or created on the server. Once the transfer mode is set, it is in effect for all files that are subsequently opened or created.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
- Minimum Server Platform:** Windows Server 2008 R2 Service Pack 1
- Header File:** cstdlib11.h
- Import Library:** csftpv11.lib

See Also

[FtpOpenFile](#), [FtpSetFileStructure](#), [FtpSetFileType](#), [FtpSetPassiveMode](#)

FtpSetFileNameEncoding Function

```
INT WINAPI FtpSetFileNameEncoding(  
    HCLIENT hClient,  
    INT nEncoding  
);
```

The **FtpSetFileNameEncoding** function specifies what type of encoding will be used when file names are sent to the server.

Parameters

hClient
Handle to the client session.

nEncoding
An integer value which specifies the encoding type. It may be one of the following values:

Value	Description
FTP_ENCODING_ANSI	File names are sent as 8-bit characters using the default character encoding for the current codepage. If the Unicode version of the functions are used, file names are converted from Unicode to ANSI using the current codepage before being sent to the server. This is the default encoding type.
FTP_ENCODING_UTF8	File names that contain non-ASCII characters are sent using UTF-8 encoding. This encoding type is only available on servers that advertise support for UTF-8 encoding and permit that encoding type to be enabled by the client.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetFileNameEncoding** function can be used to enable UTF-8 encoding of file names, which provides improved support for the use of international character sets. However, the server must provide support for UTF-8 encoding by advertising it in response to the FEAT command and it must support the OPTS command which is used to enable UTF-8 encoding. If the server does not advertise support for UTF-8, or the OPTS command fails with an error, then this function will fail with an error and the encoding type will not change.

Although it is possible to use the **FtpEnableFeature** function to explicitly enable the FTP_FEATURE_UTF8 feature, this is not recommended. If the server has not advertised support for UTF-8 encoding in response to the FEAT command, that typically indicates that UTF-8 encoding is not supported. Attempting to force UTF-8 encoding can result in unpredictable behavior when file names contain non-ASCII characters.

It is important to note that not all FTP servers support UTF-8 encoding, and in some cases servers which advertise support for UTF-8 encoding do not implement the feature correctly. For example, a server may allow a client to enable UTF-8 encoding, but once enabled will not permit the client to disable it. Some servers may advertise support for UTF-8 encoding, however if the underlying file system does not support UTF-8 encoded file names, any attempt to upload or download a file may fail

with an error indicating that the file cannot be found or created.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

FtpSetFilePermissions Function

```
INT WINAPI FtpSetFilePermissions(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    DWORD dwPermissions  
);
```

The **FtpSetFilePermissions** function returns information about the access permissions for a specific file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string which contains the name of the file to be updated. The filename cannot contain any wildcard characters.

dwPermissions

An unsigned integer which will specify the new access permissions for the file. The file permissions are represented as bit flags, and may be one or more of the following values combined with a bitwise Or operator:

Value	Description
FILE_OWNER_READ	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.
FILE_OWNER_WRITE	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_OWNER_EXECUTE	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_GROUP_READ	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.
FILE_GROUP_WRITE	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_GROUP_EXECUTE	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.

FILE_WORLD_READ	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.
FILE_WORLD_WRITE	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.
FILE_WORLD_EXECUTE	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.

Return Value

If the function succeeds, the return value is a result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the SITE CHMOD command to set the permissions for the file. This command is typically only supported on servers that are hosted on UNIX based systems. If the command is not supported, an error will be returned.

Users who are familiar with the UNIX operating system will recognize the **chmod** command used to change the file permissions. However, it should be noted that the numeric value used as an argument to the command is in octal, not decimal. For example, issuing the command **chmod 644 filename.txt** on a UNIX based system will make the file readable and writable by the owner, and readable by other users in the owner's group as well as all other users. The value 644 is an octal value, which is equivalent to the decimal value 420. If you were to mistakenly specify 644 as the value for the *dwPermissions* parameter, rather than the decimal value of 420, the permissions on the file would be incorrect. It is strongly recommended that you use the pre-defined constants to prevent this sort of error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpSetFileStructure Function

```
INT WINAPI FtpSetFileStructure(  
    HCLIENT hClient,  
    UINT nType  
);
```

The **FtpSetFileStructure** function sets the default file structure for the current client session, which indicates what type of file is being opened or created on the server.

Parameters

- hClient**
Handle to the client session.
- nType**
Specifies the default type of file structure being opened or created on the server. This parameter can be one of the following values.

Value	Description
FILE_STRUCT_NONE	The file has no inherent structure and is considered to be a stream of bytes. This is the default structure for file transfers.
FILE_STRUCT_RECORD	The file uses a record structure. This file structure is currently not supported.
FILE_STRUCT_PAGE	The file uses a page structure. This file structure is currently not supported.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The file structure should be set before a file is opened or created on the server. Once the file type is set, it is in effect for all files that are subsequently opened or created.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstdlib11.h
Import Library: csftpv11.lib

See Also

[FtpOpenFile](#), [FtpSetFileMode](#), [FtpSetFileType](#), [FtpSetPassiveMode](#)

FtpSetFileTime Function

```
INT WINAPI FtpSetFileTime(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPSYSTEMTIME lpFileTime  
);
```

The **FtpSetFileTime** function sets the modification time for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileTime

Points to a [SYSTEMTIME](#) structure that specifies the new modification time for the remote file.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetFileTime** function will change the modification time of a file on the server. The values specified in the SYSTEMTIME structure are expected to represent UTC time, not time adjusted for the local system's timezone. If the values do represent the local time, it must be converted to UTC time prior to calling this function. To populate the SYSTEMTIME structure with the current time, use the **GetSystemTime** function.

When connected to an FTP server, this function uses the MDTM command to set the modification time for the specified file. Not all servers implement this command, in which case the function call will fail. Note that some servers only support the MDTM command to return, but not change, the file modification time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpSetFileType Function

```
INT WINAPI FtpSetFileType(  
    HCLIENT hClient,  
    UINT nFileType  
);
```

The **FtpSetFileType** function sets the default file type for the current client session, which indicates what type of file is being opened or created on the server.

Parameters

hClient

Handle to the client session.

nFileType

Specifies the default type of file being opened or created on the server. This parameter can be one of the following values.

Value	Description
FILE_TYPE_AUTO	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the FtpRegisterFileType function.
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executable programs. If the type of file cannot be automatically determined, it will always be considered a binary file. If this file type is specified when uploading or downloading text files, the native end-of-line character sequences will be preserved.
FILE_TYPE_LOCAL	The file is a binary file that uses the local byte size for the server platform. On most servers, this file type is considered to be the same as FILE_TYPE_IMAGE. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The file type should be set before a file is opened or created on the server. Once the file type is set, it is in effect for all files that are subsequently opened or created. Some functions, such as **FtpOpenDirectory** and **FtpGetText**, will temporarily change the default file type to `FILE_TYPE_ASCII` and then restore the current file type when they return.

Calling this function has no practical effect when connected to an SFTP (SSH) server. They do not differentiate between text and binary files and the default file type will always be `FILE_TYPE_IMAGE`. If your application is uploading or downloading a text file, this difference between FTP and SFTP is important because the operating system that hosts the server may have different end-of-line character conventions than the client system. For example, if you download a text file from a UNIX system using SFTP, the end-of-line is indicated by a single linefeed (LF) character. However, on the Windows platform, the end-of-line is indicated by a carriage-return and linefeed sequence (CRLF).

The **FtpGetFileType** function can be used to determine the current file type. To determine the transfer file type for a specific file, use the **FtpGetAutoFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftpv11.lib`

FtpSetLastError Function

```
VOID WINAPI FtpSetLastError(  
    DWORD dwErrorCode  
);
```

The **FtpSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or FTP_ERROR. Those functions which call **FtpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **FtpGetLastError** function. The use of **FtpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpGetErrorString](#), [FtpGetLastError](#)

FtpSetPassiveMode Function

```
INT WINAPI FtpSetPassiveMode(  
    HCLIENT hClient,  
    BOOL bPassiveMode  
);
```

The **FtpSetPassiveMode** function enables or disables passive mode file transfers for the specified client session.

Parameters

hClient

Handle to the client session.

bPassiveMode

A boolean flag which specifies that the client should enter passive mode and establish all connections with the server to transfer data.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

By default, the File Transfer Protocol uses active mode transfers, whereby the data connection is established from the server back to the local client. However, this can introduce problems for a client application that is behind a proxy server, firewall or a router which uses Network Address Translation (NAT). Enabling passive mode transfers instructs the client to create an outbound connection from the local system to the server for the data connection, similarly to how the control connection is established.

Not all servers may support passive mode, in which case an error will be returned to the client when this function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

FtpSetPriority Function

```
INT WINAPI FtpSetPriority(  
    HCLIENT hClient,  
    INT nPriority  
);
```

The **FtpSetPriority** function specifies the priority for file transfers.

Parameters

hClient

Handle to the client session.

nPriority

An integer value which specifies the new priority for file transfers. It may be one of the following values:

Value	Description
FTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Return Value

If the function succeeds, the return value is the previous file transfer priority. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetPriority** function can be used to control the processor usage, memory and network bandwidth allocated for file transfers. The default priority balances resource utilization and transfer

speed while ensuring that a single-threaded application remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of transfer speed. For example, if you create a worker thread to download a file in the background and want to ensure that it has a minimal impact on the process, the `FTP_PRIORITY_BACKGROUND` value can be used.

Higher priority values increase the memory allocated for the transfers and increases processor utilization for the transfer. The `FTP_PRIORITY_CRITICAL` priority maximizes transfer speed at the expense of system resources. It is not recommended that you increase the file transfer priority unless you understand the implications of doing so and have thoroughly tested your application. If the file transfer is being performed in the main UI thread, increasing the priority may interfere with the normal processing of Windows messages and cause the application to appear to become non-responsive. It is also important to note that when the priority is set to `FTP_PRIORITY_CRITICAL`, normal progress events will not be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftpv11.lib`

See Also

[FtpGetPriority](#)

FtpSetTimeout Function

```
INT WINAPI FtpSetTimeout(  
    HCLIENT hClient,  
    UINT nTimeout  
);
```

The **FtpSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

FtpStartQueue Function

```
BOOL WINAPI FtpStartQueue(  
    HQUEUE hQueue,  
    DWORD dwQueueMode,  
    DWORD dwReserved,  
    FTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **FtpStartQueue** function begins transferring files in the queue.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An unsigned integer which specifies which files in the queue should be transferred. It may be one of the following values:

Constant	Description
FTP_QUEUE_ALL	All files in the queue should be transferred.
FTP_QUEUE_DOWNLOAD	Transfer only those files which have been queued for download.
FTP_QUEUE_UPLOAD	Transfer only those files which have been queued for upload.

dwReserved

An unsigned integer reserved for internal use. This parameter value should always be zero.

lpEventProc

Specifies the procedure-instance address of an application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, there will be no callback notifications.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

Queued file transfers are performed asynchronously using a background worker thread. If you provide the address to an event callback function, that function will always be invoked in the context of the queue manager thread. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself and you should avoid calling any functions which could cause the thread to block. For example, you should not attempt to establish other network

connections from within the event handler.

If your application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function. Controls should only be modified by the same UI thread that created their window. One common approach to address this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

To obtain the handle to the queue from within an event handler, call the **FtpGetThreadQueue** function with the *dwThreadId* parameter set to a value of zero. This will return the handle for the current queue management session which invoked the callback function.

If a callback function is provided, the FTP_QUEUE_EVENT event notification will be invoked whenever the internal state of the queue has changed. The handle value passed to the callback function will be a handle to the queue, not to a client connection. The **FtpGetQueueStatus** function can be called within the event handler to obtain the current state of the queue. This will event will always occur when the queue manager begins processing files in the queue and after it has stopped. This event will also occur whenever the queue is suspended and then resumed.

The **FtpWaitForQueue** function can be used to wait for the queue manager to complete processing the transfer queue.

Example

```
// Create a new queue
HQUEUE hQueue = FtpCreateQueue(INFINITE, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = FtpAddQueuedFile(
    hQueue,
    lpzLocalFile,
    lpzRemoteFile,
    FTP_OPTION_DEFAULT,
    FILE_TYPE_AUTO,
    FTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case FTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case FTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\\n"),
                    dwFileId,
                    queuedFile.szLocalFile,
```

```

        queuedFile.szRemoteFile);
    break;
    }
}

// Start the queued file transfers and wait for it to complete
if (FtpStartQueue(hQueue, FTP_QUEUE_ALL, 0, NULL, 0))
{
    FtpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    FtpStopQueue(hQueue);
}

// Remove all files from the queue
FtpDeleteQueue(hQueue);

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

See Also

[FtpEventProc](#), [FtpGetQueueStatus](#), [FtpGetThreadQueue](#), [FtpResumeQueue](#), [FtpStartQueue](#), [FtpStopQueue](#), [FtpSuspendQueue](#), [FtpWaitForQueue](#)

FtpStopQueue Function

```
BOOL WINAPI FtpStopQueue(  
    HQUEUE hQueue  
);
```

The **FtpStopQueue** function stops transferring queued files.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

When the **FtpStopQueue** function is called and there is a file transfer in progress, it will not immediately stop the upload or download of the file. Instead, the queue manager is signaled to stop processing additional files in the queue after the transfer has completed. To wait for the current transfer to complete, call the **FtpWaitForQueue** function.

It is permitted to call **FtpStopQueue** from within a queue event handler. In this case, the current file transfer will complete and the queue manager will terminate.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpCancelQueuedFile](#), [FtpResetQueue](#), [FtpResumeQueue](#), [FtpStartQueue](#), [FtpSuspendQueue](#), [FtpWaitForQueue](#)

FtpSuspendQueue Function

```
BOOL WINAPI FtpSuspendQueue(  
    HQUEUE hQueue  
);
```

The **FtpSuspendQueue** function pauses all file transfers for the specified queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

If there is a file transfer in progress when this function is called, the transfer will complete normally. The queue manager will enter a suspended state after the transfer has completed and before it begins processing the next file in the queue.

It is permitted to call **FtpSuspendQueue** from within a queue event handler. In this case, the current file transfer will complete and the queue manager will stop processing additional files in the queue until it is resumed or stopped.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpCancelQueuedFile](#), [FtpGetQueueStatus](#), [FtpResetQueue](#), [FtpResumeQueue](#), [FtpStartQueue](#), [FtpStopQueue](#)

FtpTaskAbort Function

```
BOOL WINAPI FtpTaskAbort(  
    UINT nTaskId,  
    DWORD dwMilliseconds  
);
```

Abort the specified asynchronous task.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to abort.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskAbort** function signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the *dwMilliseconds* parameter has a value of zero, the function returns immediately after the background thread has been signaled. If the *dwMilliseconds* parameter is non-zero, the function will wait that amount of time for the background thread to terminate.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock. To abort a file transfer within an event handler, use the **FtpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpTaskDone](#), [FtpTaskResume](#), [FtpTaskSuspend](#), [FtpTaskWait](#)

FtpTaskDone Function

```
BOOL WINAPI FtpTaskDone(  
    UINT nTaskId  
);
```

Determine if an asynchronous task has completed.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed, this function returns a non-zero value. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskDone** function is used to determine if the specified asynchronous task has completed. If you use this function to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this function rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **FtpGetTaskError** function will return the last error code associated with the task. A return value of zero indicates success, while a non-zero return value specifies an error code that indicates the cause of the failure. The last error code for the task can also be retrieved using the **FtpTaskWait** function, which causes the application to wait for the asynchronous task to complete.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftpv11.lib

See Also

[FtpGetTaskError](#), [FtpTaskAbort](#), [FtpTaskResume](#), [FtpTaskSuspend](#), [FtpTaskWait](#)

FtpTaskResume Function

```
BOOL WINAPI FtpTaskResume(  
    UINT nTaskId  
);
```

Resume execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskResume** function resumes execution of the background worker thread that was previously suspended using the **FtpTaskSuspend** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

See Also

[FtpTaskAbort](#), [FtpTaskDone](#), [FtpTaskSuspend](#), [FtpTaskWait](#)

FtpTaskSuspend Function

```
BOOL WINAPI FtpTaskSuspend(  
    UINT nTaskId  
);
```

Suspend execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskSuspend** function will suspend execution of the background worker thread associated with the task. Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **FtpTaskResume** function. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

[FtpTaskAbort](#), [FtpTaskDone](#), [FtpTaskResume](#), [FtpTaskWait](#)

FtpTaskWait Function

```
BOOL WINAPI FtpTaskWait(  
    UINT nTaskId,  
    DWORD dwMilliseconds,  
    DWORD dwReserved,  
    LPDWORD lpdwElapsed,  
    LPDWORD lpdwError  
);
```

Wait for an asynchronous task to complete.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to complete.

dwReserved

An unsigned integer reserved for future use. This value should always be zero.

lpdwElapsed

A pointer to an unsigned integer that will contain elapsed time in milliseconds when the function returns. If this information is not required, this parameter may be NULL.

lpdwError

A pointer to an unsigned integer that will contain the error code associated with the completed task. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskWait** function waits for the specified task to complete. If the task is active and the *dwMilliseconds* parameter is non-zero, this function will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *dwMilliseconds* parameter is zero, then this function will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this function is called, the function will return immediately without causing the current thread to block. If the *lpdwElapsed* parameter is not NULL, it will contain the number of milliseconds that it took for the task to complete. If the *lpdwError* parameter is not NULL, it will contain the last error code value that was set by the worker thread before it terminated. If this value is zero, that means that the background operation was successful and no error occurred. A non-zero value will indicate that the background operation has failed.

You should not call this function from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this function is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to periodically check to see if

a task has completed, create a timer to periodically call the **FtpTaskDone** function. When it returns a non-zero value (indicating that the task has completed), you can safely call **FtpTaskWait** to obtain the elapsed time and last error code without blocking the current thread.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = FtpAsyncGetFile(hClient,
                          lpszLocalFile,
                          lpszRemoteFile,
                          FTP_TRANSFER_DEFAULT,
                          0,
                          NULL,
                          0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    FtpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: csstools11.h

Import Library: csftpv11.lib

FtpUninitialize Function

```
VOID WINAPI FtpUninitialize();
```

The **FtpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **FtpInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **FtpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **FtpUninitialize** for every successful call to **FtpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpUploadFile Function

```
BOOL WINAPI FtpUploadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    UINT nTimeout  
    DWORD dwOptions  
    LPFTPTRANSFERSTATUS lpStatus  
    FTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **FtpUploadFile** function uploads the specified file from the local system to the server.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the

	server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpUploadFile** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then upload the file to the server. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @[hostname [:port] / [path / ...]
[filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be uploaded as a text or binary file. A value of "a" specifies that the file should be uploaded as a text file. A value of "i" specifies that the file should be uploaded as a binary file. If the type is not explicitly specified, the file

will be uploaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling

FtpGetTransferStatus and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpUploadFile** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpPutFile** to upload the file.

Example

```
FTPTRANSFERSTATUS ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile =
_T("ftp://update:secret@ftp.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = FtpUploadFile(lpszLocalFile,
                        lpszRemoteFile,
                        FTP_OPTION_PASSIVE,
                        &ftpStatus,
                        NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpUploadFileEx Function

```
BOOL WINAPI FtpUploadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    UINT nTimeout  
    DWORD dwOptions  
    LPFTPTRANSFERSTATUSEX lpStatus  
    FTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **FtpUploadFileEx** function uploads the specified file from the local system to the server.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this

	option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpUploadFileEx** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then upload the file to the server. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @ hostname [:port] / [path / ...]
[filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be uploaded as a text or binary file. A value of "a" specifies that the file should be uploaded as a text file. A value of "i" specifies that the file should be uploaded as a binary file. If the type is not explicitly specified, the file will be uploaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The **lpEventProc** parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **FtpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The **dwParam** parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the **this** pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for **lpEventProc** and the **dwParam** parameter will be ignored.

The **FtpUploadFileEx** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpPutFileEx** to upload the file.

Example

```
FTPTRANSFERSTATUSEX ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile =
_T("ftp://update:secret@ftp.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = FtpUploadFileEx(lpszLocalFile,
                          lpszRemoteFile,
                          FTP_OPTION_PASSIVE,
                          &ftpStatus,
                          NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpValidateHostName Function

```
BOOL WINAPI FtpValidateHostName(  
    LPCTSTR LpszHostName,  
    LPTSTR LpszAddress,  
    INT nMaxLength  
);
```

The **FtpValidateHostName** function determines if the specified host name is valid and returns its IP address.

Parameters

LpszHostName

A pointer to a null terminated string which specifies the host name. The function will fail if this parameter is NULL or an empty string.

LpszAddress

A pointer to a string buffer which will contain the IP address of the host. If specified, this string must be large enough to store the complete IP address, including the terminating null character. If this parameter is NULL or the *nMaxLength* parameter is zero, it will be ignored and the IP address will not be returned.

nMaxLength

An integer value that specifies the maximum number of characters which can be copied into the *LpszAddress* string buffer. The buffer must be large enough to store the complete address. Because this function can return either an IPv4 or IPv6 address, it is recommended the minimum length for the buffer to be 46 characters. If this parameter is zero, the *LpszAddress* parameter will be ignored.

Return Value

If the function succeeds, the host name is valid and the return value will be non-zero. If the function fails, the host name could not be resolved to an IP address and the return value will be zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpValidateHostName** function provides a convenient way to determine if a host name is valid by attempting to resolve the name into an IP address. If the Unicode version of this function is used, any non-ASCII characters in the host name will be automatically encoded into a compatible format and then resolved to an IP address. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended you use the Unicode version.

If the *LpszHostName* parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address.

If you wish to validate a complete FTP URL instead of a host name, use the **FtpValidateUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpConnectUrl](#), [FtpValidateUrl](#)

FtpValidateUrl Function

```
BOOL WINAPI FtpValidateUrl(  
    LPCTSTR LpszUrl  
);
```

The **FtpValidateUrl** function determines if a string represents a valid FTP URL.

Parameters

lpszUrl

A pointer to a string that specifies the URL to validate.

Return Value

If the specified URL is valid and the host name can be resolved to an IP address, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpValidateUrl** function will check the value of a string to ensure that it represents a complete, valid URL using either a standard or secure FTP scheme. This function will not establish a connection with the server to verify that it exists, it will only attempt to resolve the host name to an IP address. If the remote host is specified as an IP address, this function will check to make sure that the address is formatted correctly. Note that if you wish to specify an IPv6 address, you must enclose the address in brackets.

To establish a connection with a server using a URL, use the **FtpConnectUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpConnectUrl](#), [FtpValidateHostName](#)

FtpVerifyFile Function

```
BOOL WINAPI FtpVerifyFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions  
);
```

The **FtpVerifyFile** function attempts to verify that the contents of a file on the local system are the same as the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the name of file on the local system.

lpszRemoteFile

A pointer to a string that specifies the name of the file on the server.

dwOptions

Specifies the options that may be used when comparing the files. This parameter may be one or more of the following values:

Value	Description
FTP_VERIFY_DEFAULT	File verification should use the best option available based on the available server features. If the server supports the XMD5 command, the library will calculate an MD5 hash of the local file contents and compare the value with the file on the server. If the server does not support the XMD5 command, but it does support the XCRC command, the library will calculate a CRC32 checksum of the local file contents and compare the value with the file on the server. If the server does not support either the XMD5 or XCRC commands, the library will compare the size of the local and remote files.
FTP_VERIFY_SIZE	Files are verified by comparing the number of bytes of data in the local and remote files. This is the least reliable method, and should only be used if the server does not support either the XMD5 or XCRC commands.
FTP_VERIFY_CRC32	Files are verified by calculating a CRC32 checksum of the local file contents and comparing it with the value returned by the server in response to the XCRC command. This method should only be used if the server does not support the XMD5 command.
FTP_VERIFY_MD5	Files are verified by calculating an MD5 hash of the local file contents and comparing it with the value returned by the server in response to the XMD5 command. This is the preferred method for performing file verification.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpVerifyFile** function will attempt to verify that the contents of the local and remote files are identical using one of several methods, based on the features that the server supports. Preference will be given to the most reliable method available, using either an MD5 hash, a CRC-32 checksum or comparing the size of the file, in that order.

It is not recommended that you use this function with text files because of the different end-of-line conventions used by different operating systems. For example, a text file on a Windows system uses a carriage-return and linefeed pair to indicate the end of a line of text. However, on a UNIX system, a single linefeed is used to indicate the end of a line. This can cause the **FtpVerifyFile** function to indicate the files are not identical, even though the only difference is in the end-of-line characters that are used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpWaitForQueue Function

```
BOOL WINAPI FtpWaitForQueue(  
    HQUEUE hQueue,  
    DWORD dwMilliseconds,  
    LPDWORD lpdwElapsed,  
    LPDWORD lpdwError  
);
```

The **FtpWaitForQueue** function waits for the specified queue to complete the file transfers.

Parameters

hQueue

A handle to a file transfer queue.

dwMilliseconds

An unsigned integer value which specifies the number of milliseconds to wait for the queue to complete processing. If this value is zero, the function will return immediately. If this value is INFINITE (0xFFFFFFFF), the function will block indefinitely until all files in the queue have been processed.

lpdwElapsed

A pointer to an unsigned integer which will contain the number of milliseconds the queue manager has been active when the function returns. If this information is not needed, this parameter can be NULL. If this parameter is not NULL, it will always be initialized to a value of zero.

lpdwError

A pointer to an unsigned integer which will contain the last error code set if a file transfer has failed or was canceled. If this information is not needed, this parameter can be NULL. If this parameter is not NULL, it will always be initialized to a value of zero.

Return Value

If the function succeeds, the return value is non-zero, which means the queue manager has completed transferring all queued files. If the function fails, or the timeout period elapses, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until either the queue manager has completed processing all files in the queue, or until the specified number of milliseconds have elapsed. It is important to note that Windows messages will not be processed during this time. If you call this function within the main UI thread, it can potentially cause the application to become non-responsive. To determine the current state of the queue without blocking the current thread, call the **FtpGetQueueStatus** function.

If the *dwMilliseconds* parameter is non-zero and file transfers have not completed within the specified amount of time, the function will return zero and the last error code will be set to **ST_ERROR_OPERATION_TIMEOUT**.

If an event callback function has been specified when starting the queue, you should never call this function within the event handler. Attempting to do so can potentially create a situation which will cause the application to become non-responsive. The function will return zero if it determines it's being called within the context of the queue manager thread and will set the last error code to **ST_ERROR_THREAD_DEADLOCK**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

FtpWrite Function

```
INT WINAPI FtpWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **FtpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

typedef struct _FTPCLIENTQUOTA
{
    DWORD    dwFileCount;
    DWORD    dwFileLimit;
    DWORD    dwDiskUsage;
    DWORD    dwDiskLimit;
} FTPCLIENTQUOTA, *LPFTPCLIENTQUOTA;
```

Members

dwFileCount

An unsigned integer value which specifies the number of files that the user has created. If file quotas have not been enabled for the current user, this value will be zero.

dwFileLimit

An unsigned integer value which specifies the maximum number of files that may be created by the user. If file quotas have not been enabled for the current user, this value will be zero.

dwDiskUsage

An unsigned integer value which specifies the number of bytes of disk storage that has been allocated by the current user. If file quotas have not been enabled for the current user, this value will be zero.

dwDiskLimit

An unsigned integer value which specifies the maximum number of bytes of disk storage that may be allocated by the current user. If file quotas have not been enabled for the current user, this value will be zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

FTPFILESTATUS

This structure is used by the **FtpEnumFiles**, **FtpGetFirstFile** and **FtpGetNextFile** functions to return information about files on the server.

```
typedef struct _FTPFILESTATUS
{
    TCHAR          szFileName[FTP_MAXFILENAMELEN];
    TCHAR          szFileOwner[FTP_MAXOWNERNAMELEN];
    TCHAR          szFileGroup[FTP_MAXGROUPNAMELEN];
    BOOL           bIsDirectory;
    DWORD          dwFileSize;
    DWORD          dwFileLinks;
    DWORD          dwFileVersion;
    DWORD          dwFilePerms;
    SYSTEMTIME     stFileDate;
} FTPFILESTATUS, *LPFTPFILESTATUS;
```

Members

szFileName

A string buffer which contains the name of the file on the server.

szFileOwner

A string buffer which contains the name of the user that owns the file on the server. Note that not all server types support the concept of file ownership by a user. Some UNIX systems will not provide this information if an anonymous login was used. For the proprietary Sterling directory formats, the "mailbox" is stored in this member.

szFileGroup

A string buffer which contains the name of the group that owns the file on the server. Note that not all server types support the concept of file ownership by a group. For the proprietary Sterling directory formats, the "batch number" is stored in this member, with the character # prepended for the format FTP_DIRECTORY_STERLING_2.

bIsDirectory

A boolean flag which specifies if the file is actually a subdirectory.

dwFileSize

The size of the file in bytes on the server. Servers that return file information in an MS-DOS format will always set this value to zero if the file refers to a subdirectory. If the file is a text file, the file size on the server may be different than the size on the local host if different end-of-line character conventions are used. It should be noted that under VMS, the file size is reported in 512 byte blocks, so the size should be considered approximate on that platform.

dwFileLinks

The number of links to the file. Note that not all server types support the concept of file links, in which case this value will be zero.

dwFileVersion

The number of revisions made to the file. Note that not all server types support the concept of file versioning, in which case this value will be zero. Currently this value will only be non-zero for VMS platforms.

dwFilePerms

The permissions associated with the file. This value is actually a combination of bits that specify the

individual permissions for the file owner, group and world (all other users). For those familiar with UNIX, the file permissions are the same as those used by the `chmod` command. For the proprietary Sterling directory formats, a bit map representing the status codes and transfer protocol of the file is stored in this member.

stFileDate

A [SYSTEMTIME](#) structure which specifies the date that the file was created or last modified.

File Permissions

Value	Description
FILE_OWNER_READ	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.
FILE_OWNER_WRITE	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_OWNER_EXECUTE	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_GROUP_READ	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.
FILE_GROUP_WRITE	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_GROUP_EXECUTE	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_WORLD_READ	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.
FILE_WORLD_WRITE	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.
FILE_WORLD_EXECUTE	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.

Sterling Status Codes

Bits 0-25 correspond to letters of the alphabet, most of which have distinct meanings in the Sterling formats.

Letter code	Bit position	Hexadecimal value

A	0	1h
B	1	2h
C	2	4h
<i>n-th letter of alphabet</i>	n-1	2 to the (n-1) power
Z	25	2000000h

For the proprietary Sterling directory formats, bits 26-31 represent the transfer protocol associated with the file:

Protocol	Bit position	Hexadecimal value	Constant
TCP	26	4000000h	FTP_STERLING_STATUS_TCP
FTP	27	8000000h	FTP_STERLING_STATUS_FTP
BSC	28	10000000h	FTP_STERLING_STATUS_BSC
ASC	29	20000000h	FTP_STERLING_STATUS_ASC
FTS	30	40000000h	FTP_STERLING_STATUS_FTS
other	31	80000000h	FTP_STERLING_STATUS_OTHER

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FTPFILESTATUSEX

This structure is used by the **FtpEnumFilesEx**, **FtpGetFirstFileEx** and **FtpGetNextFileEx** functions to return information about files on the server. This structure is designed for use with extended functions that support files larger than 4GB.

```
typedef struct _FTPFILESTATUSEX
{
    TCHAR          szFileName[FTP_MAXFILENAMELEN];
    TCHAR          szFileOwner[FTP_MAXOWNERNAMELEN];
    TCHAR          szFileGroup[FTP_MAXGROUPNAMELEN];
    BOOL           bIsDirectory;
    ULARGE_INTEGER uiFileSize;
    DWORD          dwFileLinks;
    DWORD          dwFileVersion;
    DWORD          dwFilePerms;
    DWORD          dwFileFlags;
    SYSTEMTIME     stFileDate;
} FTPFILESTATUSEX, *LPFTPFILESTATUSEX;
```

Members

szFileName

A string buffer which contains the name of the file on the server.

szFileOwner

A string buffer which contains the name of the user that owns the file on the server. Note that not all server types support the concept of file ownership by a user. Some UNIX systems will not provide this information if an anonymous login was used. For the proprietary Sterling directory formats, the "mailbox" is stored in this member.

szFileGroup

A string buffer which contains the name of the group that owns the file on the server. Note that not all server types support the concept of file ownership by a group. For the proprietary Sterling directory formats, the "batch number" is stored in this member, with the character # prepended for the format FTP_DIRECTORY_STERLING_2.

bIsDirectory

A boolean flag which specifies if the file is actually a subdirectory.

uiFileSize

The size of the file in bytes on the server. Servers that return file information in an MS-DOS format will always set this value to zero if the file refers to a subdirectory. If the file is a text file, the file size on the server may be different than the size on the local host if different end-of-line character conventions are used. Import Library: csftpv11.lib

Unicode: Implemented as Unicode and ANSI versions

FTPQUEUEDFILE

This structure is used by the **FtpGetFirstQueuedFile**, **FtpGetNextQueuedFile** and **FtpGetQueuedFile** functions to return information about a file in the transfer queue.

```
typedef struct _FTPQUEUEDFILE
{
    DWORD          dwFileId;
    DWORD          dwQueueMode;
    DWORD          dwQueueFlags;
    DWORD          dwTimeElapsed;
    DWORD          dwLastError;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szLocalFile[FTP_MAXFILENAMELEN];
    TCHAR          szRemoteName[FTP_MAXURLPATHLEN];
} FTPQUEUEDFILE, *LPFTPQUEUEDFILE;
```

Members

dwFileId

An unsigned integer which specifies a unique identifier for the queued file. The application should not make any assumptions about the value of the file identifiers. They should be considered opaque values which are only guaranteed to uniquely identify a file in the transfer queue. In particular, there is no guarantee that the file identifiers will be sequential and they should not be used as index values into an array.

dwQueueMode

An unsigned integer value which specifies how the file was queued for transfer. It may be one of the following values:

Constant	Description
FTP_QUEUE_DOWNLOAD	The file was queued for download.
FTP_QUEUE_UPLOAD	The file was queued for upload.

dwQueueFlags

An unsigned integer which specifies one or more bit flags which provides information about the status of the file transfer. It may be one or more of the following values:

Constant	Description
FTP_QUEUE_FLAG_NONE	The file is pending transfer in queue.
FTP_QUEUE_FLAG_COMPLETED	The file has been transferred successfully. If this flag is set, no errors were encountered during the upload or download.
FTP_QUEUE_FLAG_FAILED	The file transfer failed. If this flag is set, the <i>dwError</i> member of this structure will contain the error code associated with the failed transfer.
FTP_QUEUE_FLAG_CANCELED	The file transfer was canceled. This flag is only set when the FtpCancelQueuedFile function has been called and a queued file is in the process of being uploaded or downloaded.

dwTimeElapsed

An unsigned integer which specifies the number of milliseconds required to complete the transfer. This value will be zero unless the file has been transferred successfully.

dwLastError

An unsigned integer which specifies the last error code for a failed transfer. If the file was transferred successfully, this value will be zero.

uiBytesCopied

A value which specifies the number of bytes which were copied during the file transfer. The `ULARGE_INTEGER` type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

szLocalFile

A null terminated string which specifies the full path to the local file being transferred.

szRemoteFile

A null terminated string which specifies the complete URL to the remote file being transferred.

Remarks

It is possible that the ***szLocalFile*** and ***szRemoteFile*** structure members will be different than the values passed to the **FtpAddQueuedFile** function. Those values are normalized, with any relative paths converted to absolute paths. Internationalized domain names will be encoded and the URL paths will be collapsed, removing any extraneous path information. For example, if the remote file name is specified as **ftp://ftp.server.tld/folder1/./folder2/filename.txt** it would be normalized as **ftp://ftp.server.tld/folder2/filename.txt**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftpv11.lib`

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpAddQueuedFile](#), [FtpAddQueuedFileEx](#), [FtpGetFirstQueuedFile](#), [FtpGetNextQueuedFile](#), [FtpGetQueuedFile](#)

FTPQUEUESTATUS

This structure is used by the **FtpGetQueueStatus** function to return information about the current status of the file transfer queue.

```
typedef struct _FTPQUEUESTATUS
{
    DWORD dwStatus;
    DWORD dwThreadId;
    DWORD dwQueuedFiles;
    DWORD dwPendingFiles;
    DWORD dwCopiedFiles;
    DWORD dwFailedFiles;
    DWORD dwTimeElapsed;
    DWORD dwCurrentFile;
    DWORD dwLastError;
    ULARGE_INTEGER uiBytesCopied;
    ULARGE_INTEGER uiBytesTotal;
} FTPQUEUESTATUS, *LPFTPQUEUESTATUS;
```

Members

dwStatus

An unsigned integer which specifies the current status of the queue. It can be one of the following values:

Value	Description
FTP_QUEUE_STATUS_IDLE	The file transfer queue is idle and no files are being uploaded or downloaded. This state is returned before FtpStartQueue has been called or after FtpStopQueue has been called. The queue will also automatically enter an idle state after the last file transfer has completed and the queue manager thread exits.
FTP_QUEUE_STATUS_ACTIVE	Files in the queue are being uploaded or downloaded. The dwCurrentFile member of this structure identifies the file which is currently being transferred.
FTP_QUEUE_STATUS_PAUSED	File transfers are currently paused. The queue enters this state after the FtpSuspendQueue function is called and resumes file transfers after the FtpResumeQueue function is called.

dwThreadId

An unsigned integer which specifies the thread ID for the queue manager which is performing the file transfers. All file transfers are performed asynchronously in a background worker thread. If this structure member is zero, the queue is idle and not performing file transfers. The application should not use the thread ID to obtain a handle to suspend or terminate the thread. This can potentially result in unexpected behavior or instability within the application.

dwQueuedFiles

An unsigned integer which specifies the total number of queued files. This value includes pending and completed file transfers.

dwPendingFiles

An unsigned integer which specifies the number of files which are queued to be transferred.

dwCopiedFiles

An unsigned integer which specifies the number of files which have been successfully transferred. This value reflects the total number of files which have the FTP_QUEUE_FLAG_COMPLETED status.

dwFailedFiles

An unsigned integer which specifies the number of files which have failed to transfer or the file transfer has been canceled. This value reflects the total number of files which have the FTP_QUEUE_FLAG_FAILED status.

dwTimeElapsed

An unsigned integer which specifies the total amount of time, in milliseconds, the queue manager has been active performing a file transfer. If the queue is idle, this value will reflect the total run time for the previously active queue. A value of zero indicates the queue was never active or the queue state has been reset with a call to **FtpResetQueue**.

dwCurrentFile

An unsigned integer which specifies the unique identifier for the current file being transferred. If no file transfer is in progress, this member will have a value of zero. If the value is non-zero, it can be passed to the **FtpGetQueuedFile** function to obtain information about the queued file.

dwLastError

An unsigned integer which specifies the last error code for a failed file transfer. If there have been no errors, this value will be zero.

uiBytesCopied

A value which specifies the number of bytes which were copied during the current or last transfer. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

uiBytesTotal

A value which specifies the total number of bytes which were copied during the current queue run. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftpv11.lib

See Also

FTPTRANSFERSTATUS

This structure is used by the **FtpGetTransferStatus** function to return information about a file transfer in progress.

```
typedef struct _FTPTRANSFERSTATUS
{
    DWORD    dwBytesTotal;
    DWORD    dwBytesCopied;
    DWORD    dwBytesPerSecond;
    DWORD    dwTimeElapsed;
    DWORD    dwTimeEstimated;
    TCHAR    szLocalFile[FTP_MAXFILENAMELEN];
    TCHAR    szRemoteFile[FTP_MAXFILENAMELEN];
} FTPTRANSFERSTATUS, *LPFTPTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the file is being copied from the server to the local host, this is the size of the remote file. If the file is being copied from the local host to the server, it is the size of the local file. If the file size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the file transfer is completed. This is based on the average number of bytes transferred per second.

szLocalFile

A pointer to a string which specifies the local file that is being copied to or from the server.

szRemoteFile

A pointer to a string which specifies the remote file that is being copied to or from the local system.

Remarks

If the option `FTP_OPTION_HIRES_TIMER` has been specified when connecting to the server, the values returned in the *dwTimeElapsed* and *dwTimeEstimated* members will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small files over a fast network connection.

If you are uploading or downloading large files which exceed 4GB, you should use the **FTPTRANSFERSTATUSEX** structure which uses 64-bit integers for the file size.

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only

	protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol should be used when establishing the connection. This is the default version of the protocol that is supported by most SSH servers.

dwOptions

A value which specifies one or options. This value should always be zero for connections using SSH. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library

	will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This

comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

A pointer to a null terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SFTP (SSH) connections and should always be NULL when establishing a secure connection using FTPS (FTP+TLS). If the member is NULL, then no private key is used. The private key file must be in the standard PEM format defined in RFC 1422. Both the standard RSA private key format and the proprietary OpenSSH format are supported.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The ***lpszKeyFile*** path can use environment variables enclosed in percent symbols, and the path to the private key file will be normalized. It is recommended you always use an absolute path to the private key file. If you do not include a path, it will use the current working directory for the process. This can produce inconsistent results with multithreaded applications because the current working directory for a process is a global value and it can be changed by any thread at any time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME    stCertIssued;
    SYSTEMTIME    stCertExpires;
    LPCTSTR       lpszCertIssuer;
    LPCTSTR       lpszCertSubject;
    LPCTSTR       lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol was selected. This protocol will only be used when connecting to an SSH server and is not supported with any other application protocol. Version 1.0 of the protocol is no longer considered secure and is not supported.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
-------	-------------

SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the TLS

protocol.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the TLS protocol.

lpszCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the TLS protocol.

lpszFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

File Transfer Protocol Server Library

Implements a server that enables the application to send and receive files using the File Transfer Protocol.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSFTSV11.DLL
Version	11.0.2218.1855
LibID	263021C1-CB49-4122-9D4B-244AA9EFF668
Import Library	CSFTSV11.LIB
Dependencies	None
Standards	RFC 959, RFC 1579, RFC 2228

Overview

This library provides an interface for implementing an embedded, lightweight server that can be used to exchange files with a client using the standard File Transfer Protocol. The server can accept connections from any third-party application or a program developed using the SocketTools FTP client API.

The application specifies an initial server configuration and then responds to events that are raised by the API when the client sends a request to the server. An application may implement only minimal handlers for most events, in which case the default actions are performed for most standard FTP commands. However, an application may also use the event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

The server supports active and passive mode file transfers, has compatibility options for NAT router and firewall support, and provides support for secure file transfers using explicit TLS. Secure connections require a valid security certificate to be installed on the system.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This library provides an implementation of a multithreaded server which should only be used with

languages that support the creation of multithreaded applications. It is important that you do not attempt to link against static libraries which were not built with support for threading.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

File Transfer Protocol Server Functions

Function	Description
FtpAddVirtualUser	Add a new virtual user for the specified server
FtpAuthenticateClient	Authenticate the client and assign access rights for the session
FtpChangeClientDirectory	Change the current working directory for the client session
FtpCreateServerCredentials	Create a new server security credentials structure
FtpDeleteServerCredentials	Delete a previously created security credentials structure
FtpDeleteVirtualUser	Delete a virtual user from the specified server
FtpDisconnectClient	Disconnect the specific client session, closing the control channel and aborting any file transfer
FtpEnableClientAccess	Enable or disable access rights for the specified client session
FtpEnableCommand	Enable or disable a specific server command
FtpEnumServerClients	Returns a list of active client sessions established with the specified server
FtpGetActiveClient	Return the client ID for the active client session associated with the current thread
FtpGetClientAccess	Return the access rights that have been granted to the client session
FtpGetClientAddress	Return the IP address of the specified client session
FtpGetClientCredentials	Return the credentials for the specified client session
FtpGetClientDirectory	Return the current working directory for a client session
FtpGetClientFileType	Return the current file type used for transfers by the specified client
FtpGetClientHomeDirectory	Return the home directory for an authenticated client session
FtpGetClientIdentity	Return the identity of the specified client session
FtpGetClientIdleTime	Return the idle timeout period for the specified client
FtpGetClientLocalPath	Return the full local path for the specified virtual path
FtpGetClientServer	Return the handle to the server that created the specified client session
FtpGetClientThreadId	Returns the thread ID associated with the specified client session
FtpGetClientUserName	Return the user name associated with the specified client session
FtpGetClientVirtualPath	Return the virtual path for a local file on the server
FtpGetCommandFile	Return the full path to the local file name or directory specified by the client
FtpGetCommandLine	Return the complete command line issued by the client
FtpGetCommandName	Return the name of the last command issued by the client
FtpGetCommandParam	Return the value of the specified parameter for the command issued by the client
FtpGetCommandParamCount	Return the number of parameters to the current command issued by the client
FtpGetCommandResult	Return the result code and a description of the last command processed by the server
FtpGetCommandUsage	Return the number of times a specific command has been issued by all clients
FtpGetProgramExitCode	Return the exit code of the last program executed by the client
FtpGetProgramName	Return the name of the last program executed by the client
FtpGetProgramOutput	Return a copy of the standard output from the last program executed by the client
FtpGetProgramText	Return a copy of the standard output from the last program in a string buffer
FtpGetRenamedFile	Return the original name of a file being renamed by the client
FtpGetServerAddress	Return the IP address for the server

FtpGetServerDirectory	Return the full path to the root directory assigned to the specified server
FtpGetServerError	Return information about the last server error that occurred
FtpGetServerIdentity	Return the identity and version information for the specified server
FtpGetServerLogFile	Return the current log file format and full path for the file
FtpGetServerMemoryUsage	Return the amount of memory allocated for the server and all client sessions
FtpGetServerName	Return the host name assigned to the server or specified client session
FtpGetServerOptions	Return the configuration options for the specified server
FtpGetServerPriority	Return the current priority assigned to the specified server
FtpGetServerStackSize	Return the initial size of the stack allocated for threads created by the server
FtpGetServerTransferInfo	Return information about the current file transfer for the client session
FtpGetServerUuid	Return the UUID assigned to the specified server
FtpGetServerUuidString	Return the UUID assigned to the server as a printable string
FtpIsClientAnonymous	Determine if the specified client has authenticated as an anonymous user
FtpIsClientAuthenticated	Determine if the specified client session has been authenticated
FtpIsCommandEnabled	Determine if the specified command is currently enabled or disabled
FtpRegisterProgram	Register a program for use with the SITE EXEC command
FtpRenameServerLogFile	Rename or delete the current log file being updated by the server
FtpSendResponse	Send a result code and optional message to the client in response to a command
FtpServerAsyncNotify	Enable or disable asynchronous notification of changes in server status
FtpServerDisableTrace	Disable logging of network function calls
FtpServerEnableTrace	Enable logging of network function calls to a file
FtpServerInitialize	Initialize the library and validate the specified license key at runtime
FtpServerProc	Callback function used to process server events
FtpServerRestart	Restart the server, terminating all active client sessions
FtpServerResume	Resume accepting client connections on the specified server
FtpServerStart	Start the server and begin accepting client connections
FtpServerStop	Stop the server and terminate all active client connections
FtpServerSuspend	Suspend accepting client connections on the specified server
FtpServerThrottle	Limit the number of active client connections, connections per address and connection rate
FtpServerUninitialize	Terminate use of the library by the application
FtpSetClientAccess	Change the access rights associated with the specified client session
FtpSetClientFileType	Change the current file type used for transfers by the specified client
FtpSetClientIdentity	Change the identity string associated with the specified client session
FtpSetClientIdleTime	Change the idle timeout period for the specified client session
FtpSetCommandFile	Change the name of the local file or directory that is the target of the current command
FtpSetServerAddress	Change the IP address that the server will use with passive data connections
FtpSetServerError	Set the last error code for the specified server session
FtpSetServerIdentity	Change the identity and version information for the specified server
FtpSetServerLogFile	Change the current log format, level of detail and file name
FtpSetServerName	Change the hostname assigned to the specified server or client session

FtpSetServerPriority	Change the priority assigned to the specified server
FtpSetServerStackSize	Change the initial size of the stack allocated for threads created by the server

FtpAddVirtualUser Function

```
BOOL WINAPI FtpAddVirtualUser(  
    HSERVER hServer,  
    UINT nHostId,  
    DWORD dwUserAccess,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszDirectory  
);
```

Add a new virtual user for the specified server.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host. This parameter is reserved for future use and must always have a value of zero.

dwUserAccess

An integer value which specifies the access clients will be given when authenticated as this user. For a list of user access permissions, see [User Access Constants](#).

lpszUserName

A pointer to a string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the function will fail with an error indicating the username is invalid. This parameter cannot be NULL and the name must be at least three characters in length. Usernames are not case sensitive.

lpszPassword

A pointer to a string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the function will fail with an error indicating the password is invalid. This parameter cannot be NULL and must be at least one character in length. Passwords are case sensitive.

lpszDirectory

A pointer to a string which specifies the directory that will be the virtual user's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created the first time that the virtual user successfully logs in to the server. If this parameter is NULL or an empty string, a default home directory will be created for the virtual user.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **FtpAddVirtualUser** function adds a virtual user that is associated with the specified virtual host. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this function. If a match is found, the client access rights will be updated.

If you wish to modify the information for a user, it is not necessary to delete the username first. If this function is called with a username that already exists, that record is replaced with the values passed to this function. You cannot use this function to create a virtual user named "anonymous".

The virtual users created by this function exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this function for each user that is listed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpDeleteVirtualUser](#)

FtpAuthenticateClient Function

```
BOOL WINAPI FtpAuthenticateClient(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess,  
    BOOL bCreateHome,  
    LPCTSTR lpszDirectory  
);
```

Authenticate the client and assign access rights for the session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see [User Access Constants](#).

bCreateHome

An integer value that specifies if the server should create the home directory for the authenticated client if it does not already exist. If this value is non-zero, the home directory will be created. If value is zero, the home directory will not be created and if it does not exist, this function will fail.

lpszDirectory

A pointer to a string that specifies the home directory for the user. If an absolute path is specified, it will be relative to the server root directory. If a relative path is specified, it will be a subdirectory of the home directory for the server instance. If this parameter is NULL or an empty string, a home directory will be assigned based on the server home directory and the user name.

Return Value

If the the client session could be authenticated, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has already been authenticated, this function will return zero.

Remarks

The **FtpAuthenticateClient** function is used to authenticate a specific client session, typically in response to an FTP_CLIENT_USERAUTH event that indicates a client has requested authentication. This function is also used internally to automatically grant the appropriate access rights to local user and anonymous client sessions.

It is recommended that most applications specify FTP_ACCESS_DEFAULT as the *dwUserAccess* value for a client session, since this allows the server automatically grant the appropriate access based on the server configuration options for normal and anonymous users. If the server is going to be publicly accessible or third-party FTP clients will be used to access the server, you should always grant the FTP_ACCESS_LIST permission to clients. Many client applications will not function correctly if they are unable to obtain a list of files in the user's home directory.

If FTP_ACCESS_RESTRICTED is specified and the server was started in multi-user mode, the client session will be effectively locked to its home directory and cannot navigate to the server root

directory. By default, restricted client sessions are also limited to only downloading files and requesting directory listings. If a client session is not restricted, the client can access files outside of its home directory. Regardless of this option, a client cannot access files outside of the server root directory.

If `FTP_ACCESS_RESTRICTED` or `FTP_ACCESS_ANONYMOUS` is specified, the client session will be authenticated in a restricted mode and the access rights for the session will persist until the client disconnects from the server. Unlike regular users, the access rights for a restricted client cannot be changed by the server at a later point. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

If the *lpszDirectory* parameter is `NULL` or an empty string and the server has been started in multi-user mode, each user is assigned their own home directory based on their username. If the server has not been started in multi-user mode, then the default home directory will be the server root directory and is shared by all users. The **FtpGetClientHomeDirectory** function will return the full path to the home directory for an authenticated client.

If the `FTP_ACCESS_EXECUTE` permission is granted to the client session, it can execute external programs using the `SITE EXEC` command. Because the program is executed in the context of the server process, it is recommended that you limit access to this functionality and ensure that the programs being executed do not introduce any security risks to the operating system. This permission is never granted by default, and the `SITE EXEC` command will return an error if the client session is anonymous, regardless of whether this permission is granted or not.

This function should only be used for custom authentication schemes and is not necessary if you have used the **FtpAddVirtualUser** function to create virtual users.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftsv11.lib`

Unicode: Implemented as Unicode and ANSI versions

[FtpAddVirtualUser](#), [FtpChangeClientDirectory](#), [FtpGetClientCredentials](#), [FtpGetClientDirectory](#), [FtpGetClientHomeDirectory](#)

FtpChangeClientDirectory Function

```
BOOL WINAPI FtpChangeClientDirectory(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszDirectory  
);
```

Change the current working directory for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A pointer to a string which specifies the new current working directory for the client session. If this parameter is NULL or an empty string, the current working directory will be changed to the client home directory. If this parameter is not NULL, it must specify a directory that exists and is accessible by the server process.

Return Value

If the current working directory was changed, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the directory is invalid, this function will return zero.

Remarks

The **FtpChangeClientDirectory** function will change the current working directory for the specified client session. This function is called internally when the client sends the CWD or CDUP commands, however it may be explicitly used by the application to change the client's working directory in response to a server event.

This function cannot be used to change the current working directory for a client to an arbitrary directory outside of the server root directory. If the *lpszDirectory* parameter specifies a relative path (i.e.: a path that does not begin with a drive letter or leading path delimiter) then the new working directory will be relative to the current working directory. If an absolute path is specified, the absolute path must include the complete path to either the server root directory or the user's home directory, based on the permissions granted to the client session. If a path outside of the server root directory is specified, this function will fail with an access denied error.

Use caution when calling this function to override the directory specified by the client when it sends the CWD or CDUP commands. If your application changes the current working directory to one not specified by the client, it may cause unpredictable behavior in the client application because the actual path of the current working directory will not match the directory that was requested.

If this function is used to change the current working directory in response to the CWD command, you should not call the **FtpGetCommandParam** function and pass the command parameter as an argument to this function. You must use the **FtpGetCommandFile** function to obtain the directory name provided by the client prior to calling this function.

The application should never call the **SetCurrentDirectory** function in the Windows API to change the current directory for the process to the working directory of a client session. Because the server is multithreaded and each client session is managed in its own thread, an application using this library

should avoid using relative paths.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetClientDirectory](#), [FtpGetClientHomeDirectory](#), [FtpGetCommandFile](#)

FtpCreateServerCredentials Function

```
BOOL WINAPI FtpCreateServerCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **FtpCreateServerCredentials** function creates a SECURITYCREDENTIALS structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **FtpDeleteServerCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **FtpServerStart** function.

Remarks

The structure that is created by this function may be used as server credentials when accepting a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **FtpServerStart** function.

An application only needs to call this function to support secure connections using TLS. When a certificate is specified, it must have a private key associated with it. Attempting to use a certificate

which does not have a private key will result in an error during the startup process indicating that the server credentials are invalid.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpzPassword* parameter or the library will be unable to access the certificate.

Example

```
// Create the server credentials that identifies the certificate
// that will be used for secure connections
LPSECURITYCREDENTIALS lpSecCred = NULL;

FtpCreateServerCredentials(SEcurity_PROTOCOL_DEFAULT,
                          0,
                          NULL,
                          NULL,
                          lpzCertStore,
                          lpzCertName,
                          NULL,
                          &lpSecCred);

// Start the server
hServer = FtpServerStart(lpzLocalHost,
                        FTP_PORT_DEFAULT,
                        FTP_SERVER_LOCALUSER | FTP_SERVER_UNIXMODE |
FTP_SERVER_SECURE,
                        &ftpConfig,
                        lpEventHandler,
                        0,
                        lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpDeleteServerCredentials Function

```
VOID WINAPI FtpDeleteServerCredentials(  
    LPSECURITYCREDENTIALS *lppCredentials  
);
```

The **FtpDeleteServerCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer value will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)  
    FtpDeleteServerCredentials(&lpSecCred);
```

Remarks

This function can be used to release the memory allocated for the credentials after the server has been started.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpDeleteVirtualUser Function

```
BOOL WINAPI FtpDeleteVirtualUser(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR LpszUserName  
);
```

Remove a virtual user from the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host. This parameter is reserved for future use and must always have a value of zero.

lpszUserName

A pointer to a string which specifies the user that will be removed. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

This function removes a virtual user that was created by a previous call to the **FtpAddVirtualUser** function. This function will not match partial usernames and wildcard characters cannot be used to delete multiple users. Usernames are not case sensitive. You cannot use this function to delete the "anonymous" user.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpAddVirtualUser](#)

FtpDisconnectClient Function

```
BOOL WINAPI FtpDisconnectClient(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Close the control connection for the specified client and release the resources allocated for the session

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpDisconnectClient** function will close the control channel, disconnecting the client from the server and terminating the client session thread. Resources that we allocated for the client, such as memory and open handles, will be released back to the operating system. If the client was in the process of transferring a file, the transfer will be aborted. This performs the same operation as if the client sent the QUIT command to the server.

This function sends an internal control message that notifies the server that this session should be terminated. When the session thread is signaled that it should terminate, it will abort any active file transfers and begin to release the resources allocated for that session. To ensure that the client session terminates gracefully, there may be a brief period of time where the session thread is still active after this function has returned.

After this function returns, the application should never use the same client ID with another function. Client IDs are unique to the session over the lifetime of the server, and are not reused.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

See Also

[FtpServerRestart](#), [FtpServerStop](#)

FtpEnableClientAccess Function

```
BOOL WINAPI FtpEnableClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess,  
    BOOL bEnable  
);
```

Enable or disable access rights for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies an access right to enable or disable. For a list of user access rights that can be granted to the client, see [User Access Constants](#).

bEnable

An integer value which specifies if permission should be granted or revoked for the specified access right. If this value is non-zero, permission is granted to the client to perform the action specified by the *dwUserAccess* parameter. If this value is zero, that permission is revoked.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **FtpEnableClientAccess** function is used to enable or disable access to specific functionality by the client. The function can only change a single access right and cannot be used to enable or disable multiple access rights in a single function call. To change multiple user access rights for the client, use the **FtpSetClientAccess** function.

This function cannot be used to change the access rights for a restricted or anonymous user. Those rights are granted when the client session is authenticated and will persist until the client disconnects from the server. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

See Also

[FtpAuthenticateClient](#), [FtpGetClientAccess](#), [FtpSetClientAccess](#)

FtpEnableCommand Function

```
BOOL WINAPI FtpEnableCommand(  
    HSERVER hServer,  
    LPCTSTR lpszCommand,  
    BOOL bEnable  
);
```

Enable or disable a specific server command

Parameters

hServer

The server handle.

lpszCommand

A pointer to a NULL terminated string that specifies the name of the command to be enabled or disabled. The command name is not case-sensitive, but the value must otherwise match the exact name. Partial matches are not recognized by this function. This parameter cannot be NULL.

bEnable

An integer value which specifies if the command should be enabled or disabled. If the value is non-zero, the command is enabled. If the value is zero, the command will be disabled.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the command is not recognized, the function will return zero. If the function fails, the **FtpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **FtpEnableCommand** function is used to enable or disable access to a specific command on the server. When a command is disabled, it will also disable any corresponding feature related to that command. For example, if the MDTM command is disabled and a client issues the FEAT command to request a list of supported features, the command will no longer be listed. This function is typically used to enable or disable certain commands for compatibility with older client software. The **FtpIsCommandEnabled** function can be used to determine if a command is enabled or not.

The command name provided to this function must match the commands defined in RFC 959 or related protocol standards. It is important to distinguish between commands recognized by an FTP server and the commands that client programs may use. For example, the standard Windows FTP command line program provides commands such as GET and PUT to download and upload files. However, those are not the actual commands sent to a server. Instead, the corresponding server commands issued by a client application would be RETR (retrieve) and STOR (store). Refer to [File Transfer Protocol Commands](#) for a complete list of server commands.

Some commands cannot be disabled because they are required to perform essential server functions. For example, the USER and PASS commands are required to perform client authentication and therefore cannot be disabled. If you attempt to disable a required command, this function will return zero and the last error code will be set to ST_ERROR_COMMAND_REQUIRED. Because this function affects all clients connected to the server, it should not be used to limit access to certain commands for specific clients. Instead, either assign the client the appropriate permissions using the **FtpAuthenticateClient** function, or use an event handler to filter the commands.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpEnumServerClients Function

```
INT WINAPI FtpEnumServerClients(  
    HSERVER hServer,  
    DWORD dwReserved  
    UINT *lpClients,  
    INT nMaxClients  
);
```

Return a list of active client sessions established with the specified server.

Parameters

hServer

Handle to the server socket.

dwReserved

An unsigned integer value that is reserved for future use. This parameter should always be zero.

lpClients

Pointer to an array of unsigned integers which will contain client IDs that uniquely identifies each client when the function returns. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client IDs to be returned in the *lpClients* array. If the *lpClients* parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server. If the function fails, the return value is FTP_ERROR. To get extended error information, call

FtpGetServerError.

Remarks

If the *nMaxClients* parameter is less than the number of active client connections, the function will fail and the last error code will be set to the error ST_ERROR_BUFFER_TOO_SMALL. To dynamically determine the number of active connections, call the function with the *lpClients* parameter with a value of NULL, and the *nMaxClients* parameter with a value of zero.

Example

```
INT nClients = FtpEnumServerClients(hServer, 0, NULL, 0);  
  
if (nClients > 0)  
{  
    UINT *lpClients = NULL;  
  
    // Allocate memory for an array of client IDs  
    lpClients = (UINT *)LocalAlloc(LPTR, nClients * sizeof(UINT));  
  
    if (lpClients == NULL)  
    {  
        // Virtual memory has been exhausted  
        return;  
    }  
  
    nClients = FtpEnumServerClients(hServer, 0, lpClients, nClients);  
}
```

```

if (nClients == FTP_ERROR)
{
    // Unable to obtain list of connected clients
    return;
}

for (INT nIndex = 0; nIndex < nClients; nIndex++)
{
    TCHAR szUserName[FTP_MAXUSERNAME];

    if (FtpGetClientUserName(hServer, lpClients[nIndex], szUserName,
FTP_MAXUSERNAME))
    {
        // Perform some action with the client user name
    }
}

// Free the memory allocated for the client IDs
LocalFree((HLOCAL)lpClients);
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

See Also

[FtpServerStart](#)

FtpGetActiveClient Function

```
UINT WINAPI FtpGetActiveClient(  
    HSERVER hServer  
);
```

Return the client ID for the active client session associated with the current thread.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the unique ID associated with the client session for the current thread. If the server handle is invalid or there is no client session active on the current thread, the return value is zero.

Remarks

The **FtpGetActiveClient** function is used to obtain the client ID associated with the current thread. This means this function will only return a client ID if it is called within an event handler or a function called by an event handler. If this function is called by a function that is not executing within the context of an event handler it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

FtpGetClientAccess Function

```
BOOL WINAPI FtpGetClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    LPDWORD lpdwUserAccess  
);
```

Return the access rights that have been granted to the client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwUserAccess

A pointer to an unsigned integer which specifies one or more access rights for the client session. For a list of user access rights that can be granted to the client, see [User Access Constants](#). This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **FtpGetClientAccess** function is used to obtain all of the access rights that are currently granted to an authenticated client session. The **FtpEnableClientAccess** function can be used to enable or disable specific permissions, and the **FtpSetClientAccess** function can change multiple access rights at once.

Example

```
DWORD dwUserAccess = 0;  
  
// Check if the client is a restricted user  
  
if (FtpGetClientAccess(hServer, nClientId, &dwUserAccess))  
{  
    if (dwUserAccess & FTP_ACCESS_RESTRICTED)  
    {  
        _tprintf(_T("Client %u authenticated as a restricted user\n"), nClientId);  
        return;  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

FtpGetClientAddress Function

```
INT WINAPI FtpGetClientAddress(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

Return the IP address of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszAddress

A pointer to a string buffer that will contain the client IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetClientCredentials Function

```
BOOL WINAPI FtpGetClientCredentials(  
    HSERVER hServer,  
    UINT nClientId,  
    LPFTPCLIENTCREDENTIALS lpCredentials  
);
```

Return the user credentials for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpCredentials

A pointer to an **FTPCLIENTCREDENTIALS** structure that will contain information about the user when the function returns. This parameter cannot be NULL.

Return Value

If the user credentials for the client session are available, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has not requested authentication, this function will return zero.

Remarks

The **FtpGetClientCredentials** function is used to obtain the username and password that was provided by the client when it requested authentication. Typically this function is used in an event handler to validate the credentials provided by the client. If the credentials are considered valid, the event handler would then call the **FtpAuthenticateClient** function to specify that the session has been authenticated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpAuthenticateClient](#), [FTPCLIENTCREDENTIALS](#)

FtpGetClientDirectory Function

```
INT WINAPI FtpGetClientDirectory(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszDirectory,  
    INT nMaxLength  
);
```

Returns the current working directory for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A pointer to a string buffer that will contain the current working directory for the specified client session, terminated with a null character. This buffer should be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be larger than zero or the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

This function returns the full path to the current working directory for the specified client session. For example, if the server root directory is C:\ProgramData\MyServer and the current working directory for the client is /Research/Documents, this function will return C:\ProgramData\MyServer\Research\Documents as the current working directory for the client session.

It is important to note that the current working directory for client sessions is virtual, and does not reflect the current working directory for the server process. To change the current working directory for a client, use the **FtpChangeClientDirectory** function.

This function should only be used with client sessions that have been authenticated. Unauthenticated clients are not assigned a current working directory and this function will return zero, with the last error code set to ST_ERROR_AUTHENTICATION_REQUIRED.

To convert a full path to the virtual path for a specific client session, use the **FtpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpChangeClientDirectory](#), [FtpGetClientHomeDirectory](#), [FtpGetClientVirtualPath](#)

FtpGetClientFileType Function

```
BOOL WINAPI FtpGetClientFileType(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT *lpnFileType  
);
```

Return the current file type used for transfers by the specified client.

Parameters

- hServer**
The server handle.
- nClientId**
An unsigned integer which uniquely identifies the client session.
- lpnFileType**
A pointer to an unsigned integer value that will contain the current file type used by the client for data transfers. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetClientFileType** function will return the current file type that has been specified by the client sending the TYPE command to the server. The file type determines if there is any conversion performed on the data that is being exchanged between the client and server. The following file types are supported:

Value	Description
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those clients which use a different end-of-line character sequence, the text file has been converted to the local format which uses the carriage return (CR) and linefeed (LF) characters.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type has been performed on the file. This is the default file type for most data files and executable programs. If the client specified this file type when appending to a text file, the file will contain the end-of-line sequences used by its native operating system.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
- Minimum Server Platform:** Windows Server 2008 R2 Service Pack 1
- Header File:** ctools11.h
- Import Library:** csftsv11.lib

FtpGetClientHomeDirectory Function

```
INT WINAPI FtpGetClientHomeDirectory(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszDirectory,  
    INT nMaxLength  
);
```

Returns the home directory for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A pointer to a string buffer that will contain the home directory for the specified client session, terminated with a null character. This buffer should be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be larger than zero or the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

This function returns the full path to the home working directory assigned to the specified client session. This will be the same path to the home directory specified when the **FtpAuthenticateClient** function was used to authenticate the client session. If a home directory was not explicitly assigned when the client was authenticated, then this function returns the default home directory that was created for the client, or the server root directory if the FTP_SERVER_MULTUSER option was not specified when the server was started.

This function should only be used with client sessions that have been authenticated. Unauthenticated clients are not assigned a home directory and this function will return zero, with the last error code set to ST_ERROR_AUTHENTICATION_REQUIRED.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetClientIdentity Function

```
INT WINAPI FtpGetClientIdentity(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszIdentity,  
    INT nMaxLength  
);
```

Return the identity of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszIdentity

A pointer to a string buffer that will contain the identity of the client when the function returns, terminated with a null character. This parameter cannot be NULL. It is recommended that this buffer be at least 32 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero. If the client did not identify itself, this function will return zero.

Remarks

The **FtpGetClientIdentity** function returns the string that the client used to identify itself to the server. The client may use either the CLNT or CSID command to identify itself. Although the CLNT command is considered to be deprecated, it is supported for backwards compatibility with older clients. The identity string does not have any standard format and is used for informational purposes only and does not affect the operation of the server in any way. Not all clients identify themselves, in which case this function will return zero and the *lpszIdentity* string buffer will be set to an empty string.

If the client does identify itself, it typically uses the name of the client application that was used to establish the connection. The application may choose to assign an identity to a client session for its own internal purposes using the **FtpSetClientIdentity** function, regardless of whether the client identifies itself.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetServerIdentity](#), [FtpSetClientIdentity](#), [FtpSetServerIdentity](#)

FtpGetClientIdleTime Function

```
UINT WINAPI FtpGetClientIdleTime(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT *lpnElapsed  
);
```

Return the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpnElapsed

A pointer to an unsigned integer value that will contain the number of seconds the client session has been idle. This parameter may be NULL if this information is not required.

Return Value

If the function succeeds, the return value is client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetClientIdleTime** function will return the number of seconds that the client may remain idle before being automatically disconnected by the server. The idle time of a client session is based on the last time a command was issued to the server or when a file data transfer completed. The server will never disconnect a client that is in the process of uploading or downloading a file, regardless of the idle timeout period.

The default idle timeout period for a client is 900 seconds (15 minutes), however the server can be configured to use a different value and individual clients can request the timeout period be changed by sending the IDLE command to the server. For a client to be able to change its own timeout period, it must be granted the FTP_ACCESS_IDLE permission. The minimum timeout period for a client is 60 seconds, the maximum is 7200 seconds (2 hours). An application can change the timeout period for a specific client session using the **FtpSetClientIdleTime** function.

It is important to note that the idle timeout period only affects authenticated clients. Unauthenticated clients use a different internal timer that limits the amount of time they can remain connected to the server before successfully authenticating with a valid username and password. By default, the authentication timeout period is 60 seconds and is set when the server is started; it cannot be changed for an individual client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: csftools11.h

Import Library: csftsv11.lib

See Also

[FtpSetClientIdleTime](#)

FtpGetClientLocalPath Function

```
INT WINAPI FtpGetClientLocalPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszVirtualPath,  
    LPTSTR lpszLocalPath,  
    INT nMaxLength,  
);
```

Return the full local path for a virtual filename or directory on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszVirtualPath

A pointer to a string that specifies an virtual path on the server. This parameter cannot be NULL.

lpszLocalPath

A pointer to a string buffer that will contain the full local path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

The **FtpGetClientLocalPath** function takes a virtual path and returns the full path to the specified file or directory on the local system. The virtual path may be absolute or relative to the current working directory for the client session. This function will recognize a tilde at the beginning of the path to specify the client home directory.

To obtain the virtual path for a local file or directory, use the **FtpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetClientServer Function

```
HSERVER WINAPI FtpGetClientServer(  
    UINT nClientId  
);
```

The **FtpGetClientServer** function returns a handle to the server that created the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session. If the function fails, the return value is INVALID_SERVER. To get extended error information, call the **FtpGetServerError** function.

Remarks

The **FtpGetClientServer** function returns the handle to the server that created the client session and is typically used within a notification message handler. If the server is in the process of shutting down, or the client session thread is terminating, this function will fail and return INVALID_SERVER indicating that the session ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h.

Import Library: csftsv11.lib

[FtpServerAsyncNotify](#)

FtpGetClientThreadId Function

```
DWORD WINAPI FtpGetClientThreadId(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Returns the thread ID associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is a thread ID. If the function fails, the return value is zero. To get extended error information, call the **FtpGetServerError** function.

Remarks

The **FtpGetClientThreadId** function returns a thread ID that can be used to identify the thread that is managing the client session. The thread ID can be used with other Windows API functions such as **OpenThread**. Exercise caution when using thread-related functions, interfering with the normal operation of the thread can have unexpected results. You should never use this function to obtain a thread handle and then call the **TerminateThread** function to terminate a client session. This will prevent the thread from releasing the resources that were allocated for the session and can leave the server in an unstable state. To terminate a client session, use the **FtpDisconnectClient** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

FtpGetClientUserName Function

```
INT WINAPI FtpGetClientUserName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR LpszUserName,  
    INT nMaxLength  
);
```

Return the user name associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszUserName

A pointer to a string buffer that will contain the user name associated with the client session. This buffer must be large enough to store the complete user name, including the terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value larger than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetClientUserName** function returns the user name associated with an authenticated client session. If the client has not authenticated itself by sending the USER and PASS commands, this function will return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpAuthenticateClient](#), [FtpGetClientAccess](#), [FtpGetClientHomeDirectory](#)

FtpGetClientVirtualPath Function

```
INT WINAPI FtpGetClientVirtualPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszLocalPath,  
    LPTSTR lpszVirtualPath,  
    INT nMaxLength,  
);
```

Return the virtual path for a local file on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszLocalPath

A pointer to a string that specifies an absolute path on the local system. This parameter cannot be NULL.

lpszVirtualPath

A pointer to a string buffer that will contain the virtual path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

A virtual path for the client is either relative to the server root directory, or the client home directory if the client was authenticated as a restricted user. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the *lpszLocalPath* parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this function would return the virtual path to that directory as "/Documents/Research".

If the client session was authenticated as a restricted user, then the virtual path is always relative to the client home directory instead of the server root directory. This is because restricted users are isolated to their own home directory and any subdirectories. For example, if restricted user "John" has a home directory of "C:\ProgramData\MyServer\Users\John" and the *lpszLocalPath* parameter was specified as "C:\ProgramData\MyServer\Users\John\Accounting\Projections.pdf" this function would return the virtual path as "/Accounting/Projections.pdf".

If the *lpzLocalPath* parameter specifies a file or directory outside of the server root directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_FILE_NAME. This function can only be used with authenticated clients. If the *nClientId* parameter specifies a client session that has not been authenticated, this function will return zero and the last error code will be ST_ERROR_AUTHENTICATION_REQUIRED.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

[FtpGetCommandFile](#), [FtpGetClientLocalPath](#)

FtpGetCommandFile Function

```
INT WINAPI FtpGetCommandFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

Get the full path to the local file name or directory specified by the client

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string buffer that will contain the full path to a file name or directory specified by the client when it issued a command. The string buffer will be null terminated and must be large enough to store the complete file path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. It is recommended that the buffer be at least MAX_PATH characters in size. If the maximum length specified is smaller than the actual length of the full path, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the

FtpGetServerError function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that the command issued by the client accepts a file name as an argument, but the client did not specify one.

Remarks

The **FtpGetCommandFile** function is used to obtain the full path to a local file name or directory specified by the client as an argument to a standard FTP command. For example, if the client sends the RETR command to the server, this function will return the complete path to the local file that the client wants to download. This function will only work with those standard commands that perform some action on a file or directory.

This function should always be used to obtain the file name for a command that performs a file or directory operation. The **FtpGetCommandParam** function will return the actual command parameter, but the file name will typically be relative to the user home directory or server root directory, and cannot be passed directly to a Windows API function. The **FtpGetCommandFile** function normalizes the path provided by the client and ensures that it specifies a file or directory name in the correct location.

To change the file or directory name that is the target of the current command, use the **FtpSetCommandFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetClientDirectory](#), [FtpGetClientHomeDirectory](#), [FtpGetCommandLine](#), [FtpGetCommandParam](#),
[FtpSetCommandFile](#)

FtpGetCommandLine Function

```
INT WINAPI FtpGetCommandLine(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszCmdLine,  
    INT nMaxLength  
);
```

Return the complete command line issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCmdLine

A pointer to a string buffer that will contain the command, including all arguments. The string buffer will be null terminated and must be large enough to store the complete command line. If this parameter is NULL, the function will return the length of the command line.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. The internal limit on the maximum length of a command is 1024 characters. If the maximum length specified is smaller than the actual length of the complete command, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the

FtpGetServerError function can be used to retrieve the last error code. If the last error code has a value of zero then no command has been issued by the client.

Remarks

The **FtpGetCommandLine** function is used to obtain the command that was issued by the client, and is commonly used inside FTP_CLIENT_COMMAND and FTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively. When the function returns, the string buffer provided by the caller will contain the complete command, including all command parameters. Any extraneous whitespace will be removed, however quoted parameters will be retained as-is.

To obtain a specific parameter to a command, use the **FtpGetCommandParam** function. The **FtpGetCommandParamCount** function will return the number of command parameters that were provided by the client. If the command sent by the client is used to perform an action on a file or directory, the **FtpGetCommandFile** function should be called to obtain the full path to the specified file rather than using the value of the command parameter.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetCommandName Function

```
INT WINAPI FtpGetCommandName
    HSERVER hServer,
    UINT nClientId,
    LPTSTR lpszCommand,
    INT nMaxLength
);
```

Return the name of the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCommand

A pointer to a string buffer that will contain the command name. The string buffer will be null terminated and must be large enough to store the complete command name. If this parameter is NULL, the function will only return the length of the current command in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the *lpszCommand* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **FtpGetServerError** function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that no command has been issued by the client.

Remarks

The **FtpGetCommandName** function is used to obtain the name of the last command that was issued by the client. The command name returned by this function will always be capitalized, regardless of how it was sent by the client. This function is typically used inside FTP_CLIENT_COMMAND and FTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively.

The **FtpGetCommandParam** function can be used to return the value of individual command parameters specified by the client. The **FtpGetComandLine** function can be used to obtain the complete command line issued by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetCommandFile](#), [FtpGetCommandLine](#), [FtpGetCommandParam](#)

FtpGetCommandParam Function

```
INT WINAPI FtpGetCommandParam
    HSERVER hServer,
    UINT nClientId,
    INT nParam,
    LPTSTR lpszParam,
    INT nMaxLength
);
```

Return the value of the specified command parameter from the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nParam

An integer value which specifies the command parameter. A value of zero specifies the command itself, while values greater than zero specify a particular parameter. This function will fail if this value is less than zero or greater than the number of parameters available.

lpszParam

A pointer to a string buffer that will contain the command parameter. The string buffer will be null terminated and must be large enough to store the complete parameter value. If this parameter is NULL, the function will only return the length of the specified parameter in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. The internal limit on the maximum length of a command is 1024 characters. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the *lpszParam* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the

FtpGetServerError function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that no command has been issued by the client.

Remarks

The **FtpGetCommandParam** function is used to obtain a specific parameter for the last command that was issued by the client. If the parameter was surrounded in quotes, those quotes will be included in the value returned by this function. This function is typically used inside FTP_CLIENT_COMMAND and FTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively.

The **FtpGetCommandParamCount** function will return the number of command parameters that were provided by the client. If the command sent by the client is used to perform an action on a file or directory, the **FtpGetCommandFile** function should be called to obtain the full path to the specified file rather than using the value of the command parameter. To obtain the complete command line,

use the **FtpGetCommandLine** function.

FtpGetCommandParamCount Function

```
INT WINAPI FtpGetCommandParamCount  
    HSERVER hServer,  
    UINT nClientId  
);
```

Return the number of command parameters for the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

An integer value which specifies the number of parameters that were specified in the last command issued by the client. If the command did not include any parameters, this function will return zero. If the client has not issued a command, or the client session ID is invalid, this function will return -1.

Remarks

The **FtpGetCommandParamCount** function is used to determine the number of parameters specified in the last client command, and the maximum value that may be passed as the parameter index to the **FtpGetCommandParam** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

FtpGetCommandResult Function

```
INT WINAPI FtpGetCommandResult(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

Return the result code and description for the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszResult

A pointer to a string buffer that will contain the description of the result code. The string buffer will be null terminated up to the maximum number of characters specified by the caller. This parameter can be NULL if this information is not required.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. If the *lpszResult* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the result code for the last command issued by the client. A return value of zero indicates that the command has not completed and there is no result code available.

Remarks

The **FtpGetCommandResult** function is used to determine the result of the last command that was issued by the client and is typically called in the FTP_CLIENT_RESULT event handler. This function should only be called after a command has been processed or the **FtpSendResponse** function has been called.

The result code is a three-digit integer value that indicates the success or failure of a command. Whenever a client sends a command to the server, the server must respond with this numeric code, and optionally a text message that further describes the result. The text message may be a single line, or it may span multiple lines, with each line of text terminated by a carriage return and linefeed. Result codes are generally broken down into the following categories:

Result Code	Description
100-199	Result codes in this range indicate that the requested action is being initiated, and the client should expect another reply from the server before proceeding. This is normally used with file transfers, indicating to the client that the data transfer has started.
200-299	Result codes in this range indicate that the server has successfully completed the requested action. One exception is the 202 result code which indicates that the command is not implemented, but the client should not consider this to be an error condition.
300-399	Result codes in this range indicate that the requested action cannot complete until

	additional information is provided to the server. This is normally used with commands that require a specific sequence to complete. For example, the server will send the 331 result code in response to the USER command, which tells the client that it must send the PASS command to complete the authentication process.
400-499	Result codes in this range indicate that the requested action did not take place, but the error condition is temporary and may be attempted again. This error response is usually the result of a failed authentication attempt or a file transfer that could not complete.
500-599	Result codes in this range indicate that the requested action did not take place and the failure is permanent. The client should not attempt to send the command again. This error response is usually the result of an invalid command name, a syntax error or the client not having the appropriate access rights to a resource.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

[FtpSendResponse](#)

FtpGetCommandUsage Function

```
UINT WINAPI FtpGetCommandUsage(  
    HSERVER hServer,  
    LPCTSTR LpszCommand  
);
```

Return the number of times a specific command has been issued by all clients.

Parameters

hServer

The server handle.

lpszCommand

A pointer to a string that specifies a command name. The name is not case-sensitive, but must match a valid server command exactly. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is the number of times the command has been issued by all clients since the server was started. If the server handle or command name is invalid, or the command has never been issued, the return value will be zero.

Remarks

The command name provided to this function must match the commands defined in RFC 959 or related protocol standards. It is important to distinguish between commands recognized by an FTP server and the commands that client programs may use. For example, the standard Windows FTP command line program provides commands such as GET and PUT to download and upload files. However, those are not the actual commands sent to a server. Instead, the corresponding server commands issued by a client application would be RETR (retrieve) and STOR (store). Refer to [File Transfer Protocol Commands](#) for a complete list of server commands.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpGetProgramExitCode Function

```
BOOL WINAPI FtpGetProgramExitCode(  
    HSERVER hServer,  
    UINT nClientId,  
    LPDWORD lpdwExitCode  
);
```

Return the exit code of the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwExitCode

A pointer to an unsigned integer that will contain the program exit code when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetProgramExitCode** function returns the exit code of a registered program that was executed by the client using the SITE EXEC command. By convention, most programs return an exit code in the range of 0-255, with an exit code of zero indicating success. The exit code is commonly used by custom programs to communicate status information back to the server application.

Permission to use the SITE EXEC is not granted to authenticated users by default, and is limited to only those programs which are explicitly registered with the server. Exercise caution when allowing a client to execute a program on the server because this can expose the server to significant security risks. The programs that are registered for use with the SITE EXEC command should be thoroughly tested before being deployed on the server and should only be console programs that write to standard output.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

See Also

[FtpGetProgramName](#), [FtpGetProgramOutput](#), [FtpRegisterProgram](#)

FtpGetProgramName Function

```
INT WINAPI FtpGetProgramName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszProgramName,  
    INT nMaxLength  
);
```

Return the name of the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszProgramName

A pointer to a string buffer that will contain the name of the last program executed by the client. This parameter cannot be NULL and should be at least 32 characters in size.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value greater than zero.

Return Value

If the function succeeds, the return value is the length of the command name. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, this function will return zero.

Remarks

The **FtpGetProgramName** function returns the name of the last program that was executed by the client using the SITE EXEC command. The name that is returned is the alias assigned to the program, not the full path to the executable file. The server application would typically use this function in an event handler when processing the FTP_CLIENT_EXECUTE event to determine which program has been executed on behalf of the client. The **FtpGetProgramExitCode** function will return the program's exit code and the **FtpGetProgramOutput** function can be used to obtain a copy of the output generated by the program.

Permission to use the SITE EXEC is not granted to authenticated users by default, and is limited to only those programs which are explicitly registered with the server. Exercise caution when allowing a client to execute a program on the server because this can expose the server to significant security risks. The programs that are registered for use with the SITE EXEC command should be thoroughly tested before being deployed on the server and should only be console programs that write to standard output.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

[FtpGetProgramExitCode](#), [FtpGetProgramOutput](#), [FtpRegisterProgram](#)

FtpGetProgramOutput Function

```
DWORD WINAPI FtpGetProgramOutput(  
    HSERVER hServer,  
    UINT nClientId,  
    LPBYTE lpBuffer,  
    DWORD dwBufferSize  
);
```

Return a copy of the standard output from the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A pointer to a buffer that will contain the output from the last program executed by the client. If this parameter is NULL, the function will return the number of bytes of data that was output by the program. Note that this output is not null terminated.

dwBufferSize

The maximum number of bytes that can be copied into the buffer. If the *lpBuffer* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of bytes copied into the specified buffer. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **FtpGetProgramOutput** function is used to obtain a copy of the output generated by the program executed using the SITE EXEC command. To determine the number of bytes of output available to read, call this function with the *lpBuffer* parameter as NULL and the *dwBufferSize* parameter with a value of zero. The return value will be the number of bytes of data that was output by the program. It should be noted that for Unicode builds, the buffer is a byte array, not an array of characters, and will not be null terminated.

This function returns the raw output from the command which may contain escape sequences, control characters and embedded nulls. When the application processes the output returned by this function, it should never coerce the buffer pointer to an LPTSTR value because there is no guarantee that the data will be null-terminated. To obtain the output from the command as a string, use the **FtpGetProgramText** function.

Example

```
LPBYTE lpBuffer = NULL; // A pointer to the output buffer  
DWORD cbBuffer = 0;     // Number of bytes in the output buffer  
  
// Determine the number of bytes in the output buffer  
cbBuffer = FtpGetProgramOutput(hServer, nClientId, NULL, 0);  
  
if (cbBuffer > 0)
```

```
{
    // Allocate memory for the buffer
    lpBuffer = (LPBYTE)LocalAlloc(LPTR, cbBuffer + 1);

    // Copy the program output to the buffer
    if (lpBuffer != NULL)
        cbBuffer = FtpGetProgramOutput(hServer, nClientId, lpBuffer, cbBuffer + 1);
}

// Free the memory allocated for the buffer when finished
if (lpBuffer != NULL)
{
    LocalFree((HLOCAL)lpBuffer);
    lpBuffer = NULL;
    cbBuffer = 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

See Also

[FtpGetProgramExitCode](#), [FtpGetProgramName](#), [FtpGetProgramText](#), [FtpRegisterProgram](#)

FtpGetProgramText Function

```
INT WINAPI FtpGetProgramText(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

Return a copy of the standard output from the last program in a string buffer.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszBuffer

A pointer to a buffer that will contain the output from the last program executed by the client as a string. If this parameter is NULL, the function will return the number of bytes of characters that was output by the program, not including a terminating null character.

nMaxLength

The maximum number of bytes that can be copied into the buffer. If the *lpszBuffer* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the specified string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **FtpGetProgramText** function is used to obtain a copy of the output generated by the program executed using the SITE EXEC command. To determine the number of characters of output available to read, call this function with the *lpszBuffer* parameter as NULL and the *nMaxLength* parameter with a value of zero. The return value will be the number of characters that were output by the program. If the application dynamically allocates the string buffer, make sure that it allocates an extra character for the terminating null character.

This function will only return textual output from the command and any non-printable control characters and the escape character will be replaced with a space. To obtain the unfiltered output from the last command that was executed, use the **FtpGetProgramOutput** function.

Example

```
LPTSTR lpszBuffer = NULL; // A pointer to the output buffer  
INT cchBuffer = 0;        // Number of bytes in the output buffer  
  
// Determine the number of bytes in the output buffer  
cchBuffer = FtpGetProgramText(hServer, nClientId, NULL, 0);  
  
if (cchBuffer > 0)  
{
```

```

// Allocate memory for the string buffer
lpszBuffer = (LPTSTR)LocalAlloc(LPTR, (cchBuffer + 1) * sizeof(TCHAR));

// Copy the program output to the buffer
if (lpszBuffer != NULL)
    cchBuffer = FtpGetProgramText(hServer, nClientId, lpszBuffer, cchBuffer +
1);
}

// Free the memory allocated for the buffer when finished
if (lpszBuffer != NULL)
{
    LocalFree((HLOCAL)lpszBuffer);
    lpszBuffer = NULL;
    cchBuffer = 0;
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

FtpGetRenamedFile Function

```
INT WINAPI FtpGetRenamedFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

Return the original name of a file being renamed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string buffer that will contain the full path of the last file or directory that was renamed. It is recommended that this buffer be at least MAX_PATH characters in size. The value of this parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null characters. This parameter must have a value larger than zero.

Return Value

If the function succeeds, the return value is the length of the file or directory path, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not renamed a file or directory, this function will return zero.

Remarks

When a client wishes to rename a file or directory, it must send two commands in sequence to the server. The first command is RNFR (rename from) which specifies the original name of the file or directory to be renamed. The second command is RNTD (rename to) and must be sent immediately after the RNFR command and specifies the new name for the file or directory. The **FtpGetRenamedFile** function will return the full path of the local file or directory that was specified by the RNFR command. Typically this function is used by an event handler that processes the FTP_CLIENT_COMMAND event to determine the original path name.

This function is only guaranteed to return a meaningful value when called within the context of the FTP_CLIENT_COMMAND event. Calling this function outside of the event handler will return the path of the last renamed file, but there is no way to determine at what point the client issued the command to rename a file or directory. To obtain the new file or directory name, the **FtpGetCommandFile** function should be called from within the event handler.

The RNFR and RNTD commands can also be used to move a file or directory to a new location. For example, they could be used to move a file from one directory to another. An application should never make the assumption that the paths of the original and new file will be the same.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetCommandFile](#)

FtpGetServerAddress Function

```
INT WINAPI FtpGetServerAddress(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

Return the IP address of the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszAddress

A pointer to a string buffer that will contain the server IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

This function will return the IP address assigned to the specified server as a printable string. If the *nClientId* parameter has a value of zero, this function will return the IP address assigned to the local system. If the FTP_SERVER_NATROUTER option was specified when the server was started, this function will return the external IP address assigned to the system. If the *nClientId* parameter specifies a valid client session, this function will return the IP address that the client used to establish the connection with the server. To determine the IP address assigned to the client, use the **FtpGetClientAddress** function.

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetClientAddress](#), [FtpGetServerName](#), [FtpSetServerAddress](#)

FtpGetServerDirectory Function

```
INT WINAPI FtpGetServerDirectory(  
    HSERVER hServer,  
    LPTSTR lpszDirectory,  
    INT nMaxLength  
);
```

Return the full path to the root directory assigned to the specified server.

Parameters

hServer

The server handle.

lpszDirectory

A pointer to a string buffer that will contain the server root directory, terminated with a null character. It is recommended that this buffer be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **FtpGetServerDirectory** function will return the full path to the root directory assigned to the server instance. The root directory may be specified as part of the server configuration, or if no directory is specified by the application, a temporary root directory will be created and this function can be used to obtain the full path to the directory. When the application specifies a root directory, it may use environment variables such as %AppData% in the path. This function will return the fully resolved path name, with all environment variables expanded.

There is no corresponding function to change the server root directory after the server has started. To change the root directory, you must stop the server using the **FtpServerStop** function and then start another instance of the server with a configuration that specifies the new directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpGetServerAddress](#), [FtpGetServerIdentity](#), [FtpGetServerName](#)

FtpGetServerError Function

```
DWORD WINAPI FtpGetServerError(  
    HSERVER hServer,  
    LPTSTR lpszError,  
    INT nMaxLength  
);
```

Return the last server error code and a description of the error.

Parameters

hServer

The server handle.

lpszError

A pointer to a string buffer that will contain a description of the error. If the error description is not needed, this parameter may be NULL.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the error string buffer, including the terminating null character. If the *lpszError* parameter is NULL, this value should be zero.

Return Value

An unsigned integer value that specifies the last error that occurred. A value of zero indicates that there was no error.

Remarks

Error codes are unsigned 32-bit values which are private to each server. You should call the **FtpGetServerError** function immediately when a function's return value indicates that an error has occurred. That is because some functions clear the last error code when they succeed.

If the *hServer* parameter is specified with a value of INVALID_SERVER, this function will return the last error that occurred for the current thread. This value should only be used when the function does not have access to a valid server handle, such as when the **FtpServerStart** function fails.

It is important to note that the error codes returned by this function are different than the command result codes that are defined in RFC 959, the standard protocol specification for FTP. This function is used to determine reason that an API function has failed, and should not be used to determine if a command issued by the client was successful. The **FtpSendResponse** function is used to send result codes to the client, and the **FtpGetCommandResult** function can be used to determine the result of the last command sent by the client.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or FTP_ERROR. Those functions which clear the last error code when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetServerIdentity Function

```
INT WINAPI FtpGetServerIdentity(  
    HSERVER hServer,  
    LPTSTR lpszIdentity,  
    INT nMaxLength  
);
```

Return the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A pointer to a string buffer that will contain the identity of the server when the function returns, terminated with a null character. This parameter cannot be NULL. It is recommended that this buffer be at least 32 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **FtpGetServerIdentity** function returns the identity string that was specified as part of the server configuration. It is used for informational purposes only and does not affect the operation of the server. Typically the string specifies the name of the application and a version number, and is displayed whenever a client establishes its initial connection to the server. The **FtpSetServerIdentity** function can be used to change the identity string associated with the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetServerLogFile Function

```
BOOL WINAPI FtpGetServerLogFile(  
    HSERVER hServer,  
    UINT *LpnLogFormat,  
    UINT *LpnLogLevel,  
    LPTSTR LpszFileName,  
    INT nMaxLength  
);
```

Return the current log file format and the full path to the file.

Parameters

hServer

The server handle.

lpnLogFormat

A pointer to an integer value that will contain the log file format being used when the function returns. If this information is not needed, this parameter may be NULL. The following formats are supported:

Value	Description
FTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
FTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
FTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

lpnLogLevel

A pointer to an integer value that will contain the level of detail the server uses when generating the log file. The minimum value is 1 and the maximum value is 10. If this information is not needed, this parameter may be NULL.

lpszFileName

A pointer to a string buffer that will contain the full path to the log file. This parameter may be NULL if this information is not required.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the file name string, including the terminating null character. If the *lpszFileName* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the current log file format. Refer to the **FTPSEVERCONFIG** structure definition for a list of supported log file formats. If the server handle is invalid or logging has not been enabled, this function will return a value of zero.

Remarks

If the server is configured with logging enabled, but a log file name is not explicitly provided, then the server will automatically generate one. This function can be used to get the full path to the current log file along with the format that is being used to record client session data. Normally the log file is held open by the server thread while it is active, however you can call the **FtpRenameServerLogFile** function to explicitly rename or delete the log file.

To change the name of the log file, the log file format or level of detail, use the **FtpSetServerLogFile** function.

Requirements

FtpGetServerMemoryUsage Function

```
BOOL WINAPI FtpGetServerMemoryUsage(  
    HSERVER hServer,  
    ULARGE_INTEGER *LpMemUsage  
);
```

Return the amount of memory allocated for the server and all client sessions.

Parameters

hServer

The server handle.

lpMemUsage

A pointer to a ULARGE_INTEGER variable which will specify how much memory has been allocated by the server. This parameter will be initialized to a value of zero by the function and updated with the total number of bytes allocated by the server and all active client sessions when it returns.

Return Value

If the function succeeds, the return value is non-zero and the memory usage value will be updated. If the server handle is invalid, or the server cannot be locked, the return value is zero. Call the **FtpGetServerError** function to determine the cause of the failure.

Remarks

This function returns the amount of memory allocated by the server and all active client sessions. It enumerates all of memory allocations made by the server process and client session threads and returns the total number of bytes allocated for the server process. This value reflects the amount of memory explicitly allocated by this library and does not reflect the total working set size of the process, or memory allocated by any other libraries. To determine the working set size for the process, refer to the Win32 **GetProcessWorkingSetSize** and **GetProcessMemoryInfo** functions.

This function forces the server into a locked state, and all client sessions will block until the function returns. Because this function enumerates all heaps allocated for the server process, it can be an expensive operation, particularly when there are a large number of active clients connected to the server. Frequent use of this function can significantly degrade the performance of the server. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by the function remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

FtpGetServerName Function

```
INT WINAPI FtpGetServerName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

Return the host name assigned to the specified server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A pointer to a string buffer that will contain the server host name, terminated with a null character. It is recommended that this buffer be at least 64 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will return the host name assigned to the specified server. If the *nClientId* parameter has a value of zero, the function will return the default host name that was specified as part of the server configuration. If no host name was explicitly assigned to the server, then it will return the local system name. If the *nClientId* parameter specifies a client session, then it this function will return the host name that the client used to establish the connection. If the client sends the HOST command to the server, this function will return the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

[FtpGetServerAddress](#)

FtpGetServerPriority Function

```
INT WINAPI FtpGetServerPriority(  
    HSERVER hServer  
);
```

Return the current priority assigned to the specified server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the priority for the specified server. If the function fails, the return value is FTP_PRIORITY_INVALID. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpGetServerPriority** function can be used to determine the current priority assigned to the server. It will return one of the following values:

Value	Description
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
FTP_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpGetServerStackSize Function

```
DWORD WINAPI FtpGetServerStackSize(  
    SOCKET hServer  
);
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpGetServerStackSize** function returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpGetServerTransferInfo Function

```
BOOL WINAPI FtpGetServerTransferInfo(  
    HSERVER hServer,  
    UINT nClientId,  
    LPFTPSEVERTRANSFER lpTransferInfo  
);
```

Return information about the file transfer that was performed by the server for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpTransferInfo

A pointer to an **FTPSEVERTRANSFER** structure that will contain information about the last file transfer. This parameter cannot be NULL, and the *dwSize* member of the structure must be initialized to specify the structure size prior to calling this function.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function should only be called after the client has issued the APPE, RETR, STOR or STOU commands to initiate a file transfer, otherwise the return value will be zero.

Remarks

The **FtpGetServerTransferInfo** function is used to obtain information about the last file transfer that was performed by the server for the specified client. This function is typically called within an event handler to determine how many bytes of data were transferred, the type of file and the full path to the file on the local system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetServerUuid Function

```
INT WINAPI FtpGetServerUuid(  
    HSERVER hServer,  
    UUID *lpUuid  
);
```

Return the UUID assigned to the specified server.

Parameters

hServer

The server handle.

lpUuid

A pointer to a UUID structure that will contain the server UUID when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle is invalid or the pointer to the UUID structure is NULL, the function will return a value of zero.

Remarks

The **FtpGetServerUuid** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain a printable string version of the UUID, use the **FtpGetServerUuidString** function.

There is no corresponding function to change the UUID assigned to an active server. The server UUID is assigned when the server is started, and it must be a unique value that is maintained throughout the lifetime of the server. To change the UUID associated with the server, the server must be stopped using the **FtpServerStop** function and another instance of the server started with the new UUID.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

FtpGetServerUuidString Function

```
INT WINAPI FtpGetServerUuidString(  
    HSERVER hServer,  
    LPTSTR lpszHostUuid,  
    INT nMaxLength  
);
```

Return the UUID assigned to the server as a printable string.

Parameters

hServer

The server handle.

lpszHostUuid

A pointer to a string buffer that will contain the server UUID, terminated with a null character. It is recommended that this buffer be at least 40 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the buffer is not large enough to store the complete UUID string, the function will return a value of zero.

Remarks

The **FtpGetServerUuidString** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain the numeric UUID value, use the **FtpGetServerUuid** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

FtpIsClientAnonymous Function

```
BOOL WINAPI FtpIsClientAnonymous(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Determine if the specified client has authenticated as an anonymous user.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the client session has been authenticated, this function will return a non-zero value, otherwise it will return zero. If the server handle and client ID are valid, and the client session has been authenticated, this function will clear the last error code.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftsv11.lib

FtpIsCommandEnabled Function

```
BOOL WINAPI FtpIsCommandEnabled(  
    HSERVER hServer,  
    LPCTSTR LpszCommand  
);
```

Determine if a specific server command has been enabled or disabled.

Parameters

hServer

The server handle.

lpszCommand

A pointer to a NULL terminated string that specifies the name of the command. The command name is not case-sensitive, but the value must otherwise match the exact command name. Partial matches are not recognized by this function. This parameter cannot be NULL.

Return Value

If the command is enabled, this function will return a non-zero value. If the command is disabled, the server handle is invalid or the command name does not match a supported command, this function will return zero.

Remarks

The **FtpIsCommandEnabled** function is used to determine whether a specific command is enabled. Typically this function is used in an event handler to make sure the command issued by a client is recognized by the server and enabled for use. Commands can be enabled and disabled using the **FtpEnableCommand** function.

This function does not account for the permissions granted to a specific client session. Clients are assigned access rights when they are authenticated using the **FtpAuthenticateClient** function, and certain commands can be limited by the permissions granted to the client. For example, even though the STOR command is enabled, a client must have the FTP_ACCESS_WRITE permission to use the command to upload a file to the server. For a list of access rights, see [User Access Constants](#).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpRegisterProgram Function

```
BOOL WINAPI FtpRegisterProgram(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszCommandName,  
    LPCTSTR lpszProgramFile,  
    LPCTSTR lpszParameters,  
    LPCTSTR lpszDirectory  
);
```

Register a program for use with the SITE EXEC command.

Parameters

hServer

The server handle.

nHostId

An unsigned integer that identifies the virtual host associated with the program. This value should always be zero.

lpszCommandName

A pointer to a string which specifies the name of the site specific command. This is the name that is passed to the SITE EXEC command and does not need to match the actual name of the executable file on the local system. The maximum length of the command name is 32 characters. This parameter cannot be NULL.

lpszProgramFile

A pointer to a string that specifies the full path to the executable program. This parameter cannot be NULL.

lpszParameters

A pointer to a string that specifies additional parameters for the program. If the program does not require any command line parameters, this value may be NULL or point to an empty string.

lpszDirectory

A pointer to a string that specifies the current working directory for the program. If this parameter is NULL or points to an empty string, the server will use the current working directory of the client that issues the SITE EXEC command.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpRegisterProgram** function registers an executable program for use with the SITE EXEC command. Because this can present a significant security risk to the server, clients are not given permission to use this command by default. A client must be explicitly granted permission to use SITE EXEC by including FTP_ACCESS_EXECUTE as one of the permissions when authenticating the client session with the **FtpAuthenticateClient** function or creating a virtual user using the **FtpAddVirtualUser** function.

To give the server complete control over what programs can be executed using SITE EXEC, the program must be registered with the server and referenced by an alias specified by the

lpzCommandName parameter. The maximum length of a program name is 31 characters and it must be at least 3 characters in length. The name must only consist of alphanumeric characters and the first character of the program name cannot be numeric. The program name is not case-sensitive, however convention is to use upper-case characters. If a program name is specified that already has been registered, it will be updated with the new information provided by this function.

The ***lpzProgramFile*** string specifies file name of the program that will be executed. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple command names that reference the same executable file. The only requirement is that the command names be unique. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the **C:\Program Files** folder.

It is important to note that the program specified by ***lpzProgramFile*** must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The ***lpzParameters*** string is used to define optional command line parameters that will be included with the command. This string can contain placeholders that are replaced by additional parameters specified by the client when it sends the SITE EXEC command. First replacement parameter is %1, the second is %2 and so on.

The executable program that is registered using this function must be a console application that writes to standard output. Programs that write directly to a console, or programs written to use a Windows user interface are not supported and will yield unpredictable results. In most cases, those programs that do not use standard input and output will be forcibly terminated by the server. If the program attempts to read from standard input, it will immediately encounter an end-of-file condition. Programs executed by the SITE EXEC command have no input; it is similar to a program that has its input redirected from the NUL: device. If the program must process a file on the server, the local file name should be passed as a command line parameter.

The output from the program will be redirected back to the client control channel. The output should be textual, with each line of text terminated by a carriage return and linefeed (CRLF). Programs that write binary data to standard output, particular data with embedded nulls, will yield unpredictable results and are not supported. To ensure that the program output conforms to the protocol standard, any non-printable characters will be replaced with a space and each line of output will be prefixed by a single space. The server application can obtain a copy of the output from the last command by calling the **FtpGetProgramOutput** function.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetProgramExitCode](#), [FtpGetProgramName](#), [FtpGetProgramOutput](#)

FtpRenameServerLogFile Function

```
BOOL WINAPI FtpRenameServerLogFile(  
    HSERVER hServer,  
    LPCTSTR lpszFileName  
);
```

Rename or delete the current log file being updated by the server.

Parameters

hServer

The server handle.

lpszFileName

A pointer to a string that specifies the file name the current log file should be renamed to. If this parameter is NULL or an empty string, the current log file will be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero. If logging is not currently enabled for the server, this function will return zero.

Remarks

The **FtpRenameServerLogFile** function is used to rename or delete the current log file. Note that this does not change the current log file name or disable logging by the server. It only changes the file name of the current log file, or removes the log file if the *lpszFileName* parameter is NULL. This can be useful if you want your server to perform log file rotation, archiving the current log file. By renaming the current log file, the server will automatically create a new log file with original file name.

This function must be used to rename or delete the current log file while logging is active because the server holds an open handle on the file. The application should not use the **FtpGetServerLogFile** function to obtain the log file name and then use the **MoveFileEx** or **DeleteFile** functions with that file.

To disable logging, use the **FtpSetServerLogFile** function and specify the logging format as FTP_LOGFILE_NONE.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpGetServerLogFile](#), [FtpSetServerLogFile](#)

FtpSendResponse Function

```
BOOL WINAPI FtpSendResponse(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nResultCode,  
    LPCTSTR lpszMessage  
);
```

Send a result code and message to the client in response to a command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nResultCode

An unsigned integer value which specifies the result code.

lpszMessage

A pointer to a string which specifies a message to be sent to the client. If this parameter is NULL or points to an empty string, a default message associated with the result code will be used.

Return Value

If the result code and message text was sent to the client, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the result code is invalid, this function will return zero.

Remarks

The **FtpSendResponse** function is used to respond to a command issued by the client. Command responses are normally handled by the server as a normal part of processing a command and this function is only used if the application has implemented custom commands or wishes to modify the standard responses sent by the server. The message may be a maximum of 2048 characters and may include embedded carriage-return and linefeed characters. If no message is specified, then a default message will be sent based on the result code.

Result codes must be three digits (in the range of 100 through 999) and although this function will support the use of non-standard result codes, it is recommended that the client application use the standard codes defined in RFC 959 whenever possible. The use of non-standard result codes may cause problems with FTP clients that expect specific result codes in response to a particular command. For more information, refer to the **FtpGetCommandResult** function.

This function should only be called once in response to a command sent by the client. If a result code has already been sent in response to a command and this function is called, it will fail and return a value of zero. This is necessary because sending multiple result codes in response to a single command may cause unpredictable behavior by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetCommandResult](#)

FtpServerAsyncNotify Function

```
BOOL WINAPI FtpServerAsyncNotify(  
    HSERVER hServer,  
    HWND hWnd,  
    UINT uMsg  
);
```

Enable or disable asynchronous notification of changes in server status.

Parameters

- hServer**
The server handle.
- hWnd**
A handle to the window whose window procedure will receive the notification message.
- uMsg**
The user-defined message that will be sent to the notification window.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **FtpGetServerError** function.

Remarks

The **FtpServerAsyncNotify** function is used by an application to enable or disable asynchronous notifications. The message window is typically the main UI window and these notifications are used signal to the application that it should update the user interface. If the **hWnd** parameter is not NULL, it must specify a valid window handle and the user-defined message must have a value of **WM_USER** or higher. The application cannot specify a notification message that is reserved by the operating system. The pseudo-handle **HWND_BROADCAST** cannot be specified as the notification window. If the **hWnd** parameter is NULL, notifications for the specified server will be disabled.

When asynchronous notifications are enabled for a server, the server will post the user-defined message to the window whenever there is a change in status or after a client has connected or disconnected from the server. The **wParam** message parameter will contain the notification message and the **lParam** message parameter will contain the handle to the server or the client ID. The following notification messages are defined:

Value	Description
FTP_NOTIFY_STARTUP	This notification is sent when the server has started and is preparing to accept client connections. This notification is only sent once, and only if asynchronous notifications are enabled immediately after the FtpServerStart function is called. This message will not be sent once the server has begun accepting client connections or when notification messages are disabled and then subsequently re-enabled at a later time. The lParam message parameter will specify the handle to the server.
FTP_NOTIFY_LISTEN	This notification is sent when the server is listening for client connections. This notification message may be sent to the application multiple times over the lifetime of the server. If the

	server was suspended, this notification will be sent after the application calls the FtpServerResume function to resume accepting client connections. The <i>lParam</i> message parameter will specify the handle to the server.
FTP_NOTIFY_SUSPEND	This notification is sent when the server suspends accepting new connections because the application has called the FtpServerSuspend function. This notification message may be sent to the application multiple times over the lifetime of the server. The <i>lParam</i> message parameter will specify the handle to the server.
FTP_NOTIFY_RESTART	This notification is sent when the server is restarted using the FtpServerRestart function. Note that the server socket handle provided by the <i>lParam</i> message parameter will specify the new socket handle of the restarted server instance, not the original socket handle. The <i>lParam</i> message parameter will specify the handle to the server.
FTP_NOTIFY_CONNECT	This notification is sent when the server accepts a client connection and the thread that manages the client session has begun processing network events for that client. This message notification will not be sent if the client connection is rejected by the server. The <i>lParam</i> message parameter will specify the unique ID of the client that connected to the server.
FTP_NOTIFY_DISCONNECT	This notification is sent when the client disconnects from the server and the client socket has been closed. This notification message may not occur for each client session that is forced to terminate as the result of the server being stopped using the FtpServerStop function. The <i>lParam</i> message parameter will specify the unique ID of the client that disconnected from the server.
FTP_NOTIFY_SHUTDOWN	This notification is sent when the server thread is in the process of terminating. At the time the application processes this notification message, the server handle in <i>lParam</i> will reference the defunct server and cannot be used with other server functions. The <i>lParam</i> message parameter will specify the handle to the server.

If asynchronous notifications are enabled, you should never use those notifications as a replacement for an event handler. When an event occurs, the callback function that handles the event is invoked in the context of the thread that manages the client session. The application should exchange data with the client within that event handler and not in response to a notification message. These notification messages should only be used to update the application UI in response to changes in the status of the server.

The FTP_NOTIFY_CONNECT and FTP_NOTIFY_DISCONNECT notifications are different from the other server notifications because the *lParam* message parameter does not specify the server handle, but rather the unique client ID associated with the session that connected to or disconnected from the server. Use the **FtpGetClientServer** function to obtain a handle to the server that created the client session. Note that at the time the application processes the FTP_NOTIFY_DISCONNECT notification

message, the client session will have already terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h.

FtpServerDisableTrace Function

```
BOOL WINAPI FtpServerDisableTrace();
```

Disable the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

See Also

[FtpServerEnableTrace](#)

FtpServerEnableTrace Function

```
BOOL WINAPI FtpServerEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

Enable the logging of network function calls to a file.

Parameters

lpszTraceFile

A pointer to a string that specifies the name of the log file. If this parameter is NULL or points to an empty string, a log file is created in the temporary directory for the current user.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_DEFAULT	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail, or return values which indicate a warning, are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call [FtpGetServerError](#).

Remarks

When trace logging is enabled, the log file is opened, appended to and closed for each socket function call. Using the same file name, you can do the same in your application to add additional information to the file if needed. This can provide an application-level context for the entries made by the library. Make sure that the file is closed after the data has been written. If a file name is not specified by the caller, a file named **cstrace.log** will be created in the temporary directory for the current user.

The TRACE_HEXDUMP option can produce very large files, since all data that is being sent and received by the application is logged. To reduce the size of the file, you can enable and disable logging around limited sections of code that you wish to analyze.

To redistribute an application that includes this debug logging functionality, the **cstrcv11.dll** library must be included as part of the installation package. This library provides the trace logging features, and if it is not available the **FtpServerEnableTrace** function will fail. Note that this is a standard Windows DLL and does not need to be registered, it only needs to be redistributed with your application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpServerDisableTrace](#)

FtpServerInitialize Function

```
BOOL WINAPI FtpServerInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **FtpServerInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**. All other functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **FtpServerInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **FtpServerUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **FtpServerInitialize** or **FtpServerUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[FtpServerStart](#), [FtpServerStop](#), [FtpServerUninitialize](#), [INITDATA](#)

FtpServerProc Function

```
VOID CALLBACK FtpServerProc(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **FtpServerProc** function is an application-defined callback function that processes events generated by the server process.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client that has issued a request to the server.

nEventId

An unsigned integer which specifies which event occurred. For a list of events, see [Server Event Constants](#).

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero. The **FtpGetServerError** function can be used to obtain additional information about the error code.

dwParam

A user-defined integer value which was specified when the server was started. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

Return Value

None.

Remarks

The FTP_CLIENT_COMMAND event can be used to filter commands issued by the client. If the command performs an operation on a file or directory, the **FtpGetCommandFile** function can be used to obtain the file name on the server that the client specified. It is possible for the application to change the file name using the **FtpSetCommandFile** function to direct the server to use a different file than the one specified by the client. If the file name is changed and the event handler returns a value of zero, the server will perform the default action for the command using the new file name.

The FTP_CLIENT_TIMEOUT event will only occur for authenticated client sessions. The server has a second, internal timer that is maintained for unauthenticated sessions that requires the client to successfully authenticate itself within a fixed period of time. If a client does not authenticate within the allowed time period, the server will automatically close the control channel. For more information, refer to the documentation for the *nAuthTime* member of the **FTPSERVERCONFIG** structure.

The callback function will be called in the context of the thread that is currently managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within

the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within an event handler. Controls should only be modified by the same UI thread that created their window. To change the user interface in response to a server event, use the **FtpServerAsyncNotify** function to enable asynchronous notifications and update the UI in response to the notification message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

See Also

[FtpServerAsyncNotify](#), [FtpServerStart](#)

FtpServerRestart Function

```
HSERVER WINAPI FtpServerRestart(  
    HSERVER hServer  
);
```

Restart the server, terminating all active client sessions.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the new handle for the specified server. If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerRestart** function will restart the specified server, terminating all active client sessions. The server handle that is returned by the function is the handle for the new server instance, and the old handle value is no longer valid. If the function is unable to restart the server for any reason, the server thread is terminated. The server retains all of the configuration parameters from the previous instance, however the statistical information (such as the number of clients, files transferred, etc.) will be reset.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **FtpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csftsv11.lib`

See Also

[FtpServerStart](#), [FtpServerStop](#)

FtpServerResume Function

```
BOOL WINAPI FtpServerResume(  
    HSERVER hServer  
);
```

Resume accepting client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerResume** function instructs the server to resume accepting new client connections after the **FtpServerSuspend** function has been called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

See Also

[FtpServerRestart](#), [FtpServerStart](#), [FtpServerStop](#), [FtpServerSuspend](#), [FtpServerThrottle](#)

FtpServerStart Function

```
HSERVER WINAPI FtpServerStart(  
    LPCTSTR lpszLocalHost,  
    UINT nLocalPort,  
    DWORD dwOptions,  
    LPFTPSEVERCONFIG lpServerConfig,  
    FTPSERVPROC lpServerProc,  
    DWORD_PTR dwServerParam,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **FtpServerStart** function begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the callback function specified by the caller.

Parameters

lpszLocalHost

A pointer to a string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is NULL or an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

nLocalPort

The port number the server should use to listen for client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit TLS. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

dwOptions

An unsigned integer value that specifies the options used when creating an instance of the server. For a list of options, see [Server Option Constants](#).

lpServerConfig

A pointer to an **FTPSEVERCONFIG** structure that specifies the configuration options for the server. If this parameter is NULL, then default configuration parameters will be used that starts the server in a restrictive mode.

lpServerProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **FtpServerProc** callback function. If this parameter is NULL, a default internal handler is used to process client commands.

dwServerParam

A user-defined integer value that is passed to the callback function. If the *lpServerProc* parameter is NULL, this value should be zero. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

lpCredentials

Pointer to a **SECURITYCREDENTIALS** structure. If this parameter is NULL, the default security credentials for the server host name will be used. If security is enabled for the server, it is recommended that you provide a pointer to this structure with specific information about the server

certificate that should be used. If the security options are not specified in the server configuration, this parameter is ignored.

Return Value

If the function succeeds, the return value is a handle to a server session. If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call **FtpGetServerError**.

Remarks

In most cases, the *lpzLocalHost* parameter should be a NULL pointer or an empty string. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The handle returned by this function references the listening socket that was created when the server was started. The service is managed in another thread, and all interaction with the server and active client connections are performed inside the event handler. To disconnect all active connections, close the listening socket and terminate the server thread, call the **FtpServerStop** function.

The host UUID that is defined as part of the server configuration should be generated using the **uuidgen** utility that is included with the Windows SDK. You should not use the UUID that is provided in the example code, it is for demonstration purposes only. If no host UUID is specified in the server configuration, an ephemeral UUID will be generated automatically when the server is started.

If the server is started with security enabled, the *lpCredentials* parameter should be used to provide the server certificate information in a **SECURITYCREDENTIALS** structure. If the pointer is NULL, this function will search for a certificate that matches the hostname provided as part of the server configuration. This requires that the server certificate be installed in the personal certificate store of the current process user, and it must have a private key associated with it. To use a certificate with a different name, or one that is stored in a PFX file, a **SECURITYCREDENTIALS** structure must be defined and passed to this function.

Example

```
HSERVER hServer;  
FTPSEVERCONFIG ftpConfig;  
  
// Initialize the server configuration  
ZeroMemory(&ftpConfig, sizeof(FTPSEVERCONFIG));  
ftpConfig.dwSize = sizeof(ftpConfig);  
ftpConfig.nMaxClients = 20;  
ftpConfig.nMaxGuests = 5;  
ftpConfig.nLogFormat = FTP_LOGFILE_EXTENDED;  
ftpConfig.nAuthTime = 30;  
ftpConfig.nIdleTime = 120;  
ftpConfig.lpszIdentity = _T("MyProgram");
```

```
ftpConfig.lpszHostName = _T("server.company.com");
ftpConfig.lpszHostUuid = _T("10000000-1000-1000-1000-100000000000");
ftpConfig.lpszDirectory = _T("%ProgramData%\\MyProgram\\Files");
ftpConfig.lpszLogFile = _T("%ProgramData%\\MyProgram\\Server.log");

// Start the server
hServer = FtpServerStart(lpszLocalHost,
                        FTP_PORT_DEFAULT,
                        FTP_SERVER_LOCALUSER | FTP_SERVER_UNIXMODE,
                        &ftpConfig,
                        lpEventHandler,
                        0,
                        NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

[SECURITYCREDENTIALS](#)

FtpServerStop Function

```
BOOL WINAPI FtpServerStop(  
    HSERVER hServer  
);
```

Stop the server, terminating all active client sessions and releasing the resources that were allocated for the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **FtpServerStop** function instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the server handle to be opaque and never depend on it being a specific value.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **FtpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

See Also

[FtpServerRestart](#), [FtpServerStart](#)

FtpServerSuspend Function

```
BOOL WINAPI FtpServerSuspend(  
    HSERVER hServer  
);
```

Suspend the server and reject new client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerSuspend** function instructs the server to suspend accepting new client connections. Any incoming client connections will be rejected with an error message indicating that the server is currently unavailable. To resume accepting client connections, call the **FtpServerResume** function. Suspending the server will have no effect on clients that have already established a connection with the server.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **FtpServerThrottle** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

See Also

[FtpServerRestart](#), [FtpServerResume](#), [FtpServerStart](#), [FtpServerStop](#), [FtpServerThrottle](#)

FtpServerThrottle Function

```
BOOL WINAPI FtpServerThrottle(  
    HSERVER hServer,  
    UINT nMaxClients,  
    UINT nMaxClientsPerAddress,  
    UINT nMaxGuests,  
    DWORD dwConnectionRate  
);
```

The **FtpServerThrottle** function limits the number of active client connections, connections per address and connection rate.

Parameters

hServer

Handle to the server.

nMaxClients

An integer value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections. A value of -1 specifies that the maximum number of clients should not be changed.

nMaxClientsPerAddress

An integer value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is a limit of four client connections per address. A value of -1 specifies that the maximum number of clients should not be changed.

nMaxGuests

An integer value which specifies the maximum number of guest users that may login to the server. A value of zero disables guest logins and requires that all clients authenticate with a valid username and password. A value of -1 specifies that the maximum number of guest users should not be changed.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate. A value of -1 specifies that the connection rate should not be changed.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerThrottle** function is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client

sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **FtpServerStart** function is called with the maximum number of clients set to 100, and then **FtpServerThrottle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

It is recommended that you always specify conservative connection limits for your server application based on expected usage. Allowing an unlimited number of client connections can potentially expose the system to denial-of-service attacks and should never be done for servers that are accessible over the Internet.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

See Also

[FtpServerRestart](#), [FtpServerResume](#), [FtpServerStart](#), [FtpServerSuspend](#)

FtpServerUninitialize Function

```
VOID WINAPI FtpServerUninitialize();
```

The **FtpServerUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **FtpServerInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **FtpServerUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **FtpServerUninitialize** for every successful call to **FtpServerInitialize** made by a process. Operations for all threads in the server are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

See Also

[FtpServerInitialize](#), [FtpServerStart](#), [FtpServerStop](#)

FtpSetClientAccess Function

```
BOOL WINAPI FtpSetClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess  
);
```

Change the access rights associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see [User Access Constants](#).

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **FtpSetClientAccess** function can change the access rights for an authenticated client session. This function can only be used after the **FtpAuthenticateClient** function has been used to grant the initial set of access rights to the client. The **FtpEnableClientAccess** function can be used to grant or revoke a specific permission for the client session.

The *dwUserAccess* parameter has a value of FTP_ACCESS_DEFAULT, then default permissions will be granted to the client session. A normal client cannot be changed to a restricted or anonymous client using this function. If the FTP_ACCESS_RESTRICTED or FTP_ACCESS_ANONYMOUS access flags are specified, this function will fail.

This function cannot be used to change the access rights for a restricted or anonymous user. Those rights are granted when the client session is authenticated and will persist until the client disconnects from the server. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

Example

```
DWORD dwUserAccess = 0;  
  
// Allow the client to execute programs using SITE EXEC  
if (FtpGetClientAccess(hServer, nClientId, &dwUserAccess))  
{  
    if (! (dwUserAccess & FTP_ACCESS_ANONYMOUS))  
        FtpSetClientAccess(hServer, nClientId, dwUserAccess | FTP_ACCESS_EXECUTE);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

See Also

[FtpAuthenticateClient](#), [FtpEnableClientAccess](#), [FtpGetClientAccess](#)

FtpSetClientFileType Function

```
BOOL WINAPI FtpSetClientFileType(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nFileType  
);
```

Change the current file type used for transfers by the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nFileType

Specifies the type of file that will be uploaded or downloaded. This parameter determines whether subsequent file transfers require any data conversion and may be one of the following values.

Value	Description
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those clients which use a different end-of-line character sequence, the text file has been converted to the local format which uses the carriage return (CR) and linefeed (LF) characters.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type has been performed on the file. This is the default file type for most data files and executable programs. If the client specified this file type when appending to a text file, the file will contain the end-of-line sequences used by its native operating system.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpSetClientFileType** function will change the default file type that is used for subsequent transfers by the client. If the file type is set to FILE_TYPE_ASCII then the server will automatically convert any end-of-line character sequences to match the format used by the local system. For example, if the client is connecting from a UNIX based system, the server will convert a single linefeed character to a carriage return (CR) and linefeed (LF) sequence. If the file type is set to FILE_TYPE_IMAGE, then no conversion is performed.

This function can be used to override the file type specified by filtering the TYPE command issued by the client. For example, it could be used to force file transfers to use a specific type based on the file extension, regardless of the type specified by the client. To determine the current file type set by the client, use the **FtpGetClientFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

See Also

[FtpGetClientFileType](#)

FtpSetClientIdentity Function

```
BOOL WINAPI FtpSetClientIdentity(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszIdentity  
);
```

Change the identity of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszIdentity

A pointer to a string that identifies the client. If this parameter is NULL or specifies an empty string, the current identity for the client is cleared. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the server handle or client ID is invalid, the function will return a value of zero.

Remarks

The **FtpSetClientIdentity** function associates a string value with the client that can be used to identify the session. The identity string does not have any standard format and is used for informational purposes only. Typically it is used to identify the client application that was used to establish the connection. Changing the client identity has no effect on the operation of the server. To obtain the identity string currently associated with the client, use the **FtpGetClientIdentity** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetClientIdentity](#), [FtpGetServerIdentity](#), [FtpSetServerIdentity](#)

FtpSetClientIdleTime Function

```
UINT WINAPI FtpSetClientIdleTime(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nTimeout  
);
```

Change the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nTimeout

An unsigned integer value that specifies the number of seconds that the client may remain idle. If this value is zero, the default idle timeout period for the server will be used.

Return Value

If the function succeeds, the return value is the previous client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpSetClientIdleTime** function will change the number of seconds that the client may remain idle before being automatically disconnected by the server. The minimum timeout period for a client is 60 seconds, the maximum is 7200 seconds (2 hours). The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed.

If the value INFINITE is specified as the timeout period, the client activity timer will be refreshed, extending the idle timeout period for the session. This is typically done inside an event handler to prevent the client from being disconnected due to inactivity.

To obtain the current idle timeout period for a client, along with the amount of time the client has been idle, use the **FtpGetClientIdleTime** function.

This timeout period only affects authenticated clients. Unauthenticated clients use a different internal timer that limits the amount of time they can remain connected to the server and that value cannot be changed for individual client sessions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

FtpSetCommandFile Function

```
BOOL WINAPI FtpSetCommandFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszFileName  
);
```

Change the name of the local file or directory that is the target of the current command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string that specifies the new file name. This parameter may be NULL to specify that the original file or directory name should be used.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpSetCommandFile** function is used by the application to change the target file or directory name for the current command from within an FTP_EVENT_COMMAND event handler. This can be used to effectively redirect the client to use a different file than the one that was actually requested. For example, if the client issues the RETR command to download a file from the server, this function can be used to redirect the command to use a different file name. To obtain the full path to the file or directory that is the target of the current command, use the **FtpGetCommandFile** function.

The *lpszFileName* parameter specifies the path to the new file or directory name. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the current working directory for the client session. The full path to this file is not limited to the server root directory or its subdirectory, it can specify a file anywhere on the local system. If this parameter is a NULL pointer, or points to an empty string, then the server will revert to using the actual file or directory name specified by the command. This enables the application to effectively undo a previous call to this function to change the target file name.

Typically this function would be used to redirect a client to a file or directory that it may not normally have access to. Exercise caution when using this function to provide access to data that is stored outside of the server root directory. Incorrect use of this function could expose the server to security risks or cause unpredictable behavior by client applications.

This function should only be called within the context of the FTP_EVENT_COMMAND event, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_COMMAND. To obtain the name of the current command issued by the client, use the **FtpGetCommandName** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpSetServerAddress Function

```
BOOL WINAPI FtpSetServerAddress(  
    HSERVER hServer,  
    LPCTSTR LpszAddress  
);
```

Change the IP address that the server will use with passive data connections.

Parameters

hServer

The server handle.

lpszAddress

A pointer to a string that specifies the IP address that the server should use for passive mode data transfers. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle or the IP address is invalid the function will return a value of zero.

Remarks

The **FtpSetServerAddress** function changes the IP address that the server will use when a client transfers a file using a passive mode data connection. In passive mode, the server will create a second passive (listening) socket that will accept an incoming connection from the client. The server sends the IP address and port number allocated for that socket to the client, and the client establishes the data connection to the server using that address. The IP address that the server sends to the client is normally the same as the IP address that the client used to establish the control connection, however if the server is located behind a router that performs Network Address Translation (NAT), the IP address reported to the client may not be usable.

This function enables your application to set the external IP address for the server to a specific value, rather than the server attempting to automatically discover its own external address. If you wish to set the external address for the server manually, call the **FtpServerStart** function without the FTP_SERVER_EXTERNAL option and then call this function to set the external IP address to the desired value.

This function will not change the IP address the server is using to listen for client connections. The only way to change the listening IP address is to stop and restart the server using the new address. This function only changes the IP address that is reported to clients when a passive data connection is used. Incorrect use of this function can prevent the client from establishing a data connection to the server. The address must be in the same address family as the local address that the server was started with. For example, if the server was started using an IPv4 address, the IP address passed to this function cannot be an IPv6 address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

FtpSetServerError Function

```
VOID WINAPI FtpSetServerError(  
    HSERVER hServer,  
    DWORD dwError  
);
```

Set the last error code for the specified server session.

Parameters

hServer

The server handle.

dwError

An unsigned integer that specifies an error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each server session. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or FTP_ERROR.

If the *hServer* parameter is specified as INVALID_SERVER, this function will set the last error code for the current thread, but will not change the error code associated with any server session. This should only be done if the application does not have access to a valid server handle.

If the *dwError* parameter is specified with a value of zero, this effectively clears the error code for the last function that failed. Those functions which clear the last error code when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **FtpGetServerError** function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csftsv11.lib

FtpSetServerIdentity Function

```
BOOL WINAPI FtpSetServerIdentity(  
    HSERVER hServer,  
    LPCTSTR lpszIdentity  
);
```

Change the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A pointer to a string that identifies the server. If this parameter is NULL or specifies an empty string, the current identity for the server is reset to a default value. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **FtpSetClientIdentity** function changes a string value used by the server to identify itself to clients. The identity string does not have any standard format and is used for informational purposes only. Typically it consists of the application name and a version number. Changing the server identity has no effect on the operation of the server. To obtain the identity string currently associated with the server, use the **FtpGetServerIdentity** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpSetServerLogFile Function

```
BOOL WINAPI FtpSetServerLogFile(  
    HSERVER hServer,  
    UINT nLogFormat,  
    UINT nLogLevel,  
    LPCTSTR lpszFileName  
);
```

Change the current log format, level of detail and file name.

Parameters

hServer

The server handle.

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Value	Description
FTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
FTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
FTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

nLogLevel

An integer value that specifies the level of detail that should be generated in the log file. The minimum value is 1 and the maximum value is 10. If this parameter is zero, it is the same as specifying a log file format of FTP_LOGFILE_NONE and will disable logging by the server.

lpszFileName

A pointer to a string that specifies the name of the log file that should be created or appended to. If the server was configured with logging enabled and this parameter is NULL or an empty string, the current log file name will not be changed. If the log file does not exist, it will be created. If it does exist, the contents of the log file will be appended to.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero.

Remarks

The **FtpSetServerLogFile** function can be used to change the current log file name, the format of the log file or the level of detail recorded in the log file. In some situations it may be desirable to delete the current log file contents when changing the format or ensure that a new log file is created. To do this, combine the *nLogFormat* parameter with the constant FTP_LOGFILE_DELETE.

The higher the value of the *nLogLevel* parameter, the greater the level of detail that is recorded by the server. A log level of 1 instructs the server to only record file transfers, while a level of 10 instructs the server to record all commands processed by the server. Because a higher level of logging detail can negatively impact the performance of the server, it is recommended that you do not exceed a level of 5 for most applications. A log level of 10 should only be used for debugging purposes.

Example

```
UINT nLogFormat = FTP_LOGFILE_NONE;
UINT nLogLevel = 0;
UINT nNewLevel = 5;
BOOL bChanged = FALSE;

// Change the level of detail for the current log file if logging
// has been enabled and the current level is a lower value

if (FtpGetServerLogFile(hServer, &nLogFormat, &nLogLevel, NULL, 0))
{
    if (nLogFormat != FTP_LOGFILE_NONE && nLogLevel < nNewLevel)
        bChanged = FtpSetServerLogFile(hServer, nLogFormat, nNewLevel, NULL);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[FtpGetServerLogFile](#), [FtpRenameServerLogFile](#)

FtpSetServerName Function

```
BOOL WINAPI FtpSetServerName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszHostName  
);
```

Change the host name assigned to the specified server or client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A pointer to a string that specifies the new host name assigned to the server or client session. If this value is NULL or points to an empty string, the current host name will be changed to use the default host name.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will change the host name assigned to the specified client session. If the *nClientId* parameter has a value of zero, the function will change default host name that was assigned to the server as part of the server configuration. If the *nClientId* parameter specifies a valid client session and the *lpszHostName* parameter is NULL, the host name associated with the client session will be changed to the current host name assigned to the server.

When a client connects to the server, it can specify the host name that it used to establish the connection by sending the HOST command. This is typically used with virtual hosting, where one server may accept client connections for multiple domains. The **FtpGetServerName** function will return the host name specified by the client, and **FtpSetServerName** can be used by the application to either explicitly assign a different host name to the client session, or override the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

Unicode: Implemented as Unicode and ANSI versions

FtpSetServerPriority Function

```
INT WINAPI FtpSetServerPriority(  
    HSERVER hServer,  
    INT nPriority  
);
```

Change the priority assigned to the specified server.

Parameters

hServer
The server handle.

nPriority
An integer value which specifies the new priority for the server. It may be one of the following values:

Value	Description
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
FTP_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority assigned to the server. If the function fails, the return value is FTP_PRIORITY_INVALID. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpSetServerPriority** function can be used to change the current priority assigned to the specified server. Client connections that are accepted after this function is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h.

Import Library: csftsv11.lib

FtpSetServerStackSize Function

```
BOOL WINAPI FtpSetServerStackSize(  
    SOCKET hServer,  
    DWORD dwStackSize  
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpSetServerStackSize** function changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change the stack size unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csftsv11.lib

File Transfer Protocol Server Data Structures

- `FTPCLIENTCREDENTIALS`
- `FTPSEVERCONFIG`
- `FTPSEVERTRANSFER`
- `INITDATA`
- `SECURITYCREDENTIALS`

FTPCLIENTCREDENTIALS

The **FTPCLIENTCREDENTIALS** structure defines the credentials used to authenticate a specific user.

```
typedef struct _FTPCLIENTCREDENTIALS
{
    DWORD dwSize;
    DWORD dwFlags;
    TCHAR szHostName[FTP_MAXHOSTNAME];
    TCHAR szUserName[FTP_MAXUSERNAME];
    TCHAR szPassword[FTP_MAXPASSWORD];
} FTPCLIENTCREDENTIALS, *LPFTPCLIENTCREDENTIALS;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value reserved for future use. This member will always be initialized to a value of zero.

szHostName

A pointer to a string that specifies the server host name.

szUserName

A pointer to a string that specifies the user name.

szPassword

A pointer to a string that specifies the user password.

Remarks

When an instance of this structure is passed to the **FtpGetClientCredentials** function, this member must be initialized to the size of the structure and all other members must be initialized with a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

[FtpGetClientCredentials](#)

FTPSEVERCONFIG

The **FTPSEVERCONFIG** structure provides the configuration information used to create an instance of an FTP server.

```
typedef struct _FTPSEVERCONFIG
{
    DWORD    dwSize;
    UINT     nMaxClients;
    UINT     nMaxClientsPerAddress;
    UINT     nMaxGuests;
    UINT     nLogFormat;
    UINT     nLogLevel;
    UINT     nMinPort;
    UINT     nMaxPort;
    UINT     nAuthFail;
    UINT     nAuthTime;
    UINT     nIdleTime;
    UINT     nExecTime;
    LPCTSTR  lpszIdentity;
    LPCTSTR  lpszHostUuid;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszRootPath;
    LPCTSTR  lpszTempPath;
    LPCTSTR  lpszLogFile;
} FTPSEVERCONFIG, *LPFTPSEVERCONFIG;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

nMaxClients

An integer value that specifies the maximum number of active client connections that will be accepted by the server. If the maximum number of clients is reached, any further connections are rejected by the server until one or more clients close their connection to the server or are disconnected. A value of zero specifies the default configuration value of 100 connections should be used.

nMaxClientsPerAddress

An integer value that specifies the maximum number of active client connections per IP address that will be accepted by the server. If the maximum number of clients from the same IP address is reached, any further connections are rejected until one of the clients closes its connection to the server. A value of zero specifies the default configuration value of 4 connections per address should be used.

nMaxGuests

An integer value that specifies the maximum number of anonymous client connections. If the server does not permit anonymous connections, this value is ignored. It is recommended that this value always be less than the value of the *nMaxClients* member. A value of zero specifies that the default configuration limit of 20 anonymous connections should be used.

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

--	--

Value	Description
FTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
FTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
FTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

nLogLevel

An integer value that specifies the level of detail that should be generated in the log file. The minimum value is 1 and the maximum value is 10. If the ***nLogFormat*** member specifies a valid log file format and this value is zero, a default level of detail will be selected based on the format. The common log file format generally contains less information by default, only logging the data transfers between the client and server. The W3C extended log file format defaults to a higher level of detail that includes additional information about the client session. The higher the level of detail, the larger the log file will be.

nMinPort

An integer value that specifies the minimum range of port numbers that will be used with passive data connections. A value of zero specifies that the default value of 30000 should be used. The minimum value of this member is 5000 and the maximum value is 65535. If the value is non-zero, it must be less than the value of the ***nMaxPort*** structure member.

nMaxPort

An integer value that specifies the maximum range of port numbers that will be used with passive data connections. A value of zero specifies the default value of 65535 should be used. The minimum value of this member is 5000 and the maximum value is 65535. If the value is non-zero, it must be greater than the value of the ***nMinPort*** structure member.

nAuthFail

An integer value that specifies the maximum number of user authentication attempts that are permitted until the server terminates the client connection. A value of zero specifies that the default configuration limit of 3 authentication attempts per login should be allowed. The maximum number of authentication attempts is 10.

nAuthTime

An integer value that specifies the maximum number of user authentication attempts that are permitted until the server terminates the client connection. A value of zero specifies the default value of 60 seconds. If the value is non-zero, the minimum value is 20 seconds and the maximum value is 300 seconds (5 minutes). This value is used to ensure that a client has successfully authenticated itself within a limited period of time. This prevents a potential denial-of-service attack against the server where clients establish connections and hold them open without authentication. In conjunction with the ***nAuthFail*** member, this also limits the ability of a client to attempt to probe the server for valid username and password combinations.

nIdleTime

An integer value that specifies the maximum number of seconds that a client session may be idle before the server closes the control connection to the client. A value of zero specifies the default

value of 900 seconds (15 minutes). If the value is non-zero, the minimum value is 60 seconds and the maximum value is 7200 seconds (2 hours). This value is used to initialize the default idle timeout period for each client session. A client may request that the server change the idle timeout period for its session by sending the SITE IDLE command. The server determines if a client is idle based on the time the last command was issued and whether or not a file transfer is in progress.

nExecTime

An unsigned integer value that specifies the maximum number of seconds that an external program is permitted to run on the server. External programs are registered using the **FtpRegisterProgram** function, and are executed by the client sending the SITE EXEC command to the server. If this value is zero, the default timeout period of 5 seconds will be used. The minimum execution time is 1 second and the maximum time limit is 30 seconds.

lpszIdentity

A pointer to a string that identifies the server. It is used for informational purposes only and has no effect on the operation of the server. If this member is not initialized to a value, then a default identity will be used. The server identity is provided when a client establishes the initial connection and when the client sends the STAT or CSID commands. If this member is defined, it is recommended that you only use printable ASCII characters.

lpszHostUuid

A pointer to a string that specifies a Universally Unique Identifier (UUID) that is used to uniquely identify the server. This value can be used when storing information about the server, and should be generated using a utility such as **uuidgen** which is included with Visual Studio. This structure member may be initialized to an empty string, in which case a temporary UUID will be randomly generated.

lpszHostName

A pointer to a string that specifies the fully-qualified host name for the server. If this structure member is initialized with an empty string, the local host name assigned to the Windows system will be used. This value does not need to correspond to the actual host name associated with the server's IP address. This value is used for informational purposes only and has no effect on the operation of the server.

lpszRootPath

A pointer to a string that specifies the path to the root directory for the server. If this structure member is initialized with an empty string, the current working directory for the process will be used as the root directory. It is recommended that you provide a full path to an existing directory and do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszTempPath

A pointer to a string that specifies the path to the temporary directory for the server. If this structure member is initialized with an empty string, the current temporary directory for the process will be used. The temporary directory cannot be the same as the root directory, and it is strongly recommended that you do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszLogFile

A pointer to a string that specifies the name of the server log file to create, if a logging format has been specified. If logging is enabled and this member is an empty string, then a default log file name will be created. If the file name does not include a path, then the file is created in the server log directory. If the file name includes a path, the log file will be created using that specific name. If the server is in multi-user mode, then the default location for log files will be the Logs subdirectory

in the server root directory. If the server is not in multi-user mode, the default location for log files will be the temporary directory for the server process.

Remarks

When an instance of this structure is passed to the **FtpServerStart** function, the *dwSize* member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the configuration is invalid.

The *nMaxClients* member limits the total number of client connections and the *nMaxGuests* member limits the total number of guest connections. The server will notify the client if either number of connections has been exceeded and will automatically close the connection. However, one difference is that a new client that exceeds the maximum number of connections will not generate any events; a client that exceeds the maximum number of guest connections will generate events. The reason for the difference is that the check for the number of active clients is made immediately after the client connects to the server, prior to session context being created for that client. The check for the number of anonymous clients is made later, after the client has sent the USER and PASS commands to the server. For more control over how the server accepts client connections, use the **FtpServerThrottle** function.

If the server is running on a system that is behind a firewall that restricts the range of port numbers for inbound connections, the *nMinPort* and *nMaxPort* members can be used to limit the ports which the server will use to listen for passive data connections from clients. By default, the server will use data port numbers that range from 30000 to 65535, which is typical for many firewall configurations. If you provide your own port range, the minimum number of ports available must be at least 1000. Specifying a port range that is too small will cause the **FtpServerStart** function to fail with an error indicating that the server configuration is invalid.

When specifying the root directory for the server configuration, it is important to consider that a client's access to files on the system will be limited to these directories and any subdirectories. If a root directory is not specified, then one will be created using the current working directory for the process. The root directory path may include environment variables surrounded by % symbols and these will be expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. If the root directory does not exist at the time that the server is started, it will be created.

For servers that are publicly accessible, or where you want files to be accessible across multiple server sessions, you should always populate the *szHostUuid* member with a valid UUID string, and the *szDirectory* member should specify an absolute path to an existing directory.

If the FTP_SERVER_MULTIUSER option is specified, the server will start in multi-user mode, with each user assigned to their own home directory based on their username. This option will cause the server to create a directory structure in the root directory that includes three subdirectories: Public, Users and Logs. The Public directory is the home directory for anonymous users, and they are isolated to that directory. The Users directory is where the user home directories are created. The Logs directory is where log files are created by default. If this option is not specified, then no subdirectories are created and all users will share the server root directory by default.

If the FTP_SERVER_LOCALUSER option is specified, the server will never attempt to authenticate the local Administrator or Guest accounts. This is done to prevent clients from attempting to probe for the administrator account password. However, the application can override this behavior by implementing

a handler for the FTP_CLIENT_LOGIN event.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

FTPSEVERTRANSFER

The **FTPSEVERTRANSFER** structure provides information about the last file transfer performed by a client.

```
typedef struct _FTPSEVERTRANSFER
{
    DWORD          dwSize;
    DWORD          dwReserved;
    DWORD          dwFileAccess;
    DWORD          dwTimeElapsed;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szFileName[MAX_PATH];
} FTPSEVERTRANSFER, *LPFTPSEVERTRANSFER;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

dwFileAccess

An unsigned integer value that specifies the how the local file was accessed. It can be one of the following values:

Value	Description
FTP_FILE_READ	The file was opened for reading. This mode indicates that the client issued the RETR command to download the contents of a file from the server to the client system. The <i>szFileName</i> member specifies the name of the local file on the server that was downloaded by the client.
FTP_FILE_WRITE	The file was opened for writing. This mode indicates that the client issued the STOR or STOU command to upload the contents of a file from the client system to server. The <i>szFileName</i> member specifies the name of the local file on the server that was created by the client. If a file already existed with the name name, it was replaced.
FTP_FILE_APPEND	The file was opened for writing. This mode indicates the client issued the APPE command to upload the contents of a file from the client system and append the data to a file on the server. If the file did not exist, then it was created. The <i>szFileName</i> member specifies the name of the local file that was appended to or created by the client.

dwTimeElapsed

The amount of time that it took for the file transfer to complete in milliseconds.

This value is limited to the resolution of the system timer, which is typically in the range of 10 to 16 milliseconds. This value may be zero if the transfer occurred over a local network or on the same host using a loopback address.

uiBytesCopied

A 64-bit integer value that specifies the total number of bytes copied during the file transfer. This value is represented by a `ULARGE_INTEGER` union which provides support for those programming languages that do not have intrinsic support for 64-bit integers. For more information, refer to the Windows SDK documentation. The application should not make the assumption that this is the actual size of the file. If the client specified a restart offset using the `REST` command, this value would only represent the number of bytes transferred from that byte offset, not the total file size.

szFileName

A pointer to a string value that will contain the full path to the local file that was transferred. The ***dwFileAccess*** member determines whether the file name represents a file that was downloaded by the client, or uploaded from the client and stored on the server.

Remarks

When an instance of this structure is passed to the **`FtpGetServerTransferInfo`** function, the ***dwSize*** member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the parameter is invalid. All other members should be initialized to a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Unicode: Implemented as Unicode and ANSI versions

    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify the security protocol and server certificate when accepting a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

- dwSize***
Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.
- dwProtocol***
A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpPassword* member or the library will be unable to access the certificate.

Note that the *lpUserName* and *lpPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Library Information

File Name	CSHTTPV11.DLL
Version	11.0.2218.1855
LibID	1EE620E7-5A9E-4DC3-8403-9153F19C51D9
Import Library	CSHTTPV11.LIB
Dependencies	None
Standards	RFC 1945, RFC 2616, RFC 7230, RFC 7540

Overview

The Hypertext Transfer Protocol (HTTP) is a lightweight, stateless application protocol that is used to access resources on web servers, as well as send data to those servers for processing. The library provides direct, low-level access to the server and the commands that are used to retrieve resources (i.e.: documents, images, etc.). The library also provides a simple interface for downloading resources to the local host, similar to how the HTTP library can be used to download files.

In a typical session, the library is used to establish a connection, send a request (to download a resource, post data for processing, etc.), read the data returned by the server and then disconnect. It is the responsibility of the client to process the data returned by the server, depending on the type of resource that was requested.

This library supports secure, encrypted file transfers using TLS 1.2 and later versions of the protocol.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Hypertext Transfer Protocol Functions

Function	Description
HttpAddFormField	Add the form field and its value to the specified form
HttpAddFormFile	Add the contents of the file to the specified form
HttpAddQueuedFile	Add a new file to the queue to be uploaded or downloaded
HttpAddQueuedFileEx	Add a new file to the queue with additional transfer options
HttpAddRequestHeaders	Add one or more request headers for the current client session
HttpAsyncConnect	Establish an asynchronous connection to the specified server
HttpAsyncGetData	Copy the contents of a resource on the server to a local buffer
HttpAsyncGetFile	Copy a file from the server to the local system
HttpAsyncGetFileEx	Copy a file from the server to the local system, use with files larger than 4GB
HttpAsyncPostData	Post data from a local buffer to a script executed on the server
HttpAsyncPostJson	Post JSON formatted data to a script executed on the server
HttpAsyncPostXml	Post XML formatted data to a script executed on the server
HttpAsyncProxyConnect	Establish an asynchronous connection to a proxy server
HttpAsyncPutData	Create a file on the server using the contents of a local buffer
HttpAsyncPutFile	Copy a file from the local system to the server
HttpAsyncPutFileEx	Copy a file from the local system to the server, use with files larger than 4GB
HttpAsyncSubmitForm	Submit the specified form to the server for processing
HttpAttachThread	Attach the specified client handle to another thread
HttpAuthenticate	Specify authentication information for restricted resources
HttpCancel	Cancel the current blocking operation
HttpCancelQueuedFile	Cancel the queued file transfer
HttpClearForm	Remove all defined fields from the specified form
HttpClearHeaders	Resets the the current request and response headers to their default values
HttpClearQueue	Remove all files from the current transfer queue
HttpCloseFile	Close the file opened on the server
HttpCommand	Send a command to the server
HttpConnect	Connect to the specified server
HttpConnectUrl	Establish a client connection using the specified URL
HttpCreateFile	Create or replace a file on the server
HttpCreateForm	Create a new form and return the form handle
HttpCreateQueue	Create a new file transfer queue
HttpCreateSecurityCredentials	Create a new security credentials structure

HttpDeleteFile	Remove a file from the server
HttpDeleteFormField	Delete the form field and its value from the specified form
HttpDeleteHeaders	Delete all of the response or request headers for the current session
HttpDeleteQueue	Delete a previously created file transfer queue
HttpDeleteSecurityCredentials	Delete a previously created security credentials structure
HttpDestroyForm	Destroy the specified form and free the memory allocated for it
HttpDisableEvents	Disable asynchronous event notification
HttpDisableTrace	Disable logging of network function calls to the trace log
HttpDisconnect	Disconnect from the current server
HttpDownloadFile	Download a file from the server to the local system
HttpEnableCompression	Enable or disable support for data compression
HttpEnableEvents	Enable asynchronous event notification
HttpEnableTrace	Enable logging of network function calls to a file
HttpEnumQueuedFiles	Return a list of files in the transfer queue
HttpEnumTasks	Return a list of asynchronous tasks
HttpEventProc	Callback function that processes events generated by the client
HttpFindQueuedFile	Find a file in the transfer queue which matches the search criteria
HttpFreezeEvents	Suspend asynchronous event processing
HttpGetBearerToken	Return the current OAuth 2.0 bearer token for the client session
HttpGetContentLength	Return the size of the current resource in bytes
HttpGetContentType	Return the content type for the current resource
HttpGetCookie	Return information about the specified cookie
HttpGetData	Copy the specified resource to a local buffer
HttpGetDefaultUserAgent	Return the default user agent string included with requests
HttpGetEncodingType	Determines which content encoding option is enabled
HttpGetErrorString	Return a description for the specified error code
HttpGetFile	Copy a file from the server to the local system
HttpGetFileEx	Copy a file from the server to the local system, use with large files over 4GiB
HttpGetFileSize	Return the size of a file on the server
HttpGetFileSizeEx	Return the size of a file on the server, supports large files over 4GiB
HttpGetFileTime	Return the date and time a file on the server was last modified
HttpGetFirstCookie	Return the first cookie set by the server
HttpGetFirstHeader	Return the name and value of the first request or response header field
HttpGetFirstQueuedFile	Return information about the first file in the transfer queue
HttpGetFormProperties	Return the properties of the specified form

HttpGetLastError	Return the last error code
HttpGetNextCookie	Return the next cookie set by the server
HttpGetNextHeader	Return the name and value of the next request or response header field
HttpGetNextQueuedFile	Return information about the next file in the transfer queue
HttpGetOption	Return the enabled/disabled state of a specified option
HttpGetPriority	Return the current priority for file transfers
HttpGetQueueClient	Return the handle to the current client session
HttpGetQueuedFile	Return information about a file queued for transfer
HttpGetQueueStatus	Return the status of the current file transfer queue
HttpGetQueueThread	Return a value which uniquely identifies the queue manager thread
HttpGetRedirectUrl	Return the URL for a redirected resource
HttpGetResourceUrl	Return the URL for the current request
HttpGetRequestHeader	Return the value of the specified request header field
HttpGetResponseHeader	Return the value of the specified response header field
HttpGetResultCode	Return the result code from the previous command
HttpGetResultString	Return the result string from the previous command
HttpGetSecurityInformation	Return security information about the current client connection
HttpGetStatus	Return the current client status
HttpGetTaskError	Return the last error code for the specified asynchronous task
HttpGetTaskId	Return the unique task identifier associated with the specified client session
HttpGetText	Return the contents of a text resource to a string buffer
HttpGetTextEx	Return the contents of a text resource with additional conversion options
HttpGetThreadQueue	Return the handle to a queue associated with the specified thread
HttpGetTimeout	Return the number of seconds until an operation times out
HttpGetTransferStatus	Return data transfer statistics
HttpInitialize	Initialize the library and validate the specified runtime license key
HttpIsBlocking	Determine if the client is blocked, waiting for information
HttpIsConnected	Determine if the client is connected to the server
HttpIsReadable	Determine if data can be read from the server
HttpIsWritable	Determine if data can be written to the server
HttpOpenFile	Open a file on the server for reading
HttpPatchData	Submits JSON or XML patch data to the server and returns the response
HttpPostData	Submit data to the server using the POST command and returns the response
HttpPostFile	Submit the contents of a local file to the server
HttpPostJson	Post JSON formatted data to the server and returns the response

HttpPostXml	Post XML formatted data to the server and returns the response
HttpProxyConnect	Establish a connection with the specified proxy server
HttpPutData	Create a file on the server using the contents of a local buffer
HttpPutDataEx	Submit data to the server using the PUT command and returns the response
HttpPutFile	Copy a file from the local system to the server
HttpPutFileEx	Copy a file from the local system to the server, use with large files over 4GiB
HttpPutText	Create a text file on the server from the contents of a string buffer
HttpPutTextEx	Submit text to the server using the PUT command and returns the response
HttpRead	Read data from the server
HttpRegisterEvent	Register an event callback function
HttpRemoveQueuedFile	Remove a file from the transfer queue
HttpResetQueue	Reset the internal state of file transfers in the specified queue
HttpResumeQueue	Resume the transfer of files after queue processing has been paused
HttpSetBearerToken	Set the value of the OAuth 2.0 bearer token for the client session
HttpSetContentType	Set the content type for the next request
HttpSetCookie	Set the value of the specified cookie
HttpSetDefaultUserAgent	Set the default user agent string included with requests
HttpSetEncodingType	Specifies the type of encoding to be applied to data submitted to the server
HttpSetFormProperties	Modify the properties of the specified form
HttpSetLastError	Set the last error code
HttpSetOption	Enable or disable the specified option
HttpSetPriority	Set the priority for file transfers
HttpSetRequestHeader	Set the value of a request header field
HttpSetTimeout	Set the number of seconds until an operation times out
HttpStartQueue	Begin transferring the files in the specified queue
HttpStopQueue	Stop transferring the files in the specified queue
HttpSubmitForm	Submit the specified form to the server for processing
HttpSubmitRequest	Submit a request to the server and return the response
HttpSuspendQueue	Pause the transfer of files in the specified queue
HttpTaskAbort	Abort the specified asynchronous task
HttpTaskDone	Determine if an asynchronous task has completed
HttpTaskResume	Resume execution of an asynchronous task
HttpTaskSuspend	Suspend execution of an asynchronous task
HttpTaskWait	Wait for an asynchronous task to complete
HttpUninitialize	Terminate use of the library by the application

HttpUploadFile	Upload a file from the local system to the server
HttpValidateHostName	Validate the specified host name and return the resolved IP address
HttpValidateUrl	Check the contents of a string to ensure it represents a valid URL
HttpVerifyFile	Compare the size of a local file against a file stored on the server
HttpWaitForQueue	Wait for the transfer of all queued files to complete
HttpWrite	Write data to the server

HttpAddFormField Function

```
INT WINAPI HttpAddFormField(  
    HFORM hForm,  
    LPCTSTR lpszFieldName,  
    LPVOID lpFieldData,  
    DWORD cbFieldData,  
    DWORD dwReserved  
);
```

The **HttpAddFormField** function adds a new field to the specified form.

Parameters

hForm

Handle to the virtual form.

lpszFieldName

A pointer to a string which specifies the name of the field to add to the form. If this parameter is NULL or points to an empty string, then a default field name will be assigned.

lpFieldData

A pointer to the form field data. Typically this will either be a pointer to an array of bytes or a string which specifies the value for the form field. If no data is to be associated with the form field, then this argument may be NULL.

cbFieldData

An unsigned integer value which specifies the number of bytes of data in the form field. If this value is 0xFFFFFFFF (-1) then it is assumed that the *lpFieldData* parameter is a pointer to a null-terminated string. If *lpFieldData* is NULL, this value must be zero.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpAddFormField** function is used to add a field and its associated value to a form created using the **HttpCreateForm** function. If the field name has already been added to the form, the previous value is deleted and replaced by the new value.

Example

```
HFORM hForm = INVALID_FORM;  
HGLOBAL hgb1Result = (HGLOBAL)NULL;  
DWORD cbResult = 0;  
INT nResult = 0;  
  
hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);  
  
if (hForm == INVALID_FORM)  
    return;  
  
HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);  
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);
```

```
nResult = HttpSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);
HttpDestroyForm(hForm);

if (hgblResult != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer points to data returned by the server after the form
    // data was submitted

    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpAddFormFile Function

```
INT WINAPI HttpAddFormFile(  
    HFORM hForm,  
    LPCTSTR lpszFieldName,  
    LPCTSTR lpszFileName,  
    DWORD dwReserved  
);
```

The **HttpAddFormFile** function adds the contents of a file to the specified form.

Parameters

hForm

Handle to the virtual form.

lpszFieldName

A pointer to a string which specifies the name of the field to add to the form. If this parameter is NULL or points to an empty string, then a default field name will be assigned.

lpszFileName

A pointer to a string which specifies the name of the file. The contents of the file will be added to the form data that is submitted to the server.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpAddQueuedFile Function

```
DWORD WINAPI HttpAddQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwQueueMode,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    UINT nTimeout  
);
```

The **HttpAddQueuedFile** function adds a new file to the queue with additional transfer options.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An integer value which specifies if the file should be downloaded from the server or uploaded to the server. This parameter must be one of the following options and cannot have a value of zero.

Constant	Description
HTTP_QUEUE_DOWNLOAD	The file should be queued for downloading from the server to the local system.
HTTP_QUEUE_UPLOAD	The file should be queued for uploading from the local system to the server.

lpszLocalFile

A pointer to a null terminated string which specifies the name of the local file to be queued for transfer. This parameter cannot be NULL or point to an empty string. If the file is being queued for an upload, the file must exist on the local system or the function will fail. If the file is being downloaded, it will be created or replaced on the local system.

lpszRemoteFile

A pointer to a null terminated string which specifies the URL to the location of the file on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator and can be any of the options used with the **HttpConnect** function. If this value is zero, the default options for the queue will be used. The most common options are:

Value	Description
HTTP_OPTION_DEFAULT	Default options should be used for the queued transfer. All standard headers will be included with the request and redirected resources will return an error, allowing the application to determine if it should request the resource from the new location or inform the user the resource location has changed.

HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control panel.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.

nTimeout

The number of seconds to wait for a response from the server before failing the file transfer. If this value is zero, the default timeout period for the queue will be used.

Return Value

If the function succeeds, the return value is a unique identifier which corresponds to the queued file. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function will add a file to the current transfer queue. If successful, the value returned is a unique integer which identifies that file in the queue. To obtain information about the queued file, you can call the **HttpGetQueuedFile** function and provide this return value as the *dwFileId* parameter. To remove a file from the queue, use the **HttpRemoveQueuedFile** function.

Files can only be added to the queue when in an idle or paused state. If you attempt to add a file to the queue while the queue manager is transferring files, the function will fail. To determine the current state of the queue, call the **HttpGetQueueStatus** function

There are no fixed limits to the number of files which can be queued for transfer. To release the memory allocated for the queue, call the **HttpClearQueue** function. To determine the current status of the queue, including how many file transfers have been queued and how many are pending completion, call the **HttpGetQueueStatus** function.

If the local file name includes environment variables enclosed in percentage (%) symbols, those values will automatically be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

This function will not immediately begin the process of uploading or downloading the file. It will only add the transfer request to the current queue. The file transfers are managed by a background worker thread which is created when the **HttpStartQueue** function is called.

The **HttpAddQueuedFileEx** function is an extended version of this function with additional parameters to specify a hostname, port number, user name and password. Because most file uploads require authentication, using the extended function may be preferred to composing a URL which includes the account credentials.

Example

```
// Create a new queue
HQUEUE hQueue = HttpCreateQueue(INFINITE, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = HttpAddQueuedFile(
    hQueue,
    lpzLocalFile,
    lpzRemoteFile,
    HTTP_OPTION_DEFAULT,
    HTTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case HTTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case HTTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szLocalFile,
                    queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (HttpStartQueue(hQueue, HTTP_QUEUE_ALL, 0, NULL, 0))
{
    HttpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    HttpStopQueue(hQueue);
}

// Remove all files from the queue
HttpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpAddQueuedFileEx Function

```
DWORD WINAPI HttpAddQueuedFileEx(  
    HQUEUE hQueue,  
    DWORD dwQueueMode,  
    LPCTSTR lpszHostName,  
    UINT nHostPort,  
    UINT nAuthType,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    UINT nTimeout,  
    LPVOID lpvReserved  
);
```

The **HttpAddQueuedFileEx** function adds a new file to the queue with additional transfer options.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An integer value which specifies if the file should be downloaded from the server or uploaded to the server. This parameter must be one of the following options and cannot have a value of zero.

Constant	Description
HTTP_QUEUE_DOWNLOAD	The file should be queued for downloading from the server to the local system.
HTTP_QUEUE_UPLOAD	The file should be queued for uploading from the local system to the server.

lpszHostName

A pointer to the name of the server to establish a connection with. This may be a fully-qualified domain name or an IP address. If this parameter is NULL or points to an empty string, the ***lpszRemoteFile*** parameter must specify a complete URL which identifies the server as well as the path to the remote file.

nHostPort

The port number which should be used when establishing the connection. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443. If this parameter is zero and a URL is specified with the ***lpszRemoteFile*** parameter, the port number included in the URL will be used as the default value.

nAuthType

An unsigned integer value which specifies the method to be used when authenticating the client. The following values are supported:

Value	Description
HTTP_AUTH_NONE	No client authentication should be performed. The <i>lpszUserName</i>

	and <i>lpzPassword</i> parameters are ignored and current authentication settings are cleared.
HTTP_AUTH_BASIC	The Basic authentication scheme should be used. This option is supported by all servers that support at least version 1.0 of the protocol. The user credentials are not encrypted and Basic authentication should not be used over standard (non-secure) connections. Most web services which use Basic authentication require the connection to be secure.
HTTP_AUTH_BEARER	The Bearer authentication scheme should be used. This authentication method does not require a user name and the <i>lpzPassword</i> parameter must specify the OAuth 2.0 bearer token issued by the service provider. If the access token has expired, the request will fail with an authorization error.

lpzUserName

Points to a null terminated string which specifies the user name to be used to authenticate the connection. If this parameter is NULL or an empty string, no client credentials are provided. If the authentication type is HTTP_AUTH_BEARER, this parameter is ignored.

lpzPassword

Points to a null terminated string which specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified. If the authentication type is HTTP_AUTH_BEARER, this value must be the bearer token issued by the service provider.

lpzLocalFile

A pointer to a null terminated string which specifies the name of the local file to be queued for transfer. This parameter cannot be NULL or point to an empty string. If the file is being queued for an upload, the file must exist on the local system or the function will fail. If the file is being downloaded, it will be created or replaced on the local system.

lpzRemoteFile

A pointer to a null terminated string which specifies the name of the file on the server. If the file is being downloaded, the file must exist on the server or the transfer will fail. If the file is being uploaded, the file will be created or replaced on the server. This parameter may specify a complete URL. Note that any values you specify as arguments to this function will override the values specified in the URL. If you want to use a URL as the remote file name, the *lpzHostName* parameter should be NULL and the *nHostPort* parameter should be zero.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator and can be any of the options used with the **HttpConnect** function. If this value is zero, the default options for the queue will be used. The most common options are:

Value	Description
HTTP_OPTION_DEFAULT	Default options should be used for the queued transfer. All standard headers will be included with the request and redirected resources will return an error, allowing the application to determine if it should request the resource from the new location or inform the user the resource location has changed.

HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control panel.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.

nTimeout

The number of seconds to wait for a response from the server before failing the file transfer. If this value is zero, the default timeout period for the queue will be used.

lpvReserved

A reserved parameter which should always be NULL.

Return Value

If the function succeeds, the return value is a unique identifier which corresponds to the queued file. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function will add a file to the current transfer queue. If successful, the value returned is a unique integer which identifies that file in the queue. To obtain information about the queued file, you can call the **HttpGetQueuedFile** function and provide this return value as the *dwFileId* parameter. To remove a file from the queue, use the **HttpRemoveQueuedFile** function.

Files can only be added to the queue when in an idle or paused state. If you attempt to add a file to the queue while the queue manager is transferring files, the function will fail. To determine the current state of the queue, call the **HttpGetQueueStatus** function

There are no fixed limits to the number of files which can be queued for transfer. To release the memory allocated for the queue, call the **HttpClearQueue** function. To determine the current status of the queue, including how many file transfers have been queued and how many are pending completion, call the **HttpGetQueueStatus** function.

If the local file name includes environment variables enclosed in percentage (%) symbols, those values will automatically be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

This function will not immediately begin the process of uploading or downloading the file. It will only add the transfer request to the current queue. The file transfers are managed by a background worker thread which is created when the **HttpStartQueue** function is called.

Example

```
// Create a new queue
HQUEUE hQueue = HttpCreateQueue(INFINITE, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = HttpAddQueuedFileEx(
    hQueue,
    HTTP_QUEUE_DOWNLOAD,
    lpszHostName,
    HTTP_PORT_DEFAULT,
    HTTP_AUTH_DEFAULT,
    lpszUserName,
    lpszPassword,
    lpszLocalFile,
    lpszRemoteFile,
    HTTP_OPTION_DEFAULT,
    HTTP_TIMEOUT,
    NULL);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case HTTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case HTTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szLocalFile,
                    queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (HttpStartQueue(hQueue, HTTP_QUEUE_ALL, 0, NULL, 0))
{
    HttpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    HttpStopQueue(hQueue);
}
```

```
// Remove all files from the queue  
HttpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpAddRequestHeaders Function

```
BOOL WINAPI HttpAddRequestHeaders(  
    HCLIENT hClient,  
    LPCTSTR lpszHeaderList  
);
```

The **HttpAddRequestHeaders** function adds one or more request headers for the current client session.

Parameters

hClient

Handle to the client session.

lpszHeaderList

Points to a null-terminated string which specifies one or more header values which should be set for the current client session. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpAddRequestHeaders** function enables your application to set one or more header values by providing a list of name/value pairs separated by a colon. Multiple header values may be provided by separating them with a newline character. This function is similar to calling the **HttpSetRequestHeader** function for each value. When the list of header values is parsed, extraneous whitespace is ignored; however, if the header list contains invalid text (for example, a missing colon separating a header name from its value) the function will fail and an error will be returned.

Exercise caution when providing a header list created directly from user input, such as a list of values input using a textbox control. Any header values which have been previously set by your application can be overridden by this function and may yield unpredictable results. If the service you are using requires a custom authorization header, such as an API token or other user credentials, allowing users to directly modify request header values this way can present a security risk.

Example

```
// Define a list of header values which should be included with the  
// request submitted to the server  
LPCTSTR lpszHeaderList = _T("X-API-Token: 99d2fe39-0246-4efa-98e0-4d775579fa5d\n")  
\  
                        _T("X-API-UserId: someuser@domain.tld\n") \  
                        _T("X-API-Version: 1.1\n")  
  
if (!HttpAddRequestHeaders(hClient, lpszHeaderList))  
{  
    // Unable to add the headers for this client session  
    return;  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpAsyncConnect Function

```
HCLIENT WINAPI HttpAsyncConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    DWORD dwVersion,  
    LPSECURITYCREDENTIALS lpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
  
);
```

The **HttpAsyncConnect** function is used to establish a connection with the specified server

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **HttpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to. This may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically

	<p>handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.</p>
HTTP_OPTION_PROXY	<p>This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.</p>
HTTP_OPTION_ERRORDATA	<p>This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.</p>
HTTP_OPTION_NOUSERAGENT	<p>This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. An application can provide its own custom user agent value using the HttpSetRequestHeader function.</p>
HTTP_OPTION_HTTP2	<p>This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. The value of the <i>dwVersion</i> parameter will be ignored when this option is used.</p>
HTTP_OPTION_TUNNEL	<p>This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.</p>
HTTP_OPTION_TRUSTEDSITE	<p>This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.</p>
HTTP_OPTION_SECURE	<p>This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.</p>

HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create a version value and the following values are defined:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this session. This is the same as specifying HTTP_VERSION_11 and is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_09	The client should use the original one-line protocol which includes no version number and no request header block. This version has been deprecated and should only be used with legacy servers which do not support the protocol standard. This version of the protocol does not support virtual hosts and is not supported by most modern web services.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.
HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined

	in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
HTTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.

HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event is generated when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

To cancel asynchronous notification and return the client to a blocking mode, use the **HttpDisableEvents** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

If the HTTP_OPTION_KEEPALIVE option is specified and the server does not support persistent connections, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is automatically enabled when using HTTP/2.

Under some circumstances, a server may forcibly close or abort a connection if the request fails. For example, this can happen when a malformed request is submitted to the server or a server-side error occurs. When this happens, the application will need to disconnect from the server and establish a new connection, even if the keep-alive option has been specified.

Applications should use HTTP_VERSION_DEFAULT as the value for the *dwVersion* parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support the features required for a secure HTTP/2 connection.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return `INVALID_CLIENT`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpAsyncGetData Function

```
UINT WINAPI HttpAsyncGetData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Copies the contents of a resource on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource on the server that will be transferred to the local system.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function.

HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.
-------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncGetData** function is used to download the contents of a server resource into a local buffer. This function is similar to the **HttpGetData** function, however it retrieves the contents of the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being copied to the local system.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, such as with the example listed below, then you must ensure that your code does not return from the function while the data is being downloaded. In the example, this is achieved by calling the **HttpTaskWait** function. You can also perform other operation and poll the status of the task by calling the **HttpTaskDone** function. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvBuffer* and *lpdwLength* parameters on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

The *lpvBuffer* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the file or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpdwLength* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpdwLength*

must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hgb1Buffer = NULL;
DWORD dwLength = 0;
UINT nTaskId;

// Copy the data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgb1Buffer parameter

nTaskId = HttpAsyncGetData(hClient,
                           lpzResource,
                           &hgb1Buffer,
                           &dwLength,
                           HTTP_TRANSFER_DEFAULT,
                           NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // contents of the file data
    lpBuffer = (LPBYTE)GlobalLock(hgb1Buffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgb1Buffer);
    GlobalFree(hgb1Buffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpAsyncGetFile Function

```
UINT WINAPI HttpAsyncGetFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Downloads the specified file from the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be transferred to the local system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function. This option is ignored if the <i>dwOffset</i> parameter is non-zero.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset

requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncGetFile** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **HttpGetFile** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = HttpAsyncGetFile(hClient,
```

```
        lpzLocalFile,  
        lpzRemoteFile,  
        HTTP_TRANSFER_DEFAULT,  
        0, NULL, 0);  
  
if (nTaskId != 0)  
{  
    DWORD dwError = NO_ERROR;  
    DWORD dwElapsed = 0;  
  
    // Wait for the transfer to complete  
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);  
}
```

Requirements

HttpAsyncGetFileEx Function

```
UINT WINAPI HttpAsyncGetFileEx(
    HCLIENT hClient,
    LPCTSTR lpszLocalFile,
    LPCTSTR lpszRemoteFile,
    DWORD dwOptions,
    ULARGE_INTEGER uiOffset,
    HTTPEVENTPROC lpEventProc,
    DWORD_PTR dwParam
);
```

Downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

- hClient***
Handle to the client session.
- lpszLocalFile***
A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.
- lpszRemoteFile***
A pointer to a string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.
- dwOptions***
An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function. This option is ignored if the dwOffset parameter is non-zero.

uiOffset
A byte offset which specifies where the file transfer should begin. The default value of zero specifies

that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the **lpEventProc** parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncGetFileEx** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **HttpGetFileEx** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

HttpAsyncPostData Function

```
UINT WINAPI HttpAsyncPostData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPVOID lpvBuffer,  
    DWORD cbBuffer,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions,  
    HTTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

Post data from a local buffer to a script executed on the server.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource that the data will be posted to on the server. Typically this is the name of a script that will be executed. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to the data that will be provided to the script. This parameter may be NULL if the script does not require any additional data from the client.

cbBuffer

The number of bytes to copy from the buffer. If this *lpvBuffer* parameter is NULL, this value should be zero.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is

	automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.
HTTP_POST_MULTIPART	The contents of the buffer being sent to the server consists of multipart form data and will be sent as-is without any encoding.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPostData** function is used to submit data to a script that executes on the server and then copy the output from that script into a local buffer. This function is similar to the **HttpPostData** function, however it submits the data using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent and the response from the server is being returned to the caller.

Because this function works asynchronously, it is important that the memory allocated for the *lpvBuffer* and *lpvResult* parameters will not be released before the asynchronous task completes. If you provide pointers to memory that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

If you wish to submit XML formatted data to the server, it is recommended that you use the **HttpAsyncPostXml** function instead.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;
UINT nTaskId;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nTaskId = HttpAsyncPostData(hClient,
                           lpzResource,
                           lpParameters,
                           cbParameters,
                           &hgblBuffer,
                           &cbBuffer,
                           HTTP_POST_CONVERT,
                           NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

[HttpTaskWait](#)

HttpAsyncPostJson Function

```
UINT WINAPI HttpAsyncPostJson(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszJsonData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Submit JSON formatted data to the server and return the response to the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource name that the JSON data will be submitted to. Typically this is the name of a script on the server.

lpszJsonData

A pointer to a string that specifies the JSON data that will be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.
---------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPostJson** function is used to submit JSON formatted data to a script that executes on the server and then copy the output from that script into a local buffer. It automatically sets the correct content type and encoding required for submitting JSON data to a server, however it does not parse the JSON data itself to ensure that it is well-formed. Your application is responsible for ensuring that the JSON data that is being submitted to the server is formatted correctly. This function is similar to the **HttpPostJson** function, however it submits the data using a background worker thread and does not block the current working thread.

Because this function works asynchronously, it is important that the memory allocated for the *lpszJsonData* and *lpvResult* parameters will not be released before the asynchronous task completes. If you provide pointers to memory that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

Example

```

HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;
UINT nTaskId;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nTaskId = HttpAsyncPostJson(hClient,
                           lpzResource,
                           lpzJsonData,
                           &hgblBuffer,
                           &cbBuffer,
                           HTTP_POST_CONVERT,
                           NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAsyncGetData](#), [HttpAsyncPostData](#), [HttpEventProc](#), [HttpPostJson](#), [HttpTaskWait](#)

HttpAsyncPostXml Function

```
UINT WINAPI HttpAsyncPostXml(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszXmlData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Submit XML formatted data to the server and return the response to the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource name that the XML data will be submitted to. Typically this is the name of a script on the server.

lpszXmlData

A pointer to a string that specifies the XML data that will be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.
---------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the ***lpEventProc*** parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPostXml** function is used to submit XML formatted data to a script that executes on the server and then copy the output from that script into a local buffer. It automatically sets the correct content type and encoding required for submitting XML data to a server, however it does not parse the XML data itself to ensure that it is well-formed. Your application is responsible for ensuring that the XML data that is being submitted to the server is formatted correctly. This function is similar to the **HttpPostXml** function, however it submits the data using a background worker thread and does not block the current working thread.

Because this function works asynchronously, it is important that the memory allocated for the ***lpSzXmlData*** and ***lpvResult*** parameters will not be released before the asynchronous task completes. If you provide pointers to memory that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The ***lpvResult*** parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the ***lpcbResult*** parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then ***lpcbResult*** must be initialized to a value of zero. See the example code below.

Example

```

HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;
UINT nTaskId;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nTaskId = HttpAsyncPostXml(hClient,
                           lpzResource,
                           lpzXmlData,
                           &hgblBuffer,
                           &cbBuffer,
                           HTTP_POST_CONVERT,
                           NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}

```

HttpAsyncProxyConnect Function

```
HCLIENT WINAPI HttpAsyncProxyConnect(  
    UINT nProxyType,  
    LPCTSTR LpszProxyHost,  
    UINT nProxyPort,  
    LPCTSTR LpszProxyUser,  
    LPCTSTR LpszProxyPassword,  
    LPCTSTR LpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    DWORD dwVersion,  
    LPSECURITYCREDENTIALS LpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **HttpAsyncProxyConnect** function is used to establish a connection through a proxy server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **HttpProxyConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

nProxyType

An unsigned integer which specifies the type of proxy that the client is connecting to. The supported proxy server types are as follows:

Value	Description
HTTP_PROXY_NONE	A direct connection will be established with the server. When this value is specified the proxy parameters are ignored.
HTTP_PROXY_STANDARD	A standard connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard connections.
HTTP_PROXY_SECURE	A secure connection is established through the specified proxy server. This proxy type should be used with secure connections and the HTTP_OPTION_SECURE option should also be set via the <i>dwOptions</i> parameter.
HTTP_PROXY_WINDOWS	The configuration options for the current system should be used. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. These settings are the same proxy server settings configured in Windows.

lpszProxyHost

A pointer to a string which specifies the proxy server host name or IP address. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

nProxyPort

The port number that the proxy server is listening for connections on. A value of zero specifies that the default port number 80 should be used. Note that in most cases, a proxy server is not configured to use the default port. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

lpszProxyUser

A pointer to a string which specifies the user name that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpszProxyPassword

A pointer to a string which specifies the password that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpszRemoteHost

A pointer to a string which specifies the name of the server to connect to through the proxy server. This may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection

	and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. An application can provide its own custom user agent value using the HttpSetRequestHeader function.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. The value of the <i>dwVersion</i> parameter will be ignored when this option is used.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the proxy server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4

	address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create a version value and the following values are defined:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this session. This is the same as specifying HTTP_VERSION_11 and is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_09	The client should use the original one-line protocol which includes no version number and no request header block. This version has been deprecated and should only be used with legacy servers which do not support the protocol standard. This version of the protocol does not support virtual hosts and is not supported by most modern web services.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.
HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

If the HTTP_PROXY_WINDOWS proxy type is specified, then the proxy configuration for the local system is used. If no proxy server has been defined, then the proxy-related parameters will be ignored and the function will establish a connection directly to the server.

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
HTTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event is generated when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

To cancel asynchronous notification and return the client to a blocking mode, use the **HttpDisableEvents** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

If the HTTP_OPTION_KEEPALIVE option is specified and the server does not support persistent connections, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is automatically enabled when using HTTP/2.

Applications should use HTTP_VERSION_DEFAULT as the value for the *dwVersion* parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support the features required for a secure HTTP/2 connection.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return INVALID_CLIENT.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpAsyncConnect](#), [HttpConnect](#), [HttpDisconnect](#), [HttpInitialize](#), [HttpProxyConnect](#)

HttpAsyncPutData Function

```
UINT WINAPI HttpAsyncPutData(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPVOID lpvBuffer,  
    DWORD dwLength,  
    DWORD dwReserved,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Copies the contents of the specified buffer to a file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

lpvBuffer

A pointer to the data that will be copied to the server and stored in the specified file.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPutData** function is used to upload the contents of a local buffer to the server. This function is similar to the **HttpPutData** function, however it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent to the server.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the

stack, ensure that your code does not return from the function while the data is being uploaded. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the transfer has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvBuffer* parameter on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

If the *lpvBuffer* parameter is pointing to a Unicode string, it is important to note that the value of the *dwLength* parameter should specify the number of bytes, not the number of characters. When using UTF-16, each character is two bytes long and therefore the length of the buffer is effectively double the length of the string. Because Unicode strings can contain null characters, you must also set the current file type to FILE_TYPE_IMAGE prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAsyncGetData](#), [HttpAsyncGetFile](#), [HttpAsyncPutFile](#), [HttpEventProc](#), [HttpPutData](#), [HttpTaskWait](#)

HttpAsyncPutFile Function

```
UINT WINAPI HttpAsyncPutFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Uploads the specified file from the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error

information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPutFile** function is used to upload the contents of a local file to the server. This function is similar to the **HttpPutFile** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpAsyncPutFileEx Function

```
UINT WINAPI HttpAsyncPutFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Uploads the specified file from the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique

asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPutFileEx** function is used to upload the contents of a local file to the server. This function is similar to the **HttpPutFileEx** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAsyncGetFileEx](#), [HttpEventProc](#), [HttpGetFileEx](#), [HttpPutFileEx](#), [HttpTaskDone](#), [HttpTaskWait](#)

HttpAsyncSubmitForm Function

```
UINT WINAPI HttpAsyncSubmitForm(  
    HCLIENT hClient,  
    HFORM hForm,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

Submit the specified form to the server for processing and return the response to the caller.

Parameters

hClient

Handle to the client session.

hForm

Handle to the virtual form which contains the data to be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_SUBMIT_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_SUBMIT_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncSubmitForm** function is used to submit form data to a script that executes on the server and then copy the output from that script into a local buffer. This function is similar to the **HttpSubmitForm** function, however it submits the data using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent and the response from the server is being returned to the caller.

Because this function works asynchronously, it is important that the memory allocated for the *lpvResult* parameter will not be released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate the buffer on the heap and free that memory after the task has completed and the data is no longer needed.

Do not call the **HttpDestroyForm** function to release the memory allocated for the virtual form until the background task completes. Doing so may result in unpredictable behavior and could cause your application to terminate abnormally.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

Example

```
HFORM hForm = INVALID_FORM;  
HGLOBAL hgb1Result = (HGLOBAL)NULL;  
DWORD cbResult = 0;  
INT nResult = 0;  
UINT nTaskId;
```

```
hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);
```

```
if (hForm == INVALID_FORM)  
    return;
```

```

HttpAddFormField(hForm, _T("UserName"), lpzUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpzPassword, (DWORD)-1L, 0);

nTaskId = HttpAsyncSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);

    // Get a pointer to the data returned by the server
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer now points to data returned by the server after
    // the form data was submitted

    // Release the memory allocated for the buffer
    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}

// Release the memory allocated for the virtual form
HttpDestroyForm(hForm);

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpAttachThread Function

```
DWORD WINAPI HttpAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **HttpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **HttpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **HttpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **HttpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **HttpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpAuthenticate Function

```
INT WINAPI HttpAuthenticate(  
    HCLIENT hClient,  
    UINT nAuthType,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword  
);
```

Parameters

hClient

Handle to the client session.

nAuthType

An unsigned integer value which specifies the method to be used when authenticating the client. The following values are supported:

Value	Description
HTTP_AUTH_NONE	No client authentication should be performed. The <i>lpszUserName</i> and <i>lpszPassword</i> parameters are ignored and current authentication settings are cleared.
HTTP_AUTH_BASIC	The Basic authentication scheme should be used. This option is supported by all servers that support at least version 1.0 of the protocol. The user credentials are not encrypted and Basic authentication should not be used over standard (non-secure) connections. Most web services which use Basic authentication require the connection to be secure.
HTTP_AUTH_BEARER	The Bearer authentication scheme should be used. This authentication method does not require a user name and the <i>lpszPassword</i> parameter must specify the OAuth 2.0 bearer token issued by the service provider. If the access token has expired, the request will fail with an authorization error. This function will not automatically refresh an expired token.

lpszUserName

A null terminated string which specifies the user name used to authenticate the client session. This parameter may be NULL or an empty string if a user name is not required for the specified authentication type. If the authentication type is HTTP_AUTH_BEARER, this parameter is ignored.

lpszPassword

A pointer to a string that specifies the password used to authenticate the client session. If the authentication type is HTTP_AUTH_BEARER, this value must be the bearer token issued by the service provider.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function will set the **Authorization** request header for the client session using the credentials

provided by the caller. This function will always override any custom **Authorization** header value that may have been previously set using the **HttpSetRequestHeader** function.

If both the *lpzUserName* and *lpzPassword* parameters are NULL pointers or specify zero length strings, the current authentication type will always be set to HTTP_AUTH_NONE regardless of the value of the *nAuthType* parameter. This effectively clears the current user credentials for the client session.

If the web service requires OAuth 2.0 authentication, it is recommended you use the **HttpSetBearerToken** function to specify the access token.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpConnect](#), [HttpSetBearerToken](#), [HttpSetRequestHeader](#)

HttpCancel Function

```
INT WINAPI HttpCancel(  
    HCLIENT hClient  
);
```

The **HttpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When the **HttpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpIsBlocking](#)

HttpCancelQueuedFile Function

```
BOOL WINAPI HttpCancelQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwFileId  
);
```

The **HttpCancelQueuedFile** function cancels the queued file transfer.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. If this value is zero, the function will cancel the current file transfer in progress. If queue transfers have been suspended, this parameter cannot be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

When this function is called, the queued file transfer may not immediately stop. An internal flag is set which causes the file transfer to exit with an error and the queue manager will begin processing the next file in the queue. If the queue is in an idle state, this function will fail.

It is permitted to call **HttpCancelQueuedFile** from within a queue event handler to cancel the current file transfer. In this case, the *dwFileId* parameter should be zero. If you specify a file which has not been transferred, it will be flagged as canceled and skipped by the queue manager when processing the queue. If you specify a file which has already been processed, this function will fail.

A canceled file transfer is also considered a failed transfer. When you call **HttpGetQueueStatus** after a queued file transfer is canceled, the *dwFailedFiles* member of the [HTTPQUEUESTATUS](#) structure will be incremented to reflect this change. You can determine the status of an individual file transfer by calling the **HttpGetQueuedFile** function and checking the value of the *dwQueueFlags* member of the [HTTPQUEUEDFILE](#) structure.

The **HttpResetQueue** function can be used to reset the state of previously canceled transfers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpClearForm Function

```
INT WINAPI HttpClearForm(  
    HFORM hForm  
);
```

The **HttpClearForm** function clears the specified form, removing all fields.

Parameters

hForm

Handle to the virtual form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshttpv11.lib

[HttpAddFormField](#), [HttpAddFormFile](#), [HttpCreateForm](#), [HttpDeleteFormField](#), [HttpDestroyForm](#), [HttpSubmitForm](#)

HttpClearHeaders Function

```
INT WINAPI HttpClearHeaders(  
    HCLIENT hClient  
);
```

The **HttpClearHeaders** function resets the the current request and response headers to their default values.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, it will return HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpClearHeaders** function removes all custom header values for the current client session and clears the response headers for the previous request. This function is useful when using persistent connections and you want to ensure that any custom header values from the previous request will not be included with subsequent requests made during the same session. Because this function clears all of the request headers for the client session, this means it will also remove any cookies which have been set using the **HttpSetCookie** function.

This function will clear any authentication credentials or tokens specified for the current client session. If the next request you make requires authentication, you must provide those credentials again using the **HttpAuthenticate** or **HttpSetBearerToken** function.

It is not necessary to use this function if the **HTTP_OPTION_KEEPALIVE** option was not specified when the connection was established. The headers for the previous request are automatically cleared when a new connection is established.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

HttpClearQueue Function

```
BOOL WINAPI HttpClearQueue(  
    HQUEUE hQueue  
);
```

The **HttpClearQueue** function removes all files from the queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function can only be called when the queue is in an idle state. An error will be returned if the function is called while the queue manager is paused or actively transferring files in the queue. To determine the current state of the queue, call the **HttpGetQueueStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpCancelQueuedFile](#), [HttpGetQueueStatus](#), [HttpResetQueue](#), [HttpResumeQueue](#), [HttpStartQueue](#), [HttpStopQueue](#), [HttpSuspendQueue](#)

HttpCloseFile Function

```
INT WINAPI HttpCloseFile(  
    HCLIENT hClient  
);
```

The **HttpCloseFile** function flushes the internal client buffers and closes the previously opened file on the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

If the file is opened for writing, all buffered data is written to the server before the file is closed. This may cause the client to block until all of the data can be written. The client application should not perform any other action until the function returns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpCommand](#), [HttpGetData](#), [HttpGetFile](#), [HttpOpenFile](#), [HttpPutData](#), [HttpPutFile](#)

HttpCommand Function

```
INT WINAPI HttpCommand(  
    HCLIENT hClient,  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszResource,  
    LPBYTE lpParameter,  
    DWORD cbParameter,  
    DWORD dwReserved  
);
```

The **HttpCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for extended commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

A pointer to a string which specifies the command to be executed by the server. The following table lists the standard commands recognized by most HTTP servers. Other commands may also be used, such as those extensions used by WebDAV to edit and manage files on a server.

Command	Description
GET	Return the contents of the specified resource. This command is recognized by all servers.
HEAD	Return only header information for the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
POST	Post data to the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
PUT	Create or replace the specified resource on the server. This command is recognized by servers that support at least version 1.0 of the protocol. Not all servers support this command.
DELETE	Delete the specified resource from the server. This command is recognized by servers that support at least version 1.1 of the protocol. Not all servers support this command.

lpszResource

A pointer to a string which specifies the resource to be used with the command. This can be the name of a file, an executable script or any other valid resource name recognized by the server. Resource names must be absolute and include the complete path to the resource.

lpParameter

A pointer to a byte array which contains data that is to be passed to the command as one or more parameters. Typically this is used to pass additional information to a script that executes on the server. The data is encoded according to the encoding type specified for the client session. If the resource does not require any parameters, this value should be NULL.

cbParameter

Specifies the number of bytes stored in the parameter buffer. If the resource does not require any

parameters, this value should be zero.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the result code returned by the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Not all servers support all of the listed commands, and some commands may require specific changes to the server configuration. In particular, the PUT and DELETE commands typically require that configuration changes be made by the site administrator. All servers will support the use of the GET command, and all servers that support at least version 1.0 of the protocol will support the POST command.

If the ***lpSzResource*** parameter specifies a path that contains reserved or restricted characters, such as a space, it will automatically be URL encoded by the library.

It is permissible to include a query string in the resource name specified by the ***lpSzResource*** parameter. Query strings begin with a question mark, and then are followed by one or more name/value pairs separated by an equal sign. For example, the following resource includes a query string:

```
/cgi-bin/test.cgi?field1=value1&field2=value2
```

In this case, the query string is "?field1=value1&field2=value2". If the query string contains reserved or restricted characters, such as spaces, then it will be automatically URL encoded prior to being sent to the server. If additional resource data is specified in the ***lpParameter*** argument along with a query string in the resource name, the action taken by the library depends on the command being sent. If the command is a POST or PUT command, then query string is included with command request to the server and the parameter data is sent separately. For example, if the POST command was used, the script running on the server would see that both query data and form data has been provided to it. However, if any other command is specified, the parameter data is simply appended to the query string.

The ***lpParameter*** argument is used to pass additional information to the server when a resource is requested. This is most commonly used to provide information to scripts, similar to how arguments are used when executing a program from the command line. Unless the POST command is being executed, the data in the buffer will automatically be encoded using the current encoding mechanism specified for the client. By default, the data is URL encoded, which means that any spaces and non-printable characters are converted to printable characters before submitted to the server. The type of encoding that is performed can be set by calling the **HttpSetEncodingType** function. Although the default encoding is appropriate for most applications, those that submit XML formatted data may need to change the encoding type.

Only one request may be in progress at one time for each client session. Use the **HttpCloseFile** function to terminate the request after all of the data has been read from the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttp11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpConnect Function

```
HCLIENT WINAPI HttpConnect(  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    DWORD dwVersion,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

Parameters

lpszRemoteHost

A pointer to the name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the

	server is established. The local proxy configuration can be changed in the system settings or control panel.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. An application can provide its own custom user agent value using the HttpSetRequestHeader function.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. The value of the <i>dwVersion</i> parameter will be ignored when this option is used.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4

	address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create a version value, or the following values can be used:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this session. This is the same as specifying HTTP_VERSION_11 and is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_09	The client should use the original one-line protocol which includes no version number and no request header block. This version has been deprecated and should only be used with legacy servers which do not support the protocol standard. This version of the protocol does not support virtual hosts and is not supported by most modern web services.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.
HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **HttpConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

If the HTTP_OPTION_KEEPALIVE option is specified and the server does not support persistent connections, the client will automatically attempt to reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is automatically enabled when using HTTP/2.

Under some circumstances, a server may forcibly close or abort a connection if the request fails. For example, this can happen when a malformed request is submitted to the server or a server-side error occurs. When this happens, the application will need to disconnect from the server and establish a new connection, even if the keep-alive option has been specified.

Applications should use HTTP_VERSION_DEFAULT as the value for the *dwVersion* parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support the features required for a secure HTTP/2 connection.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return INVALID_CLIENT.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

[HttpConnectUrl](#), [HttpDisconnect](#), [HttpInitialize](#), [HttpProxyConnect](#)

HttpConnectUrl Function

```
HCLIENT WINAPI HttpConnectUrl(  
    LPCTSTR lpszUrl,  
    UINT nTimeout,  
    DWORD dwOptions  
);
```

The **HttpConnectUrl** function establishes a connection with the specified server using a URL.

Parameters

lpszUrl

A pointer to a string which specifies the URL for the server. The URL must follow the conventions for the Hypertext Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control panel.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the

	content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. An application can provide its own custom user agent value using the HttpSetRequestHeader function.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this

	function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is `INVALID_CLIENT`. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpConnectUrl** function uses an HTTP URL to establish a connection with a server. The URL must be in the following format:

```
[http|https]://[username : password] @[hostname [:port] / [path / ...]
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the `HTTP_OPTION_SECURE` option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified. The **HttpValidateUrl** function can be used to verify that a URL is valid prior to calling this function.

The **HttpConnectUrl** function is designed to provide a simpler, more convenient interface to establishing a connection with a server. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to use the lower-level connection functions. If you only need to upload or download a file using a URL, then refer to the **HttpUploadFile** and **HttpDownloadFile** functions.

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **HttpConnectUrl** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the `HTTP_OPTION_FREETHREAD` option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

If the `HTTP_OPTION_KEEPALIVE` option is specified and the server does not support persistent connections, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is

automatically enabled when using HTTP/2.

If your application specifies the HTTP_OPTION_HTTP2 option, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of Windows do not support the features required for a secure HTTP/2 connection. If the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return INVALID_CLIENT.

Example

```
HCLIENT hClient;
LPCTSTR lpszUrl = _T("https://www.example.com/");

// Connect to the site specified by the URL
hClient = HttpConnectUrl(lpszUrl, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hClient == INVALID_CLIENT)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpCreateFile Function

```
INT WINAPI HttpCreateFile(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwLength,  
    DWORD dwOffset  
);
```

The **HttpCreateFile** function creates the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

Points to a string that specifies the name of the file being created on the server. The client must have the appropriate access rights to create the file or an error will be returned.

dwLength

Specifies the length of the file that will be created on the server. This value must be greater than zero.

dwOffset

Specifies a byte offset in the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to create the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpCreateFile** function uses the PUT command to create the file. The server must support this command and the user must have the appropriate permission to create the specified file. If this function is successful, the client should then use the **HttpWrite** function to send the contents of the file to the server. Once all of the data has been written, the **HttpCloseFile** function should be called to close the file and complete the operation. Note that this function is typically only accepted by servers that support version 1.1 of the protocol or later.

When using **HttpWrite** to send the contents of the file to the server, it is recommended that the data be written in logical blocks that are no larger than 8,192 bytes in size. Attempting to write very large amounts of data in a single call can either cause the thread to block or, in the case of an asynchronous connection, return an error if the internal buffers cannot accommodate all of the data. To send the entire contents of a file in a single function call, use the **HttpPutData** function instead of calling **HttpCreateFile**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpCreateFileEx Function

```
INT WINAPI HttpCreateFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    ULARGE_INTEGER uiLength,  
    ULARGE_INTEGER uiOffset  
);
```

The **HttpCreateFileEx** function creates the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

Points to a string that specifies the name of the file being created on the server. The client must have the appropriate access rights to create the file or an error will be returned.

uiLength

Specifies the length of the file that will be created on the server. This value must be greater than zero.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to create the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpCreateFileEx** function uses the PUT command to create the file. The server must support this command and the user must have the appropriate permission to create the specified file. If this function is successful, the client should then use the **HttpWrite** function to send the contents of the file to the server. Once all of the data has been written, the **HttpCloseFile** function should be called to close the file and complete the operation. Note that this function is typically only accepted by servers that support version 1.1 of the protocol or later.

When using **HttpWrite** to send the contents of the file to the server, it is recommended that the data be written in logical blocks that are no larger than 8,192 bytes in size. Attempting to write very large amounts of data in a single call can either cause the thread to block or, in the case of an asynchronous connection, return an error if the internal buffers cannot accommodate all of the data. To send the entire contents of a file in a single function call, use the **HttpPutData** function instead of calling **HttpCreateFileEx**.

Requirements

HttpCreateForm Function

```
HFORM WINAPI HttpCreateForm(  
    LPCTSTR lpszAction,  
    UINT nFormMethod,  
    UINT nFormType,  
    DWORD dwReserved  
);
```

The **HttpCreateForm** function creates a new form and returns a handle for use with the other form-related functions.

Parameters

lpszAction

A pointer to a string which specifies the name of the resource that the form data will be submitted to. Typically this is the name of a script that is executed on the server.

nFormMethod

An unsigned integer value which specifies how the form data will be submitted to the server. This parameter may be one of the following values:

Value	Description
HTTP_METHOD_DEFAULT	The form data should be submitted using the default method, using the GET command.
HTTP_METHOD_GET	The form data should be submitted using the GET command. This method should be used when the amount of form data is relatively small. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used instead.
HTTP_METHOD_POST	The form data should be submitted using the POST command. This is the preferred method of submitting larger amounts of form data. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used.

nFormType

An unsigned integer value which specifies the type of form and how the data will be encoded when it is submitted to the server. This parameter may be one of the following values:

Value	Description
HTTP_FORM_DEFAULT	The form data should be submitted using the default encoding method.
HTTP_FORM_ENCODED	The form data should be submitted as URL encoded values. This is typically used when the GET method is used to submit the data to the server.
HTTP_FORM_MULTIPART	The form data should be submitted as multipart form data. This is typically used when the POST method is used to submit a file to the server. Note that the script must understand how to process multipart form data if this form type is specified.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is a handle to the virtual form. If the function fails, the return value is `INVALID_FORM`. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpCreateForm** function is used to create a new form that will be populated with values and then submitted to the server for processing. When the form is no longer needed, it should be destroyed using the **HttpDestroyForm** function.

Example

```
HFORM hForm = INVALID_FORM;
HGLOBAL hgblResult = (HGLOBAL)NULL;
DWORD cbResult = 0;
INT nResult = 0;

hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);

if (hForm == INVALID_FORM)
    return;

HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);

nResult = HttpSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);
HttpDestroyForm(hForm);

if (hgblResult != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer points to data returned by the server after the form
    // data was submitted

    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `cshttpv11.lib`

Unicode: Implemented as Unicode and ANSI versions

HttpCreateQueue Function

```
HQUEUE WINAPI HttpCreateQueue(  
    UINT nMaxFiles,  
    UINT nTimeout,  
    DWORD dwOptions  
);
```

The **HttpCreateQueue** function creates new file transfer queue.

Parameters

nMaxFiles

An unsigned integer which specifies the maximum number of files which can be added to the queue. The constant INFINITE can be used to specify that there is no fixed limit to the number of files in the queue.

nTimeout

An unsigned integer which specifies the default timeout for all queued file transfers. If this value is zero, a reasonable default timeout period will be used. This timeout period is used when a file is added to the queue without providing a timeout period for that specific file transfer. If a timeout period is specified for a particular file, it will override this value.

dwOptions

An unsigned integer value which specifies one or more default options for all queued files. This parameter is constructed by using a bitwise operator and can be any of the options used with the **HttpConnect** function. If transfer options are specified for a particular file, it will override this value. The most common options are:

Value	Description
HTTP_OPTION_DEFAULT	Default options should be used for queued file transfers. All standard headers will be included with the request and redirected resources will return an error, allowing the application to determine if it should request the resource from the new location or inform the user the resource location has changed.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control panel.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect

	using an earlier version of the protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.

Return Value

If the function succeeds, the return value is a handle to the queue which can be used with subsequent function calls. If the function fails, the return value is `INVALID_QUEUE`. To get extended error information, call **HttpGetLastError**.

Remarks

If the *nMaxFiles* parameter is `INFINITE`, memory will be dynamically allocated on the process heap with no limit to the number of files which can be queued. If there is a logic error which causes the application to recursively add files to the queue, or repeatedly queue the same file, this can result in virtual memory being exhausted for the process. You can avoid this by specifying a reasonable maximum queue size, which will cause the **HttpAddQueuedFile** function to fail if that limit is exceeded.

The memory allocated for the queue will be released when the **HttpDeleteQueue** function is called.

Example

```
// Create a new queue
HQUEUE hQueue = HttpCreateQueue(INFINITE, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = HttpAddQueuedFile(
    hQueue,
    lpzLocalFile,
    lpzRemoteFile,
    HTTP_OPTION_DEFAULT,
    HTTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case HTTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case HTTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\\n"),
                    dwFileId,
```

```

        queuedFile.szLocalFile,
        queuedFile.szRemoteFile);
    break;
}
}

// Start the queued file transfers and wait for it to complete
if (HttpStartQueue(hQueue, HTTP_QUEUE_ALL, 0, NULL, 0))
{
    HttpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    HttpStopQueue(hQueue);
}

// Remove all files from the queue
HttpDeleteQueue(hQueue);

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

HttpCreateSecurityCredentials Function

```
BOOL WINAPI HttpCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **HttpCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpzUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpzPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpzCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **HttpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **HttpConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify

the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpzPassword* parameter or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
HttpCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                             0,
                             NULL,
                             NULL,
                             lpzCertStore,
                             lpzCertName,
                             NULL,
                             &lpSecCred);

hClient = HttpConnect(lpzHostName,
                     HTTP_PORT_SECURE,
                     HTTP_TIMEOUT,
                     HTTP_OPTION_SECURE | HTTP_OPTION_KEEPALIVE,
                     HTTP_VERSION_11,
                     lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpDeleteFile Function

```
INT WINAPI HttpDeleteFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName  
);
```

The **HttpDeleteFile** function deletes the specified file from the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to delete. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function uses the DELETE command to delete the specified file from the server. The server must be configured to support this command, and client must have the appropriate permission to delete the file, or an error will be returned.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetFile](#), [HttpPutFile](#)

HttpDeleteFormField Function

```
INT WINAPI HttpDeleteFormField(  
    HFORM hForm,  
    LPCTSTR lpszFieldName  
);
```

The **HttpDeleteFormField** function deletes the specified field from the form.

Parameters

hForm

Handle to the virtual form.

lpszFieldName

Points to a string that specifies the name of the field to delete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpDeleteHeaders Function

```
BOOL WINAPI HttpDeleteHeaders(  
    HCLIENT hClient,  
    UINT nHeaderType  
);
```

Delete all of the response or request headers for the current session.

Parameters

hClient

Handle to the client session.

nHeaderType

Specifies the type of header to delete. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Delete all of the request headers that have been set for the next request sent to the server. This will clear all of the header values that were set using the HttpSetRequestHeader function.
HTTP_HEADERS_RESPONSE	Delete all of the headers that were set in response to the previous request. A call to the HttpGetResponseHeader function to obtain a specific header value will fail after this function returns.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpDeleteHeaders** function will release the memory allocated for the request or response headers for the current session. This function is typically used to clear all of the current request headers so that the application may create a new set of headers when a persistent connection is being used. The memory allocated for the request and response headers is normally released when the session handle is closed by calling the **HttpDisconnect** function.

Whenever a request for a resource is sent to the server, the response headers from the previous request are automatically cleared. It is not necessary for an application to call the **HttpDeleteHeaders** function to delete the response headers prior to each request.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpGetFirstHeader](#), [HttpGetNextHeader](#), [HttpGetResponseHeader](#), [HttpSetRequestHeader](#)

HttpDeleteQueue Function

```
BOOL WINAPI HttpDeleteQueue(  
    HQUEUE hQueue  
);
```

The **HttpDeleteQueue** function deletes the specified file transfer queue, releasing all memory allocated for the queued files.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function can only be called when the queue is in an idle state. If the queue manager is in the process of uploading or downloading files, the function will fail and return a value of zero. You can determine the current state of the queue by calling the **HttpGetQueueStatus** function. It is not necessary to explicitly clear the queue prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpCreateQueue](#), [HttpGetQueueStatus](#), [HttpCancelQueuedFile](#), [HttpClearQueue](#), [HttpStartQueue](#), [HttpStopQueue](#), [HttpWaitForQueue](#)

HttpDeleteSecurityCredentials Function

```
VOID WINAPI HttpDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **HttpDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)  
    HttpDeleteSecurityCredentials(&lpSecCred);  
  
HttpUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpCreateSecurityCredentials](#), [HttpUninitialize](#)

HttpDestroyForm Function

```
INT WINAPI HttpDestroyForm(  
    HFORM hForm  
);
```

The **HttpDestroyForm** function destroys the specified form, releasing the memory allocated for it.

Parameters

hForm

Handle to the form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpAddFormField](#), [HttpAddFormFile](#), [HttpClearForm](#), [HttpCreateForm](#), [HttpDeleteFormField](#), [HttpSubmitForm](#)

HttpDisableEvents Function

```
INT WINAPI HttpDisableEvents(  
    HCLIENT hClient  
);
```

The **HttpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpEnableEvents](#), [HttpFreezeEvents](#), [HttpRegisterEvent](#)

HttpDisableTrace Function

BOOL WINAPI HttpDisableTrace();

The **HttpDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpEnableTrace](#)

HttpDisconnect Function

```
INT WINAPI HttpDisconnect(  
    HCLIENT hClient  
);
```

The **HttpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpDownloadFile Function

```
BOOL WINAPI HttpDownloadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    UINT nTimeout  
    DWORD dwOptions  
    LPHTTPTRANSFERSTATUS lpStatus  
    HTTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **HttpDownloadFile** function downloads the specified file from the server to the local system.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a

	User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. If this option is not specified, a default user agent string will be included with the request.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

A pointer to an **HTTPTRANSFERSTATUS** structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpDownloadFile** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then download the file to the local system. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @[hostname [:port] / [path / ...]  
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the **HTTP_OPTION_SECURE** option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return a value of zero.

The ***lpStatus*** parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The ***lpEventProc*** parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The ***dwParam*** parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the ***this*** pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for ***lpEventProc*** and the ***dwParam*** parameter will be ignored.

The **HttpDownloadFile** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpGetFile** to download the file.

Example

```

HTTPTRANSFERSTATUS httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile = _T("http://www.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = HttpDownloadFile(lpszLocalFile,
                           lpszRemoteFile,
                           HTTP_OPTION_DEFAULT,
                           &httpStatus,
                           NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpDownloadFileEx Function

```
BOOL WINAPI HttpDownloadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    UINT nTimeout  
    DWORD dwOptions  
    LPHTTPTRANSFERSTATUSEX lpStatus  
    HTTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **HttpDownloadFileEx** function downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.

HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. If this option is not specified, a default user agent string will be included with the request.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

lpStatus

A pointer to an HTTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpDownloadFileEx** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then download the file to the local system. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @[hostname [:port] / [path / ...]  
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return a value of zero.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **HttpDownloadFileEx** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpGetFile** to download the file.

Example

```
HTTPTRANSFERSTATUSEX httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile = _T("http://www.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = HttpDownloadFileEx(lpszLocalFile,
                             lpszRemoteFile,
                             HTTP_OPTION_DEFAULT,
                             &httpStatus,
                             NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpEnableCompression Function

```
INT WINAPI HttpEnableCompression(  
    HCLIENT hClient,  
    BOOL bEnable  
);
```

The **HttpEnableCompression** function enables or disables support for data compression.

Parameters

hClient

Handle to the client session.

bEnable

A boolean value which specifies if data compression should be enabled or disabled. A non-zero value enables compression, while a value of zero will disable compression.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpEnableCompression** function is used to indicate to the server whether or not it is acceptable to compress the data that is returned to the client. If compression is enabled, the client will advertise that it will accept compressed data by setting the **Accept-Encoding** request header. The server will decide whether a resource being requested can be compressed. If the data is compressed, the library will automatically expand the data before returning it to the caller.

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. Disabling compression informs the server that the client is not willing to accept compressed data; this is the default.

If the **HttpSetRequestHeader** function is used to explicitly set the **Accept-Encoding** header to request compressed data and compression is not enabled, the library will not attempt to automatically expand the data returned by the server. In this case, the raw compressed data will be returned to the caller and the application is responsible for processing it. This behavior is by design to maintain backwards compatibility with previous versions of the library that did not have internal support for compression.

To determine if the server compressed the data returned to the client, use the **HttpGetResponseHeader** function to get the value of the **Content-Encoding** header. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

Enabling compression is only meaningful when downloading files from a server that supports file compression. It has no effect on file uploads.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

HttpEnableEvents Function

```
INT WINAPI HttpEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **HttpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **HttpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs.

This parameter's value must be greater than the value of WM_USER. If the *hEventWnd* parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
HTTP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.

HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event is generated when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

HttpEnableTrace Function

```
BOOL WINAPI HttpEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **HttpEnableTrace** function enables the logging of Windows Sockets function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv11.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the server.

Logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

When logging is enabled for HTTP/2 client sessions, it is normal to see HTTP/1.1 in the request and server response. HTTP/2 is a binary protocol and the request and response header blocks emulate a standard HTTP/1.1 text response for backwards compatibility. Applications running on the server

should work in the same way regardless of which protocol version is selected, however it is possible to check the server environment to determine which version of HTTP was used with the request.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpEnumQueuedFiles Function

```
LONG WINAPI HttpEnumQueuedFiles(  
    HQUEUE hQueue,  
    LPCTSTR lpszFileMask,  
    DWORD dwQueueMode,  
    DWORD dwExcludeFiles,  
    LPDWORD lpFileList,  
    LONG nMaxFiles  
);
```

The **HttpEnumQueuedFiles** function returns a list of files in the current transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpszFileMask

A pointer to a null terminated string which specifies a file name which can include wildcards. Only those files which match this value will be enumerated. The character '?' will match against any single character, and '*' will match any number of characters. If this parameter is NULL or points to an empty string, all eligible files in the queue will be matched.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. Only those files which match the queue mode will be enumerated. This is a bitmask which may be one or more of the following values:

Constant	Description
HTTP_QUEUE_ALL	Match the file name to all files in the queue.
HTTP_QUEUE_DOWNLOAD	Match file names which are queued for download.
HTTP_QUEUE_UPLOAD	Match file names which are queued for upload.
HTTP_QUEUE_LOCAL	Match against the local file name instead of the remote file name.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the enumeration. If this value is zero, no files will be excluded; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_QUEUE_FLAG_NONE	No files should be excluded.
HTTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
HTTP_QUEUE_FLAG_FAILED	Exclude files which where not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.

HTTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the HttpCancelQueuedFile function has been called and a queued file is in the process of being uploaded or downloaded.
--------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

lpFileList

A pointer to an array of unsigned integer values which will contain the unique file identifiers for each matching file in the queue. This parameter must specify an array large enough to store all of the file identifiers, otherwise the function will fail with a ST_ERROR_BUFFER_TOO_SMALL error. If this parameter is NULL, the function will return the number of matching files.

nMaxFiles

An integer value which specifies the maximum number of file identifiers which can be copied into the *lpFileList* array. If the *lpFileList* parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of matching files. If the queue is empty or there are no matching files, this function will return zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function populates an array of unique file identifiers which can be used to obtain information about the files in the current queue. The values returned in the *lpFileList* array can be used in conjunction with the **HttpGetQueuedFile** function. This provides an alternative to using the **HttpGetFirstQueuedFile** and **HttpGetNextQueuedFile** functions.

The application should not make any assumptions about the value of the file identifiers returned by this function. They should be considered opaque values which are only guaranteed to uniquely identify a file in the transfer queue. In particular, there is no guarantee that the file identifiers will be sequential and they should not be used as index values into an array.

Example

```
// Get the total number of files in the queue
LONG nFiles = HttpEnumQueuedFiles(hQueue, NULL, HTTP_QUEUE_ALL,
HTTP_QUEUE_FLAG_NONE, NULL, 0)

// Display information about the queued files
if (nFiles > 0)
{
    DWORD *pdwFileList = new DWORD[nFiles];

    nFiles = HttpEnumQueuedFiles(hQueue, NULL, HTTP_QUEUE_ALL,
HTTP_QUEUE_FLAG_NONE, pdwFileList, nFiles);

    for (LONG nIndex = 0; nIndex < nFiles; nIndex++)
    {
        HTTPQUEUEDFILE queuedFile;

        if (HttpGetQueuedFile(hQueue, pdwFileList[nIndex], &queuedFile) == FALSE)
            break;

        switch (queuedFile.dwMode)
        {
            case HTTP_QUEUE_DOWNLOAD:
```

```

        _tprintf(_T("%u: Download \"%s\" to \"%s\"\\n"),
                queuedFile.dwFileId,
                queuedFile.szRemoteFile,
                queuedFile.szLocalFile);
        break;

    case HTTP_QUEUE_UPLOAD:
        _tprintf(_T("%u: Upload \"%s\" to \"%s\"\\n"),
                queuedFile.dwFileId,
                queuedFile.szLocalFile,
                queuedFile.szRemoteFile);
        break;
    }
}

delete pdwFileList;
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpEnumTasks Function

```
INT WINAPI HttpEnumTasks(  
    UINT *lpTasks,  
    INT nMaxTasks,  
    DWORD dwOptions  
);
```

Return a list of active, suspended or finished asynchronous tasks.

Parameters

lpTasks

A pointer to an array of unsigned integer values that will contain unique task identifiers when the function returns. If this parameter is NULL, the function will return the number of tasks.

nMaxTasks

An integer value that specifies the maximum number of task identifiers that may be copied into the *lpTasks* array. If the *lpTasks* parameter is NULL, this value must be zero.

dwOptions

An unsigned integer that specifies the type of asynchronous tasks that may be returned by this function. It may be a combination of the following values:

Value	Description
HTTP_TASK_DEFAULT	The list of asynchronous task IDs should include both active and suspended tasks. This option is the same as specifying both the HTTP_TASK_ACTIVE and HTTP_TASK_SUSPENDED options.
HTTP_TASK_ACTIVE	The list of asynchronous task IDs should include those tasks which are currently active. An active task represents a background connection to a server that is in the process of performing the requested action, such as uploading or downloading a file.
HTTP_TASK_SUSPENDED	The list of asynchronous task IDs should include those tasks which have been suspended. A suspended task represents a background connection that has been established, but the worker thread is not scheduled for execution.
HTTP_TASK_FINISHED	The list of asynchronous task IDs should include those tasks which have completed recently.

Return Value

If the function is successful, the return value is the number of task identifiers copied into the provided array. If there are no tasks which match the requested criteria, the return value is zero. A return value of HTTP_ERROR indicates an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpEnumTasks** function can be used to obtain a list of numeric identifiers that represent the asynchronous tasks that have been started or those that have completed. These task IDs are used by other functions to reference the background worker thread that has been created and obtain status information for the task. For example, the **HttpTaskDone** function can be used to determine if a

particular task has completed, and the **HttpTaskWait** function can be used to wait for a task to complete and return an error status code if the background operation failed.

There is an internal limit of 128 asynchronous tasks per process that may be active at any one time. When a task completes, the status information about that task is maintained for period of time after the task has completed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpEventProc Function

```
VOID CALLBACK HttpEventProc(  
    HCLIENT hClient,  
    UINT nEvent,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **HttpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **HttpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **HttpRegisterEvent** function. This callback function is also used by asynchronous tasks to notify the application when the task has started and completed. The **HttpEventProc** function is a placeholder for the application-defined function name.

If the callback function is invoked by an asynchronous task, it will execute in the context of the worker thread that is managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function for an asynchronous task. Controls should only be modified by the same UI thread that created their window. One common approach to resolve this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpFindQueuedFile Function

```
DWORD WINAPI HttpFindQueuedFile(  
    HQUEUE hQueue,  
    LPCTSTR lpszFileName,  
    DWORD dwQueueMode,  
    DWORD dwExcludeFiles  
);
```

The **HttpFindQueuedFile** function finds a file in the transfer queue which matches the search criteria.

Parameters

hQueue

A handle to a file transfer queue.

lpszFileName

A pointer to a null terminated string which specifies the name of the file to search for. The string may contain the wildcard character '?' to match against any single character, and '*' will match any number of characters. This parameter cannot be NULL or point to an empty string.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. This is a bitmask which may be one or more of the following values:

Constant	Description
HTTP_QUEUE_ALL	Match the file name to all files in the queue.
HTTP_QUEUE_DOWNLOAD	Match file names which are queued for download.
HTTP_QUEUE_UPLOAD	Match file names which are queued for upload.
HTTP_QUEUE_LOCAL	Match against the local file name instead of the remote file name.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the search. If this value is zero, no files will be excluded from the search; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_QUEUE_FLAG_NONE	No files should be excluded from the search.
HTTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
HTTP_QUEUE_FLAG_FAILED	Exclude files which were not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.
HTTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the HttpCancelQueuedFile function has been called and

a queued file is in the process of being uploaded or downloaded.

Return Value

If the function succeeds, the return value is a unique identifier for the file. To obtain information about the file, call the **HttpGetQueuedFile** function. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns a unique file identifier for the first file which matches the specified file name in the queue. If the *lpszFileName* parameter includes wildcard characters, this function will return the first file in the queue which matches the name. File name matches are not case-sensitive, even when matching against remote file names on servers which use case-sensitive naming, such as UNIX based servers.

To perform more complex searches based on the file name, or to find multiple files, you can use the **HttpGetFirstQueuedFile** and **HttpGetNextQueuedFile** functions to iterate through all queued files.

Example

```
// Find a local file in the download queue
DWORD dwFileId = HttpFindQueuedFile(
    hQueue,
    lpszFileName,
    HTTP_QUEUE_DOWNLOAD | HTTP_QUEUE_LOCAL,
    HTTP_QUEUE_FLAG_NONE);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case HTTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case HTTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szLocalFile,
                    queuedFile.szRemoteFile);
                break;
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

HttpFreezeEvents Function

```
INT WINAPI HttpFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **HttpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpGetBearerToken Function

```
INT WINAPI HttpGetBearerToken(  
    HCLIENT hClient,  
    LPTSTR lpszBearerToken,  
    INT nMaxLength  
);
```

The **HttpGetBearerToken** function returns the OAuth 2.0 bearer token used to authenticate the client session with a web service.

Parameters

hClient

Handle to the client session.

lpszBearerToken

A pointer to a string buffer which will contain the bearer token when the function returns. The string will be null terminated and the buffer must be large enough to accommodate the entire bearer token or the function will fail. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that may be copied into the string buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the length of the bearer token string. A return value of zero indicates that no bearer token has been specified. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns the bearer token which was previously set by a call to **HttpSetBearerToken**. Bearer tokens can be very long strings and do not contain any human readable information. For Google services, these tokens are usually about 180 characters in length. For Microsoft services, their bearer tokens are typically 1,200 characters in length. It is recommended that you provide a buffer size of at least 2,000 characters.

Your application should not store the bearer tokens provided by a web service. These tokens are short-lived and typically only valid for about an hour. If the token has expired, the authorization to access the resource will fail and it must be refreshed. The refresh tokens used to acquire a new bearer token should be stored and they are typically valid for a period of months.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetContentLength Function

```
BOOL WINAPI HttpGetContentLength(  
    HCLIENT hClient,  
    LPDWORD lpdwLength  
);
```

The **HttpGetContentLength** function returns the size of the current resource in bytes.

Parameters

hClient

Handle to the client session.

lpdwLength

A pointer to a unsigned integer which will contain the content length for the current resource. This value will be initialized to zero and updated with the length when the function returns.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

When this function is called after a GET or POST request has completed, the *lpdwLength* parameter will contain the total number of bytes returned by the server. If this function is called while a request is being processed (for example, from within an event handler), it will return the value of the Content-Length response header provided by the server. If it's possible the server will return more than 4GiB of data to the client, the **HttpGetContentLengthEx** function should be used. That version of the function accepts an unsigned 64-bit integer and will prevent the content length from being truncated to a 32-bit value.

Most servers will only include a Content-Length header in the response for static resources like documents or image files. For other types of resources where the response payload is generated dynamically, such as server-side scripts, servers typically use "chunked" output and there is no Content-Length header. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. In this case, the content length can only be determined after the request has completed.

This function should only be used after a request has completed and will not return a value for dynamic resources as they are being retrieved from the server. To obtain the current number of bytes copied from within an event handler, use the **HttpGetTransferStatus** function.

If the content type for the current resource is textual, the content length reported by the server may be different than what is stored on the local system due to different end-of-line character conventions. For example, on Windows the end of a line of text is indicated by a carriage-return and linefeed pair, while on Linux the end-of-line is indicated by a single linefeed. Depending on the options specified when the request is made, text returned by the server may be normalized for the Windows platform.

This function does not use the HEAD command to request the size of a document on the server. It will only return the content length of a resource which has already been requested, typically after using functions such as **HttpGetText** or **HttpPostXml**. To ask the server for the size of document without downloading the contents of that document, use the **HttpGetFileSize** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

See Also

[HttpGetContentLengthEx](#), [HttpGetContentType](#), [HttpGetFileSize](#), [HttpGetResponseHeader](#),
[HttpGetTransferStatus](#), [HttpSetContentType](#)

HttpGetContentLengthEx Function

```
BOOL WINAPI HttpGetContentLengthEx(  
    HCLIENT hClient,  
    ULARGE_INTEGER *lpLength  
);
```

The **HttpGetContentLengthEx** function returns the size of the current resource in bytes.

Parameters

hClient

Handle to the client session.

lpLength

A pointer to a ULARGE_INTEGER union which will contain the content length for the current resource. This value will be initialized to zero and updated with the length when the function returns.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

When this function is called after a GET or POST request has completed, the *lpLength* parameter will contain the total number of bytes returned by the server. If this function is called while a request is being processed (for example, from within an event handler), it will return the value of the Content-Length response header provided by the server. This version of the function accepts an unsigned 64-bit integer as the *lpLength* parameter and is intended to support very large documents which exceed 4GiB.

Most servers will only include a Content-Length header in the response for static resources like documents or image files. For other types of resources where the response payload is generated dynamically, such as server-side scripts, servers typically use "chunked" output and there is no Content-Length header. In this case, the content length can only be determined after the request has completed.

This function should only be used after a request has completed and will not return a value for dynamic resources as they are being retrieved from the server. To obtain the current number of bytes copied from within an event handler, use the **HttpGetTransferStatusEx** function.

If the content type for the current resource is textual, the content length reported by the server may be different than what is stored on the local system due to different end-of-line character conventions. For example, on Windows the end of a line of text is indicated by a carriage-return and linefeed pair, while on Linux the end-of-line is indicated by a single linefeed. Depending on the options specified when the request is made, text returned by the server may be normalized for the Windows platform.

This function does not use the HEAD command to request the size of a document on the server. It will only return the content length of a resource which has already been requested, typically after using functions such as **HttpGetText** or **HttpPostXml**. To ask the server for the size of document without downloading the contents of that document, use the **HttpGetFileSizeEx** function.

Requirements

[HttpGetContentLength](#), [HttpGetContentType](#), [HttpGetFileSizeEx](#), [HttpGetResponseHeader](#),
[HttpGetTransferStatusEx](#), [HttpSetContentType](#)

HttpGetContentType Function

```
INT WINAPI HttpGetContentType(  
    HCLIENT hClient,  
    LPTSTR lpszContentType,  
    INT nMaxLength  
);
```

The **HttpGetContentType** function returns the content type for the current resource.

Parameters

hClient

Handle to the client session.

lpszContentType

A pointer to a buffer which will contain the MIME content type of the resource returned by the web server. The buffer must be large enough to contain the entire content type string including the terminating null character. This parameter is optional and may be NULL if the information is not required.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the buffer. If the *lpszContentType* parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the value indicates the type of resource returned by the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Value	Description
HTTP_CONTENT_UNKNOWN	The content type for the resource could not be determined. This can occur if the content type returned by the server does not match a known value, such as an experimental or non-standard content type.
HTTP_CONTENT_BINARY	Application specific binary data which doesn't explicitly fall into any of the other standard MIME types. The most common type for binary data is application/octet-stream which can represent any type of data. Other examples are application/pdf and application/zip.
HTTP_CONTENT_TEXT	Textual data which can include plain text, HTML documents, XML, comma-separated value (CSV) data or any other human readable text formats. Examples are text/plain and text/html.
HTTP_CONTENT_AUDIO	Audio data which can include MPEG audio and Windows Media formats. Examples are audio/mpeg, audio/mp4 and audio/x-ms-wma.
HTTP_CONTENT_IMAGE	Image data which can include GIF, JPEG and PNG image formats. Examples are image/gif and image/jpeg.
HTTP_CONTENT_MESSAGE	A content type which specifies the response includes other messages, typically email messages in a standard MIME

	format. This content type is not commonly used with web services.
HTTP_CONTENT_MULTIPART	A content type which includes multiple types of data in a single response. The payload will typically be encoded text and the contents will need to be decoded to extract any binary data included in the message.
HTTP_CONTENT_VIDEO	Video data which can include MP4 movies or Window Media format video. Examples are video/mp4 and video/x-ms-wmv.
HTTP_CONTENT_FONT	Font data which can include TrueType and OpenType fonts. Examples are font/ttf and font/otf.
HTTP_CONTENT_MODEL	Model data for 3D objects and scenes, such as those used with the Virtual Reality Modeling Language (VRML). Examples are model/3mf and model/vrml.

Remarks

This function does not examine the contents of the payload returned by the server and only returns a value based on the Content-Type response header. If the web server does not recognize the data format of the resource it is returning, it should identify it as **application/octet-stream** and the content type would be returned as HTTP_CONTENT_BINARY. However, some servers incorrectly return unrecognized formats as **text/plain**, causing the payload to be identified as human-readable text rather than binary data.

Some servers will return a content type of **text/plain** for JSON responses and others will use the IANA standard type of **application/json**. To ensure consistency with these two content types, this function will always return MIME_CONTENT_TEXT for JSON responses.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpGetCookie Function

```
BOOL WINAPI HttpGetCookie(  
    HCLIENT hClient,  
    LPCTSTR lpszCookieName,  
    LPTSTR lpszCookieValue,  
    INT nCookieValue,  
    LPTSTR lpszCookiePath,  
    INT nCookiePath,  
    LPTSTR lpszCookieDomain,  
    INT nCookieDomain,  
    LPSYSTEMTIME lpCookieExpires,  
    LPDWORD lpdwCookieFlags  
);
```

The **HttpGetCookie** function returns information about a cookie set by the server.

Parameters

hClient

Handle to the client session.

lpszCookieName

A pointer to a string which specifies the name of the cookie to return information about.

lpszCookieValue

A pointer to a string buffer that will contain the value of the cookie. If this information is not required, a NULL pointer may be specified.

nCookieValue

The maximum number of characters that may be copied into the buffer specified by the *lpszCookieValue* parameter, including the terminating null character.

lpszCookiePath

A pointer to a string buffer that will contain the cookie path. If this information is not required, a NULL pointer may be specified.

nCookiePath

The maximum number of characters that may be copied into the buffer specified by the *lpszCookiePath* parameter, including the terminating null character.

lpszCookieDomain

A pointer to a string buffer that will contain the cookie domain. If this information is not required, a NULL pointer may be specified.

nCookieDomain

The maximum number of characters that may be copied into the buffer specified by the *lpszCookieDomain* parameter, including the terminating null character.

lpCookieExpires

A pointer to a [SYSTEMTIME](#) structure which specifies the date and time that the cookie expires. If this information is not required, a NULL pointer may be specified.

lpdwCookieFlags

One or more bit flags which specify status information about the cookie. A value of zero indicates that there are no special status flags for the cookie. This parameter may be NULL if the information

is not required. The following values are currently defined:

Value	Description
HTTP_COOKIE_SECURE	This flag specifies that the cookie should only be provided to the server if the connection is secure.
HTTP_COOKIE_SESSION	This flag specifies that the cookie should only be used for the current application session and should not be stored permanently on the local system.

Return Value

If the function succeeds, the return value is non-zero. If the specified cookie does not exist or function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The Hypertext Transfer Protocol uses special tokens called "cookies" to maintain persistent state information between requests for a resource. These cookies are exchanged between the client and server by setting specific header fields. When a server wants the client to use a cookie, it will include a header field named Set-Cookie in the response header when the client requests a resource. The client can then take this cookie and store it, either temporarily in memory or permanently in a file on the local system. The next time that the client requests a resource from that server, it can send the cookie back to the server by setting the Cookie header field. The **HttpGetCookie** function searches for a cookie set by the server in the Set-Cookie header field. The **HttpSetCookie** function creates or modifies the Cookie header field for the next resource requested by the client.

There are two general types of cookies that are used by servers. Session cookies exist only for the duration of the client session; they are stored in memory and not saved in any kind of permanent storage. When the client application terminates, session cookies are deleted and no longer used. Persistent cookies are stored on the local system and are used by the client until their expiration time. It is the responsibility of the client application to store persistent cookies; applications may use a flat text file, a database or any other storage method available.

In addition to the cookie name and value, the server may return additional information about the cookie which the client should use to determine if it should send the cookie back to the server:

The **cookie path** specifies a path for the resources where the cookie should be used. For example, a path of "/" indicates that the cookie should be provided for all resources requested from the server. A path of "/data" would mean that the cookie should be included if the resource is found in the /data folder or a sub-folder, such as /data/projections.asp. However, the cookie would not be provided if the resource /info/status.asp was requested, since it is not in the /data path.

The **cookie domain** specifies the domain for which the cookie should be used. Matches are made by comparing the name of the server against the domain name specified in the cookie. If the domain is example.com, then any server in the example.com domain would match; for example, both shipping.example.com and orders.example.com would match the domain value. However, if the cookie domain was orders.example.com, then the cookie would only be sent if the resource was requested from orders.example.com, not if the resource was located on shipping.example.com or www.example.com.

The **cookie expiration** specifies the date and time that the cookie should be deleted and no longer sent when a resource is requested from the server. This is only valid for persistent cookies, since session cookies are automatically deleted when the client application terminates. The time is always expressed as Coordinated Universal Time.

The *cookie flags* provide additional information about the cookie. In some cases, a cookie should only be submitted to the server if the resource is requested using a secure connection. In this case, the bit flag HTTP_COOKIE_SECURE will be set.

It is the responsibility of the client application to determine if a cookie meets the criteria required to be submitted to the server. If the application wishes to send the cookie, it can use the **HttpSetCookie** function and specify the cookie name and value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpGetData Function

```
INT WINAPI HttpGetData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength,  
    DWORD dwOptions  
);
```

The **HttpGetData** function requests a resource from the server and copies the data to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to a byte buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to

	accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function.
HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetData** function is used to retrieve a resource from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated and the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpdwLength* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the GET request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

When encountering a server error during a request, the **HttpGetData** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. Additionally, servers may provide further details about the failure, such as XML or JSON formatted data containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the HTTP_TRANSFER_ERRORDATA option. When this option is enabled, the behavior of **HttpGetData** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the buffer provided by the caller.

If compression has been enabled and the server returns compressed data, it will be automatically expanded before being returned to the caller. This will result in a difference between the value returned in the *lpdwLength* parameter, which contains the actual number of bytes copied into the buffer, and the values reported by **HttpGetTransferStatus**. For example, if the server returns 5,000 bytes of compressed data that expands into 15,000 bytes, this function will return 15,000 as the number of bytes copied into the buffer. However, the **HttpGetTransferStatus** function will return the content length as the original 5,000 bytes of compressed data. For this reason, you should always use

the value returned in the *lpdwLength* parameter to determine the amount of data that has been copied into the buffer.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Store the response in a block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgb1Buffer parameter
nResult = HttpGetData(hClient,
                     lpszResource,
                     &hgb1Buffer,
                     &cbBuffer,
                     HTTP_TRANSFER_DEFAULT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    lpBuffer = (LPBYTE)GlobalLock(hgb1Buffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgb1Buffer);
    GlobalFree(hgb1Buffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetDefaultUserAgent Function

```
INT WINAPI HttpGetDefaultUserAgent(  
    LPTSTR lpszUserAgent,  
    INT nMaxLength  
);
```

The **HttpGetDefaultUserAgent** function returns the default user agent string which is included with all requests.

Parameters

lpszUserAgent

A pointer to a buffer which will contain the default user agent string when the function returns. The buffer must be large enough to contain the entire user agent string including the terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When you submit a request to the server, a header named **User-Agent** is automatically defined which identifies your application. It typically uses a format where you have a product name and version number separated by a slash. There can be multiple products listed in the user agent string, with additional optional information enclosed in parenthesis.

A server uses the user agent to determine what type of client has issued the request, including what operating system and browser version was used. The **HttpGetDefaultUserAgent** function returns a copy of that default value. The value of the user agent string depends on which version of Windows the client is running on and whether the process is 32-bit or 64-bit. For example, a 64-bit application will typically return a value like this:

```
Mozilla/5.0 (Windows NT 6.2; Win64; x64) Chrome/74.0.3729.169  
Safari/537.36 SocketTools/11.0
```

Some web services check the value of the user agent string to determine if a compatible client is being used to issue the request. The default value is designed to emulate a common browser, but some services may require you change the user agent to use a specific value or include certain product names and versions.

You can change the value of the user agent string in one of two ways. You can use **HttpSetRequestHeader** to set the **User-Agent** header to a specific value for a client session, or you can use **HttpSetDefaultUserAgent** to set the default user agent string for all requests. If you use **HttpSetRequestHeader** to change the user agent string for a client session, it will always override the default value.

To prevent any user agent string from being included with a request, include the HTTP_OPTION_NOUSERAGENT option when connecting to the server or use **HttpSetOption** to enable that option after a connection has been established.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpSetDefaultUserAgent](#), [HttpSetOption](#), [HttpSetRequestHeader](#)

HttpGetEncodingType Function

```
INT WINAPI HttpGetEncodingType(  
    HCLIENT hClient  
);
```

The **HttpGetEncodingType** function determines which content-encoding option is enabled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is one of the following values:

Value	Description
HTTP_ENCODING_NONE	No encoding will be applied to the content of a request and no default content type will be specified. This encoding type should be used with REST APIs and other services which expect XML or JSON request payloads.
HTTP_ENCODING_URL	Non-printable and extended ASCII characters will be encoded so they can be safely used with URLs and form data. Encoded characters will be represented by a percent symbol prefix, followed by a two digit hexadecimal value which represents the ASCII character code. This encoding is typically used with web services which process HTML form data.
HTTP_ENCODING_XML	This encoding is identical to URL encoding, except spaces are not encoded. It is used with legacy web services which expect form data in an XML format and cannot process encoded whitespace. This encoding should not be specified for services which use REST APIs.

If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The default encoding type is HTTP_ENCODING_URL which is used for submitting data to services which expect HTML form data using the **HttpPostData** or **HttpSubmitForm** functions.

When submitting a JSON or XML request to a service using a REST API, your application should use HTTP_ENCODING_NONE and set the appropriate content type for the request payload. The HTTP_ENCODING_XML encoding type should only be used if the server expects URL encoded form data. The **HttpPostJson** and **HttpPostXml** functions will automatically set the correct encoding and content type for those requests.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpGetErrorString Function

```
INT WINAPI HttpGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **HttpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **HttpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetLastError](#), [HttpSetLastError](#)

HttpGetFile Function

```
INT WINAPI HttpGetFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    DWORD dwOffset  
);
```

The **HttpGetFile** function transfers the specified file on the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local system.

lpszRemoteFile

A pointer to a string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function. This option is ignored if the <i>dwOffset</i> parameter is non-zero.

HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed. If this option is used, your application should call HttpGetResultCode to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.
-------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

dwOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to download the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. To determine if the server compressed the data returned to the client, use the **HttpGetResponseHeader** function to get the value of the **Content-Encoding** header after this function returns. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

To download large files that are over 4GB, use the **HttpGetFileEx** function.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
LPCTSTR lpszLocalFile = _T("index.html");
LPCTSTR lpszRemoteFile = _T("http://sockettools.com/");

if (HttpGetFile(hClient, lpszLocalFile, lpszRemoteFile) == HTTP_ERROR)
{
    dwError = HttpGetLastError();
    _tprintf(stderr, "Unable to download %s, error 0x%lx\n", lpszRemoteFile,
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetFileEx Function

```
INT WINAPI HttpGetFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions,  
    ULARGE_INTEGER uiOffset  
);
```

The **HttpGetFileEx** function transfers the specified file on the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the HttpEnableCompression function. This option is ignored if the <i>uiOffset</i> parameter is

	non-zero.
HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed. If this option is used, your application should call HttpGetResultCode to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to download the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. To determine if the server compressed the data returned to the client, use the **HttpGetResponseHeader** function to get the value of the **Content-Encoding** header after this function returns. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetFileSize Function

```
INT WINAPI HttpGetFileSize(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPDWORD lpdwFileSize  
);
```

The **HttpGetFileSize** function returns the size of the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpdwFileSize

Points to an unsigned integer that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. If the file does not exist or the client does not have permission to access the file, this method will fail and the *lpdwFileSize* parameter will be set to zero.

The server may not return a file size for some resources. This is typically the case with scripts that generate dynamic content because the server has no way of determining the size of the output generated by the script without actually executing it. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. If the request to the server was successful and the file exists, but the server does not return a file size, the function will succeed but the file size returned to the caller will be zero.

When a request is made to the server for information about the file, the library will attempt to keep the connection alive, even if the HTTP_OPTION_KEEPALIVE option has not been specified for the session. This allows an application to request the file size and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the client handle will no longer be valid. If this happens, the *lpdwFileSize* parameter may still contain a valid value. If the library was able to determine the file size, but was not able to maintain the connection to the server, the returned file size will be greater than zero even if the function returns an error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetFileSizeEx Function

```
INT WINAPI HttpGetFileSizeEx(  
    HCLIENT hClient,  
    LPCTSTR lpFileName,  
    ULARGE_INTEGER *lpFileSize  
);
```

The **HttpGetFileSizeEx** function returns the size of the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpFileName

Points to a string that specifies the name of the remote file.

lpFileSize

Points to an unsigned 64-bit integer that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. If the file does not exist or the client does not have permission to access the file, this method will fail and the *lpFileSize* parameter will be set to zero.

The server may not return a file size for some resources. This is typically the case with scripts that generate dynamic content because the server has no way of determining the size of the output generated by the script without actually executing it. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. If the request to the server was successful and the file exists, but the server does not return a file size, the function will succeed but the file size returned to the caller will be zero.

When a request is made to the server for information about the file, the library will attempt to keep the connection alive, even if the HTTP_OPTION_KEEPALIVE option has not been specified for the session. This allows an application to request the file size and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the client handle will no longer be valid. If this happens, the *lpFileSize* parameter may still contain a valid value. If the library was able to determine the file size, but was not able to maintain the connection to the server, the returned file size will be greater than zero even if the function returns an error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpCommand](#), [HttpGetFileTime](#), [HttpVerifyFile](#)

HttpGetFileTime Function

```
INT WINAPI HttpGetFileTime(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPSYSTEMTIME lpFileTime,  
    BOOL bLocalize  
);
```

The **HttpGetFileTime** function returns the modification time for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileTime

Points to a [SYSTEMTIME](#) structure that will be set to the current modification time for the remote file.

bLocalize

A boolean flag which specifies if the file time is localized to the current timezone. If this value is non-zero, then the file time is adjusted to that the time is local to the current system. If this value is zero, the file time is returned in UTC time.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetFileTime** function can be used to determine the date and time that a file was last modified on the server. The time may either be localized to the current system, or it may be returned as UTC time.

This function uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. This requires that the server support at least version 1.0 of the protocol standard, or an error will be returned.

The server may not return a modification time for some resources. If the request to the server was successful and the file exists, but the server does not return a modification time, the function will succeed but all of the members of the SYSTEMTIME structure will be zero.

When a request is made to the server for information about the file, the library will attempt to keep the connection alive, even if the HTTP_OPTION_KEEPALIVE option has not been specified for the session. This allows an application to request the modification time and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the client handle will no longer be valid. If this happens, the SYSTEMTIME structure may still contain a valid value. If the library was able to determine the modification time, but was not able to maintain the connection to the server, the members of the SYSTEMTIME structure will specify a valid date and time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpCommand](#), [HttpGetFileSize](#)

HttpGetFirstCookie Function

```
DWORD_PTR WINAPI HttpGetFirstCookie(  
    HCLIENT hClient,  
    LPTSTR lpszCookieName,  
    LPINT lpnNameLen,  
    LPTSTR lpszCookieValue,  
    LPINT lpnValueLen  
);
```

The **HttpGetFirstCookie** function returns the first cookie set by the server.

Parameters

hClient

Handle to the client session.

lpszCookieName

A pointer to a string buffer which will contain the name of the first cookie set by the server.

lpnNameLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie name string.

lpszCookieValue

A pointer to a string buffer which will contain the name of the first cookie value set by the server. If the cookie value is not required, this parameter may be NULL.

lpnValueLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie value string. If the *lpszCookieValue* parameter is NULL, this parameter should also be NULL.

Return Value

If the function succeeds, the return value is an opaque token which will be passed to the **HttpGetNextCookie** function to retrieve the next cookie. If there are no cookies or the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetFirstCookie** function is used to enumerate the cookies set by the server after a resource has been requested. The return value is an unsigned integer where the size depends on whether the application targets 32-bit or 64-bit platforms. This value should always be treated as an opaque integer which is only valid during the enumeration of the session cookies and should never be stored by the application.

To get information about a specific cookie, use the **HttpGetCookie** function.

Example

```
TCHAR szCookieName[MAXCOOKIENAME];  
TCHAR szCookieValue[MAXCOOKIEVALUE];  
INT nNameLen, nValueLen;  
DWORD_PTR dwCookie;
```

```
// Initialize the nNameLen and nValueLen variables to
```

```

// the maximum number of characters that can be copied
// into the string buffers
nNameLen = MAXCOOKIENAME;
nValueLen = MAXCOOKIEVALUE;

// Get the first cookie set by the server
dwCookie = HttpGetFirstCookie(hClient,
                               szCookieName,
                               &nNameLen,
                               szCookieValue,
                               &nValueLen);

while (dwCookie != 0)
{
    // The szCookieName and szCookieValue strings contain the
    // the name and value for a cookie set by the server

    // Re-initialize the nNameLen and nValueLen variables
    // to the maximum length of the strings
    nNameLen = MAXCOOKIENAME;
    nValueLen = MAXCOOKIEVALUE;

    // Get the next cookie set by the server
    dwCookie = HttpGetNextCookie(hClient,
                                  dwCookie,
                                  szCookieName,
                                  &nNameLen,
                                  szCookieValue,
                                  &nValueLen);
};

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetCookie](#), [HttpGetNextCookie](#), [HttpGetResponseHeader](#), [HttpSetCookie](#), [HttpSetRequestHeader](#)

HttpGetFirstHeader Function

```
BOOL WINAPI HttpGetFirstHeader(  
    HCLIENT hClient,  
    UINT nHeaderType,  
    LPTSTR lpszHeader,  
    LPINT lpcchHeader  
    LPTSTR lpszValue,  
    LPINT lpcchValue  
);
```

The **HttpGetFirstHeader** function returns the name and value of the first request or response header.

Parameters

hClient

Handle to the client session.

nHeaderType

Specifies the type of header to return. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Return the first header set by the client before a resource has been requested. Request headers typically specify information that the server needs to complete the request, such as the name of the host that has the resource, or what types of resources are acceptable to the client.
HTTP_HEADERS_RESPONSE	Return the first header set by the server after a request has been submitted to the server. The response headers typically contain information about the resource, such as its size, the content type and the date it was last modified.

lpszHeader

A pointer to a string buffer that will contain the name of the header field when the function returns.

lpcchHeader

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header name string.

lpszValue

A pointer to a string buffer that will contain the name of the header value when the function returns.

lpcchValue

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header value string.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

Use this function together with **HttpGetNextHeader** to enumerate all request or response headers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetFirstQueuedFile Function

```
DWORD WINAPI HttpGetFirstQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwQueueMode,  
    DWORD dwExcludeFiles,  
    LPHTTPQUEUEDFILE lpFileInfo  
);
```

The **HttpGetFirstQueuedFile** function returns information about the first file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. It may be one of the following values:

Constant	Description
HTTP_QUEUE_ALL	Return information about all files in the queue.
HTTP_QUEUE_DOWNLOAD	Return information for files which are queued for download.
HTTP_QUEUE_UPLOAD	Return information for files which are queued for upload.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the search. If this value is zero, no files will be excluded from the search; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_QUEUE_FLAG_NONE	No files should be excluded.
HTTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
HTTP_QUEUE_FLAG_FAILED	Exclude files which were not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.
HTTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the HttpCancelQueuedFile function has been called and a queued file is in the process of being uploaded or downloaded.

lpFileInfo

A pointer to a [HTTPQUEUEDFILE](#) structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is an unsigned integer with a non-zero value which uniquely identifies the file in the queue. If there are no queued files which match the specified parameters, or the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns information about the first file in the current transfer queue. It is used in conjunction with the **HttpGetNextQueuedFile** function to obtain information about all queued files.

Example

```
// List all files in a file transfer queue
HTTPQUEUEDFILE queuedFile;
DWORD dwFileId;

dwFileId = HttpGetFirstQueuedFile(hQueue, HTTP_QUEUE_ALL, HTTP_QUEUE_FLAG_NONE,
&queuedFile);

while (dwFileId != 0)
{
    switch (queuedFile.dwQueueMode)
    {
    case HTTP_QUEUE_DOWNLOAD:
        _tprintf(_T("%u: download \"%s\" to \"%s\"\n"),
            queuedFile.dwFileId,
            queuedFile.szRemoteFile,
            queuedFile.szLocalFile);
        break;

    case HTTP_QUEUE_UPLOAD:
        _tprintf(_T("%u: upload \"%s\" to \"%s\"\n"),
            queuedFile.dwFileId,
            queuedFile.szRemoteFile,
            queuedFile.szLocalFile);
        break;
    }

    dwFileId = HttpGetNextQueuedFile(hQueue, &queuedFile);
}
```

Requirements

HttpGetFormProperties Function

```
INT WINAPI HttpGetFormProperties(  
    HFORM hForm,  
    LPHTTPFORMPROPERTIES LpFormProp  
);
```

The **HttpGetFormProperties** function returns information about the specified form.

Parameters

hForm

Handle to the virtual form.

lpFormProp

Points to a HTTPFORMPROPERTIES structure which will contain information about the specified form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetLastError Function

DWORD WINAPI HttpGetLastError();

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **HttpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **HttpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **HttpSetLastError(0)** when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or HTTP_ERROR. Those functions which call **HttpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpGetNextCookie Function

```
DWORD_PTR WINAPI HttpGetNextCookie(  
    HCLIENT hClient,  
    DWORD_PTR dwCookie,  
    LPTSTR lpszCookieName,  
    LPINT lpnNameLen,  
    LPTSTR lpszCookieValue,  
    LPINT lpnValueLen  
);
```

The **HttpGetNextCookie** function returns the next cookie set by the server.

Parameters

hClient

Handle to the client session.

dwCookie

An unsigned integer value which specifies a cookie token returned by a previous call to either **HttpGetFirstCookie** or **HttpGetNextCookie**.

lpszCookieName

A pointer to a string buffer which will contain the name of the first cookie set by the server.

lpnNameLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie name string.

lpszCookieValue

A pointer to a string buffer which will contain the name of the first cookie value set by the server. If the cookie value is not required, this parameter may be NULL.

lpnValueLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie value string. If the *lpszCookieValue* parameter is NULL, this parameter should also be NULL.

Return Value

If the function succeeds, the return value is an opaque token which will be passed to the **HttpGetNextCookie** function to retrieve the next cookie. If there are no more cookies or the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetNextCookie** function is used to enumerate the cookies set by the server after a resource has been requested. The return value is an unsigned integer where the size depends on whether the application targets 32-bit or 64-bit platforms. This value should always be treated as an opaque integer which is only valid during the enumeration of the session cookies and should never be stored by the application.

To get information about a specific cookie, use the **HttpGetCookie** function.

Example

```

TCHAR szCookieName[MAXCOOKIENAME];
TCHAR szCookieValue[MAXCOOKIEVALUE];
INT nNameLen, nValueLen;
DWORD_PTR dwCookie;

// Initialize the nNameLen and nValueLen variables to
// the maximum number of characters that can be copied
// into the string buffers
nNameLen = MAXCOOKIENAME;
nValueLen = MAXCOOKIEVALUE;

// Get the first cookie set by the server
dwCookie = HttpGetFirstCookie(hClient,
                             szCookieName,
                             &nNameLen,
                             szCookieValue,
                             &nValueLen);

while (dwCookie != 0)
{
    // The szCookieName and szCookieValue strings contain the
    // the name and value for a cookie set by the server

    // Re-initialize the nNameLen and nValueLen variables
    // to the maximum length of the strings
    nNameLen = MAXCOOKIENAME;
    nValueLen = MAXCOOKIEVALUE;

    // Get the next cookie set by the server
    dwCookie = HttpGetNextCookie(hClient,
                                dwCookie,
                                szCookieName,
                                &nNameLen,
                                szCookieValue,
                                &nValueLen);
};

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetCookie](#), [HttpGetFirstCookie](#), [HttpGetResponseHeader](#), [HttpSetCookie](#), [HttpSetRequestHeader](#)

HttpGetNextHeader Function

```
BOOL WINAPI HttpGetNextHeader(  
    HCLIENT hClient,  
    UINT nHeaderType,  
    LPTSTR lpszHeader,  
    LPINT lpcchHeader,  
    LPTSTR lpszValue,  
    LPINT lpcchValue  
);
```

The **HttpGetNextHeader** function returns the name and value of the next request or response header.

Parameters

hClient
Handle to the client session.

nHeaderType
Specifies the type of header to return. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Return the first header set by the client before a resource has been requested. Request headers typically specify information that the server needs to complete the request, such as the name of the host that has the resource, or what types of resources are acceptable to the client.
HTTP_HEADERS_RESPONSE	Return the first header set by the server after a request has been submitted to the server. The response headers typically contain information about the resource, such as its size, the content type and the date it was last modified.

lpszHeader
A pointer to a string buffer that will contain the name of the header field when the function returns.

lpcchHeader
A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header name string.

lpszValue
A pointer to a string buffer that will contain the name of the header value when the function returns.

lpcchValue
A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header value string.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call

HttpGetLastError.

Remarks

Use this function iteratively after **HttpGetFirstHeader** to enumerate all request or response headers.

Unlike the **HttpGetResponseHeader** function, which returns a single header name and value, the **HttpGetFirstHeader** and **HttpGetNextHeader** functions will return multiple headers that have the same common name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetResponseHeader](#), [HttpSetRequestHeader](#), [HttpGetFirstHeader](#)

HttpGetNextQueuedFile Function

```
DWORD WINAPI HttpGetNextQueuedFile(  
    HQUEUE hQueue,  
    LPHTTPQUEUEDFILE lpFileInfo  
);
```

The **HttpGetNextQueuedFile** function returns information about the next file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpFileInfo

A pointer to a [HTTPQUEUEDFILE](#) structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is an unsigned integer with a non-zero value which uniquely identifies the file in the queue. If there are no additional queued files which match the exclusion criteria specified with the call to **HttpGetFirstQueuedFile**, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns information about the next file in the current transfer queue after an initial call to **HttpGetFirstQueuedFile**. To obtain a list of all matching files in the queue, call this function repeatedly until it returns a value of zero. When information about the last file in the queue has been returned, the last error code will be set to **ST_ERROR_END_OF_QUEUE**.

Example

```
// List all files in a file transfer queue  
HTTPQUEUEDFILE queuedFile;  
DWORD dwFileId;  
  
dwFileId = HttpGetFirstQueuedFile(hQueue, HTTP_QUEUE_ALL, HTTP_QUEUE_FLAG_NONE,  
&queuedFile);  
  
while (dwFileId != 0)  
{  
    switch (queuedFile.dwQueueMode)  
    {  
    case HTTP_QUEUE_DOWNLOAD:  
        _tprintf(_T("%u: download \"%s\" to \"%s\"\\n"),  
            queuedFile.dwFileId,  
            queuedFile.szRemoteFile,  
            queuedFile.szLocalFile);  
        break;  
  
    case HTTP_QUEUE_UPLOAD:  
        _tprintf(_T("%u: upload \"%s\" to \"%s\"\\n"),  
            queuedFile.dwFileId,  
            queuedFile.szRemoteFile,  
            queuedFile.szLocalFile);  
        break;  
    }  
}
```

```
    dwFileId = HttpGetNextQueuedFile(hQueue, &queuedFile);  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

HttpGetOption Function

```
INT WINAPI HttpGetOption(  
    HCLIENT hClient,  
    DWORD dwOption,  
    LPBOOL lpbEnabled  
);
```

The **HttpGetOption** function determines whether a specified HTTP option is enabled.

Parameters

hClient

Handle to the client session.

dwOption

An unsigned integer which specifies the option that is to be checked. It may be one of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number,

	default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

lpbEnabled

A pointer to an integer which will be set to a non-zero value when the function returns if the specified option has been enabled. If the option has not been enabled, a zero value will be returned in the variable.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**. Note that the value returned in the *lpbEnabled* parameter is only valid if the function succeeds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

See Also

[HttpConnect](#), [HttpSetOption](#)

HttpGetPriority Function

```
INT WINAPI HttpGetPriority(  
    HCLIENT hClient  
);
```

The **HttpGetPriority** function returns a value which specifies the priority of file transfers.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the current file transfer priority. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetPriority** function can be used to determine the current priority assigned to file transfers performed by the client. It may be one of the following values:

Value	Description
HTTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpSetPriority](#)

HttpGetQueueClient Function

```
HCLIENT WINAPI HttpGetQueueClient(  
    HQUEUE hQueue  
);
```

The **HttpGetQueueClient** function returns a handle to the current client session.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, it will return `INVALID_CLIENT`. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetQueueClient** function returns the handle to a client session which may be used with other functions, such as **HttpGetTransferStatus**. A valid handle will only be returned if the queue manager is currently uploading or downloading a file. If the queue is active but there are no file transfers in progress at the time this function is called, it will fail and set the last error code to `ST_ERROR_NO_QUEUED_TRANSFER`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `cshttpv11.lib`

See Also

[HttpGetTransferStatus](#), [HttpGetTransferStatusEx](#), [HttpGetQueueStatus](#), [HttpGetThreadQueue](#), [HttpStartQueue](#), [HttpStopQueue](#)

HttpGetQueuedFile Function

```
BOOL WINAPI HttpGetQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwFileId,  
    LPHTTPQUEUEDFILE lpFileInfo  
);
```

The **HttpGetQueuedFile** function returns information about the specified file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. This value cannot be zero.

lpFileInfo

A pointer to a [HTTPQUEUEDFILE](#) structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the file identifier is not valid or the file has been removed from the queue, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The file identifier can be obtained by several different functions, including **HttpEnumQueuedFiles** and **HttpGetQueueStatus**, which provides information about the current file being processed in the queue. Do not make any assumptions about the value of the identifier. Although the value is guaranteed to be unique for the specified queue, it is not guaranteed that file identifiers will be assigned in sequential order.

Example

```
// Get the number of files in the queue  
LONG nFiles = HttpEnumQueuedFiles(hQueue, NULL, 0)  
  
// Display information about the queued files  
if (nFiles > 0)  
{  
    DWORD *pdwFileList = new DWORD[nFiles];  
  
    nFiles = HttpEnumQueuedFiles(hQueue, pdwFileList, nFiles);  
  
    for (LONG nIndex = 0; nIndex < nFiles; nIndex++)  
    {  
        HTTPQUEUEDFILE queuedFile;  
  
        if (HttpGetQueuedFile(hQueue, pdwFileList[nIndex], &queuedFile) == FALSE)  
            break;  
  
        switch (queuedFile.dwMode)  
        {  
        case HTTP_QUEUE_DOWNLOAD:  
            _tprintf(_T("%u: Download \"%s\" to \"%s\"\\n"),
```

```

        queuedFile.dwFileId,
        queuedFile.szRemoteFile,
        queuedFile.szLocalFile);
    break;

case HTTP_QUEUE_UPLOAD:
    _tprintf(_T("%u: Upload \"%s\" to \"%s\"\\n"),
        queuedFile.dwFileId,
        queuedFile.szLocalFile,
        queuedFile.szRemoteFile);
    break;
}
}

delete pdwFileList;
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAddQueuedFile](#), [HttpEnumQueuedFiles](#), [HttpFindQueuedFile](#), [HttpGetFirstQueuedFile](#),
[HttpGetNextQueuedFile](#), [HttpGetQueueStatus](#)

HttpGetQueueStatus Function

```
INT WINAPI HttpGetQueueStatus(  
    HQUEUE hQueue,  
    LPHTTPQUEUESTATUS lpQueueStatus  
);
```

The **HttpGetQueuedFile** function returns information about the specified file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpQueueStatus

A pointer to a [HTTPQUEUESTATUS](#) structure which will contain information about the current state of the file transfer queue. If this parameter is NULL, the function will ignore the parameter and only return the current status of the queue.

Return Value

If the function succeeds, the return value is the current queue status. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**. The following status values may be returned:

Value	Description
HTTP_QUEUE_STATUS_IDLE	The file transfer queue is idle and no files are being uploaded or downloaded. This state is returned before HttpStartQueue has been called or after HttpStopQueue has been called. The queue will also automatically enter an idle state after the last file transfer has completed and the queue manager thread exits.
HTTP_QUEUE_STATUS_ACTIVE	The queue manager is active and files are currently being uploaded or downloaded.
HTTP_QUEUE_STATUS_PAUSED	The queue manager is active although file transfers are currently paused. The queue enters this state after the HttpSuspendQueue function is called and resumes file transfers after the HttpResumeQueue function is called.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
- Minimum Server Platform:** Windows Server 2008 R2 Service Pack 1
- Header File:** ctools11.h
- Import Library:** cshttpv11.lib

See Also

[HttpCancelQueuedFile](#), [HttpResetQueue](#), [HttpResumeQueue](#), [HttpStartQueue](#), [HttpSuspendQueue](#), [HttpStopQueue](#)

HttpGetQueueThread Function

```
DWORD WINAPI HttpGetQueueThread(  
    HQUEUE hQueue  
);
```

The **HttpGetQueueThread** function returns a value which uniquely identifies the queue manager thread.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero and specifies a unique identifier for the queue manager thread. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetQueueThread** function can be used to obtain a unique identifier for the queue manager thread which is responsible for performing the file transfers. If the function returns zero, this indicates that either the queue handle is no longer valid, or the queue is idle and no files are currently being processed. To obtain the handle to a queue associated with a particular thread, call the **HttpGetThreadQueue** function.

You should not store the thread ID or consider it a persistent value, even during the lifetime of the process. It is only valid while the queue manager is actively processing files in the queue. The thread ID value will change every time the **HttpStartQueue** function is called.

Never use the thread ID to obtain a handle to the thread and call Windows API functions such as **SuspendThread** or **TerminateThread**. This can result inconsistency within the internal state of the queue manager and may result in incomplete or corrupted file transfers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

See Also

[HttpGetQueueStatus](#), [HttpGetThreadQueue](#), [HttpStartQueue](#), [HttpStopQueue](#)

HttpGetRedirectUrl Function

```
INT WINAPI HttpGetRedirectUrl(  
    HCLIENT hClient,  
    LPTSTR lpszResource,  
    INT nMaxLength  
);
```

The **HttpGetRedirectUrl** function returns the URL for a redirected resource.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string buffer which will contain the URL of the redirected resource when the function returns. The string will be null terminated and the buffer must be large enough to accommodate the entire URL or the function will fail. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that may be copied into the string buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the length of the URL. A return value of zero indicates that the request was not redirected. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns the complete URL for a request which has been redirected to a different resource. This is useful for applications which do not wish to use automatic redirection and instead prefer to handle the redirection by establishing a new connection by passing this value to the **HttpConnectUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpConnectUrl](#), [HttpGetResourceUrl](#), [HttpGetResponseHeader](#)

HttpGetRequestHeader Function

```
BOOL WINAPI HttpGetRequestHeader(  
    HCLIENT hClient,  
    LPCTSTR lpszHeader,  
    LPTSTR lpszValue,  
    INT nMaxLength  
);
```

The **HttpGetRequestHeader** function returns the value of the specified request header field.

Parameters

hClient

Handle to the client session.

lpszHeader

Pointer to a string which specifies the header value to be returned.

lpszValue

Pointer to a buffer which will contain the null-terminated string value of the specified header field.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call

HttpGetLastError.

Remarks

When a resource is requested from the server, it consists of two parts. The first part is the command issued to the server, along with the name of the resource and any optional encoded parameters. The second part consists of one or more header fields which can be used to provide additional information to the server. For example, here is what the command and header may look like for a simple request:

```
GET /test HTTP/1.0  
Host: api.sockettools.com  
Accept: text/*
```

The first line consists of the command, the resource and the protocol version. The subsequent lines are the header, which is similar to the headers used in email messages. The Host field specifies the name of the server the resource is being requested from, and the Accept field specifies the type of resources that are acceptable to the client; in this case, any type of text file.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetResourceUrl Function

```
INT WINAPI HttpGetResourceUrl(  
    HCLIENT hClient,  
    LPTSTR lpszResource,  
    INT nMaxLength  
);
```

The **HttpGetResourceUrl** function returns the URL for the current request.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string buffer which will contain the URL of the current resource when the function returns. The string will be null terminated and the buffer must be large enough to accommodate the entire URL or the function will fail. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that may be copied into the string buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the length of the URL. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns the URL for the current request which has been submitted to the server. This can be useful for applications which need to compose a URL for display or logging purposes, combining the connection information and resource path provided to functions such as **HttpGetData** or **HttpPostData**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpConnectUrl](#), [HttpGetData](#), [HttpGetRedirectUrl](#), [HttpPostData](#)

HttpGetResponseHeader Function

```
BOOL WINAPI HttpGetResponseHeader(  
    HCLIENT hClient,  
    LPCTSTR lpszHeader,  
    LPTSTR lpszValue,  
    INT nMaxLength  
);
```

The **HttpGetResponseHeader** function returns the value of the specified response header field.

Parameters

hClient

Handle to the client session.

lpszHeader

Pointer to a string which specifies the header value to be returned.

lpszValue

Pointer to a buffer which will contain the null-terminated string value of the specified header field.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call

HttpGetLastError.

Remarks

When a resource is returned by the server, it consists of three parts. The first part consists of a single line that indicates the result of the request. The second part is one or more header fields which provides specific information about the resource, such as its size in bytes. The third part consists of the resource data itself, such as the HTML document or image data. For example, this is what the response to a request for a simple HTML document can look like:

```
HTTP/1.0 200 OK  
Date: Mon, 5 Jan 2004 20:18:33 GMT  
Content-Type: text/html  
Last-Modified: Mon, 5 Jan 2004 19:34:19 GMT  
Content-Length: 115
```

```
<html>  
<head>  
<title>Simple Document</title>  
</head>  
<body>  
This is a simple HTML document.  
</body>  
</html>
```

The first line consists of the protocol version, a numeric response code and some text describing the result. The subsequent lines are the header, which is similar to the headers used in email messages. For example, the Date field specifies the date the resource was requested, the Content-Type field specifies what type of resource was requested, and the Content-Length field specifies the size of the

resource in bytes. The end of the header block is indicated by an empty line (two carriage-return/linefeed sequences), and is followed by the resource itself, in this case a simple HTML document.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetResultCode Function

```
INT WINAPI HttpGetResultCode(  
    HCLIENT hClient  
);
```

The **HttpGetResultCode** function reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
- Minimum Server Platform:** Windows Server 2008 R2 Service Pack 1
- Header File:** ctools11.h
- Import Library:** cshttpv11.lib

HttpGetResultString Function

```
INT WINAPI HttpGetResultString(  
    HCLIENT hClient,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

The **HttpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

A pointer to the buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **HttpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpCommand](#), [HttpGetResultCode](#)

HttpGetSecurityInformation Function

```
BOOL WINAPI HttpGetSecurityInformation(  
    HCLIENT hClient,  
    LPSECURITYINFO lpSecurityInfo  
);
```

The **HttpGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a [SECURITYINFO](#) structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value `SECURITY_PROTOCOL_NONE`.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;
```

```
securityInfo.dwSize = sizeof(SECURITYINFO);  
if (HttpGetSecurityInformation(hClient, &securityInfo))  
{  
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)  
    {  
        MessageBox(NULL, _T("The connection is not secure"),  
                    _T("Connection"), MB_OK);  
    }  
    else  
    {  
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)  
        {  
            MessageBox(NULL, _T("The connection is secure"),  
                        _T("Connection"), MB_OK);  
        }  
        else  
        {  
            MessageBox(NULL, _T("The server certificate not valid"),  
                        _T("Connection"), MB_OK);  
        }  
    }  
}
```

```
}
```

Requirements

HttpGetStatus Function

```
INT WINAPI HttpGetStatus(  
    HCLIENT hClient  
);
```

The **HttpGetStatus** function returns the current status of the client session.

Parameters

hClient
Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
HTTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
HTTP_STATUS_CONNECT	The client is establishing a connection with the server.
HTTP_STATUS_READ	The client is reading data from the server.
HTTP_STATUS_WRITE	The client is writing data to the server.
HTTP_STATUS_DISCONNECT	The client is disconnecting from the server.
HTTP_STATUS_GETDATA	The client is downloading data from the server.
HTTP_STATUS_PUTDATA	The client is uploading data to the server.
HTTP_STATUS_POSTDATA	The client is posting data to a script on the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session. To obtain status information about a file transfer, use the **HttpGetTransferStatus** function.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
- Minimum Server Platform:** Windows Server 2008 R2 Service Pack 1
- Header File:** ctools11.h
- Import Library:** cshttpv11.lib

[HttpIsBlocking](#), [HttpIsReadable](#), [HttpIsWritable](#), [HttpGetTransferStatus](#)

HttpGetTaskError Function

```
DWORD WINAPI HttpGetTaskError(  
    UINT nTaskId  
);
```

Return the last error code for the specified asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed successfully, this function returns a value of zero. A non-zero return value indicates an error has occurred.

Remarks

The **HttpGetTaskError** function returns the last error code associated with the specified asynchronous task. If the task completed successfully, the return value will be zero. If the task is still active, the function will return the error ST_ERROR_TASK_ACTIVE. If the task has been suspended, the function will return ST_ERROR_TASK_SUSPENDED. Any other value indicates that the task completed, but the operation has failed and the error code will specify the cause of the failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpTaskAbort](#), [HttpTaskResume](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpGetTaskId Function

```
UINT WINAPI HttpGetTaskId(  
    HCLIENT hClient  
);
```

Return the asynchronous task identifier associated with the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the client handle is not associated with an asynchronous task, the function will return a value of zero.

Remarks

The **HttpGetTaskId** function will return the task ID that is associated with a client session. This is a unique unsigned integer value that references the worker thread that was created to manage the asynchronous client session. This function should only be called within an event handler that is invoked by a background task that has been started using a function such as **HttpAsyncGetFile**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpGetText Function

```
INT WINAPI HttpGetText(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

The **HttpGetText** function returns the contents of a text resource in a null-terminated string buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource that will be transferred to the local system. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

lpszBuffer

A pointer to a string buffer which will contain the contents of the text file when the function returns. This buffer should be large enough to store the contents of the file, including a terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. This value must be larger than zero. If this value is smaller than the actual size of the text file, the data returned will be truncated.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetText** function is used to retrieve the contents of a text resource and return it in a null-terminated string buffer. Because binary data can include embedded null characters which would truncate the string, this function should only be used with text files or script output that is known to be textual. For example, it is safe to use this function when a resource returns HTML or XML data, but should not be used if it returns an image or executable file.

This function has been included as a convenience for applications that need to retrieve relatively small amounts of textual data and manipulate the contents as a string. If the Unicode version of this function is called, the text is automatically converted to a Unicode string. If the maximum amount of data being returned is unknown or the amount of text is very large, it is recommended that you use the **HttpGetTextEx** or **HttpGetFile** functions.

If the ANSI version of this function is called, the text returned will always be UTF-8 encoded. If you need to return the text using a different code page, use the **HttpGetTextEx** function which will allow you to specify a different code page used for the conversion.

If you use the **HttpGetFileSize** function to determine how large the string buffer should be prior to calling this function, it is important to be aware that the actual number of characters may differ based

on the end-of-line conventions used by the host operating system. For example, if you call **HttpGetFileSize** to obtain the size of a text file on a UNIX system, the value will not be large enough to store the complete file because UNIX uses a single linefeed (LF) character to indicate the end-of-line, while a Windows system will use a carriage-return and linefeed (CRLF) pair. To accommodate this difference, you should always allocate extra memory for the string buffer to store the additional end-of-line characters.

HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
LPTSTR lpszBuffer = (LPTSTR)calloc(MAXFILESIZE, sizeof(TCHAR));

if (lpszBuffer == NULL)
    return;

nResult = HttpGetText(hClient, lpszRemoteFile, lpszBuffer, MAXFILESIZE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetTextEx Function

```
INT WINAPI HttpGetTextEx(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPVOID lpvBuffer,  
    LPINT lpcchBuffer,  
    UINT nCodePage,  
    DWORD dwOptions  
);
```

The **HttpGetDataEx** function requests the contents of text resource from the server and copies the data to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server.

lpvBuffer

A pointer to a null-terminated string buffer which will contain the text return by the server, or a pointer to a global memory handle which will reference the text when the function returns. If you are providing a pre-allocated string buffer, it must be large enough to store the terminating null character.

lpcchBuffer

A pointer to an integer which should be initialized to the maximum number of characters which can be copied to the string specified by the *lpvBuffer* parameter. If the *lpvBuffer* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of characters copied into the string.

nCodePage

An unsigned integer that specifies the ANSI code page which should be used to convert the text returned by the server. A value of zero specifies the default system code page should be used with the conversion. See the remarks below for more information.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.

HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. This option is enabled by default.
HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed. If this option is used, your application should call HttpGetResultCode to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetTextEx** function is used to retrieve the contents of a text resource and return it in a null-terminated string buffer. Because binary data can include embedded null characters which would truncate the string, this function should only be used with text files or script output that is known to be textual. For example, it is safe to use this function when a resource returns HTML or XML data, but should not be used if it returns an image or executable file. Attempting to use this function to retrieve a resource which is not textual will result in an error.

This function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated and the value the *lpcchBuffer* parameter points to should be initialized to the size of that buffer. The buffer must be large enough to contain the entire response from the server, including a terminating null character to indicate the end of the string. If the string buffer is too small, the function will fail.

The second approach is to have the *lpvBuffer* parameter point to a global memory handle which will contain the text when the function returns. In this case, the value that the *lpcchBuffer* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

Important: The *lpcchBuffer* parameter specifies the number of characters, not the number of bytes. If the Unicode version of this function is called, the string buffer will contain Unicode text. If the ANSI version of the function is called, the string will contain ANSI text using the code page specified by the *nCodePage* parameter. When the function returns, the *lpcchBuffer* parameter will contain the number of characters copied into the string buffer, not including the terminating null character.

The *nCodePage* parameter is only meaningful when using the ANSI version of this function. If the Unicode version of the function is called, this value of this parameter should always be either **CP_ACP** or **CP_UTF8**. When the ANSI version of this function is called, the text returned by the server will be automatically converted to the requested code page. For example, if you specify **CP_ACP** as the code page and the server returns the text as UTF-8 encoded text, this function will attempt to convert the text to the local system's default code page. If the conversion cannot be performed, the function

will fail. This can occur if you use a code page which cannot represent all of the characters in the string. In most cases, it is recommended you use **CP_UTF8** as the code page.

This function will attempt to determine the encoding used based on the character set returned by the server. If the character set used is not explicitly specified by the server, the function will try to determine the character set based on the contents of the server response. The function will always check if the text is UTF-8 encoded first, and then check if the text matches the default character set used by the local system (e.g.: windows-1252 or iso-8859-1). The function will fail if it cannot determine how the text should be converted to Unicode or the specified ANSI code page.

If you use the **HttpGetFileSize** function to determine how large the string buffer should be prior to calling this function, it is important to be aware that the actual number of characters may differ based on the end-of-line conventions and character encoding used by the host operating system. For example, if you call **HttpGetFileSize** to obtain the size of a text file on a UNIX system, the value will not be large enough to store the complete file because UNIX uses a single linefeed (LF) character to indicate the end-of-line, while a Windows system will use a carriage-return and linefeed (CRLF) pair. To accommodate this difference, you should always allocate extra memory for the string buffer to store the additional end-of-line characters.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the **HTTP_EVENT_PROGRESS** event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = NULL;
DWORD cchBuffer = 0;

// Store the response in a block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = HttpGetTextEx(hClient,
                        lpszResource,
                        &hgblBuffer,
                        &cchBuffer,
                        CP_UTF8,
                        HTTP_TRANSFER_DEFAULT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    LPTSTR lpszBuffer = (LPTSTR)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

HttpGetThreadQueue Function

```
HQUEUE WINAPI HttpGetThreadQueue(  
    DWORD dwThreadId  
);
```

The **HttpGetThreadQueue** function returns a handle to the queue associated with the specified thread.

Parameters

dwThreadId

An unsigned integer value which specifies a unique identifier for the queue manager thread. If this value is zero, it will return the handle associated with the current thread.

Return Value

If the function succeeds, the return value is the handle to the queue. If the function fails, it will return INVALID_QUEUE. To get extended error information, call **HttpGetLastError**.

Remarks

All queued file transfers are handled by a queue manager which executes asynchronously in a background worker thread. This worker thread is created when the **HttpStartQueue** function is called and terminates when all files in the queue have been processed, or when the **HttpStopQueue** function is called. This function will return the queue handle associated with that worker thread.

The most common use of this function would be to obtain the handle for the queue from within a queue event handler. The application would pass in a value of zero as the thread ID and the function will return the handle to the queue which invoked the event notification.

If you call this function outside of an event handler and the *dwThreadId* parameter is zero, or if the queue is idle and not transferring files, this function will return INVALID_QUEUE. The thread ID is only valid while the queue manager is actively processing files in the queue.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

[HttpGetQueueStatus](#), [HttpGetQueueThread](#), [HttpStartQueue](#), [HttpStopQueue](#)

HttpGetTimeout Function

```
INT WINAPI HttpGetTimeout(  
    HCLIENT hClient  
);
```

The **HttpGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpGetTransferStatus Function

```
INT WINAPI HttpGetTransferStatus(  
    HCLIENT hClient,  
    LPHTTPTRANSFERSTATUS lpStatus  
);
```

The **HttpGetTransferStatus** function returns information about the current data transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [HTTPTRANSFERSTATUS](#) structure which contains information about the status of the current data transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetTransferStatus** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option HTTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the [HTTPTRANSFERSTATUS](#) structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

If you are uploading or downloading large files which exceed 4GB, you should use the **HttpGetTransferStatusEx** function which returns the size as a 64-bit value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

See Also

[HttpEnableEvents](#), [HttpGetTransferStatusEx](#), [HttpRegisterEvent](#), [HTTPTRANSFERSTATUS](#), [HTTPTRANSFERSTATUSEX](#)

HttpGetTransferStatusEx Function

```
INT WINAPI HttpGetTransferStatusEx(  
    HCLIENT hClient,  
    LPHTTPTRANSFERSTATUSEX lpStatus  
);
```

The **HttpGetTransferStatusEx** function returns information about the current data transfer in progress. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an [HTTPTRANSFERSTATUSEX](#) structure which contains information about the status of the current data transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetTransferStatusEx** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option HTTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the [HTTPTRANSFERSTATUSEX](#) structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

HttpInitialize Function

```
BOOL WINAPI HttpInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **HttpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **HttpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **HttpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **HttpInitialize** or **HttpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpIsBlocking Function

```
BOOL WINAPI HttpIsBlocking(  
    HCLIENT hClient  
);
```

The **HttpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **HttpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshttpv11.lib

See Also

[HttpCancel](#), [HttpIsConnected](#), [HttpIsReadable](#), [HttpIsWritable](#), [HttpRead](#), [HttpWrite](#)

HttpIsConnected Function

```
BOOL WINAPI HttpIsConnected(  
    HCLIENT hClient  
);
```

The **HttpIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpIsBlocking](#), [HttpIsReadable](#), [HttpIsWritable](#)

HttpIsReadable Function

```
BOOL WINAPI HttpIsReadable(  
    HCLIENT hClient,  
    INT nTimeout,  
    LPDWORD lpdwAvail  
);
```

The **HttpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

HttpIsWritable Function

```
BOOL WINAPI HttpIsWritable(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **HttpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

);
```

The **HttpOpenFile** function opens the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to open.

dwOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Use the **HttpCloseFile** function to close the file on the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpOpenFileEx Function

```
INT WINAPI HttpOpenFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    ULARGE_INTEGER uiOffset  
);
```

The **HttpOpenFileEx** function opens the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to open.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Use the **HttpCloseFile** function to close the file on the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

HttpPatchData Function

```
INT WINAPI HttpPatchData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszPatchData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPatchData** function submits patch data to the server and returns the result in a buffer provided by the caller.

Parameters

- hClient*
Handle to the client session.
- lpszResource*
A pointer to a string that specifies the resource name that the patch data will be submitted to. Typically this is the name of a script on the server.
- lpszPatchData*
A pointer to a string that specifies the patch data that will be submitted to the server.
- lpvResult*
A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.
- lpcbResult*
A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.
- dwOptions*
An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_PATCH_DEFAULT	The default post mode. The contents of the buffer will be submitted without encoding. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_PATCH_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

HTTP_PATCH_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.
----------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPatchData** function is used to submit XML or JSON formatted patch data to a service, and then returns a copy of the response from the server into a local buffer. This function will not perform any encoding and will not automatically define the type of patch data being submitted. Your application is responsible for specifying the content type for the patch data, and ensuring that the XML or JSON data that is being submitted to the server is formatted correctly.

This function sends a PATCH command to the server, which is similar to a POST or PUT request. It is used to make partial updates to a resource, rather than creating or replacing it entirely. The format of the patch data is specific to the service being used. If the resource being patched does not exist, the behavior is defined by the server. If enough information is provided, it may choose to create the resource just as if a PUT command was used, or it may return an error.

Your application should use the **HttpSetRequestHeader** function to define the Content-Type header prior to calling the **HttpPatchData** function. One of the most common formats used is the JSON Merge Patch which is defined in RFC 7396. The value for the Content-Type header for this patch format is "application/merge-patch+json". Refer to your service API documentation to determine what patch formats are acceptable, along with any additional header values that must be defined.

The function may be used in one of two ways, depending on the needs of the application. The first approach is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second approach is to have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpcbResult* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the PATCH request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

When encountering a server error during a request, the **HttpPatchData** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the PATCH request fails, servers may also provide further details about the failure, such as XML or JSON formatted data containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the HTTP_PATCH_ERRORDATA option. When this

option is enabled, the behavior of **HttpPatchData** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification can be enabled by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgb1Buffer parameter. Since the output from the
// script is textual, the HTTP_PATCH_CONVERT option is used

nResult = HttpPatchData(hClient,
                        lpszResource,
                        lpszPatchData,
                        &hgb1Buffer,
                        &cbBuffer,
                        HTTP_PATCH_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgb1Buffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgb1Buffer);
    GlobalFree(hgb1Buffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpPostData Function

```
INT WINAPI HttpPostData(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCVOID lpvBuffer,  
    DWORD cbBuffer,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPostData** function submits the contents of the specified buffer to a script on the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource that the data will be posted to on the server. Typically this is the name of a script that will be executed. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to the data that will be provided to the script. This parameter may be NULL if the script does not require any additional data from the client.

cbBuffer

The number of bytes to copy from the buffer. If this *lpvBuffer* parameter is NULL, this value should be zero.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character

	sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.
HTTP_POST_MULTIPART	The contents of the buffer being sent to the server consists of multipart form data and will be sent as-is without any encoding.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostData** function is used to submit data to a script that executes on the server and then copy the output from that script into a local buffer. If you are submitting XML or JSON formatted data to the server, it is recommended that you use the **HttpPostXml** or **HttpPostJson** functions instead to ensure that the correct content type and encoding is automatically selected.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpcbResult* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the POST request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

When encountering a server error during a request, the **HttpPostData** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the POST request fails, servers may also provide further details about the failure, such as XML or JSON formatted data containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the HTTP_POST_ERRORDATA option. When this option is enabled, the behavior of **HttpPostData** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call

HttpGetResultCode to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification can be enabled by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Store the response in block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nResult = HttpPostData(hClient,
                      lpzResource,
                      lpParameters,
                      cbParameters,
                      &hgblBuffer,
                      &cbBuffer,
                      HTTP_POST_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetData](#), [HttpGetTransferStatus](#), [HttpPostJson](#), [HttpPostXml](#), [HttpPutData](#), [HttpRegisterEvent](#), [HttpSubmitRequest](#)

HttpPostFile Function

```
INT WINAPI HttpPostFile(  
    HCLIENT hClient,  
    LPCTSTR lpszFileName,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszFieldName,  
    DWORD dwOptions,  
    DWORD dwReserved  
);
```

The **HttpPostFile** function posts the contents of the specified file to a script executed on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszResource

A pointer to a string that specifies the resource on the server that the file data will be posted to. Typically this is the name of a script that is responsible for processing and storing the file data.

lpszFieldName

A pointer to a string that corresponds to the form field name that the script expects. If this parameter is NULL or an empty string, a default field name of "File1" is used.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostFile** function is similar to the **HttpPutFile** function in that it can be used to upload the contents of a local file to a server. However, instead of using the PUT command, the POST command is used to send the file data to a script that is executed on the server. This method has the advantage of not requiring any special configuration settings on the server, however it does require that the script be able to process multipart/form-data as defined in RFC 2388.

To support uploading files from a form on a webpage, the FILE input type is used along with the action that specifies the script that will accept the file data and process it. For example, the HTML code

could look like this:

```
<form action="/cgi-bin/upload.cgi" method="post" enctype="multipart/form-  
data">  
<input type="file" name="datafile" size="20">  
<input type="submit">  
</form>
```

In this example, the script `/cgi-bin/upload.cgi` is responsible for processing the file data that is posted by the client, and the form field name `"datafile"` is used. The user can select a file, and when the Submit button is clicked, the file data is posted to the script. To simulate this using the **HttpPostFile** function, the *lpszFileName* parameter should be set to the name of the local file that will be posted to the server. The *lpszResource* parameter should be the name of the script, in this case `"/cgi-bin/upload.cgi"`. The *lpszFieldName* parameter should be specified as the string `"datafile"` to match the name of the field used by the form.

Note that the **HttpPostFile** function always submits the file contents as `multipart/form-data` with the content type set to `application/octet-stream`. The script that accepts the posted data must be able to parse the multipart header block and correctly process 8-bit data. If the script assumes that the data will be posted using a specific encoding type such as `base64` then the file data may not be accepted or may be corrupted by the script.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the `HTTP_EVENT_PROGRESS` event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `cshttpv11.lib`

Unicode: Implemented as Unicode and ANSI versions

HttpPostJson Function

```
INT WINAPI HttpPostJson(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszJsonData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPostJson** function submits JSON formatted data to the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource name that the JSON data will be submitted to. Typically this is the name of a script on the server.

lpszJsonData

A pointer to a string that specifies the JSON data that will be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer will be submitted without encoding and should use the standard JSON format. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the

server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is `HTTP_ERROR`. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostJson** function is used to submit JSON formatted data to a script that executes on the server and then copy the output from that script into a local buffer. This function automatically sets the correct content type and encoding required for submitting JSON data to a server, however it does not parse the JSON data itself to ensure that it is well-formed. Your application is responsible for ensuring that the JSON data that is being submitted to the server is formatted correctly.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpcbResult* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the POST request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "application/json" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

When encountering a server error during a request, the **HttpPostJson** function normally returns `HTTP_ERROR`, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the POST request fails, servers may also provide further details about the failure, such as XML or JSON formatted data containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the `HTTP_POST_ERRORDATA` option. When this option is enabled, the behavior of **HttpPostJson** changes; it does not return `HTTP_ERROR` for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the post completes, a timeout occurs or the

operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification can be enabled by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Store the response in a block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgb1Buffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nResult = HttpPostJson(hClient,
                      lpzResource,
                      lpzJsonData,
                      &hgb1Buffer,
                      &cbBuffer,
                      HTTP_POST_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgb1Buffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgb1Buffer);
    GlobalFree(hgb1Buffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpPostXml Function

```
INT WINAPI HttpPostXml(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszXmlData,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPostXml** function submits XML formatted data to the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource name that the XML data will be submitted to. Typically this is the name of a script on the server.

lpszXmlData

A pointer to a string that specifies the XML data that will be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer will be submitted without encoding and should use the standard XML format. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the

	server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.
--	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is `HTTP_ERROR`. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostXml** function is used to submit XML formatted data to a script that executes on the server and then copy the output from that script into a local buffer. This function automatically sets the correct content type and encoding required for submitting XML data to a server, however it does not parse the XML data itself to ensure that it is well-formed. Your application is responsible for ensuring that the XML data that is being submitted to the server is formatted correctly.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpcbResult* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the POST request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "text/xml" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

When encountering a server error during a request, the **HttpPostXml** function normally returns `HTTP_ERROR`, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the POST request fails, servers may also provide further details about the failure, such as XML or JSON formatted data containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the `HTTP_POST_ERRORDATA` option. When this option is enabled, the behavior of **HttpPostXml** changes; it does not return `HTTP_ERROR` for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the post completes, a timeout occurs or the

operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification can be enabled by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgb1Buffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Store the response in a block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgb1Buffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nResult = HttpPostXml(hClient,
                     lpszResource,
                     lpszXmlData,
                     &hgb1Buffer,
                     &cbBuffer,
                     HTTP_POST_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgb1Buffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgb1Buffer);
    GlobalFree(hgb1Buffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpProxyConnect Function

```
HCLIENT WINAPI HttpProxyConnect(  
    UINT nProxyType,  
    LPCTSTR lpszProxyHost,  
    UINT nProxyPort,  
    LPCTSTR lpszProxyUser,  
    LPCTSTR lpszProxyPassword,  
    LPCTSTR lpszRemoteHost,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    DWORD dwVersion,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **HttpProxyConnect** function is used to establish a connection through a proxy server.

Parameters

nProxyType

An unsigned integer which specifies the type of proxy that the client is connecting to. The supported proxy server types are as follows:

Value	Description
HTTP_PROXY_NONE	A direct connection will be established with the server. When this value is specified the proxy parameters are ignored.
HTTP_PROXY_STANDARD	A standard connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard connections.
HTTP_PROXY_SECURE	A secure connection is established through the specified proxy server. This proxy type should be used with secure connections and the HTTP_OPTION_SECURE option should also be set via the <i>dwOptions</i> parameter.
HTTP_PROXY_WINDOWS	The configuration options for the current system should be used. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. These settings are the same proxy server settings configured in Windows.

lpszProxyHost

A pointer to a string which specifies the proxy server host name or IP address. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

nProxyPort

The port number that the proxy server is listening for connections on. A value of zero specifies that the default port number 80 should be used. Note that in most cases, a proxy server is not configured to use the default port. This argument is ignored if the proxy type is set to

HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

lpzProxyUser

A pointer to a string which specifies the user name that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpzProxyPassword

A pointer to a string which specifies the password that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpzRemoteHost

A pointer to a string which specifies the name of the server to connect to through the proxy server. This may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 80 should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.

HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. An application can provide its own custom user agent value using the HttpSetRequestHeader function.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. The value of the <i>dwVersion</i> parameter will be ignored when this option is used.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.
-------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create a version value and the following values are defined:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this session. This is the same as specifying HTTP_VERSION_11 and is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_09	The client should use the original one-line protocol which includes no version number and no request header block. This version has been deprecated and should only be used with legacy servers which do not support the protocol standard. This version of the protocol does not support virtual hosts and is not supported by most modern web services.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.
HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.

lpCredentials

Pointer to credentials structure [SECURITYCREDENTIALS](#). This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields *dwSize*, *lpzCertStore*, and *lpzCertName* must be defined, while other fields may be left undefined. Set *dwSize* to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to the client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **HttpProxyConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

If the HTTP_PROXY_WINDOWS proxy type is specified, then the proxy configuration for the local system is used. If no proxy server has been defined, then the proxy-related parameters will be ignored and the function will establish a connection directly to the server.

The username and password information is only used when connecting to a server which supports version 1.1 or later of the protocol.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

If the HTTP_OPTION_KEEPALIVE option is specified and the server does not support persistent connections, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is automatically enabled when using HTTP/2.

Applications should use HTTP_VERSION_DEFAULT as the value for the *dwVersion* parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2.0 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support the features required for a secure HTTP/2 connection.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return `INVALID_CLIENT`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpPutData Function

```
INT WINAPI HttpPutData(  
    HCLIENT hClient,  
    LPCTSTR lpszRemoteFile,  
    LPCVOID lpvBuffer,  
    DWORD dwLength,  
    DWORD dwReserved  
);
```

The **HttpPutData** function copies the contents of the specified buffer and stores it in a file on the server.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to a buffer which will contain the data to be transferred from the client and stored in a file on the server.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutData** function is used to store the contents of the specified buffer in a file on the server. Not all servers permit files to be created using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** function prior to uploading the data.

This function is designed for uploading the contents of a buffer to be stored as a file on the server. If you need to use the PUT command to as part of a RESTful API where the PUT command is used to submit data to the server, use the **HttpPutDataEx** function. That function will return the success or failure responses back to the client.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **HttpGetTransferStatus**

function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpEnableEvents](#), [HttpGetData](#), [HttpGetFile](#), [HttpGetTransferStatus](#), [HttpPostData](#), [HttpPutDataEx](#), [HttpPutFile](#), [HttpRegisterEvent](#)

HttpPutDataEx Function

```
INT WINAPI HttpPutDataEx(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCVOID lpvBuffer,  
    DWORD cbBuffer,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPutDataEx** function submits the contents of the specified buffer to the server using the PUT command and returns the server's response to the command.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string which specifies the resource path on the server. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A pointer to a buffer which will contain the data to be transferred from the client and submitted to the server. This parameter may not be NULL.

cbBuffer

The number of bytes to copy from the buffer. This value must be larger than zero.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_PUT_DEFAULT	The default mode. The contents of the buffer are sent unmodified and the data returned by the server is copied to the result buffer exactly as it is returned from the server. This option should be used if the server is expected to return binary data in the response to the PUT request.
HTTP_PUT_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual

	carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_PUT_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutDataEx** function is used to submit data to the server using the PUT command. This is typically used with RESTful APIs and is similar in functionality to the POST command. However, the data that is submitted will be sent to the server as-is and will not be encoded.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the response from the server. In this case, the *lpvResult* parameter will point to the buffer allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method is to have the *lpvResult* parameter point to a global memory handle which will reference the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

If the Unicode version of this function is called and the server returns a text response to the PUT request, it is the application's responsibility to convert the contents of the *lpvResult* buffer to UTF-16 text. If the server returns text, most likely it will use UTF-8 encoding.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "application/octet-stream" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

It is common for servers to return additional information about a failed request in their response to the client. If you need to process this information, use the HTTP_PUT_ERRORDATA option which causes the error message to be returned in the *lpvResult* buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a data transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```

HGLOBAL hgblResponse = (HGLOBAL)NULL;
LPBYTE lpResponse = (LPBYTE)NULL;
DWORD cbResponse = 0;

// Store the response into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the response from
// the server is textual, the HTTP_PUT_CONVERT option is used

nResult = HttpPutDataEx(hClient,
                        lpszResource,
                        lpRequest,
                        cbRequest,
                        &hgblResponse,
                        &cbResponse,
                        HTTP_PUT_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // response from the server
    lpResponse = (LPBYTE)GlobalLock(hgblResponse);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblResponse);
    GlobalFree(hgblResponse);
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpPutFile Function

```
INT WINAPI HttpPutFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions  
    DWORD dwOffset  
);
```

The **HttpPutFile** function transfers the specified file on the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local system.

lpszRemoteFile

A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. This string may specify a valid URL for the current server that the client is connected to.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

dwOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutFile** function is used to transfer a file from the local system to a server. Not all servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** function prior to uploading the file.

To upload large files that are over 4GB, use the **HttpPutFileEx** function.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be

enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpPutFileEx Function

```
INT WINAPI HttpPutFileEx(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwOptions  
    ULARGE_INTEGER uiOffset  
);
```

The **HttpPutFileEx** function transfers the specified file on the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

- hClient**
Handle to the client session.
- lpszLocalFile**
A pointer to a string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.
- lpszRemoteFile**
A pointer to a string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.
- dwOptions**
An unsigned integer that specifies one or more options. This parameter may be any one of the following values:
- | Value | Description |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| HTTP_TRANSFER_DEFAULT | This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file. |
- uiOffset**
Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutFileEx** function is used to transfer a file from the local system to a server. Not all servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** function prior to uploading the file.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the

HttpRegisterEvent function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpEnableEvents](#), [HttpGetFileEx](#), [HttpGetTransferStatusEx](#), [HttpPostData](#), [HttpPostFile](#), [HttpPutData](#), [HttpRegisterEvent](#)

HttpPutText Function

```
INT WINAPI HttpPutText(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszBuffer  
);
```

The **HttpPutText** function creates a text file on the server using the contents of a string buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string that specifies the resource on the server which will be created or overwritten. This string may specify a valid URL for the current server.

lpszBuffer

A pointer to a string that contains the text which will be submitted to the server .

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutText** function is used to create a text file on the server from the contents of a string. If the specified file already exists on the server, its contents will be overwritten. Not all servers permit files to be created using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** command prior to uploading the data.

If the Unicode version of this function is called, the string will be automatically converted to UTF-8 and then uploaded to the server. If you wish to upload UTF-16 Unicode or ANSI text to the server, you must use the **HttpPutData** function. This function should never be used to upload binary data.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpEnableEvents](#), [HttpGetText](#), [HttpGetTransferStatus](#), [HttpPutData](#), [HttpPutFile](#), [HttpRegisterEvent](#)

HttpPutTextEx Function

```
INT WINAPI HttpPutTextEx(  
    HCLIENT hClient,  
    LPCTSTR lpszResource,  
    LPCTSTR lpszBuffer,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpPutTextEx** function submits the contents of a string buffer to the server using the PUT command and returns the server's response to the command.

Parameters

hClient

Handle to the client session.

lpszResource

A pointer to a string which specifies the resource path on the server. This string may specify a valid URL for the current server.

lpszBuffer

A pointer to a string that contains the text that will be submitted to the server. This parameter cannot be NULL and may not specify an empty string.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResult* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_PUT_DEFAULT	The default mode. automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_PUT_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutTextEx** function is used to submit the contents of a null terminated string to the server using the PUT command. This is typically used with RESTful APIs and is similar in functionality to the POST command. However, the text that is submitted will not be encoded in the same way that the **HttpPostData** function submits data.

If the Unicode version of this function is called, the text will be converted to UTF-8 and then submitted to the server. If you wish to submit the contents of the string as UTF-16 Unicode text, or the payload contains binary data, you must use the **HttpPutDataEx** function. This function should never be used to upload binary data. If the server returns a text response and the Unicode version of this function is called, it is the application's responsibility to convert the contents of the *lpvResult* buffer to UTF-16 text. If the server returns text, most likely it will use UTF-8 encoding.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "text/plain" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

It is common for servers to return additional information about a failed request in their response to the client. If you need to process this information, use the HTTP_PUT_ERRORDATA option which causes the error message to be returned in the *lpvResult* buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a data transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpRead Function

```
INT WINAPI HttpRead(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **HttpRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When **HttpRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpIsBlocking](#), [HttpIsReadable](#), [HttpIsWritable](#), [HttpWrite](#)

HttpRegisterEvent Function

```
INT WINAPI HttpRegisterEvent(  
    HCLIENT hClient,  
    UINT nEventId,  
    HTTPEVENTPROC LpEventProc,  
    DWORD_PTR dwParam  
);
```

The **HttpRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
HTTP_EVENT_CONNECT	The connection to the server has completed.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface

	components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event is generated when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **HttpRegisterEvent** function associates a callback function with a specific event. The event handler is an **HttpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a file is being uploaded or downloaded. The HTTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one HTTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

HttpRemoveQueuedFile Function

```
BOOL WINAPI HttpRemoveQueuedFile(  
    HQUEUE hQueue,  
    DWORD dwFileId  
);
```

The **HttpRemoveQueuedFile** removes the specified file from the queue.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. This value cannot be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

Files can only be removed from the queue when in an idle or paused state. If you attempt to remove a file while the queue manager is in the process of uploading or download files, the function will fail.

The file identifier can be obtained by several different functions, including **HttpEnumQueuedFiles** and **HttpGetQueueStatus**, which provides information about the current file being processed in the queue. Do not make any assumptions about the value of the identifier. Although the value is guaranteed to be unique for the specified queue, it is not guaranteed that file identifiers will be assigned in sequential order.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpAddQueuedFile](#), [HttpClearQueue](#), [HttpEnumQueuedFiles](#), [HttpGetQueuedFile](#),
[HttpGetQueueStatus](#), [HttpSuspendQueue](#), [HttpResetQueue](#)

HttpResetQueue Function

```
BOOL WINAPI HttpResetQueue(  
    HQUEUE hQueue,  
    DWORD dwOptions  
);
```

The **HttpResetQueue** function resets the state of all file transfers in the current queue.

Parameters

hQueue

A handle to a file transfer queue.

dwOptions

An integer value which specifies which files should be reset in the queue. It may be one of the following values:

Value	Description
HTTP_QUEUE_RESET_ALL	All files in the queue should be reset to their initial state.
HTTP_QUEUE_RESET_COMPLETED	All files in the queue which have been successfully transferred will be reset to their initial state.
HTTP_QUEUE_RESET_FAILED	All files in the queue which were not transferred will be reset to their initial state.
HTTP_QUEUE_RESET_CANCELED	All files in the queue which were canceled will be reset to their initial state.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

When the **HttpStartQueue** function is called multiple times using the same queue handle, it will not attempt to transfer files which have already been successfully copied, and it will not attempt to re-transfer files if the previous transfer failed. This function resets queued files back to their initial state, prior to when the queue manager attempted to perform the transfer. The most common use would be to call the function with the HTTP_QUEUE_RESET_FAILED mode and then call **HttpStartQueue** to retry failed or canceled file transfers.

Because canceled file transfers are also considered failed transfers, specifying HTTP_QUEUE_RESET_FAILED will reset queued files which either encountered an error during the transfer or were explicitly canceled by calling the **HttpCancelQueuedFile** function. The HTTP_QUEUE_RESET_CANCELED option will only reset the state of queued file transfers which were canceled.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpCancelQueuedFile](#), [HttpGetQueuedFile](#), [HttpResumeQueue](#), [HttpStartQueue](#), [HttpStopQueue](#),
[HttpSuspendQueue](#)

HttpResumeQueue Function

```
BOOL WINAPI HttpResumeQueue(  
    HQUEUE hQueue  
);
```

The **HttpResumeQueue** function resumes transfers in the queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function signals the queue manager to resume processing files in the transfer queue after the **HttpSuspendQueue** function has been called. This function will fail if the queue is in an idle (stopped) state, and will be ignored if the queue manager is already transferring files. The **HttpGetQueueStatus** function can be called to obtain the current status of the queue.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

HttpSetBearerToken Function

```
INT WINAPI HttpSetBearerToken(  
    HCLIENT hClient,  
    LPTSTR lpszBearerToken  
);
```

The **HttpSetBearerToken** function sets the OAuth 2.0 bearer token used to authenticate the client session with a web service.

Parameters

hClient

Handle to the client session.

lpszBearerToken

A pointer to a null terminated string buffer which contains the bearer token used to authorize client requests. If this parameter is NULL or a zero length string, the current bearer token will be cleared and no client authentication will be performed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Using OAuth 2.0 requires you to understand the process of how to request the bearer (access) token. Obtaining a bearer token requires registering your application with the web service provider, getting a unique client ID associated with your application and then requesting the token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access the service.

Your application should not store a bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)

Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAuthenticate](#), [HttpGetBearerToken](#), [HttpSetRequestHeader](#)

HttpSetContentType Function

```
BOOL WINAPI HttpSetContentType(  
    HCLIENT hClient,  
    LPCTSTR lpszContentType  
);
```

The **HttpSetContentType** function sets the content type for the next request.

Parameters

hClient

Handle to the client session.

lpszContentType

A pointer to a null terminated string which contains the MIME content type of the data being submitted to the web server. If this parameter is NULL or an empty string, the current type will be cleared and the client will use a default type based on the request and content encoding.

Return Value

If the function succeeds, it will return a non-zero value. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

The content type string must use the standard IANA format which consists of a type and subtype separated by a forward slash. Some common content types are:

Content Type	Description
text/plain	The request payload is unstructured text in a human readable format. This content type serves a default for textual data which does not explicitly have another standard subtype.
text/csv	The request payload is in a comma-separated value (CSV) text format.
application/octet-stream	The request payload contains binary data. This content type serves a default for binary data which does not explicitly have another standard subtype.
application/json	The request payload is standard JSON formatted text. This is the default content type used when submitting JSON requests, however some servers may expect the client to use the non-standard text/json type.
application/xml	The request payload is standard XML formatted text. This is the default content type used when submitting XML requests, however some servers may expect the client use the deprecated text/xml type. The standard content type for XML is defined in RFC 7303, however most servers will recognize both types as valid.

If a content type is not explicitly specified with a request, an appropriate default content type will be automatically selected. For example, the **HttpPostJson** function will set the content type to

application/json by default. This function can be used to override that default value.

This function will validate the content type, but does not validate the subtype. Unregistered subtypes should always be prefixed with "x-" which designates it as experimental. Some commonly used types also use this designation, such as **text/x-vcalendar** for the vCalendar format.

If your application needs to set the content type to a non-standard value for a proprietary API, use the **HttpSetRequestHeader** function to set the **Content-Type** header value. That function will not perform any validation on the header value and will include it in the request as-is.

The contents of the payload is not checked to ensure the content type is valid. It is the responsibility of the application to ensure that the correct content type is used when submitting the request.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpSetCookie Function

```
BOOL WINAPI HttpSetCookie(  
    HCLIENT hClient,  
    LPCTSTR lpszCookieName,  
    LPCTSTR lpszCookieValue  
);
```

The **HttpSetCookie** function sends the specified cookie to the server when a resource is requested.

Parameters

hClient

Handle to the client session.

lpszCookieName

Pointer to a string which specifies the name of the cookie that will be sent to the server when the next resource is requested.

lpszCookieValue

Pointer to a string which specifies the value of the cookie. To delete a cookie that has been previously set, this parameter should be NULL or point to an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetCookie** function submits the cookie name and value to the server when a resource is requested or data is posted to a script. For more information about cookies and how they are used, refer to the **HttpGetCookie** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpClearHeaders](#), [HttpGetCookie](#), [HttpGetFirstCookie](#), [HttpGetNextCookie](#), [HttpSetRequestHeader](#)

HttpSetDefaultUserAgent Function

```
INT WINAPI HttpSetDefaultUserAgent(  
    LPCTSTR lpszUserAgent  
);
```

The **HttpSetDefaultUserAgent** function sets the default user agent string which is included with all requests.

Parameters

lpszUserAgent

A pointer to a null terminated string which specifies the new default user agent string. If this parameter is NULL or an empty string, the client will revert to using the default user agent string defined when the library was first initialized.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetDefaultUserAgent** function changes the default user agent string which is included with each request made by the client. This default value is global and changing it will change the default user agent for all client sessions in all threads created by the process.

The user agent string should use a format with the product name and version number separated by a slash. There can be multiple products listed in the user agent string separated by spaces, with additional optional information enclosed in parenthesis. For example, a valid user agent string for an application named "MyProgram" could look like this:

MyProgram/1.0 (Win32)

Some web services check the value of the user agent string to determine if a compatible client is being used to issue the request. The default value used by SocketTools is designed to emulate a common browser, but some services may require you change the user agent to use a specific value or include certain product names and versions.

To change the user agent string for a specific client session, use the **HttpSetRequestHeader** function to set a value for the **User-Agent** header. To get the current value of the default user agent string, use the **HttpGetDefaultUserAgent** function.

To prevent any user agent string from being included with a request, include the HTTP_OPTION_NOUSERAGENT option when connecting to the server or use **HttpSetOption** to enable that option after a connection has been established.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetDefaultUserAgent](#), [HttpSetOption](#), [HttpSetRequestHeader](#)

HttpSetEncodingType Function

```
INT WINAPI HttpSetEncodingType(  
    HCLIENT hClient  
    INT nEncodingType  
);
```

The **HttpSetEncodingType** function specifies the type of encoding to be applied to the content of a HTTP request.

Parameters

hClient

Handle to the client session.

nEncodingType

Specifies the content encoding type for the request. The following values are defined:

Value	Description
HTTP_ENCODING_NONE	No encoding will be applied to the content of a request and no default content type will be specified. This encoding type should be used with REST APIs and other services which expect XML or JSON request payloads.
HTTP_ENCODING_URL	Non-printable and extended ASCII characters will be encoded so they can be safely used with URLs and form data. Encoded characters will be represented by a percent symbol prefix, followed by a two digit hexadecimal value which represents the ASCII character code. This encoding is typically used with web services which process HTML form data.
HTTP_ENCODING_XML	This encoding is identical to URL encoding, except spaces are not encoded. It is used with legacy web services which expect form data in an XML format and cannot process encoded whitespace. This encoding should not be specified for services which use REST APIs.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetEncodingType** function explicitly sets the type of encoding used when optional parameter data is submitted with a request for a resource. If an encoding type is specified, and the content type for the request payload has not been defined, it will default to **application/x-www-form-urlencoded**.

When submitting a JSON or XML request to a service using a REST API, your application should use HTTP_ENCODING_NONE and set the appropriate content type for the request payload. The HTTP_ENCODING_XML encoding type should only be used if the server expects URL encoded form data. The **HttpPostJson** and **HttpPostXml** functions will automatically set the correct encoding and content type for those requests.

If an application specifies HTTP_ENCODING_NONE, parameter data is not encoded and no content

type header will be created by default. The client application can specify the content type by calling the **HttpSetContentType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

See Also

[HttpGetEncodingType](#), [HttpPostData](#), [HttpPostJson](#), [HttpPostXml](#), [HttpSetContentType](#),

HttpSetFormProperties Function

```
INT WINAPI HttpSetFormProperties(  
    HFORM hForm,  
    LPHTTPFORMPROPERTIES LpFormProp  
);
```

The **HttpSetFormProperties** function updates the properties of the specified form.

Parameters

hForm

Handle to the virtual form.

lpFormProp

Points to a HTTPFORMPROPERTIES structure which specifies the new properties for the form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpCreateForm](#), [HttpGetFormProperties](#), [HttpSubmitForm](#), [HTTPFORMPROPERTIES](#)

HttpSetLastError Function

```
VOID WINAPI HttpSetLastError(  
    DWORD dwErrorCode  
);
```

The **HttpSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or HTTP_ERROR. Those functions which call **HttpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **HttpGetLastError** function. The use of **HttpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpSetOption Function

```
INT WINAPI HttpSetOption(  
    HCLIENT hClient,  
    DWORD dwOption,  
    BOOL bEnabled  
);
```

The **HttpSetOption** function enables or disables the specified option.

Parameters

hClient

Handle to the client session.

dwOption

An unsigned integer which specifies one of the following options:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested. If the server does not support the keep-alive option, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the

	thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

bEnabled

An integer value which determines if the option should be enabled or disabled. A non-zero value specifies that the option should be enabled, while a zero value specifies that the option should be disabled.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetOption** function can only enable or disable the options listed above. Other options are only available when the connection is initially established. For example, you cannot use this function to enable security options or switch to using HTTP/2 after the connection has been made.

If you use HTTP_OPTION_FREETHREAD to permit any thread to reference a client handle allocated in another thread, your application is responsible for ensuring it does not attempt to submit requests using the same handle on different threads at the same time. If two different threads attempt to perform an operation using the same handle, there is no guarantee as to which thread will complete the operation first.

HttpSetPriority Function

```
INT WINAPI HttpSetPriority(  
    HCLIENT hClient,  
    INT nPriority  
);
```

The **HttpSetPriority** function specifies the priority for file transfers.

Parameters

hClient

Handle to the client session.

nPriority

An integer value which specifies the new priority for file transfers. It may be one of the following values:

Value	Description
HTTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Return Value

If the function succeeds, the return value is the previous file transfer priority. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetPriority** function can be used to control the processor usage, memory and network bandwidth allocated for file transfers. The default priority balances resource utilization and transfer

speed while ensuring that a single-threaded application remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of transfer speed. For example, if you create a worker thread to download a file in the background and want to ensure that it has a minimal impact on the process, the HTTP_PRIORITY_BACKGROUND value can be used.

Higher priority values increase the memory allocated for the transfers and increases processor utilization for the transfer. The HTTP_PRIORITY_CRITICAL priority maximizes transfer speed at the expense of system resources. It is not recommended that you increase the file transfer priority unless you understand the implications of doing so and have thoroughly tested your application.

If the file transfer is being performed in the main UI thread, increasing the priority may interfere with the normal processing of Windows messages and cause the application to appear to become non-responsive. It is also important to note that when the priority is set to HTTP_PRIORITY_CRITICAL, normal progress events will not be generated during the transfer.

HttpSetRequestHeader Function

```
BOOL WINAPI HttpSetRequestHeader(  
    HCLIENT hClient,  
    LPCTSTR lpszHeader,  
    LPCTSTR lpszValue  
);
```

The **HttpSetRequestHeader** function sets the value of the specified request header field.

Parameters

hClient

Handle to the client session.

lpszHeader

Points to a string which specifies the request header field name.

lpszValue

Points to a string which specifies the value of the request header field.

Return Value

If the function succeeds, the return value is non-zero. If the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetRequestHeader** function defines a header field and value that is submitted to the server when a resource is requested. If the header field has already been defined, it will be replaced by the new value. There are a number of header fields which are automatically created by the library, and others that are conditionally created depending on whether or not certain options are specified. The following header fields are automatically created by the library:

Header Field	Description
Accept	This header specifies the types of resources that are acceptable to the client. By default, all resource data types are accepted by the client.
Authorization	This header is automatically created if the client uses the <code>HttpAuthenticate</code> function to authenticate a client session.
Connection	This header determines if the connection is maintained after a resource has been requested, or if the connection should be immediately closed. The value of this header depends on whether the <code>HTTP_OPTION_KEEPALIVE</code> option has been specified.
Content-Length	This header defines the length of the data that is being posted to the server or the size of a file being uploaded to the server.
Content-Type	This header defines the content type for data posted to the server. This header is automatically created if required.
Host	This header specifies the name of the server that the client has connected to. This is automatically generated when any resource is requested.
Pragma	This header is used to control caching performed by the server. If the

	option HTTP_OPTION_NOCACHE has been specified, this header will automatically be defined with the value "no-cache".
Proxy-Authorization	This header is automatically created if a proxy connection has been established and a username and password is required to authenticate the client session.

Request headers are generated by functions that send resource requests. In some cases, header values are supplied by the requesting function only if the application has not previously defined the header. For others, the requesting function overrides what the application may have defined.

If you use this function to set the Authorization header to a custom value for this client session, you must not call the **HttpAuthenticate** function. The **HttpAuthenticate** function will always override any custom Authorization header value and replace it with the credentials token generated from the username and password provided. If your application was using this function to specify an OAuth 2.0 bearer token, it is recommended you use the **HttpSetBearerToken** function instead.

If you need to change the default content type for the next request, it is recommended you use the **HttpSetContentType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpSetTimeout Function

```
INT WINAPI HttpSetTimeout(  
    HCLIENT hClient,  
    INT nTimeout  
);
```

The **HttpSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

[HttpGetTimeout](#), [HttpIsBlocking](#), [HttpIsReadable](#), [HttpIsWritable](#)

HttpStartQueue Function

```
BOOL WINAPI HttpStartQueue(  
    HQUEUE hQueue,  
    DWORD dwQueueMode,  
    DWORD dwReserved,  
    HTTPEVENTPROC lpEventProc,  
    DWORD_PTR dwParam  
);
```

The **HttpStartQueue** function begins transferring files in the queue.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An unsigned integer which specifies which files in the queue should be transferred. It may be one of the following values:

Constant	Description
HTTP_QUEUE_ALL	All files in the queue should be transferred.
HTTP_QUEUE_DOWNLOAD	Transfer only those files which have been queued for download.
HTTP_QUEUE_UPLOAD	Transfer only those files which have been queued for upload.

dwReserved

An unsigned integer reserved for internal use. This parameter value should always be zero.

lpEventProc

Specifies the procedure-instance address of an application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, there will be no callback notifications.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

Queued file transfers are performed asynchronously using a background worker thread. If you provide the address to an event callback function, that function will always be invoked in the context of the queue manager thread. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself and you should avoid calling any functions which could cause the thread to block. For example, you should not attempt to establish other network

connections from within the event handler.

If your application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function. Controls should only be modified by the same UI thread that created their window. One common approach to address this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

To obtain the handle to the queue from within an event handler, call the **HttpGetThreadQueue** function with the *dwThreadId* parameter set to a value of zero. This will return the handle for the current queue management session which invoked the callback function.

If a callback function is provided, the HTTP_QUEUE_EVENT event notification will be invoked whenever the internal state of the queue has changed. The handle value passed to the callback function will be a handle to the queue, not to a client connection. The **HttpGetQueueStatus** function can be called within the event handler to obtain the current state of the queue. This will event will always occur when the queue manager begins processing files in the queue and after it has stopped. This event will also occur whenever the queue is suspended and then resumed.

The **HttpWaitForQueue** function can be used to wait for the queue manager to complete processing the transfer queue.

Example

```
// Create a new queue
HQUEUE hQueue = HttpCreateQueue(INFINITE, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = HttpAddQueuedFile(
    hQueue,
    lpzLocalFile,
    lpzRemoteFile,
    HTTP_OPTION_DEFAULT,
    HTTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
            case HTTP_QUEUE_DOWNLOAD:
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szRemoteFile,
                    queuedFile.szLocalFile);
                break;

            case HTTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                    dwFileId,
                    queuedFile.szLocalFile,
                    queuedFile.szRemoteFile);
                break;
        }
    }
}
```

```

        break;
    }
}

// Start the queued file transfers and wait for it to complete
if (HttpStartQueue(hQueue, HTTP_QUEUE_ALL, 0, NULL, 0))
{
    HttpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    HttpStopQueue(hQueue);
}

// Remove all files from the queue
HttpDeleteQueue(hQueue);

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpStopQueue Function

```
BOOL WINAPI HttpStopQueue(  
    HQUEUE hQueue  
);
```

The **HttpStopQueue** function stops transferring queued files.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

When the **HttpStopQueue** function is called and there is a file transfer in progress, it will not immediately stop the upload or download of the file. Instead, the queue manager is signaled to stop processing additional files in the queue after the transfer has completed. To wait for the current transfer to complete, call the **HttpWaitForQueue** function.

It is permitted to call **HttpStopQueue** from within a queue event handler. In this case, the current file transfer will complete and the queue manager will terminate.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

HttpSubmitForm Function

```
INT WINAPI HttpSubmitForm(  
    HCLIENT hClient,  
    HFORM hForm,  
    LPVOID lpvResult,  
    LPDWORD lpcbResult,  
    DWORD dwOptions  
);
```

The **HttpSubmitForm** function submits the contents of the specified form to a script on the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

hForm

Handle to the virtual form which contains the data to be submitted to the server.

lpvResult

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvBuffer* parameter. If the *lpvResult* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_SUBMIT_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_SUBMIT_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSubmitForm** function is used to submit form data to a script that executes on the server and then copy the output from that script into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HFORM hForm = INVALID_FORM;
HGLOBAL hgblResult = (HGLOBAL)NULL;
DWORD cbResult = 0;
INT nResult = 0;

hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);

if (hForm == INVALID_FORM)
    return;

HttpAddFormField(hForm, _T("UserName"), lpzUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpzPassword, (DWORD)-1L, 0);

nResult = HttpSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);
HttpDestroyForm(hForm);

if (hgblResult != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer points to data returned by the server after the form
    // data was submitted

    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpSubmitRequest Function

```
INT WINAPI HttpSubmitRequest(  
    DWORD dwRequestType,  
    LPCTSTR lpszResource,  
    LPHTTPCONNECTION lpConnection,  
    LPCVOID lpvRequest,  
    DWORD dwRequestLength,  
    LPVOID lpvResponse,  
    LPDWORD lpdwResponseLength  
);
```

The **HttpSubmitRequest** function provides a high-level interface for submitting requests to a web service.

Parameters

dwRequestType

An unsigned integer which specifies the type of request being submitted to the server. It may be one of the following values:

Value	Description
HTTP_METHOD_DEFAULT	Perform a default request action based on the value of parameters passed to this function. If there is no request payload, the action will default to HTTP_METHOD_GET, otherwise it will default to HTTP_METHOD_POST. It is generally recommended that you explicitly specify the request method; however, this default value can be useful if your application does not know if a payload will be included with the request at the time the function is called.
HTTP_METHOD_GET	Use the GET method when submitting the request to the server. If this action is used, the <i>lpvRequest</i> and <i>dwRequestLength</i> parameters will be ignored. The buffer specified by the <i>lpvResponse</i> parameter will contain the server's response to the request.
HTTP_METHOD_POST	Use the POST method when submitting the request to the server. The payload specified by the <i>lpvRequest</i> parameter will be included with the request and the buffer specified by the <i>lpvResponse</i> parameter will contain the server's response to the request.
HTTP_METHOD_PUT	Use the PUT method when submitting the request to the server. The payload specified by the <i>lpvRequest</i> parameter will be included with the request. This method is typically used with persistent storage on the server, such as uploading the contents of a file. If the <i>lpvResponse</i> parameter is not NULL, it will contain any response from the server after the operation has completed.

lpszResource

A pointer to a null-terminated string which specifies the complete URL for the resource. Both

standard and secure connections are supported, and query parameters may be included with the URL. This parameter cannot be NULL and must specify an absolute (fully qualified) URI which begins with either http:// or https://.

lpConnection

A pointer to a **HTTPCONNECTION** structure which contains additional information about the client connection. This structure is required if your application must connect through a proxy server or when authentication is required to access a resource. This parameter can be NULL, in which case default values will be used when establishing the connection.

lpvRequest

A pointer to a buffer which contains the payload data submitted to the server as part of the request. This parameter may point to a byte buffer or a null-terminated string. If there is no payload required for the request this parameter may be NULL. If the Unicode version of this function is called and the request buffer contains text, it will be automatically converted to UTF-8 prior to submitting the data to the server. If the *dwRequestLength* parameter is -1, the payload will always be processed as a null-terminated string and the function will fail if the buffer does not contain text characters.

dwRequestLength

An unsigned integer which specifies the size of the request payload. If the payload contains text, this should specify the number of characters in the buffer. If the payload contains binary data, this value should specify the number of bytes in the buffer. If the *lpvRequest* parameter points to a null-terminated string, this value can be -1 and the length of the payload will be determined automatically. If the Unicode version of this function is called and the length is -1, the request payload will be UTF-8 encoded prior to being submitted to the server.

lpvResponse

A pointer to a byte buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns. This parameter may be NULL if the response data is not required. If this parameter is NULL, the *lpdwResponseLength* parameter must also be NULL. If a response buffer is provided, the data will always be returned as a byte stream, even when the Unicode version of this function is called. If the server returns a text payload, it will typically be UTF-8 encoded and the application can convert the text to Unicode using the **MultiByteToWideChar** function.

lpdwResponseLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the *lpvResponse* parameter. If the *lpvResponse* parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned. If the *lpvResponse* parameter is not NULL, this parameter cannot be NULL.

Return Value

If the function succeeds, the return value is the server status code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**. The application should always check the return value to determine if the request was successful. If the server returns a 4xx or 5xx status code, this indicates the request was not accepted and the response buffer will typically contain information about the cause of the failure.

Remarks

The **HttpSubmitRequest** function provides a single high-level interface for submitting requests to a web server and returning the server's response. This function is entirely self-contained and does not

require a client session handle. The current thread will block until the function returns and will not generate event notifications. If you need to download a large file from a web server and want progress updates, it is recommended you use the **HttpDownloadFile** function.

If the service you are using requires authentication, you will need to allocate a **HTTPCONNECTION** structure and set the appropriate member values to specify the authentication method and user credentials. This structure also allows you to provide additional information, such as additional request header values, a custom timeout period and additional connection options.

When the *lpvRequest* parameter is not NULL, the contents of the buffer will be examined to determine if it contains text or binary data. If the *dwRequestLength* parameter is -1, the *lpvRequest* parameter is always considered to be a pointer to a null-terminated string, with the length calculated by counting the number of characters up to the terminating null character. If the request payload is text, the function will also attempt to determine if the payload looks like XML or JSON and will automatically set the appropriate content type. The application can explicitly provide a MIME content type by setting the *lpszContentType* member of the **HTTPCONNECTION** structure.

Example

```
// Submit an XML payload to the server and return the response in a global
// memory buffer allocated by the function
LPCTSTR lpszResource = _T("https://www.example.com/postxml");
LPCTSTR lpszRequest = _T("<?xml version='1.0' encoding='utf-8'>\r\n") \
    _T("<test>\r\n") \
    _T("  <data param='A'>Value1</data>\r\n") \
    _T("  <data param='B'>Value2</data>\r\n") \
    _T("</test>\r\n");

// Provide additional connection information which includes user credentials
// and a custom header which includes an API token for the service; note that
// we need to initialize the dwSize member of the structure
HTTPCONNECTION httpConnection = { 0, };
httpConnection.dwSize = sizeof(httpConnection);
httpConnection.nAuthType = HTTP_AUTH_BASIC;
httpConnection.lpszUserName = _T("userid");
httpConnection.lpszPassword = _T("secret");
httpConnection.lpszContentType = _T("application/xml");
httpConnection.lpszHeaders = _T("X-API-Token: 99d2fe39-0246-4efa-98e0-
4d775579fa5d");

// Declare the global memory handle which will contain the server response
// and initialize the length to 0, which tells the API that a HGLOBAL handle
// is being used rather than a pointer to a pre-allocated buffer
HGLOBAL hgb1Response = NULL;
DWORD dwLength = 0;

INT nResult = HttpSubmitRequest(
    HTTP_METHOD_POST,
    lpszResource,
    &httpConnection,
    lpszRequest,
    (DWORD)-1,
    &hgb1Response,
    &dwLength);

if (nResult != HTTP_ERROR && hgb1Response != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgb1Response);
```

```
// The lpBuffer variable points to the data returned by the server and
// the application is responsible for freeing the global memory handle

GlobalUnlock(hgblResponse);
GlobalFree(hgblResponse);
}
```

HttpSuspendQueue Function

```
BOOL WINAPI HttpSuspendQueue(  
    HQUEUE hQueue  
);
```

The **HttpSuspendQueue** function pauses all file transfers for the specified queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

If there is a file transfer in progress when this function is called, the transfer will complete normally. The queue manager will enter a suspended state after the transfer has completed and before it begins processing the next file in the queue.

It is permitted to call **HttpSuspendQueue** from within a queue event handler. In this case, the current file transfer will complete and the queue manager will stop processing additional files in the queue until it is resumed or stopped.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpCancelQueuedFile](#), [HttpGetQueueStatus](#), [HttpResetQueue](#), [HttpResumeQueue](#), [HttpStartQueue](#), [HttpStopQueue](#)

HttpTaskAbort Function

```
BOOL WINAPI HttpTaskAbort(  
    UINT nTaskId,  
    DWORD dwMilliseconds  
);
```

Abort the specified asynchronous task.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to abort.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskAbort** function signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the *dwMilliseconds* parameter has a value of zero, the function returns immediately after the background thread has been signaled. If the *dwMilliseconds* parameter is non-zero, the function will wait that amount of time for the background thread to terminate.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock. To abort a file transfer within an event handler, use the **HttpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpTaskDone](#), [HttpTaskResume](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpTaskDone Function

```
BOOL WINAPI HttpTaskDone(  
    UINT nTaskId  
);
```

Determine if an asynchronous task has completed.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed, this function returns a non-zero value. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskDone** function is used to determine if the specified asynchronous task has completed. If you use this function to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this function rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **HttpGetTaskError** function will return the last error code associated with the task. A return value of zero indicates success, while a non-zero return value specifies an error code that indicates the cause of the failure. The last error code for the task can also be retrieved using the **HttpTaskWait** function, which causes the application to wait for the asynchronous task to complete.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpGetTaskError](#), [HttpTaskAbort](#), [HttpTaskResume](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpTaskResume Function

```
BOOL WINAPI HttpTaskResume(  
    UINT nTaskId  
);
```

Resume execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskResume** function resumes execution of the background worker thread that was previously suspended using the **HttpTaskSuspend** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshttpv11.lib

See Also

[HttpTaskAbort](#), [HttpTaskDone](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpTaskSuspend Function

```
BOOL WINAPI HttpTaskSuspend(  
    UINT nTaskId  
);
```

Suspend execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskSuspend** function will suspend execution of the background worker thread associated with the task. Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **HttpTaskResume** function. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpTaskAbort](#), [HttpTaskDone](#), [HttpTaskResume](#), [HttpTaskWait](#)

HttpTaskWait Function

```
BOOL WINAPI HttpTaskWait(  
    UINT nTaskId,  
    DWORD dwMilliseconds,  
    DWORD dwReserved,  
    LPDWORD lpdwElapsed,  
    LPDWORD lpdwError  
);
```

Wait for an asynchronous task to complete.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to complete.

dwReserved

An unsigned integer reserved for future use. This value should always be zero.

lpdwElapsed

A pointer to an unsigned integer that will contain elapsed time in milliseconds when the function returns. If this information is not required, this parameter may be NULL.

lpdwError

A pointer to an unsigned integer that will contain the error code associated with the completed task. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskWait** function waits for the specified task to complete. If the task is active and the *dwMilliseconds* parameter is non-zero, this function will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *dwMilliseconds* parameter is zero, then this function will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this function is called, the function will return immediately without causing the current thread to block. If the *lpdwElapsed* parameter is not NULL, it will contain the number of milliseconds that it took for the task to complete. If the *lpdwError* parameter is not NULL, it will contain the last error code value that was set by the worker thread before it terminated. If this value is zero, that means that the background operation was successful and no error occurred. A non-zero value will indicate that the background operation has failed.

You should not call this function from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this function is blocked waiting for the background task to complete, and this can cause your application to appear non-responsive to the end-user. If you have a GUI application and you need to periodically check to see if

a task has completed, create a timer to periodically call the **HttpTaskDone** function. When it returns a non-zero value (indicating that the task has completed), you can safely call **HttpTaskWait** to obtain the elapsed time and last error code without blocking the current thread.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = HttpAsyncGetFile(hClient,
                           lpszLocalFile,
                           lpszRemoteFile,
                           HTTP_TRANSFER_DEFAULT,
                           0,
                           NULL,
                           0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    HttpTaskWait(nTaskId, INFINITE, &dwElapsed, &dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpTaskDone](#), [HttpTaskResume](#), [HttpTaskSuspend](#), [HttpTaskWait](#)

HttpUninitialize Function

```
VOID WINAPI HttpUninitialize();
```

The **HttpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **HttpInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **HttpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **HttpUninitialize** for every successful call to **HttpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpDisconnect](#), [HttpInitialize](#)

HttpUploadFile Function

```
BOOL WINAPI HttpUploadFile(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    UINT nTimeout  
    DWORD dwOptions  
    LPHTTPTRANSFERSTATUS lpStatus  
    HTTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **HttpUploadFile** function uploads the specified file from the local system to the server.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the Hypertext Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.

HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. If this option is not specified, a default user agent string will be included with the request.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

lpStatus

A pointer to an HTTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpUploadFile** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then upload the file to the server. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @[hostname [:port] / [path / ...]  
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

Not all web servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the URL specify a username and password to upload a file.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the method will fail and return a value of zero.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **HttpUploadFile** function is designed to provide a simpler interface for uploading a file. However,

complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpPutFile** to upload the file. If the server does not support the PUT command, you may be able to upload files using the **HttpPostFile** function. Refer to that function for more information.

Example

```
HTTPTRANSFERSTATUS httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile =
_T("https://update:secret@www.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = HttpUploadFile(lpszLocalFile,
                        lpszRemoteFile,
                        HTTP_OPTION_DEFAULT,
                        &httpStatus,
                        NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpSubmitRequest](#), [HTTPTRANSFERSTATUS](#)

HttpUploadFileEx Function

```
BOOL WINAPI HttpUploadFileEx(  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    UINT nTimeout  
    DWORD dwOptions  
    LPHTTPTRANSFERSTATUSEX lpStatus  
    HTTPEVENTPROC lpEventProc  
    DWORD_PTR dwParam  
);
```

The **HttpUploadFileEx** function uploads the specified file from the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

lpszLocalFile

A pointer to a string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A pointer to a string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the Hypertext Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration

	can be changed using the system Control Panel.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. If this option is not specified, a default user agent string will be included with the request.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network

lpStatus

A pointer to an HTTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpUploadFileEx** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then upload the file to the server. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @[hostname [:port] / [path / ...]
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

Not all web servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the URL specify a username and password to upload a file.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the method will fail and return a value of zero.

The ***lpStatus*** parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The ***lpEventProc*** parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The ***dwParam*** parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the ***this*** pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for

lpEventProc and the *dwParam* parameter will be ignored.

The **HttpUploadFileEx** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpPutFileEx** to upload the file. If the server does not support the PUT command, you may be able to upload files using the **HttpPostFile** function. Refer to that function for more information.

Example

```
HTTPTRANSFERSTATUSEX httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile =
_T("http://update:secret@www.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = HttpUploadFileEx(lpszLocalFile,
                          lpszRemoteFile,
                          HTTP_OPTION_DEFAULT,
                          &httpStatus,
                          NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpValidateHostName Function

```
BOOL WINAPI HttpValidateHostName(  
    LPCTSTR lpszHostName,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **HttpValidateHostName** function determines if the specified host name is valid and returns its IP address.

Parameters

lpszHostName

A pointer to a null terminated string which specifies the host name. The function will fail if this parameter is NULL or an empty string.

lpszAddress

A pointer to a string buffer which will contain the IP address of the host. If specified, this string must be large enough to store the complete IP address, including the terminating null character. If this parameter is NULL or the *nMaxLength* parameter is zero, it will be ignored and the IP address will not be returned.

nMaxLength

An integer value that specifies the maximum number of characters which can be copied into the *lpszAddress* string buffer. The buffer must be large enough to store the complete address. Because this function can return either an IPv4 or IPv6 address, it is recommended the minimum length for the buffer to be 46 characters. If this parameter is zero, the *lpszAddress* parameter will be ignored.

Return Value

If the function succeeds, the host name is valid and the return value will be non-zero. If the function fails, the host name could not be resolved to an IP address and the return value will be zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpValidateHostName** function provides a convenient way to determine if a host name is valid by attempting to resolve the name into an IP address. If the Unicode version of this function is used, any non-ASCII characters in the host name will be automatically encoded into a compatible format and then resolved to an IP address. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended you use the Unicode version.

If the *lpszHostName* parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address.

If you wish to validate a complete HTTP URL instead of a host name, use the **HttpValidateUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpConnectUrl](#), [HttpValidateUrl](#)

HttpValidateUrl Function

```
BOOL WINAPI HttpValidateUrl(  
    LPCTSTR lpszUrl  
);
```

The **HttpValidateUrl** function determines if a string represents a valid HTTP URL.

Parameters

lpszUrl

A pointer to a string that specifies the URL to validate.

Return Value

If the specified URL is valid and the host name can be resolved to an IP address, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpValidateUrl** function will check the value of a string to ensure that it represents a complete, valid URL using either a standard or secure HTTP scheme. This function will not establish a connection with the server to verify that it exists, it will only attempt to resolve the host name to an IP address. If the remote host is specified as an IP address, this function will check to make sure that the address is formatted correctly. Note that if you wish to specify an IPv6 address, you must enclose the address in brackets.

To establish a connection with a server using a URL, use the **HttpConnectUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpConnectUrl](#), [HttpValidateHostName](#)

HttpVerifyFile Function

```
BOOL WINAPI HttpVerifyFile(  
    HCLIENT hClient,  
    LPCTSTR lpszLocalFile,  
    LPCTSTR lpszRemoteFile,  
    DWORD dwReserved  
);
```

The **HttpVerifyFile** function attempts to verify that the size of a file on the local system is the same as the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A pointer to a string that specifies the name of file on the local system.

lpszRemoteFile

A pointer to a string that specifies the name of the file on the server.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpVerifyFile** function will attempt to verify that the contents of the local and remote files are identical by comparing the size of the files. This function is provided for compatibility with the File Transfer Protocol API, and should not be considered a reliable method for comparing files. Web servers may not consistently return file size information for dynamically created content such as HTML pages which use server-side includes.

It is not recommended that you use this function with text files because of the different end-of-line conventions used by different operating systems. For example, a text file on a Windows system uses a carriage-return and linefeed pair to indicate the end of a line of text. However, on a UNIX system, a single linefeed is used to indicate the end of a line. This can cause the **HttpVerifyFile** function to indicate the files are not identical, even though the only difference is in the end-of-line characters that are used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpDeleteFile](#), [HttpGetFile](#), [HttpGetFileSize](#), [HttpPutFile](#)

HttpWaitForQueue Function

```
BOOL WINAPI HttpWaitForQueue(  
    HQUEUE hQueue,  
    DWORD dwMilliseconds,  
    LPDWORD lpdwElapsed,  
    LPDWORD lpdwError  
);
```

The **HttpWaitForQueue** function waits for the specified queue to complete the file transfers.

Parameters

hQueue

A handle to a file transfer queue.

dwMilliseconds

An unsigned integer value which specifies the number of milliseconds to wait for the queue to complete processing. If this value is zero, the function will return immediately. If this value is INFINITE (0xFFFFFFFF), the function will block indefinitely until all files in the queue have been processed.

lpdwElapsed

A pointer to an unsigned integer which will contain the number of milliseconds the queue manager has been active when the function returns. If this information is not needed, this parameter can be NULL. If this parameter is not NULL, it will always be initialized to a value of zero.

lpdwError

A pointer to an unsigned integer which will contain the last error code set if a file transfer has failed or was canceled. If this information is not needed, this parameter can be NULL. If this parameter is not NULL, it will always be initialized to a value of zero.

Return Value

If the function succeeds, the return value is non-zero, which means the queue manager has completed transferring all queued files. If the function fails, or the timeout period elapses, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function will cause the current thread to block until either the queue manager has completed processing all files in the queue, or until the specified number of milliseconds have elapsed. It is important to note that Windows messages will not be processed during this time. If you call this function within the main UI thread, it can potentially cause the application to become non-responsive. To determine the current state of the queue without blocking the current thread, call the **HttpGetQueueStatus** function.

If the *dwMilliseconds* parameter is non-zero and file transfers have not completed within the specified amount of time, the function will return zero and the last error code will be set to **ST_ERROR_OPERATION_TIMEOUT**.

If an event callback function has been specified when starting the queue, you should never call this function within the event handler. Attempting to do so can potentially create a situation which will cause the application to become non-responsive. The function will return zero if it determines it's being called within the context of the queue manager thread and will set the last error code to **ST_ERROR_THREAD_DEADLOCK**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpSuspendQueue](#)

HttpWrite Function

```
INT WINAPI HttpWrite(  
    HCLIENT hClient,  
    LPBYTE lpBuffer,  
    INT cbBuffer  
);
```

The **HttpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the *cbBuffer* parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for an asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Hypertext Transfer Protocol Data Structures

- HTTPCONNECTION
- HTTPFORMPROPERTIES
- HTTPQUEUEDFILE
- HTTPQUEUESTATUS
- HTTPTRANSFERSTATUS
- HTTPTRANSFERSTATUSEX
- INITDATA
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

HTTPCONNECTION

The **HTTPCONNECTION** structure provides additional information used when submitting a request to the server.

```
typedef struct _HTTPCONNECTION
{
    DWORD    dwSize;
    DWORD    dwOptions;
    DWORD    dwVersion;
    UINT     nTimeout;
    UINT     nEncoding;
    UINT     nProxyType;
    UINT     nProxyPort;
    UINT     nAuthType;
    LPCTSTR  lpszProxyServer;
    LPCTSTR  lpszProxyUser;
    LPCTSTR  lpszProxyPassword;
    LPCTSTR  lpszUserAgent;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszContentType;
    LPCTSTR  lpszHeaders;
    LPSECURITYCREDENTIALS lpCredentials;
} HTTPCONNECTION, *LPHTTPCONNECTION;
```

Members

dwSize

The size of this structure in bytes. If this member is not initialized to the correct value, the structure will be considered invalid.

dwOptions

A bitmask of supported options. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control

	panel.
HTTP_OPTION_NOUSERAGENT	This option specifies the client should not include a User-Agent header with any requests made during the session. The user agent is a string which is used to identify the client application to the server. If this option is set, the value of the <i>lpszUserAgent</i> member will be ignored.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. The value of the <i>dwVersion</i> member will be ignored when this option is used.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects secure connections.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server even if the request URL does not use the https:// scheme. If this option is not specified, the type of connection depends on the URL scheme provided when submitting the request.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

dwVersion

A value which specifies the requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. If this value is zero, the default protocol version will be used. The HTTPVERSION macro can be used to create a version value, or the following values can be used:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this session. This is the same as specifying HTTP_VERSION_11 and

	is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.
HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the operation. If this value is zero, a default timeout period of 20 seconds will be used.

nEncoding

A value which specifies the content encoding type for the request. If the value is zero, no encoding will be used. The following values are defined:

Value	Description
HTTP_ENCODING_NONE	No encoding will be applied to the content of a request and no default content type will be specified. This encoding type should be used with REST APIs and other services which expect XML or JSON request payloads.
HTTP_ENCODING_URL	Non-printable and extended ASCII characters will be encoded so they can be safely used with URLs and form data. Encoded characters will be represented by a percent symbol prefix, followed by a two digit hexadecimal value which represents the ASCII character code. This encoding is typically used with web services which process HTML form data.
HTTP_ENCODING_XML	This encoding is identical to URL encoding, except spaces are not encoded. It is used with legacy web services which expect form data in an XML format and cannot process encoded whitespace. This encoding should not be specified for services which use REST APIs.

nProxyType

A value which specifies the type of proxy server the client is connecting to. A value of zero specifies no proxy server is being used and the client should establish a direct connection to the server. The following proxy server types are supported:

Value	Description
-------	-------------

HTTP_PROXY_NONE	A direct connection will be established with the server. When this value is specified the proxy parameters are ignored.
HTTP_PROXY_STANDARD	A standard connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard connections.
HTTP_PROXY_SECURE	A secure connection is established through the specified proxy server. This proxy type should be used with secure connections and the HTTP_OPTION_SECURE option should also be set via the <i>dwOptions</i> parameter.
HTTP_PROXY_WINDOWS	The configuration options for the current system should be used. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. These settings are the same proxy server settings configured in Windows.

nProxyPort

A value which specifies the port the proxy server will use to accept connections. This value is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

nAuthType

A value which specifies the type of authentication used to establish the connection. If the value is zero, the client session will not be authenticated. The following values are defined:

Value	Description
HTTP_AUTH_NONE	No client authentication should be performed. The <i>lpszUserName</i> and <i>lpszPassword</i> members are ignored.
HTTP_AUTH_BASIC	The Basic authentication scheme should be used. This option is supported by all servers that support at least version 1.0 of the protocol. The user credentials are not encrypted and Basic authentication should not be used over standard (non-secure) connections. Most web services which use Basic authentication require the connection to be secure.
HTTP_AUTH_BEARER	The Bearer authentication scheme should be used. This authentication method does not require a user name and the <i>lpszPassword</i> member must specify the OAuth 2.0 bearer token issued by the service provider. If the access token has expired, the request will fail with an authorization error.

lpszProxyServer

A pointer to a null terminated string which identifies the proxy server which should be used to establish the connection. If this value is ignored if the *nProxyType* member is zero. If a proxy server type has been specified, this value cannot be a NULL pointer or an empty string.

lpszProxyUser

A pointer to a null terminated string which specifies the user name used to authenticate the connection to the proxy server. If the proxy server does not require user authentication, this

member can be a NULL pointer or an empty string. This member is ignored if the *nProxyType* member is zero.

lpszProxyPassword

A pointer to a null terminated string which specifies the password used to authenticate the connection to the proxy server. If the proxy server does not require user authentication, this member can be a NULL pointer or an empty string. This member is ignored if the *nProxyType* member is zero.

lpszUserAgent

A pointer to a null terminated string which identifies the application which is making a request to the server. If this value is NULL or an empty string, a default user agent string will be included with the request. To prevent a user agent from being included with the request, use the HTTP_OPTION_NOUSERAGENT option.

lpszUserName

A pointer to a null terminated string which specifies the user name used to authenticate the client session. This member may be NULL or an empty string if a user name is not required for the specified authentication type.

lpszPassword

A pointer to a null terminated string which specifies the password used to authenticate the client session. This member may be NULL or an empty string if a password is not required for the specified authentication type. If the authentication type is HTTP_AUTH_BEARER, this value must be the bearer token issued by the service provider.

lpszContentType

A pointer to a null terminated string which specifies the MIME content type for the request. If this member is NULL or specifies an empty string, the content type will be automatically determined based on the contents of the request payload. This value will only be used with PUT and POST methods.

lpszHeaders

A pointer to a null terminated string which specifies one or more additional header values which should be included with the request. The string must contain header name and value pairs separated by a colon, and multiple header values must be terminated with a carriage return/linefeed (CRLF) sequence after each value. The header values defined in this string will override any default values.

lpCredentials

A pointer to a **SECURITYCREDENTIALS** structure. This value is only used if the HTTP_OPTION_SECURE option is specified in the *dwOptions* member. This member may be NULL, in which case no client credentials will be provided to the server.

Remarks

This structure is used with the **HttpSubmitRequest** function to provide additional information used to establish a connection with the server. The *dwSize* member must be initialized to the actual size of the structure in bytes, and all other members should be initialized to a value of zero or NULL. If the structure is not initialized correctly, the function will fail and the last error code will be set to ST_ERROR_INVALID_PARAMETER.

Member values which are zero or NULL pointers will either be ignored or cause the function to use appropriate default values.

Applications should use HTTP_VERSION_DEFAULT as the value for the *dwVersion* parameter. This will

default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies `HTTP_VERSION_20`, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support the features required for a secure HTTP/2 connection.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the connection attempt will fail.

If the server requires a secure connection with a client certificate, the **HttpCreateSecurityCredentials** function can be used to allocate a credentials structure which can be assigned to the *lpCredentials* member. Call **HttpDeleteSecurityCredentials** after the **HttpSubmitRequest** function has returned to ensure the memory allocated for the security credentials has been freed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Unicode: Implemented as Unicode and ANSI versions

See Also

HTTPFORMPROPERTIES

This structure is used by the **HttpGetFormProperties** and **HttpSetFormProperties** function to return and modify the properties of the specified form.

```
typedef struct _HTTPFORMPROPERTIES
{
    UINT      nFormMethod;
    UINT      nFormType;
    LPCTSTR   lpszFormAction;
    DWORD     dwReserved1;
    DWORD     dwReserved2;
} HTTPFORMPROPERTIES, *LPHTTPFORMPROPERTIES;
```

Members

nFormMethod

An unsigned integer value which specifies how the form data will be submitted to the server. It may be one of the following values:

Value	Description
HTTP_METHOD_GET	The form data should be submitted using the GET command. This method should be used when the amount of form data is relatively small. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used instead.
HTTP_METHOD_POST	The form data should be submitted using the POST command. This is the preferred method of submitting larger amounts of form data. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used.

nFormType

An unsigned integer value which specifies the type of form and how the data will be encoded when it is submitted to the server. It may be one of the following values:

Value	Description
HTTP_FORM_ENCODED	The form data should be submitted as URL encoded values. This is typically used when the GET method is used to submit the data to the server.
HTTP_FORM_MULTIPART	The form data should be submitted as multipart form data. This is typically used when the POST method is used to submit a file to the server. Note that the script must understand how to process multipart form data if this form type is specified.

lpszFormAction

A pointer to a string which specifies the name of the resource that the form data will be submitted to. Typically this is the name of a script that is executed on the server.

dwReserved1

A reserved structure member.

dwReserved2

A reserved structure member.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpCreateForm](#), [HttpGetFormProperties](#), [HttpSetFormProperties](#), [HttpSubmitForm](#)

HTTPQUEUEDFILE

This structure is used by the **HttpGetFirstQueuedFile**, **HttpGetNextQueuedFile** and **HttpGetQueuedFile** functions to return information about a file in the transfer queue.

```
typedef struct _HTTPQUEUEDFILE
{
    DWORD          dwFileId;
    DWORD          dwQueueMode;
    DWORD          dwQueueFlags;
    DWORD          dwTimeElapsed;
    DWORD          dwLastError;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szLocalFile[HTTP_MAXFILENAMELEN];
    TCHAR          szRemoteFile[HTTP_MAXURLPATHLEN];
} HTTPQUEUEDFILE, *LPHTTPQUEUEDFILE;
```

Members

dwFileId

An unsigned integer which specifies a unique identifier for the queued file. The application should not make any assumptions about the value of the file identifiers. They should be considered opaque values which are only guaranteed to uniquely identify a file in the transfer queue. In particular, there is no guarantee that the file identifiers will be sequential and they should not be used as index values into an array.

dwQueueMode

An unsigned integer value which specifies how the file was queued for transfer. It may be one of the following values:

Constant	Description
HTTP_QUEUE_DOWNLOAD	The file was queued for download.
HTTP_QUEUE_UPLOAD	The file was queued for upload.

dwQueueFlags

An unsigned integer which specifies one or more bit flags which provides information about the status of the file transfer. It may be one or more of the following values:

Constant	Description
HTTP_QUEUE_FLAG_NONE	The file is pending transfer in queue.
HTTP_QUEUE_FLAG_COMPLETED	The file has been transferred successfully. If this flag is set, no errors were encountered during the upload or download.
HTTP_QUEUE_FLAG_FAILED	The file transfer failed. If this flag is set, the <i>dwError</i> member of this structure will contain the error code associated with the failed transfer.
HTTP_QUEUE_FLAG_CANCELED	The file transfer was canceled. This flag is only set when the HttpCancelQueuedFile function has been called and a queued file is in the process of being uploaded or downloaded.

dwTimeElapsed

An unsigned integer which specifies the number of milliseconds required to complete the transfer. This value will be zero unless the file has been transferred successfully.

dwLastError

An unsigned integer which specifies the last error code for a failed transfer. If the file was transferred successfully, this value will be zero.

uiBytesCopied

A value which specifies the number of bytes which were copied during the file transfer. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

szLocalFile

A null terminated string which specifies the full path to the local file being transferred.

szRemoteFile

A null terminated string which specifies the complete URL to the remote file being transferred.

Remarks

It is possible that the ***szLocalFile*** and ***szRemoteFile*** structure members will be different than the values passed to the **HttpAddQueuedFile** function. Those values are normalized, with any relative paths converted to absolute paths. Internationalized domain names will be encoded and the URL paths will be collapsed, removing any extraneous path information. For example, if the remote file name is specified as **https://www.server.tld/folder1/./folder2/filename.txt** it would be normalized as **https://www.server.tld/folder2/filename.txt**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAddQueuedFile](#), [HttpAddQueuedFileEx](#), [HttpGetFirstQueuedFile](#), [HttpGetNextQueuedFile](#), [HttpGetQueuedFile](#)

HTTPQUEUESTATUS

This structure is used by the **HttpGetQueueStatus** function to return information about the current status of the file transfer queue.

```
typedef struct _HTTPQUEUESTATUS
{
    DWORD dwStatus;
    DWORD dwThreadId;
    DWORD dwQueuedFiles;
    DWORD dwPendingFiles;
    DWORD dwCopiedFiles;
    DWORD dwFailedFiles;
    DWORD dwTimeElapsed;
    DWORD dwCurrentFile;
    DWORD dwLastError;
    ULARGE_INTEGER uiBytesCopied;
    ULARGE_INTEGER uiBytesTotal;
} HTTPQUEUESTATUS, *LPHTTPQUEUESTATUS;
```

Members

dwStatus

An unsigned integer which specifies the current status of the queue. It can be one of the following values:

Value	Description
HTTP_QUEUE_STATUS_IDLE	The file transfer queue is idle and no files are being uploaded or downloaded. This state is returned before HttpStartQueue has been called or after HttpStopQueue has been called. The queue will also automatically enter an idle state after the last file transfer has completed and the queue manager thread exits.
HTTP_QUEUE_STATUS_ACTIVE	Files in the queue are being uploaded or downloaded. The <i>dwCurrentFile</i> member of this structure identifies the file which is currently being transferred.
HTTP_QUEUE_STATUS_PAUSED	File transfers are currently paused. The queue enters this state after the HttpSuspendQueue function is called and resumes file transfers after the HttpResumeQueue function is called.

dwThreadId

An unsigned integer which specifies the thread ID for the queue manager which is performing the file transfers. All file transfers are performed asynchronously in a background worker thread. If this structure member is zero, the queue is idle and not performing file transfers. The application should not use the thread ID to obtain a handle to suspend or terminate the thread. This can potentially result in unexpected behavior or instability within the application.

dwQueuedFiles

An unsigned integer which specifies the total number of queued files. This value includes pending and completed file transfers.

dwPendingFiles

An unsigned integer which specifies the number of files which are queued to be transferred.

dwCopiedFiles

An unsigned integer which specifies the number of files which have been successfully transferred. This value reflects the total number of files which have the HTTP_QUEUE_FLAG_COMPLETED status.

dwFailedFiles

An unsigned integer which specifies the number of files which have failed to transfer or the file transfer has been canceled. This value reflects the total number of files which have the HTTP_QUEUE_FLAG_FAILED status.

dwTimeElapsed

An unsigned integer which specifies the total amount of time, in milliseconds, the queue manager has been active performing a file transfer. If the queue is idle, this value will reflect the total run time for the previously active queue. A value of zero indicates the queue was never active or the queue state has been reset with a call to **HttpResetQueue**.

dwCurrentFile

An unsigned integer which specifies the unique identifier for the current file being transferred. If no file transfer is in progress, this member will have a value of zero. If the value is non-zero, it can be passed to the **HttpGetQueuedFile** function to obtain information about the queued file.

dwLastError

An unsigned integer which specifies the last error code for a failed file transfer. If there have been no errors, this value will be zero.

uiBytesCopied

A value which specifies the number of bytes which were copied during the current or last transfer. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

uiBytesTotal

A value which specifies the total number of bytes which were copied during the current queue run. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshttpv11.lib

See Also

[HttpGetQueuedFile](#), [HttpGetQueueStatus](#), [HttpCancelQueuedFile](#), [HttpResetQueue](#), [HttpResumeQueue](#), [HttpStartQueue](#), [HttpStopQueue](#), [HttpSuspendQueue](#)

HTTPTRANSFERSTATUS

This structure is used by the **HttpGetTransferStatus** function to return information about a data transfer in progress.

```
typedef struct _HTTPTRANSFERSTATUS
{
    DWORD    dwBytesTotal;
    DWORD    dwBytesCopied;
    DWORD    dwBytesPerSecond;
    DWORD    dwTimeElapsed;
    DWORD    dwTimeEstimated;
} HTTPTRANSFERSTATUS, *LPHTTPTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the data is being downloaded from the server to the local host, this is the size of the requested resource. If the data is being uploaded from the local host to the server, it is the size of the local file or memory buffer. If the size of the resource cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

Remarks

If the option HTTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values returned in the *dwTimeElapsed* and *dwTimeEstimated* members will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

HTTPTRANSFERSTATUSEX

This structure is used by the **HttpGetTransferStatusEx** function to return information about a data transfer in progress. This structure is designed for use with extended functions that support files larger than 4GB.

```
typedef struct _HTTPTRANSFERSTATUSEX
{
    ULARGE_INTEGER uiBytesTotal;
    ULARGE_INTEGER uiBytesCopied;
    DWORD          dwBytesPerSecond;
    DWORD          dwTimeElapsed;
    DWORD          dwTimeEstimated;
} HTTPTRANSFERSTATUSEX, *LPHTTPTRANSFERSTATUSEX;
```

Members

uiBytesTotal

The total number of bytes that will be transferred. If the data is being downloaded from the server to the local host, this is the size of the requested resource. If the data is being uploaded from the local host to the server, it is the size of the local file or memory buffer. If the size of the resource cannot be determined, this value will be zero.

uiBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

Remarks

If the option `HTTP_OPTION_HIRES_TIMER` has been specified when connecting to the server, the values returned in the *dwTimeElapsed* and *dwTimeEstimated* members will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

- dwSize*

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.
- dwProtocol*

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpPassword* member or the library will be unable to access the certificate.

Note that the *lpUserName* and *lpPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
    DWORD        dwSize;
    DWORD        dwProtocol;
    DWORD        dwCipher;
    DWORD        dwCipherStrength;
    DWORD        dwHash;
    DWORD        dwHashStrength;
    DWORD        dwKeyExchange;
    DWORD        dwCertStatus;
    SYSTEMTIME    stCertIssued;
    SYSTEMTIME    stCertExpires;
    LPCTSTR      lpszCertIssuer;
    LPCTSTR      lpszCertSubject;
    LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KED	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A pointer to a string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpzCertSubject

A pointer to a string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpzFingerprint

A pointer to a string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpzCertIssuer*** and ***lpzCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: windows.h.

Hypertext Transfer Protocol Server Library

Implements a server that enables the application to access documents using the Hypertext Transfer Protocol.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSHTSV11.DLL
Version	11.0.2218.1855
LibID	475FBDFE-E206-4E5A-93E0-D69A7FC2E858
Import Library	CSHTSV11.LIB
Dependencies	None
Standards	RFC 1945, RFC 2616, RFC 3875

Overview

This library provides an interface for implementing an embedded, lightweight server that can be used to provide access to documents and other resources using the Hypertext Transfer Protocol. The server can accept connections from any standard web browser, third-party applications or programs developed using the SocketTools HTTP client API.

The application specifies an initial server configuration and then responds to events that are generated when the client sends a request to the server. An application may implement only minimal handlers for most events, in which case the default actions are performed for most standard HTTP commands. However, an application may also use the event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

The server includes support for CGI scripting, virtual hosting, client authentication and the creation of virtual directories and files. The server also supports secure connections using TLS 1.2 and later versions. Secure connections require that a valid security certificate be installed on the system.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This library provides an implementation of a multithreaded server which should only be used with

languages that support the creation of multithreaded applications. It is important that you do not link against static libraries which were not built with support for threading.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Hypertext Transfer Protocol Server Functions

Function	Description
HttpAddVirtualHost	Add a new virtual host to the server virtual host table
HttpAddVirtualHostAlias	Add an alternate host name for an existing virtual host
HttpAddVirtualPath	Add a new virtual path for the specified host
HttpAddVirtualUser	Add a new virtual user for the specified host
HttpAuthenticateClient	Authenticate the client and assign access rights for the session
HttpCheckVirtualPath	Determine if the client has permission to access the specified virtual path
HttpCreateServerCredentials	Create a new server security credentials structure
HttpDeleteAllClientHeaders	Delete all of the request or response headers for the specified client session
HttpDeleteClientHeader	Delete a request or response header for the specified client session
HttpDeleteServerCredentials	Delete a previously created security credentials structure
HttpDeleteVirtualHost	Delete a virtual host associated with the specified server
HttpDeleteVirtualPath	Delete a virtual path from the specified virtual host
HttpDeleteVirtualUser	Delete a virtual user from the specified virtual host
HttpDisconnectClient	Disconnect the specific client session, closing the control channel and aborting any file transfer
HttpEnableClientAccess	Enable or disable access rights for the specified client session
HttpEnableCommand	Enable or disable a specific server command
HttpEnumServerClients	Returns a list of active client sessions established with the specified server
HttpGetActiveClient	Return the client ID for the active client session associated with the current thread
HttpGetAllClientHeaders	Return all client request or response headers in a string buffer
HttpGetClientAccess	Return the access rights that have been granted to the client session
HttpGetClientAddress	Return the IP address of the specified client session
HttpGetClientCredentials	Return the credentials for the specified client session
HttpGetClientDirectory	Return the root document directory for a client session
HttpGetClientHeader	Return the value of a request or response header for the specified client session
HttpGetClientIdleTime	Return the idle timeout period for the specified client
HttpGetClientLocalPath	Return the full local path for the specified virtual path
HttpGetClientServer	Return the handle to the server that created the specified client session
HttpGetClientThreadId	Returns the thread ID associated with the specified client session
HttpGetClientUserName	Return the user name associated with the specified client session
HttpGetClientVariable	Return the value of a CGI environment variable for the specified client
HttpGetClientVirtualHost	Return the name of the virtual host the client used to establish the connection
HttpGetClientVirtualHostId	Return the virtual host ID associated with the specified client session
HttpGetClientVirtualPath	Return the virtual path for a local file on the server
HttpGetCommandFile	Return the full path to the local file name or directory specified by the client
HttpGetCommandLine	Return the complete command line issued by the client
HttpGetCommandName	Return the name of the command that was issued by the client

HttpGetCommandQuery	Return the query parameters included with the command
HttpGetCommandResource	Return the path for the resource requested by the client
HttpGetCommandResult	Return the result code and a description of the last command processed by the server
HttpGetCommandUrl	Return the complete URL of the resource requested by the client
HttpGetProgramExitCode	Return the exit code of the last program executed by the client
HttpGetProgramName	Return the name of the CGI program executed by the client
HttpGetProgramOutput	Return a copy of the standard output from a CGI program executed by the client
HttpGetProgramText	Return a copy of the standard output from a CGI program in a string buffer
HttpGetServerAddress	Return the IP address for the server
HttpGetServerDirectory	Return the full path to the root directory assigned to the specified server
HttpGetServerError	Return information about the last server error that occurred
HttpGetServerIdentity	Return the identity and version information for the specified server
HttpGetServerLogFile	Return the current log file format and full path for the file
HttpGetServerMemoryUsage	Return the amount of memory allocated for the server and all client sessions
HttpGetServerName	Return the host name assigned to the server or specified client session
HttpGetServerOptions	Return the configuration options for the specified server
HttpGetServerPriority	Return the current priority assigned to the specified server
HttpGetServerStackSize	Return the initial size of the stack allocated for threads created by the server
HttpGetServerTransferInfo	Return information about the current file transfer
HttpGetServerUuid	Return the UUID assigned to the specified server
HttpGetServerUuidString	Return the UUID assigned to the server as a printable string
HttpGetVirtualHostId	Return the virtual host ID associated with the specified hostname
HttpGetVirtualHostName	Return the hostname associated with the specified virtual host ID
HttpIsClientAuthenticated	Determine if the specified client session has been authenticated
HttpIsCommandEnabled	Determine if the specified command is currently enabled or disabled
HttpReceiveRequest	Receive the request that was sent by the client to the server
HttpRedirectRequest	Redirect the request from the client to another URL
HttpRegisterHandler	Register a CGI program for use and associate it with a file name extension
HttpRegisterProgram	Register a CGI program for use and associate it with a virtual path on the server
HttpRenameServerLogFile	Rename or delete the current log file being updated by the server
HttpRequireAuthentication	Send a response to the client indicating that authentication is required
HttpSendErrorResponse	Send a customized error response to the specified client
HttpSendResponse	Send a response from the server to the specified client
HttpSendResponseData	Send additional data to the client in response to a command
HttpServerAsyncNotify	Enable or disable asynchronous notification of changes in server status
HttpServerDisableTrace	Disable logging of network function calls
HttpServerEnableTrace	Enable logging of network function calls to a file
HttpServerInitialize	Initialize the library and validate the specified license key at runtime
HttpServerProc	Callback function used to process server events
HttpServerRestart	Restart the server, terminating all active client sessions

HttpServerResume	Resume accepting client connections on the specified server
HttpServerStart	Start the server and begin accepting client connections
HttpServerStop	Stop the server and terminate all active client connections
HttpServerSuspend	Suspend accepting client connections on the specified server
HttpServerThrottle	Limit the number of active client connections, connections per address and connection rate
HttpServerUninitialize	Terminate use of the library by the application
HttpSetClientAccess	Change the access rights associated with the specified client session
HttpSetClientHeader	Create or change the value of a request or response header for the client session
HttpSetClientIdleTime	Change the idle timeout period for the specified client session
HttpSetClientVariable	Create or change the value of a CGI environment variable for the specified client
HttpSetCommandFile	Change the name of the local file or directory that is the target of the current command
HttpSetServerError	Set the last error code for the specified server session
HttpSetServerIdentity	Change the identity and version information for the specified server
HttpSetServerLogFile	Change the current log format, level of detail and file name
HttpSetServerName	Change the hostname assigned to the specified server or client session
HttpSetServerPriority	Change the priority assigned to the specified server
HttpSetServerStackSize	Change the initial size of the stack allocated for threads created by the server.

HttpAddVirtualHost Function

```
UINT WINAPI HttpAddVirtualHost(  
    HSERVER hServer,  
    LPCTSTR lpszHostName,  
    UINT nHostPort,  
    LPCTSTR lpszDirectory  
);
```

Add a new virtual host to the server virtual host table.

Parameters

hServer

The server handle.

lpszHostName

A pointer to a string which specifies the hostname that will be added to the virtual host table. This parameter must specify a valid hostname and cannot be a NULL pointer or a zero-length string.

nHostPort

An integer value which specifies the port number for the virtual host. This value must be zero or the same value as the original port number that the server was configured to use.

lpszDirectory

A pointer to a NULL terminated string which specifies the root document directory for the virtual host. If this parameter is NULL or a zero-length string, the virtual host will use the same root directory that was specified when the server was started. This parameter may contain environment variables enclosed in % symbols.

Return Value

If the function is successful, it will return a non-zero integer value that identifies the virtual host. If the function fails, it will return INVALID_VIRTUAL_HOST and the last error code will be updated to indicate the cause of the failure.

Remarks

Virtual hosting is a method for sharing multiple domain names on a single instance of a server. The client provides the server with the hostname that it has used to establish the connection, and that name is compared against a table of virtual hosts configured for the server. If the hostname matches a virtual host, the client will use the root directory and any virtual paths that have been assigned to that host.

When the server is first started, a default virtual host with an ID of zero is automatically created and is identified as VIRTUAL_HOST_DEFAULT. This virtual host uses the same hostname, port number and root directory that the server instance was created with. The application should treat all other host IDs as opaque values and never make assumptions about how they are allocated.

The *nHostPort* parameter should always be specified with a value of zero, or the same port number that the server was configured to use. Port-based virtual hosting is currently not supported and this parameter is included for future use.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAddVirtualHostAlias](#), [HttpAddVirtualPath](#), [HttpAddVirtualUser](#), [HttpDeleteVirtualHost](#)

HttpAddVirtualHostAlias Function

```
BOOL WINAPI HttpAddVirtualHostAlias(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszHostAlias  
);
```

Add an alternate host name for an existing virtual host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszHostAlias

A pointer to a string which specifies the alias for the virtual host. The alias must be a valid domain name that uniquely identifies the host. This parameter cannot be a NULL pointer or specify an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpAddVirtualHostAlias** function adds an alias for an existing virtual host. This enables a client to establish a connection using a number of different domain names which all reference the same virtual host. When the server responds to the client, it will identify itself with the primary domain name assigned to the virtual host rather than the alias provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAddVirtualHost](#), [HttpAddVirtualPath](#)

HttpAddVirtualPath Function

```
BOOL WINAPI HttpAddVirtualPath(  
    HSERVER hServer,  
    UINT nHostId,  
    DWORD dwFileAccess,  
    LPCTSTR lpszVirtualPath,  
    LPCTSTR lpszLocalPath  
);
```

Add a new virtual path for the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

dwFileAccess

An integer value which specifies the access clients will be given to the virtual path. For a list of file access permissions, see [User and File Access Constants](#).

lpszVirtualPath

A pointer to a string which specifies the virtual path that will be created. This parameter cannot be a NULL pointer or an empty string. The maximum length of the virtual path is 1024 characters.

lpszLocalPath

A pointer to a string which specifies the local directory or file name that the virtual path will be mapped to. This path must exist and can be no longer than MAX_PATH characters. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpAddVirtualPath** function maps a virtual path name to a directory or file name on the local system. Virtual paths are assigned to specific hosts and if multiple virtual hosts are created for the server, each can have its own virtual paths which map to different files. To create a virtual path for the default server, the *nHostId* parameter should be specified as VIRTUAL_HOST_DEFAULT.

It is recommended that the *lpszLocalPath* parameter always specify the full path to the local file or directory. If the path is relative, it will be considered relative to the current working directory for the process and expanded to its full path name. The local path can include environment variables surrounded by % symbols. For example, if the value %ProgramData% is included in the path, it will be expanded to the full path for the common application data folder. The local path cannot specify a Windows system folder or the root directory of a mounted drive volume.

The local file or directory does not need to be located in the document root directory for the server or virtual host. It can specify any valid local path that the server process has the appropriate permissions to access. You should exercise caution when creating virtual paths to files or directories outside of the server root directory. If the *lpszLocalPath* parameter specifies a directory, clients will have access to

that directory and all subdirectories using its virtual path.

If you wish to password protect the virtual file or directory, include the HTTP_ACCESS_PROTECTED flag in the file permissions. The default command handlers will recognize this flag and require that the client authenticate itself to grant access to the resource. If the server application implements a custom command handler, it is responsible for checking for the presence of this flag and perform the appropriate checks to ensure that the client session has been authenticated.

If the server was started in restricted mode, the client will be unable to access documents outside of the server root directory and its subdirectories. This restriction also applies to virtual paths that reference documents or other resources outside of the root directory. To allow a client to access a document outside of the server root directory, the **HttpSetClientAccess** function should be used to grant the client HTTP_ACCESS_READ permission.

The **HttpGetClientVirtualPath** function will return the virtual path that is associated with a local file or directory. The **HttpGetClientLocalPath** function will return the full path to a local file or directory that is mapped to a virtual path.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpAddVirtualUser Function

```
BOOL WINAPI HttpAddVirtualUser(  
    HSERVER hServer,  
    UINT nHostId,  
    DWORD dwUserAccess,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszDirectory  
);
```

Add a new virtual user for the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

dwUserAccess

An integer value which specifies the access clients will be given when authenticated as this user. For a list of user access permissions, see [User and File Access Constants](#).

lpszUserName

A pointer to a string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the function will fail with an error indicating the username is invalid. This parameter cannot be NULL and the name must be at least three characters in length. Usernames are not case sensitive.

lpszPassword

A pointer to a string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the function will fail with an error indicating the password is invalid. This parameter cannot be NULL and must be at least one character in length. Passwords are case sensitive.

lpszDirectory

A pointer to a string which specifies the local directory that is considered to be the virtual user's home directory. This path must exist and can be no longer than MAX_PATH characters. The maximum length of the local path is 260 characters. The directory cannot be located in a Windows system folder or the root directory of a mounted disk volume. If this parameter is NULL or an empty string, the server root directory will be assigned as the user home directory.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpAddVirtualUser** function adds a virtual user that is associated with the specified virtual host.

If a client attempts to access a protected document and provides credentials, the server will attempt to automatically authenticate the session by searching for virtual user with the same username and password. If a match is found, then the client session is assigned the same access permissions as the virtual user.

If the server is started with the HTTP_SERVER_MULTUSER option, then documents in the virtual user's home directory can be accessed by specifying their username using a specially formatted request URL. For example, if a virtual user named "Thomas" is created, the documents in that user's home directory could be accessed as `http://servername/~thomas/document.html`

All files and subdirectories in the user's home directory are considered to be read-only. A client cannot create files in a user's home directory, even if they are authenticated as that user. In addition, CGI programs and scripts cannot be executed from a user's home directory.

If you wish to modify the information for a user, it is not necessary to delete the username first. If this function is called with a username that already exists, that record is replaced with the values passed to this function.

The virtual users created by this function exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this function for each user that is listed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `cshtsv11.lib`

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAddVirtualHost](#), [HttpDeleteVirtualUser](#)

HttpAuthenticateClient Function

```
BOOL WINAPI HttpAuthenticateClient(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess  
);
```

Authenticate the client and assign access rights for the session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see [User and File Access Constants](#).

Return Value

If the the client session could be authenticated, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has already been authenticated, this function will return zero.

Remarks

The **HttpAuthenticateClient** function is used to authenticate a specific client session, typically in response to an HTTP_CLIENT_USERAUTH event that indicates a client has provided authentication credentials as part of the request for a document or other resource.

To enable the server to automatically authenticate a client session, use the **HttpAddVirtualUser** function to add one or more virtual users. The server will search the list of virtual users for a match to the credentials provided by the client and will set the appropriate permissions for the session without requiring a event handler to manually authenticate the session using this function.

If the server was started with the HTTP_SERVER_LOCALUSER option and the client session is not authenticated using this function, the server will attempt to authenticate the client session using the local Windows user database. Although this option can be convenient because it does not require the implementation of an event handler for the HTTP_CLIENT_USERAUTH event, it can be used by clients to attempt to discover valid usernames and passwords for the local system. It is recommended that you use the **HttpAddVirtualUser** function to create virtual users rather than using the local user database.

It is recommended that most applications specify HTTP_ACCESS_DEFAULT as the *dwUserAccess* value for a client session, since this allows the server automatically grant the appropriate access based on the server configuration options.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpAddVirtualUser](#), [HttpGetClientCredentials](#), [HttpGetClientDirectory](#)

HttpCreateServerCredentials Function

```
BOOL WINAPI HttpCreateServerCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **HttpCreateServerCredentials** function creates a SECURITYCREDENTIALS structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This value should always be zero for connections using SSH. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpzUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpzPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpzCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **HttpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The structure that is created by this function may be used as server credentials when accepting a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **HttpServerStart** function.

An application only needs to call this function to support secure connections using TLS. When a certificate is specified, it must have a private key associated with it. Attempting to use a certificate which does not have a private key will result in an error during the startup process indicating that the server credentials are invalid.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpzPassword* parameter or the library will be unable to access the certificate.

Example

```
// Create the server credentials that identifies the certificate
// that will be used for secure connections
LPSECURITYCREDENTIALS lpSecCred = NULL;

HttpCreateServerCredentials(SEcurityProtocolDefault,
                           0,
                           NULL,
                           NULL,
                           lpzCertStore,
                           lpzCertName,
                           NULL,
                           &lpSecCred);

// Start the server
hServer = HttpServerStart(lpzLocalHost,
                          HTTP_PORT_SECURE,
                          HTTP_SERVER_SECURE,
                          &httpConfig,
                          lpEventHandler,
                          0,
                          lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpDeleteServerCredentials](#), [HttpServerStart](#), [SECURITYCREDENTIALS](#)

HttpCheckVirtualPath Function

```
BOOL WINAPI HttpCheckVirtualPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszVirtualPath,  
    DWORD dwFileAccess  
);
```

Determine if the client has permission to access the specified virtual path.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszVirtualPath

A pointer to a string which specifies the virtual path that should be checked. This path must be absolute and cannot be a NULL pointer or an empty string. The maximum length of the virtual path is 1024 characters.

dwFileAccess

An unsigned integer value which specifies the access permissions that should be checked. For a list of file access permissions, see [User and File Access Constants](#).

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the client ID does not specify a valid client, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpCheckVirtualPath** function is used to determine if the client has permission to access the virtual file or directory, based on the value of the *dwFileAccess* parameter. For example, if the *dwFileAccess* parameter has the value HTTP_ACCESS_WRITE, this function will check if the client has write permission for the file or directory. The function will return a non-zero value if the client does have the requested permission, or zero if it does not.

Applications that implement their own custom handlers for standard HTTP commands should use this function to ensure that the client has the appropriate permissions to access the requested resource. Failure to check the access permissions for the client can result in the client being able to access restricted documents and other resources. It is recommended that most applications use the default command handlers.

To obtain the path to the local file or directory that the virtual path is mapped to, use the **HttpGetClientLocalPath** function.

Example

```
TCHAR szPathName[1024];  
  
// Get the current request URL path  
INT cchPathName = HttpGetCommandResource(  
    hServer,
```

```

        nClientId,
        szPathName,
        1024);

if (cchPathName == 0)
{
    HttpSendErrorResponse(hServer, nClientId, 500, NULL);
    return;
}

// Check if the client has write access to that resource
BOOL bAllowed = HttpCheckVirtualPath(
    hServer,
    nClientId,
    szPathName,
    HTTP_ACCESS_WRITE);

if (!bAllowed)
{
    HttpSendErrorResponse(hServer, nClientId, 403, NULL);
    return;
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAddVirtualPath](#), [HttpDeleteVirtualPath](#), [HttpGetClientLocalPath](#), [HttpGetClientVirtualPath](#)

HttpDeleteAllClientHeaders Function

```
BOOL WINAPI HttpDeleteAllClientHeaders(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nHeaderType  
);
```

Delete all of the request or response headers for the specified client session.

Parameters

hServer

The server handle.

nClientId

Delete all of the request or response headers for the specified client session.

nHeaderType

Specifies the type of headers to delete. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Delete all of the request headers that were provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Delete all of the response headers that were created by the server in response to a request made by the client. Response header values provide additional information to the client about the type of information that is being returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpDeleteAllClientHeaders** function is used to delete all of the request or response headers that were set as the result of the client issuing a request for a document or other resource. If this function is used to delete all of the response headers, the server will automatically generate a standard set of response headers when it returns the requested information to the client.

It is not necessary to call this function inside an HTTP_CLIENT_DISCONNECT event handler to delete the header values that were set during the client session. This is done automatically when the client disconnects from the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpDeleteClientHeader](#), [HttpSetClientHeader](#)

HttpDeleteClientHeader Function

```
BOOL WINAPI HttpDeleteClientHeader(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nHeaderType,  
    LPCTSTR LpszHeaderName  
);
```

Delete a request or response header for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header to delete. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Delete a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Delete a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A pointer to a string that specifies the name of the header that should be deleted. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpDeleteClientHeader** function will delete a request or response header for the specified client session. There are a number of required response headers that are always sent to a client and deleting the header using this function will cause the server to automatically generate a new default header value. You should not delete response header values unless you are certain of the impact that it would have on the normal operation of the client.

It is not necessary for you to delete a header value to change the value of an existing header. The **HttpSetClientHeader** function will replace an existing header value with a new value, or create a new header if the header name does not already exist.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpDeleteAllClientHeaders](#), [HttpGetClientHeader](#), [HttpSetClientHeader](#)

HttpDeleteServerCredentials Function

```
VOID WINAPI HttpDeleteServerCredentials(  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **HttpDeleteServerCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer value will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)  
    HttpDeleteServerCredentials(&lpSecCred);
```

Remarks

This function can be used to release the memory allocated for the credentials after the server has been started.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpDeleteVirtualHost Function

```
BOOL WINAPI HttpDeleteVirtualHost(  
    HSERVER hServer,  
    UINT nHostId  
);
```

Delete a virtual host associated with the specified server.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpDeleteVirtualHost** function removes a virtual host that was created by a previous call to the **HttpAddVirtualHost** function. All virtual paths and users associated with the specified host are no longer valid. It is not necessary to call this function to delete any of the virtual hosts prior to stopping the server. Part of the normal shutdown process is releasing the resources allocated for each virtual host that was added to the server.

This function cannot be used to delete the virtual host with an ID of zero, which is the default virtual host that is allocated when the server is started.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

See Also

HttpDeleteVirtualPath Function

```
BOOL WINAPI HttpDeleteVirtualPath(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszVirtualPath  
);
```

Remove a virtual path from the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszVirtualPath

A pointer to a string which specifies the virtual path that will be removed. This path must be absolute and cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

This function removes a virtual path that was created by a previous call to the **HttpAddVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpDeleteVirtualUser Function

```
BOOL WINAPI HttpDeleteVirtualUser(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszUserName  
);
```

Remove a virtual user from the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszUserName

A pointer to a string which specifies the user that will be removed. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

This function removes a virtual user that was created by a previous call to the **HttpAddVirtualUser** function. This function will not match partial usernames and wildcard characters cannot be used to delete multiple users. Usernames are not case sensitive.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpAddVirtualHost](#), [HttpAddVirtualUser](#)

HttpDisconnectClient Function

```
BOOL WINAPI HttpDisconnectClient(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Close the control connection for the specified client and release the resources allocated for the session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpDisconnectClient** function will close the control channel, disconnecting the client from the server and terminating the client session thread. Resources that we allocated for the client, such as memory and open handles, will be released back to the operating system. If the client was in the process of transferring a file, the transfer will be aborted.

This function sends an internal control message that notifies the server that this session should be terminated. When the session thread is signaled that it should terminate, it will abort any active data transfers and begin to release the resources allocated for that session. To ensure that the client session terminates gracefully, there may be a brief period of time where the session thread is still active after this function has returned.

After this function returns, the application should never use the same client ID with another function. Client IDs are unique to the session over the lifetime of the server, and are not reused.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpServerRestart](#), [HttpServerStop](#)

HttpEnableClientAccess Function

```
BOOL WINAPI HttpEnableClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess,  
    BOOL bEnable  
);
```

Enable or disable access rights for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies an access right to enable or disable. For a list of user access rights that can be granted to the client, see [User and File Access Constants](#).

bEnable

An integer value which specifies if permission should be granted or revoked for the specified access right. If this value is non-zero, permission is granted to the client to perform the action specified by the *dwUserAccess* parameter. If this value is zero, that permission is revoked.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpEnableClientAccess** function is used to enable or disable access to specific functionality by the client. The function can only change a single access right and cannot be used to enable or disable multiple access rights in a single function call. To change multiple user access rights for the client, use the **HttpSetClientAccess** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpAuthenticateClient](#), [HttpGetClientAccess](#), [HttpSetClientAccess](#)

HttpEnableCommand Function

```
BOOL WINAPI HttpEnableCommand(  
    HSERVER hServer,  
    LPCTSTR lpszCommand,  
    BOOL bEnable  
);
```

Enable or disable a specific server command

Parameters

hServer

The server handle.

lpszCommand

A pointer to a NULL terminated string that specifies the name of the command to be enabled or disabled. The command name is not case-sensitive, but the value must otherwise match the exact name. Partial matches are not recognized by this function. This parameter cannot be NULL.

bEnable

An integer value which specifies if the command should be enabled or disabled. If the value is non-zero, the command is enabled. If the value is zero, the command will be disabled.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the command is not recognized, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpEnableCommand** function is used to enable or disable access to a specific command on the server. This function is typically used to enable or disable certain commands for security purposes. For example, the PUT command can be disabled, preventing any client from attempting to upload files directly to the server. The **HttpIsCommandEnabled** function can be used to determine if a command is enabled or not.

The command name provided to this function must match the commands defined in RFC 2616 or related protocol standards. Refer to [Hypertext Transfer Protocol Commands](#) for a complete list of server commands.

Some commands cannot be disabled because they are required to perform essential server functions. For example, the GET and HEAD commands cannot be disabled. If you attempt to disable a required command, this function will return zero and the last error code will be set to ST_ERROR_COMMAND_REQUIRED. Because this function affects all clients connected to the server, it should not be used to limit access to certain commands for specific clients. Instead, use an event handler to filter the commands.

The OPTIONS and TRACE commands are disabled by default for all server instances and must be explicitly enabled using the **EnableCommand** method if you wish permit clients to use them. It is not recommended that you enable these commands if your server is going to be publicly accessible over the Internet. If the server started with the option HTTP_SERVER_READONLY, commands that can be used to create or modify files on the server will be disabled by default.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpAuthenticateClient](#), [HttpIsCommandEnabled](#)

HttpEnumServerClients Function

```
INT WINAPI HttpEnumServerClients(  
    HSERVER hServer,  
    DWORD dwReserved  
    UINT *lpClients,  
    INT nMaxClients  
);
```

Return a list of active client sessions established with the specified server.

Parameters

hServer

Handle to the server socket.

dwReserved

An unsigned integer value that is reserved for future use. This parameter should always be zero.

lpClients

Pointer to an array of unsigned integers which will contain client IDs that uniquely identifies each client when the function returns. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client IDs to be returned in the *lpClients* array. If the *lpClients* parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call

HttpGetServerError.

Remarks

If the *nMaxClients* parameter is less than the number of active client connections, the function will fail and the last error code will be set to the error ST_ERROR_BUFFER_TOO_SMALL. To dynamically determine the number of active connections, call the function with the *lpClients* parameter with a value of NULL, and the *nMaxClients* parameter with a value of zero.

Example

```
INT nClients = HttpEnumServerClients(hServer, 0, NULL, 0);  
  
if (nClients > 0)  
{  
    UINT *lpClients = NULL;  
  
    // Allocate memory for an array of client IDs  
    lpClients = (UINT *)LocalAlloc(LPTR, nClients * sizeof(UINT));  
  
    if (lpClients == NULL)  
    {  
        // Virtual memory has been exhausted  
        return;  
    }  
  
    nClients = HttpEnumServerClients(hServer, 0, lpClients, nClients);  
}
```

```

if (nClients == HTTP_ERROR)
{
    // Unable to obtain list of connected clients
    return;
}

for (INT nIndex = 0; nIndex < nClients; nIndex++)
{
    TCHAR szUserName[HTTP_MAXUSERNAME];

    if (HttpGetClientUserName(hServer, lpClients[nIndex], szUserName,
HTTP_MAXUSERNAME))
    {
        // Perform some action with the client user name
    }
}

// Free the memory allocated for the client IDs
LocalFree((HLOCAL)lpClients);
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpServerStart](#)

HttpGetActiveClient Function

```
UINT WINAPI HttpGetActiveClient(  
    HSERVER hServer  
);
```

Return the client ID for the active client session associated with the current thread.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the unique ID associated with the client session for the current thread. If the server handle is invalid or there is no client session active on the current thread, the return value is zero.

Remarks

The **HttpGetActiveClient** function is used to obtain the client ID associated with the current thread. This means this function will only return a client ID if it is called within an event handler or a function called by an event handler. If this function is called by a function that is not executing within the context of an event handler it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpEnumServerClients](#)

HttpGetClientAccess Function

```
BOOL WINAPI HttpGetClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    LPDWORD lpdwUserAccess  
);
```

Return the access rights that have been granted to the client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwUserAccess

A pointer to an unsigned integer which specifies one or more access rights for the client session. For a list of user access permissions that can be granted to the client, see [User and File Access Constants](#). This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **HttpGetClientAccess** function is used to obtain all of the access rights that are currently granted to the client session. The **HttpEnableClientAccess** function can be used to enable or disable specific permissions, and the **HttpSetClientAccess** function can change multiple access rights at once.

Example

```
DWORD dwUserAccess = 0;  
  
// Check if the client has execute permission  
if (HttpGetClientAccess(hServer, nClientId, &dwUserAccess))  
{  
    if (dwUserAccess & HTTP_ACCESS_EXECUTE)  
    {  
        _tprintf(_T("Client %u can execute programs and scripts\n"), nClientId);  
        return;  
    }  
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpAuthenticateClient](#), [HttpEnableClientAccess](#), [HttpSetClientAccess](#)

HttpGetClientAddress Function

```
INT WINAPI HttpGetClientAddress(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

Return the IP address of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszAddress

A pointer to a string buffer that will contain the client IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetServerAddress](#)

HttpGetClientCredentials Function

```
BOOL WINAPI HttpGetClientCredentials(  
    HSERVER hServer,  
    UINT nClientId,  
    LPHTTPCLIENTCREDENTIALS lpCredentials  
);
```

Return the user credentials for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpCredentials

A pointer to an **HTTPCLIENTCREDENTIALS** structure that will contain information about the user when the function returns. This parameter cannot be NULL.

Return Value

If the user credentials for the client session are available, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has not requested authentication, this function will return zero.

Remarks

The **HttpGetClientCredentials** function is used to obtain the username and password that was provided by the client when it requested authentication. Typically this function is used in an event handler to validate the credentials provided by the client. If the credentials are considered valid, the event handler would then call the **HttpAuthenticateClient** function to specify that the session has been authenticated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAuthenticateClient](#), [HttpRequireAuthentication](#), [HTTPCLIENTCREDENTIALS](#)

HttpGetClientDirectory Function

```
INT WINAPI HttpGetClientDirectory(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszDirectory,  
    INT nMaxLength  
);
```

Returns the root document directory for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A pointer to a string buffer that will contain the root directory for the specified client session, terminated with a null character. This buffer should be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be larger than zero or the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

This function returns the full path to the root document directory for the specified client session. If no virtual hosts have been configured, then this path will be the same as the root directory assigned to the server when it was started. If the server has been configured with multiple virtual hosts, this function will return the path to the root directory associated with the hostname provided by the client.

To convert a full path to the virtual path for a specific client session, use the **HttpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetClientVirtualPath](#)

HttpGetClientHeader Function

```
INT WINAPI HttpGetClientHeader(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nHeaderType,  
    LPCTSTR lpszHeaderName,  
    LPTSTR lpszHeaderValue,  
    INT nMaxLength,  
);
```

Return the value of a request or response header for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Return the value of a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Return the value of a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A pointer to a string that specifies the name of the header field. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszHeaderValue

A pointer to a buffer that will contain the header value, terminated with a null character. To determine the length of the header value, this parameter can be NULL and the *nMaxLength* parameter should be specified with a value of zero.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the header value buffer, including the terminating null character. If the *lpszHeaderValue* parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the return value is the length of the header value, not including the terminating null character. If the server handle and client ID do not specify a valid client session, or there is no header that matches the given name, the function will return zero. If the *lpszHeaderValue*

parameter is not NULL and the buffer is not large enough to store the complete header value, the function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpGetClientHeader** function will return the value of a request or response header for the specified client session. If the *lpzHeaderName* value matches an existing header field, its value will be copied to the string buffer provided by the caller.

Refer to [Hypertext Transfer Protocol Headers](#) for a list of common request and response headers that are used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetClientIdleTime Function

```
UINT WINAPI HttpGetClientIdleTime(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT *lpnElapsed  
);
```

Return the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpnElapsed

A pointer to an unsigned integer value that will contain the number of seconds the client session has been idle. This parameter may be NULL if this information is not required.

Return Value

If the function succeeds, the return value is client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetClientIdleTime** function will return the number of seconds that the client may remain idle before being automatically disconnected by the server. The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed. The server will never disconnect a client that is in the process of sending or receiving data, regardless of the idle timeout period.

The default idle timeout period for a client session is 60 seconds, however the server can be configured to use a different value. The minimum timeout period for a client is 10 seconds, the maximum is 300 seconds (5 minutes). An application can change the timeout period for a specific client session using the **HttpSetClientIdleTime** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpSetClientIdleTime](#)

HttpGetClientLocalPath Function

```
INT WINAPI HttpGetClientLocalPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszVirtualPath,  
    LPTSTR lpszLocalPath,  
    INT nMaxLength,  
);
```

Return the full local path for a virtual filename or directory on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszVirtualPath

A pointer to a string that specifies an virtual path on the server. This parameter cannot be NULL.

lpszLocalPath

A pointer to a string buffer that will contain the full local path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

The **HttpGetClientLocalPath** function takes a virtual path and returns the full path to the specified file or directory on the local system. The virtual path may be absolute or relative to the root directory for the client session.

To obtain the virtual path for a local file or directory, use the **HttpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetClientVirtualPath](#)

HttpGetClientServer Function

```
HSERVER WINAPI HttpGetClientServer(  
    UINT nClientId  
);
```

The **HttpGetClientServer** function returns a handle to the server that created the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session. If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call the **HttpGetServerError** function.

Remarks

The **HttpGetClientServer** function returns the handle to the server that created the client session and is typically used within a notification message handler. If the server is in the process of shutting down, or the client session thread is terminating, this function will fail and return `INVALID_SERVER` indicating that the session ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `cshtsv11.lib`

See Also

[HttpServerAsyncNotify](#)

HttpGetClientThreadId Function

```
DWORD WINAPI HttpGetClientThreadId(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Returns the thread ID associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is a thread ID. If the function fails, the return value is zero. To get extended error information, call the **HttpGetServerError** function.

Remarks

The **HttpGetClientThreadId** function returns a thread ID that can be used to identify the thread that is managing the client session. The thread ID can be used with other Windows API functions such as **OpenThread**. Exercise caution when using thread-related functions, interfering with the normal operation of the thread can have unexpected results. You should never use this function to obtain a thread handle and then call the **TerminateThread** function to terminate a client session. This will prevent the thread from releasing the resources that were allocated for the session and can leave the server in an unstable state. To terminate a client session, use the **HttpDisconnectClient** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpEnumServerClients](#), [HttpGetActiveClient](#)

HttpGetClientUserName Function

```
INT WINAPI HttpGetClientUserName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszUserName,  
    INT nMaxLength  
);
```

Return the user name associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszUserName

A pointer to a string buffer that will contain the user name associated with the client session. This buffer must be large enough to store the complete user name, including the terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value larger than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetClientUserName** function returns the user name associated with an authenticated client session. If the client has not authenticated itself, this function will return zero and the *lpszUserName* parameter will be set to an empty string.

The **HttpIsClientAuthenticated** function can be used to determine if the client has provided credentials as part of the request made to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAuthenticateClient](#), [HttpGetClientAccess](#), [HttpIsClientAuthenticated](#)

HttpGetClientVariable Function

```
INT WINAPI HttpGetClientVariable(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszName,  
    LPTSTR lpszValue,  
    INT nMaxLength,  
);
```

Return the value of a CGI environment variable for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszName

A pointer to a string that specifies the name of the environment variable. Variable names are not case-sensitive and should not include the equal sign which acts as a delimiter that separates the variable name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszValue

A pointer to a buffer that will contain the value of the environment variable, terminated with a null character. To determine the length of the header value, this parameter can be NULL and the *nMaxLength* parameter should be specified with a value of zero.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the value buffer, including the terminating null character. If the *lpszValue* parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the return value is the length of the environment variable value, not including the terminating null character. If the server handle and client ID do not specify a valid client session, or there is no environment variable that matches the given name, the function will return zero. If the *lpszValue* parameter is not NULL and the buffer is not large enough to store the complete header value, the function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpGetClientVariable** function will return the value of an environment variable that has been defined for the client. Each client session inherits a copy of the process environment block, which is then modified to define various environment variables that are used with CGI programs and scripts. The **HttpSetClientVariable** function can be used to change existing environment variables or create new variables.

The standard CGI environment variables that are defined by the server are not created until the client request has been processed. This means that environment variables such as REMOTE_ADDR and SERVER_NAME will not be defined inside an HTTP_CLIENT_CONNECT event handler.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpSetClientVariable](#)

HttpGetClientVirtualHost Function

```
INT WINAPI HttpGetClientVirtualHost(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

Return the name of the virtual host the client used to establish the connection.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszHostName

A pointer to a string buffer that will contain the virtual host name. The string buffer will be null terminated and must be large enough to store the complete hostname. If this parameter is NULL, the function will only return the length of the current command in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the *lpszHostName* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetClientVirtualHost** function is used to obtain the hostname that the client used to establish a connection with the server. This function is typically used within an event handler to determine the hostname associated with the request made by the client. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the virtual host has not been selected at that point. If the virtual hostname is not available at the time this function is called, the function will return zero and the last error code will be set to ST_ERROR_VIRTUAL_HOST_NOT_FOUND.

The **HttpGetClientVirtualHostId** function can be used to obtain the virtual host ID associated with the hostname.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetClientVirtualHostId](#), [HttpGetCommandUrl](#)

HttpGetClientVirtualHostId Function

```
UINT WINAPI HttpGetClientVirtualHostId(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Return the virtual host ID associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

An unsigned integer value which specifies the virtual host ID. If the function fails, the return value will be `INVALID_VIRTUAL_HOST` and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetClientVirtualHostId** function is used to obtain the virtual host ID associated with the hostname the client used to establish a connection with the server. This function should not be called inside a `HTTP_CLIENT_CONNECT` event handler because the virtual host has not been selected at that point. If the virtual host ID is not available at the time this function is called, the function will return `INVALID_VIRTUAL_HOST` and the last error code will be set to `ST_ERROR_VIRTUAL_HOST_NOT_FOUND`.

The **HttpGetClientVirtualHost** function can be used to obtain the hostname that the client used to establish the connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `cshtsv11.lib`

See Also

[HttpGetClientVirtualHost](#), [HttpGetCommandUrl](#), [HttpGetVirtualHostId](#), [HttpGetVirtualHostName](#)

HttpGetClientVirtualPath Function

```
INT WINAPI HttpGetClientVirtualPath(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszLocalPath,  
    LPTSTR lpszVirtualPath,  
    INT nMaxLength,  
);
```

Return the virtual path for a local file on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszLocalPath

A pointer to a string that specifies an absolute path on the local system. This parameter cannot be NULL.

lpszVirtualPath

A pointer to a string buffer that will contain the virtual path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

A virtual path for the client is relative to the root directory for the specified client session. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the ***lpszLocalPath*** parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this function would return the virtual path to that directory as "/Documents/Research".

If the ***lpszLocalPath*** parameter specifies a file or directory outside of the server root directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_FILE_NAME. This function can only be used with authenticated clients. If the ***nClientId*** parameter specifies a client session that has not been authenticated, this function will return zero and the last error code will be ST_ERROR_AUTHENTICATION_REQUIRED.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetCommandFile](#), [HttpGetClientLocalPath](#)

HttpGetCommandFile Function

```
INT WINAPI HttpGetCommandFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

Get the full path to a file name or directory specified by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string buffer that will contain the full path to a file name or directory specified by the client when it issued a command. The string buffer will be null terminated and must be large enough to store the complete file path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. It is recommended that the buffer be at least MAX_PATH characters in size. If the maximum length specified is smaller than the actual length of the full path, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the

HttpGetServerError function can be used to retrieve the last error code.

Remarks

The **HttpGetCommandFile** function is used to obtain the full path to a local file name or directory specified by the client as an argument to a standard HTTP command. For example, if the client sends the GET command to the server, this function will return the complete path to the local file that the client wants to retrieve. This function will only work with those standard commands that perform some action on a file or directory.

This function should always be used to obtain the file name for a command that performs a file or directory operation. It normalizes the path provided by the client and ensures that it specifies a file or directory name in the correct location. The **HttpGetCommandUrl** function can be used to obtain the URL that was provided by the client.

To map a virtual path to a file or directory on the local system, use the **HttpAddVirtualPath** function. To redirect a client to use a different URL to access the resource, use the **HttpRedirectRequest** function.

The **HttpSetCommandFile** function can be used to change the name of the local file or directory that is the target of the command, however using this function to redirect access to a resource can have unintended side-effects, particularly in the case where the URL provided by the client actually resolves to an executable CGI program that handles the request.

If the client has provided a URL that resolves to a CGI program that handles the request, this function

behaves differently than if the URL is resolved to a local file or directory. If the client uses the GET or POST command that results in a program being executed to handle the request, this function will return the path to the server root directory along with any additional path information provided in the URL. In other words, the file name returned by this function will be the same as the PATH_TRANSLATED value passed to the CGI program.

This function should only be called after the client request has been received by the server, typically inside a HTTP_CLIENT_COMMAND or HTTP_CLIENT_EXECUTE event handler. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpAddVirtualPath](#), [HttpGetCommandUrl](#), [HttpRedirectRequest](#), [HttpSetCommandFile](#)

HttpGetCommandLine Function

```
INT WINAPI HttpGetCommandLine(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR LpszCmdLine,  
    INT nMaxLength  
);
```

Return the complete command line issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCmdLine

A pointer to a string buffer that will contain the command, including all arguments. The string buffer will be null terminated and must be large enough to store the complete command line. If this parameter is NULL, the function will return the length of the command line.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. The internal limit on the maximum length of a command is 1024 characters. If the maximum length specified is smaller than the actual length of the complete command, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the

HttpGetServerError function can be used to retrieve the last error code. If the last error code has a value of zero then no command has been issued by the client.

Remarks

The **HttpGetCommandLine** function is used to obtain the command that was issued by the client, and is commonly used inside HTTP_CLIENT_COMMAND and HTTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively. When the function returns, the string buffer provided by the caller will contain the complete command, including the resource path and requested HTTP version. Any extraneous whitespace will be removed, however all encoding will be preserved.

To obtain the complete URL associated with the request issued by the client, use the **HttpGetCommandUrl** function. If the command sent by the client is used to perform an action on a file or directory, the **HttpGetCommandFile** function should be called to obtain the full path to the local file rather than using the resource path.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetCommandFile](#), [HttpGetCommandUrl](#)

HttpGetCommandName Function

```
INT WINAPI HttpGetCommandName  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszCommand,  
    INT nMaxLength  
);
```

Return the name of the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCommand

A pointer to a string buffer that will contain the command name. The string buffer will be null terminated and must be large enough to store the complete command name. If this parameter is NULL, the function will only return the length of the current command in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the *lpszCommand* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that no command has been issued by the client.

Remarks

The **HttpGetCommandName** function is used to obtain the name of the last command that was issued by the client. The command name returned by this function will always be capitalized, regardless of how it was sent by the client. This function is typically used inside HTTP_CLIENT_COMMAND and HTTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

The **HttpGetCommandUrl** function can be used to return the resource that was requested by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetCommandFile](#), [HttpGetCommandUrl](#)

HttpGetCommandQuery Function

```
INT WINAPI HttpGetCommandQuery(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszParameters,  
    INT nMaxLength  
);
```

Return the query parameters included with the command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszParameters

A pointer to a string buffer that will contain the query parameters when the function returns. The string buffer will be null terminated up to the maximum number of characters specified by the caller. If this parameter is NULL the function will return the length of the query string.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. If the *lpszParameters* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code. If the client did not provide any query parameters, this function will return zero and the last error code will be zero.

Remarks

The **HttpGetCommandQuery** function is used to obtain a copy of the query parameters that were included in the request URL. If there were no query parameters, the string buffer will be empty and the return value will be zero. If the request did include query parameters, they will be returned to the caller in their original, encoded form.

This function should not be called within a HTTP_CLIENT_CONNECT event handler because the client request has not been processed at that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetCommandName](#), [HttpGetCommandResource](#), [HttpReceiveRequest](#)

HttpGetCommandResource Function

```
INT WINAPI HttpGetCommandResource(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszResource,  
    INT nMaxLength  
);
```

Return the URL path for the resource requested by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszResource

A pointer to a string buffer that will contain the URL path provided by the client for the current command. The string buffer will be null terminated and must be large enough to store the complete path. If this parameter is NULL, the function will only return the length of the path.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the *lpszResource* parameter is NULL, this value should be zero. If this value is less than the length of the URL, the function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetCommandResource** function returns the URL path that the client provided to access the requested resource. The path will not include the URI scheme, user credentials or query parameters. The **HttpGetCommandFile** function can be used to determine the name of the local file on the server that will be accessed using this URL.

If you require the complete URL, not just the path to the resource, use the **HttpGetCommandUrl** function.

This function should only be called after the client request has been received by the server, typically inside a HTTP_CLIENT_COMMAND event handler. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetCommandResult Function

```
INT WINAPI HttpGetCommandResult(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszResult,  
    INT nMaxLength  
);
```

Return the result code and description for the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszResult

A pointer to a string buffer that will contain the description of the result code. The string buffer will be null terminated up to the maximum number of characters specified by the caller. This parameter can be NULL if this information is not required.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. If the *lpszResult* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the result code for the last command issued by the client. A return value of zero indicates that the command has not completed and there is no result code available.

Remarks

The **HttpGetCommandResult** function is used to determine the result of the last command that was issued by the client and is typically called in the HTTP_CLIENT_RESULT event handler. This function should only be called after a command has been processed or the **HttpSendResponse** function has been called.

The result code is a three-digit integer value that indicates the success or failure of a command. Whenever a client sends a command to the server, the server must respond with this numeric code and a brief description of the the result. Result codes are generally broken down into the following categories:

Result Code	Description
100-199	Result codes in this range are informational and only used with version 1.1 of the protocol. If the server returns a result code in this range, it means that it has received the request and that the client should proceed.
200-299	Result codes in this range indicate that the server has successfully completed the requested action. In most cases this means that the server has returned the requested data to the client, however if a 204 result code is sent, this indicates that the request has been processed but there is no data available.
300-399	Result codes in this range indicate that the requested resource has been moved to a new location. The most common result codes are 301 and 302. A value of 301

	indicates that the location of the resource has changed permanently and all future requests should be sent to the new URL. A value of 302 indicates that the resource location has changed temporarily. The new location of the resource is sent to the client by setting the Location response header field.
400-499	Result codes in this range indicate an error with the request that was made by the client. These types of errors include invalid commands, requests that can only be issued by authenticated clients, or resources that cannot be accessed on the server. The most common result code in this range is the 404 code which indicates that the requested document could not be found.
500-599	Result codes in this range indicate a server error has occurred while processing a valid request. These types of errors are returned when a command has not been implemented, the execution of a CGI program or script has failed unexpectedly, or an internal server error has occurred.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetCommandUrl Function

```
INT WINAPI HttpGetCommandUrl(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszCmdUrl,  
    INT nMaxLength  
);
```

Return the complete URL of the resource requested by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCmdUrl

A pointer to a string buffer that will contain the URL provided by the client for the current command. The string buffer will be null terminated and must be large enough to store the complete URL. If this parameter is NULL, the function will only return the length of the URL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the *lpszCmdUrl* parameter is NULL, this value should be zero. If this value is less than the length of the URL, the function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetCommandUrl** function returns the complete URL that the client provided to access the requested resource. The URL will include any query parameters that were specified by the client, but it will not include any user credentials. The **HttpGetCommandFile** function can be used to determine the name of the local file on the server that will be accessed using this URL.

If you only require the URL path, without the URI scheme or the query parameters, use the **HttpGetCommandResource** function.

This function should only be called after the client request has been received by the server, typically inside a HTTP_CLIENT_COMMAND event handler. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

HttpGetProgramExitCode Function

```
BOOL WINAPI HttpGetProgramExitCode(  
    HSERVER hServer,  
    UINT nClientId,  
    LPDWORD lpdwExitCode  
);
```

Return the exit code of the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwExitCode

A pointer to an unsigned integer that will contain the program exit code when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetProgramExitCode** function returns the exit code of a registered CGI program or script that was executed. By convention, most programs return an exit code in the range of 0-255, with an exit code of zero indicating success. The exit code is commonly used by programs to communicate status information back to the server application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshtsv11.lib

[HttpGetProgramOutput](#), [HttpRegisterProgram](#)

HttpGetProgramName Function

```
INT WINAPI HttpGetProgramName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszProgramName,  
    INT nMaxLength  
);
```

Return the name of the CGI program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszProgramName

A pointer to a string buffer that will contain the name of the CGI program executed by the client. This parameter cannot be NULL and should be at least MAX_PATH characters in size.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value greater than zero.

Return Value

If the function succeeds, the return value is the length of the executable file name. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed a CGI program this function will return zero and the last error code will be set to zero.

Remarks

The **HttpGetProgramName** function returns the local file name of the CGI program that was executed in response to a request from the client. This is the full path to the executable that was registered with the server using the **HttpRegisterProgram** function. If the client specified a regular document or directory, this function will return a value of zero, indicating that no CGI program has been executed to handle the request.

To obtain the resource URL that was provided by the client, use the **HttpGetCommandUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetProgramOutput Function

```
DWORD WINAPI HttpGetProgramOutput(  
    HSERVER hServer,  
    UINT nClientId,  
    LPBYTE lpBuffer,  
    DWORD dwBufferSize  
);
```

Return a copy of the standard output from a CGI program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A pointer to a buffer that will contain the output from the last program executed by the client. If this parameter is NULL, the function will return the number of bytes of data that was output by the program. Note that this output is not null terminated.

dwBufferSize

The maximum number of bytes that can be copied into the buffer. If the *lpBuffer* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of bytes copied into the specified buffer. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **HttpGetProgramOutput** function is used to obtain a copy of the output generated by a CGI program. To determine the number of bytes of output available to read, call this function with the *lpBuffer* parameter as NULL and the *dwBufferSize* parameter with a value of zero. The return value will be the number of bytes of data that was output by the program. It should be noted that for Unicode builds, the buffer is a byte array, not an array of characters, and will not be null terminated.

This function returns the raw output from the program which may contain a response header block, escape sequences, control characters and embedded nulls. When the application processes the output returned by this function, it should never coerce the buffer pointer to an LPTSTR value because there is no guarantee that the data will be null-terminated. To obtain the output from the program as a string, use the **HttpGetProgramText** function.

This function should only be used within an HTTP_CLIENT_EXECUTE event handler, which occurs after the program has terminated.

Example

```
LPBYTE lpBuffer = NULL; // A pointer to the output buffer  
DWORD cbBuffer = 0;      // Number of bytes in the output buffer  
  
// Determine the number of bytes in the output buffer  
cbBuffer = HttpGetProgramOutput(hServer, nClientId, NULL, 0);
```

```

if (cbBuffer > 0)
{
    // Allocate memory for the buffer
    lpBuffer = (LPBYTE)LocalAlloc(LPTR, cbBuffer + 1);

    // Copy the program output to the buffer
    if (lpBuffer != NULL)
        cbBuffer = HttpGetProgramOutput(hServer, nClientId, lpBuffer, cbBuffer +
1);
}

// Free the memory allocated for the buffer when finished
if (lpBuffer != NULL)
{
    LocalFree((HLOCAL)lpBuffer);
    lpBuffer = NULL;
    cbBuffer = 0;
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

See Also

[HttpGetProgramExitCode](#), [HttpGetProgramText](#), [HttpRegisterProgram](#)

HttpGetProgramText Function

```
INT WINAPI HttpGetProgramText(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszBuffer,  
    INT nMaxLength  
);
```

Return a copy of the standard output from a CGI program in a string buffer.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszBuffer

A pointer to a buffer that will contain the output from the last program executed by the client as a string. If this parameter is NULL, the function will return the number of bytes of characters that was output by the program, not including a terminating null character.

nMaxLength

The maximum number of bytes that can be copied into the buffer. If the *lpszBuffer* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the specified string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **HttpGetProgramText** function is used to obtain a copy of the output generated by a CGI program. To determine the number of characters of output available to read, call this function with the *lpszBuffer* parameter as NULL and the *nMaxLength* parameter with a value of zero. The return value will be the number of characters that were output by the program. If the application dynamically allocates the string buffer, make sure that it allocates an extra character for the terminating null character.

This function will only return textual output from the program and any non-printable control characters and the escape character will be replaced with a space. To obtain the unfiltered output from the program, use the **HttpGetProgramOutput** function. If the program outputs a response header block, this will be included in the string buffer.

This function should only be used within an HTTP_CLIENT_EXECUTE event handler, which occurs after the program has terminated.

Example

```
LPTSTR lpszBuffer = NULL; // A pointer to the output buffer  
INT cchBuffer = 0;        // Number of bytes in the output buffer  
  
// Determine the number of bytes in the output buffer
```

```

cchBuffer = HttpGetProgramText(hServer, nClientId, NULL, 0);

if (cchBuffer > 0)
{
    // Allocate memory for the string buffer
    lpszBuffer = (LPTSTR)LocalAlloc(LPTR, (cchBuffer + 1) * sizeof(TCHAR));

    // Copy the program output to the buffer
    if (lpszBuffer != NULL)
        cchBuffer = HttpGetProgramText(hServer, nClientId, lpszBuffer, cchBuffer +
1);
}

// Free the memory allocated for the buffer when finished
if (lpszBuffer != NULL)
{
    LocalFree((HLOCAL)lpszBuffer);
    lpszBuffer = NULL;
    cchBuffer = 0;
}

```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetProgramExitCode](#), [HttpGetProgramOutput](#), [HttpRegisterProgram](#)

HttpGetServerAddress Function

```
INT WINAPI HttpGetServerAddress(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

Return the IP address of the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszAddress

A pointer to a string buffer that will contain the server IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

This function will return the IP address assigned to the specified server as a printable string. If the *nClientId* parameter has a value of zero, this function will return the IP address assigned to the local system. If the HTTP_SERVER_NATROUTER option was specified when the server was started, this function will return the external IP address assigned to the system. If the *nClientId* parameter specifies a valid client session, this function will return the IP address that the client used to establish the connection with the server. To determine the IP address assigned to the client, use the **HttpGetClientAddress** function.

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetClientAddress](#), [HttpGetServerName](#)

HttpGetServerDirectory Function

```
INT WINAPI HttpGetServerDirectory(  
    HSERVER hServer,  
    LPTSTR lpszDirectory,  
    INT nMaxLength  
);
```

Return the full path to the root directory assigned to the specified server.

Parameters

hServer

The server handle.

lpszDirectory

A pointer to a string buffer that will contain the server root directory, terminated with a null character. It is recommended that this buffer be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **HttpGetServerDirectory** function will return the full path to the root directory assigned to the server instance. The root directory may be specified as part of the server configuration, or if no directory is specified by the application, a temporary root directory will be created and this function can be used to obtain the full path to the directory. When the application specifies a root directory, it may use environment variables such as %AppData% in the path. This function will return the fully resolved path name, with all environment variables expanded.

There is no corresponding function to change the server root directory after the server has started. To change the root directory, you must stop the server using the **HttpServerStop** function and then start another instance of the server with a configuration that specifies the new directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetServerAddress](#), [HttpGetServerIdentity](#), [HttpGetServerName](#)

HttpGetServerError Function

```
DWORD WINAPI HttpGetServerError(  
    HSERVER hServer,  
    LPTSTR lpszError,  
    INT nMaxLength  
);
```

Return the last server error code and a description of the error.

Parameters

hServer

The server handle.

lpszError

A pointer to a string buffer that will contain a description of the error. If the error description is not needed, this parameter may be NULL.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the error string buffer, including the terminating null character. If the *lpszError* parameter is NULL, this value should be zero.

Return Value

An unsigned integer value that specifies the last error that occurred. A value of zero indicates that there was no error.

Remarks

Error codes are unsigned 32-bit values which are private to each server. You should call the **HttpGetServerError** function immediately when a function's return value indicates that an error has occurred. That is because some functions clear the last error code when they succeed.

If the *hServer* parameter is specified with a value of INVALID_SERVER, this function will return the last error that occurred for the current thread. This value should only be used when the function does not have access to a valid server handle, such as when the **HttpServerStart** function fails.

It is important to note that the error codes returned by this method are different than the command result codes that are defined in RFC 2616, the standard protocol specification for HTTP. This function is used to determine reason that an API function has failed, and should not be used to determine if a command issued by the client was successful. The **HttpSendResponse** function is used to send responses to the client, and the **HttpGetCommandResult** function can be used to determine the result of the last command sent by the client.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or HTTP_ERROR. Those functions which clear the last error code when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetCommandResult](#), [HttpSendResponse](#), [HttpSetServerError](#)

HttpGetServerIdentity Function

```
INT WINAPI HttpGetServerIdentity(  
    HSERVER hServer,  
    LPTSTR lpszIdentity,  
    INT nMaxLength  
);
```

Return the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A pointer to a string buffer that will contain the identity of the server when the function returns, terminated with a null character. This parameter cannot be NULL. It is recommended that this buffer be at least 32 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **HttpGetServerIdentity** function returns the identity string that was specified as part of the server configuration. It is used for informational purposes only and does not affect the operation of the server. Typically the string specifies the name of the application and a version number. The **HttpSetServerIdentity** function can be used to change the identity string associated with the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpSetServerIdentity](#)

HttpGetServerLogFile Function

```
BOOL WINAPI HttpGetServerLogFile(  
    HSERVER hServer,  
    UINT *lpnLogFormat,  
    UINT *lpnLogLevel,  
    LPTSTR lpszFileName,  
    INT nMaxLength  
);
```

Return the current log file format and the full path to the file.

Parameters

hServer

The server handle.

lpnLogFormat

A pointer to an integer value that will contain the log file format being used when the function returns. If this information is not needed, this parameter may be NULL. The following formats are supported:

Value	Description
HTTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
HTTP_LOGFILE_COMBINED	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

lpnLogLevel

A pointer to an integer value that will contain the level of detail the server uses when generating the log file. The minimum value is 1 and the maximum value is 10. If this information is not needed, this parameter may be NULL.

lpszFileName

A pointer to a string buffer that will contain the full path to the log file. This parameter may be NULL if this information is not required.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the file name string, including the terminating null character. If the *lpszFileName* parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the current log file format. Refer to the **HTTPSERVERCONFIG** structure definition for a list of supported log file formats. If the server handle is invalid or logging has not been enabled, this function will return a value of zero.

Remarks

If the server is configured with logging enabled, but a log file name is not explicitly provided, then the server will automatically generate one. This function can be used to get the full path to the current log file along with the format that is being used to record client session data. Normally the log file is held open by the server thread while it is active, however you can call the **HttpRenameServerLogFile** function to explicitly rename or delete the log file.

To change the name of the log file, the log file format or level of detail, use the **HttpSetServerLogFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpRenameServerLogFile](#), [HttpSetServerLogFile](#)

HttpGetServerMemoryUsage Function

```
BOOL WINAPI HttpGetServerMemoryUsage(  
    HSERVER hServer,  
    ULARGE_INTEGER *LpMemUsage  
);
```

Return the amount of memory allocated for the server and all client sessions.

Parameters

hServer

The server handle.

lpMemUsage

A pointer to a ULARGE_INTEGER variable which will specify how much memory has been allocated by the server. This parameter will be initialized to a value of zero by the function and updated with the total number of bytes allocated by the server and all active client sessions when it returns.

Return Value

If the function succeeds, the return value is non-zero and the memory usage value will be updated. If the server handle is invalid, or the server cannot be locked, the return value is zero. Call the **HttpGetServerError** function to determine the cause of the failure.

Remarks

This function returns the amount of memory allocated by the server and all active client sessions. It enumerates all of memory allocations made by the server process and client session threads and returns the total number of bytes allocated for the server process. This value reflects the amount of memory explicitly allocated by this library and does not reflect the total working set size of the process, or memory allocated by any other libraries. To determine the working set size for the process, refer to the Win32 **GetProcessWorkingSetSize** and **GetProcessMemoryInfo** functions.

This function forces the server into a locked state, and all client sessions will block until the function returns. Because this function enumerates all heaps allocated for the server process, it can be an expensive operation, particularly when there are a large number of active clients connected to the server. Frequent use of this function can significantly degrade the performance of the server. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by the function remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpGetServerStackSize](#), [HttpSetServerStackSize](#)

HttpGetServerName Function

```
INT WINAPI HttpGetServerName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

Return the host name assigned to the specified server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A pointer to a string buffer that will contain the server host name, terminated with a null character. It is recommended that this buffer be at least 64 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will return the host name assigned to the specified server. If the *nClientId* parameter has a value of zero, the function will return the default host name that was specified as part of the server configuration. If no host name was explicitly assigned to the server, then it will return the local system name. If the *nClientId* parameter specifies a client session, then it this function will return the host name that the client used to establish the connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetServerAddress](#)

HttpGetServerOptions Function

```
BOOL WINAPI HttpGetServerOptions(  
    HSERVER hServer,  
    LPDWORD lpdwOptions  
);
```

Return the configuration options for the specified server.

Parameters

hServer

The server handle.

lpdwOptions

A pointer to an unsigned integer that will contain the options that were specified when the server was started. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

This function will return the options that were specified when the server was started. For a list of server options see [Server Option Constants](#).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

[HttpServerStart](#)

HttpGetServerPriority Function

```
INT WINAPI HttpGetServerPriority(  
    HSERVER hServer  
);
```

Return the current priority assigned to the specified server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the priority for the specified server. If the function fails, the return value is HTTP_PRIORITY_INVALID. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpGetServerPriority** function can be used to determine the current priority assigned to the server. It will return one of the following values:

Value	Description
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
HTTP_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

HttpGetServerStackSize Function

```
DWORD WINAPI HttpGetServerStackSize(  
    SOCKET hServer  
);
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpGetServerStackSize** function returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

HttpGetServerTransferInfo Function

```
BOOL WINAPI HttpGetServerTransferInfo(  
    HSERVER hServer,  
    UINT nClientId,  
    LPHTTPSERVERTRANSFER lpTransferInfo  
);
```

Return information about the current file transfer.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpTransferInfo

A pointer to an **HTTPSERVERTRANSFER** structure that will contain information about the last file transfer. This parameter cannot be NULL, and the *dwSize* member of the structure must be initialized to specify the structure size prior to calling this function.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetServerTransferInfo** function is used to obtain information about the last file transfer that was performed by the server for the specified client. This function is typically called within an event handler to determine how many bytes of data were transferred, the type of file and the full path to the file on the local system.

This function will only return information about a file transfer using the GET or PUT commands, with any other command causing this function to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetServerUuid Function

```
INT WINAPI HttpGetServerUuid(  
    HSERVER hServer,  
    UUID *lpUuid  
);
```

Return the UUID assigned to the specified server.

Parameters

hServer

The server handle.

lpUuid

A pointer to a UUID structure that will contain the server UUID when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle is invalid or the pointer to the UUID structure is NULL, the function will return a value of zero.

Remarks

The **HttpGetServerUuid** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain a printable string version of the UUID, use the **HttpGetServerUuidString** function.

There is no corresponding function to change the UUID assigned to an active server. The server UUID is assigned when the server is started, and it must be a unique value that is maintained throughout the lifetime of the server. To change the UUID associated with the server, the server must be stopped using the **HttpServerStop** function and another instance of the server started with the new UUID.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

HttpGetServerUuidString Function

```
INT WINAPI HttpGetServerUuidString(  
    HSERVER hServer,  
    LPTSTR lpszHostUuid,  
    INT nMaxLength  
);
```

Return the UUID assigned to the server as a printable string.

Parameters

hServer

The server handle.

lpszHostUuid

A pointer to a string buffer that will contain the server UUID, terminated with a null character. It is recommended that this buffer be at least 40 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the buffer is not large enough to store the complete UUID string, the function will return a value of zero.

Remarks

The **HttpGetServerUuidString** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain the numeric UUID value, use the **HttpGetServerUuid** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetVirtualHostId Function

```
UINT WINAPI HttpGetVirtualHostId(  
    HSERVER hServer,  
    LPCTSTR lpszHostName,  
    UINT nHostPort  
);
```

Return the virtual host ID associated with the specified hostname.

Parameters

hServer

The server handle.

lpszHostName

A string that specifies the virtual host name.

nHostPort

An integer value which specifies the port number for the virtual host. This value must be zero or the same value as the original port number that the server was configured to use.

Return Value

If the function succeeds, the return value is the host ID that uniquely identifies the virtual host. If the server handle is invalid, or there is no virtual host with the specified name, the function will return `VIRTUAL_HOST_UNKNOWN`. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpGetVirtualHostId** function is used to obtain the unique virtual host ID that is associated with a specific hostname. This function will match both the primary virtual hostname added using the **HttpAddVirtualHost** function, as well as any aliases that were added using the **HttpAddVirtualHostAlias** function. To obtain the virtual host ID associated with the active client session, use the **HttpGetClientVirtualHostId** function.

The *nHostPort* parameter should always be specified with a value of zero, or the same port number that the server was configured to use. Port-based virtual hosting is currently not supported and this parameter is included for future use.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `cshtsv11.lib`

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpAddVirtualHost](#), [HttpAddVirtualHostAlias](#), [HttpDeleteVirtualHost](#), [HttpGetClientVirtualHostId](#), [HttpGetVirtualHostName](#)

HttpGetVirtualHostName Function

```
INT WINAPI HttpGetVirtualHostName(  
    HSERVER hServer,  
    UINT nHostId,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

Return the hostname associated with the specified virtual host ID.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszHostName

A pointer to a string buffer that will contain the virtual host name, terminated with a null character. It is recommended that this buffer be at least 64 characters in length. If this parameter is NULL, the function will return the length of the virtual hostname.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. If the *lpszHostName* parameter is NULL this value must be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the host ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

The **HttpGetVirtualHostName** function returns the primary hostname associated with the specified virtual host ID. This is the same hostname that was specified when the virtual host was added to the server configuration using the **HttpAddVirtualHost** function. To obtain the hostname that was used by the active client session to connect to the server, use the **HttpGetClientVirtualHost** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpIsClientAuthenticated Function

```
BOOL WINAPI HttpIsClientAuthenticated(  
    HSERVER hServer,  
    UINT nClientId  
);
```

Determine if the specified client session has been authenticated.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the client session has been authenticated, this function will return a non-zero value, otherwise it will return zero. If the server handle and client ID are valid, this function will clear the last error code.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

HttpIsCommandEnabled Function

```
BOOL WINAPI HttpIsCommandEnabled(  
    HSERVER hServer,  
    LPCTSTR LpszCommand  
);
```

Determine if a specific server command has been enabled or disabled.

Parameters

hServer

The server handle.

lpszCommand

A pointer to a NULL terminated string that specifies the name of the command. The command name is not case-sensitive, but the value must otherwise match the exact command name. Partial matches are not recognized by this function. This parameter cannot be NULL.

Return Value

If the command is enabled, this function will return a non-zero value. If the command is disabled, the server handle is invalid or the command name does not match a supported command, this function will return zero.

Remarks

The **HttpIsCommandEnabled** function is used to determine whether a specific command is enabled. Typically this function is used in an event handler to make sure the command issued by a client is recognized by the server and enabled for use. Commands can be enabled and disabled using the **HttpEnableCommand** function.

This function does not account for the permissions granted to a specific client session. Clients are assigned access rights when they are authenticated using the **HttpAuthenticateClient** function, and certain commands can be limited by the permissions granted to the client. For example, even if the PUT command is enabled, a client must have the HTTP_ACCESS_WRITE permission to use the command to upload a file to the server. For a list of access rights, see [User Access Constants](#).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpAuthenticateClient](#), [HttpEnableCommand](#), [HttpGetCommandName](#)

HttpReceiveRequest Function

```
BOOL WINAPI HttpReceiveRequest(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwOptions,  
    LPHTTPREQUEST LpRequest,  
    LPVOID lpvBuffer,  
    LPDWORD lpdwLength  
);
```

Receive the request that was sent by the client to the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwOptions

An unsigned integer which specifies how the client request data will be stored. It may be one of the following values:

Value	Description
HTTP_REQUEST_DEFAULT	If the <i>lpdwLength</i> parameter points to a integer with a non-zero value, the <i>lpvBuffer</i> parameter is considered to be a pointer to a block of memory that has been allocated to store the request data. This is the same as specifying the HTTP_REQUEST_MEMORY option. If the <i>lpdwLength</i> parameter points to an integer with a value of zero, the <i>lpvBuffer</i> parameter is considered to be a pointer to an HGLOBAL memory handle. This is the same as specifying the HTTP_REQUEST_HGLOBAL option.
HTTP_REQUEST_MEMORY	The <i>lpvBuffer</i> parameter is a pointer to a block of memory that has been allocated to store the request data. The maximum number of bytes of data that can stored is determined by the value of the integer that the <i>lpdwLength</i> parameter points to. When the function returns, that value will updated with with actual number of bytes copied into the buffer.
HTTP_REQUEST_STRING	The <i>lpvBuffer</i> parameter is a pointer to a string buffer that has been allocated to store the request data. The maximum number of bytes of data that can be copied is determined by the value of the integer that the <i>lpdwLength</i> parameter points to. When the function returns, that value will updated with with actual number of bytes copied into the buffer. If the Unicode version of this function is called, the request data will be converted to a null-terminated Unicode string.
HTTP_REQUEST_HGLOBAL	The <i>lpvBuffer</i> parameter is a pointer to an HGLOBAL memory

	handle. When the function returns, the handle will reference a block of memory that contains the request data submitted by the client. The <i>lpdwLength</i> parameter will contain the number of bytes copied to the buffer.
HTTP_REQUEST_FILE	The <i>lpvBuffer</i> parameter is a pointer to a string which specifies the name of a file that will contain the request data. If the file does not exist, it will be created. If it does exist, the contents will be replaced. This option is typically used in conjunction with the PUT command. If the <i>lpdwLength</i> parameter is not NULL, the value it points to will be updated with the actual number of bytes stored in the file.
HTTP_REQUEST_HANDLE	The <i>lpvBuffer</i> parameter is a handle to an open file. This option is typically used in conjunction with the POST or PUT commands. If the <i>lpdwLength</i> parameter is not NULL, the value it points to will be updated with the actual number of bytes written to the file. If this option is specified, the request data will be written from the current position in the file and will advance the file pointer by the number of bytes received from the client.

lpRequest

A pointer to a **HTTPREQUEST** structure which contains information about the request from the client. This parameter cannot be NULL. The structure that is passed to this function must have all members set to a value of zero except the *dwSize* member, which must be initialized to the size of the structure.

lpvBuffer

A pointer to the buffer that will contain any request data that was submitted by the client. The *dwOptions* parameter determines if this pointer references a block of memory, a null-terminated string buffer, a global memory handle or a file name. If this parameter is NULL, any data submitted by the client will not be copied.

lpdwLength

A pointer to an unsigned integer that will contain the number of bytes of data submitted by the client when the function returns. If the *lpvBuffer* parameter specifies a memory or string buffer, this value must be initialized to the maximum size of the buffer before the function is called. If the *lpvBuffer* parameter points to a global memory handle, this value must be initialized to zero. If *lpvBuffer* is NULL or specifies a file name, this parameter may be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpReceiveRequest** function is called within a HTTP_CLIENT_COMMAND event handler to process the command issued by the client and return information about the request to the server application. It is only necessary for the application to call this function if it wants to implement its own custom handling for a command. It is recommended that most applications use the default command processing for standard commands such as GET and POST to ensure that the appropriate security checks are performed and the response conforms to the protocol standard.

This function may only be called once per command issued by the client and the data referenced in the **HTTPREQUEST** structure only remains valid while the client is connected to the server. You should never attempt to directly modify the data referenced by any of the structure members. If you wish to store or modify any of the string values returned in the structure, you should allocate a buffer large enough to store the contents of the string, including the terminating null character, and copy the string into that buffer.

If the HTTP_REQUEST_HGLOBAL option is used to return a copy of the request data in a global memory buffer, the HGLOBAL handle must be freed by the application when the data is no longer needed. Failure to free this handle will result in a memory leak.

If the HTTP_REQUEST_HANDLE option is used to write a copy of the request data to an open file, the handle must reference a disk file that was opened or created using the **CreateFile** function with GENERIC_WRITE access. It cannot be a handle to a device or named pipe. If the function succeeds, the file pointer is advanced by the number of bytes of request data submitted by the client. If the function fails, the file pointer is returned to its original position prior to the function being called.

Example

```
// Initialize the HTTPREQUEST structure
HTTPREQUEST httpRequest;
ZeroMemory(&httpRequest, sizeof(httpRequest));
httpRequest.dwSize = sizeof(httpRequest);

// Return the data in a global memory buffer
HGLOBAL hglbBuffer = NULL;
DWORD dwLength = 0;

bSuccess = HttpReceiveRequest(hServer,
                             nClientId,
                             HTTP_REQUEST_HGLOBAL,
                             &httpRequest,
                             &hglbBuffer,
                             &dwLength);

if (bSuccess && hglbBuffer != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hglbBuffer);

    if (lpBuffer != NULL)
    {
        // Process dwLength bytes of data submitted by the client
    }

    GlobalUnlock(hglbBuffer);
    GlobalFree(hglbBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpSendResponse](#), [HTTPREQUEST](#)

HttpRedirectRequest Function

```
BOOL WINAPI HttpRedirectRequest(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nMethod,  
    LPCTSTR lpszLocation  
);
```

Redirect the request from the client to another URL.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nMethod

An integer value that specifies if the redirection is permanent or temporary. The following values may be used:

Value	Description
HTTP_REDIRECT_PERMANENT	This value is used for permanent redirection, indicating that the client should update any record of the link with the new URL specified by the <i>lpszLocation</i> parameter. This result is cacheable and when the client makes subsequent requests for the resource, it should always use the new URL.
HTTP_REDIRECT_TEMPORARY	This value is used for temporary redirection, indicating that the client should issue a request for the resource using the new URL specified by the <i>lpszLocation</i> parameter, but subsequent requests should continue to use the original URL.
HTTP_REDIRECT_OTHER	This value is used for temporary redirection, however it instructs the client that it should use the GET command to request the redirected resource. This option is typically used to redirect a client after it has used the POST command.

lpszLocation

A pointer to a string that specifies the new location for the requested resource. This value must be a complete URL, including the http:// or https:// scheme. This parameter cannot be NULL or point to zero-length string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRedirectRequest** function can be used within a HTTP_CLIENT_COMMAND event handler to

redirect the client to a new location for the resource that it has requested. This redirection can be permanent or temporary, depending on whether the server expects the client to continue to use the original URL when requesting the resource.

If the HTTP_REDIRECT_TEMPORARY method is used, the actual status code that is returned to the client depends on the version of the protocol that is being used. If the client has issued the request using HTTP 1.0 then the server will return a 302 code to the client. If the client used HTTP 1.1, the server will return a 307 code to the client that indicates it should use the same command verb (GET, POST, etc.) when requesting the resource at the new location.

If the HTTP_REDIRECT_OTHER method is used, the status code that is returned to the client depends on which version of the protocol is being used. For clients who are using HTTP 1.0, the server will return a 302 code to the client just as with the HTTP_REDIRECT_TEMPORARY method. If the client is using HTTP 1.1, the server will return a 303 code to the client that indicates it should always use the GET command to request the new resource, regardless if a different command was originally used (POST, PUT, etc.)

This function provides a simplified interface for sending a redirection status code that also implicitly sets the Location response header to the value of the *lpzLocation* parameter. If the server application needs to send alternate redirection codes such as 305 (Use Proxy) then it should use the **HttpSendReponse** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpRequireAuthentication](#), [HttpSendErrorResponse](#), [HttpSendResponse](#)

HttpRegisterHandler Function

```
BOOL WINAPI HttpRegisterHandler(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszExtension,  
    LPCTSTR lpszProgramFile,  
    LPCTSTR lpszParameters,  
    LPCTSTR lpszDirectory  
);
```

Register a CGI program for use and associate it with a file name extension.

Parameters

hServer

The server handle.

nHostId

An unsigned integer that identifies the virtual host associated with the program. The value `VIRTUAL_HOST_DEFAULT` should be used for the default host that is created when the server is first started.

lpszExtension

A pointer to a string which specifies the file name extension that is associated with the CGI program. This parameter cannot be NULL.

lpszProgramFile

A pointer to a string that specifies the full path to the executable program. This parameter cannot be NULL.

lpszParameters

A pointer to a string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the program does not require any command line parameters, this value may be NULL or point to an empty string.

lpszDirectory

A pointer to a string that specifies the current working directory for the program. If this parameter is NULL or points to an empty string, the server will use the root document directory for the virtual host.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRegisterHandler** function registers an executable CGI program and associates it with a file name extension. When the client issues a GET or POST command that specifies a file with that extension, the program will be executed and the output return to the client.

The *lpszProgramFile* string specifies file name of the CGI program. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple file name extensions that reference the same program. The only requirement is that the extension be unique for the given host. The program name may contain environment variables surrounded by % symbols. For example,

%ProgramFiles% would be expanded to the **C:\Program Files** folder.

It is important to note that the program specified by *lpzProgramFile* must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The *lpzParameters* string can specify additional command line parameters that should be passed to the CGI program as arguments. This string can also contain a placeholder named "%1" that will be replaced by the full path to the local script filename. If no placeholder is included in the parameters, or *lpzParameters* is a NULL pointer, the script file name will be passed to the program as its only argument.

The executable program that is registered using this program must be a console application that conforms to the CGI/1.1 specification defined in RFC 3875. Request data submitted by the client as part of a POST will be provided to the program as standard input. The output from the program must be written to standard output. The first lines of output from the program should be any response headers, followed by an empty line. Each line should be terminated with a carriage-return and linefeed (CRLF) sequence. If the CGI program outputs additional data to be processed by the client, it should provide Content-Type and Content-Length response headers.

The application can obtain a copy of the output from the command by calling the **HttpGetProgramOutput** function from within a HTTP_CLIENT_EXECUTE event handler.

When developing a CGI program, it is important to take into consideration the environment that it will be executing in. The program will be started as a child process of the server application, and will inherit the same privileges. This means that it will typically have access to the boot drive, the Windows folders and the system registry. CGI programs must ensure that all query parameters and request data submitted by the client have been validated.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

Example

```
// Register a handler for VBScript
HttpRegisterHandler(hServer,
    VIRTUAL_HOST_DEFAULT,
    _T("vbs"),
    _T("%SystemRoot%\System32\cscript.exe"),
    _T("/nologo /b \"%1\""),
    NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpRegisterProgram Function

```
BOOL WINAPI HttpRegisterProgram(  
    HSERVER hServer,  
    UINT nHostId,  
    LPCTSTR lpszVirtualPath,  
    LPCTSTR lpszProgramFile,  
    LPCTSTR lpszParameters,  
    LPCTSTR lpszDirectory  
);
```

Register a CGI program for use and associate it with a virtual path on the server.

Parameters

hServer

The server handle.

nHostId

An unsigned integer that identifies the virtual host associated with the program. The value `VIRTUAL_HOST_DEFAULT` should be used for the default host that is created when the server is first started.

lpszVirtualPath

A pointer to a string which specifies the virtual path to the CGI program. This must be an absolute path, but does not have to specify a pre-existing virtual path or map to the directory structure of the root document directory for the server. This parameter cannot be NULL. The maximum length of the virtual path is 1024 characters.

lpszProgramFile

A pointer to a string that specifies the full path to the executable program. This parameter cannot be NULL.

lpszParameters

A pointer to a string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the program does not require any command line parameters, this value may be NULL or point to an empty string.

lpszDirectory

A pointer to a string that specifies the current working directory for the program. If this parameter is NULL or points to an empty string, the server will use the root document directory for the virtual host.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRegisterProgram** function registers an executable CGI program and associates it with a virtual path. When the client issues a GET or POST command specifying the virtual path associated with the program, the program will be executed and the output return to the client.

The *lpszProgramFile* string specifies file name of the CGI program. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple virtual paths that

reference the same executable file. The only requirement is that the virtual path be unique for the given host. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the **C:\Program Files** folder.

It is important to note that the program specified by *lpzProgramFile* must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The *lpzParameters* string can specify additional command line parameters that should be passed to the CGI program as arguments. This string can also contain a placeholder named "%1" that will be replaced by the virtual path associated with the program. If *lpzParameters* is NULL or a zero-length string, then no additional parameters are passed to the program.

The executable program that is registered using this program must be a console application that conforms to the CGI/1.1 specification defined in RFC 3875. Request data submitted by the client as part of a POST will be provided to the program as standard input. The output from the program must be written to standard output. The first lines of output from the program should be any response headers, followed by an empty line. Each line should be terminated with a carriage-return and linefeed (CRLF) sequence. If the CGI program outputs additional data to be processed by the client, it should provide Content-Type and Content-Length response headers.

The application can obtain a copy of the output from the command by calling the **HttpGetProgramOutput** function from within a HTTP_CLIENT_EXECUTE event handler.

When developing a CGI program, it is important to take into consideration the environment that it will be executing in. The program will be started as a child process of the server application, and will inherit the same privileges. This means that it will typically have access to the boot drive, the Windows folders and the system registry. CGI programs must ensure that all query parameters and request data submitted by the client have been validated.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

Example

```
HttpRegisterProgram(hServer,
    VIRTUAL_HOST_DEFAULT,
    HTTP_METHOD_DEFAULT,
    _T("/order/invoice"),
    _T("%ProgramData%\MyServer\Programs\invoice.exe"),
    NULL,
    NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetProgramExitCode](#), [HttpGetProgramOutput](#), [HttpRegisterHandler](#)

HttpRenameServerLogFile Function

```
BOOL WINAPI HttpRenameServerLogFile(  
    HSERVER hServer,  
    LPCTSTR lpszFileName  
);
```

Rename or delete the current log file being updated by the server.

Parameters

hServer

The server handle.

lpszFileName

A pointer to a string that specifies the file name the current log file should be renamed to. If this parameter is NULL or an empty string, the current log file will be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero. If logging is not currently enabled for the server, this function will return zero.

Remarks

The **HttpRenameServerLogFile** function is used to rename or delete the current log file. Note that this does not change the current log file name or disable logging by the server. It only changes the file name of the current log file, or removes the log file if the *lpszFileName* parameter is NULL. This can be useful if you want your server to perform log file rotation, archiving the current log file. By renaming the current log file, the server will automatically create a new log file with original file name.

This function must be used to rename or delete the current log file while logging is active because the server holds an open handle on the file. The application should not use the **HttpGetServerLogFile** function to obtain the log file name and then use the **MoveFileEx** or **DeleteFile** functions with that file.

To disable logging, use the **HttpSetServerLogFile** function and specify the logging format as HTTP_LOGFILE_NONE.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetServerLogFile](#), [HttpSetServerLogFile](#)

HttpRequireAuthentication Function

```
BOOL WINAPI HttpRequireAuthentication(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nAuthType,  
    LPCTSTR lpszRealm  
);
```

Send a response to the client indicating that authentication is required.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nAuthType

An integer value that corresponds to a result code, informing the client if the redirection is permanent or temporary. The following values may be used:

Value	Description
HTTP_AUTH_BASIC	This option specifies the Basic authentication scheme should be used. This option is supported by all clients that support at least version 1.0 of the protocol.

lpszRealm

A pointer to a string that is displayed by a web browser to indicate to the user which username and password they should use. If this parameter is NULL or an empty string, the domain name the client used to establish the connection will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRequireAuthentication** function can be used within a HTTP_CLIENT_COMMAND event handler to indicate to the client that it must provide a username and password to access the requested resource. The client should respond by issuing another request that includes the required credentials. To determine if a client has included credentials with its request, use the **HttpIsClientAuthenticated** function. The **HttpGetClientCredentials** function will return the username and password that was provided by the client.

Some clients may require that the session be secure if authentication is requested or display warning messages to the user if the connection is not secure. It is recommended that you enable security using the HTTP_OPTION_SECURE option if your application will require clients to authenticate before accessing specific resources.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpGetClientCredentials](#), [HttpIsClientAuthenticated](#), [HttpSendResponse](#)

HttpSendErrorResponse Function

```
BOOL WINAPI HttpSendErrorResponse(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nErrorCode,  
    LPCTSTR lpszMessage  
);
```

Send a customized error response to the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nErrorCode

An integer value that specifies the error code that should be sent to the client. This value should correspond to the error result codes defined for HTTP in RFC 2616, which are three-digit values in the range of 400 through 599. The function will fail if an invalid error code is specified.

lpszMessage

A pointer to a string that describes the error. If this parameter is NULL or specifies a zero-length string, a default message will be selected based on the error code.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSendErrorResponse** function sends a response to the client indicating that an error has occurred, providing a numeric error code and HTML formatted text which may be displayed to the user. The *lpszMessage* parameter should provide a brief description of the error that will be included in the output sent to the client. Note that the message should not contain any special formatting control characters or HTML markup.

This function provides a simplified interface for sending an error response to the client. In some cases, a browser may choose to display its own error message to the user in place of the generic HTML document generated by this function. If you want your application to send a customized HTML document for a specific type of error, you should use the **HttpSendResponse** function.

If you wish to redirect the client to use an alternate URL to access the requested resource, it is recommended that you use the **HttpRedirectRequest** function rather than sending an error response.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpRedirectRequest](#), [HttpSendResponse](#)

HttpSendResponse Function

```
BOOL WINAPI HttpSendResponse(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwOptions,  
    LPHTTPRESPONSE LpResponse,  
    LPVOID lpvBuffer,  
    DWORD dwLength  
);
```

Send a response from the server to the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwOptions

An unsigned integer which specifies how the client request data will be copied. It may be one of the following values:

Value	Description
HTTP_RESPONSE_DEFAULT	The <i>lpvBuffer</i> parameter is a pointer to a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the <i>dwLength</i> parameter. This is the same as specifying the HTTP_RESPONSE_MEMORY option.
HTTP_RESPONSE_MEMORY	The <i>lpvBuffer</i> parameter is a pointer to a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the <i>dwLength</i> parameter. The data will be sent to the client as a stream of bytes. If the server application was compiled using Unicode, it is responsibility of the application to convert any Unicode text to either ANSI or UTF-8, depending on the resource that was requested by the client.
HTTP_RESPONSE_STRING	The <i>lpvBuffer</i> parameter is a pointer to a string buffer that contains the response data. The maximum number of bytes of data that will be sent to the client is determined by the <i>dwLength</i> parameter. If the value of the <i>dwLength</i> parameter exceeds the string length, the value will be ignored and the contents of the string will be sent up to the terminating null character. If the Unicode version of this function is called, the string will be converted to a byte array before being sent to the client.
HTTP_RESPONSE_HGLOBAL	The <i>lpvBuffer</i> parameter is an HGLOBAL memory handle which references a block of memory that contains the response data. The number of bytes of data that in the

	buffer is specified by the <i>dwLength</i> parameter. The data will be sent to the client as a stream of bytes. It is the responsibility of the application to free the global memory handle after it is no longer needed.
HTTP_RESPONSE_FILE	The <i>lpvBuffer</i> parameter is a pointer to a string which specifies the name of a file that contains the response data. If the file does not exist, or does not specify a regular file, this function will fail. The <i>dwLength</i> parameter is ignored. If the content type for the specified file is not explicitly defined in the response, the function will attempt to automatically determine the correct type based on the file name extension and/or the contents of the file.
HTTP_RESPONSE_HANDLE	The <i>lpvBuffer</i> parameter is a handle to an open file and the <i>dwLength</i> parameter specifies the number of bytes to be read from the file and send to the client. If this option is specified, the response data will be read from the current position in the file and will advance the file pointer by the number of bytes sent to the client.
HTTP_RESPONSE_DYNAMIC	The response data will be generated dynamically. This prevents the content length from being included in the response header, and forces the connection to close, regardless if the client has requested to keep the connection open. This option must be specified if the application wishes to use the HttpSendResponseData function to send additional data to the client.
HTTP_RESPONSE_NOCACHE	Informs the client that the data being returned by the server should not be cached. Typically this is used in conjunction with the HTTP_RESPONSE_DYNAMIC option when the data is being generated dynamically.

lpResponse

A pointer to a **HTTPRESPONSE** structure which contains additional information about the response to the client. The structure that is passed by reference to this function must have the ***dwSize*** member initialized to the size of the structure or the function will fail. This parameter may be NULL, in which case a default response of "200 OK" is sent to the client along with any data specified by the ***lpvBuffer*** parameter.

lpvBuffer

A pointer to the buffer that will contain any response data that should be sent to the client. The ***dwOptions*** parameter determines if this pointer references a block of memory, a null-terminated string buffer, a global memory handle or a file name. This parameter may be NULL, in which case no data will be sent to the client. If this function is called in response to a HEAD command being sent by the client, this parameter is ignored.

dwLength

An unsigned integer that specifies the number of bytes of data to be sent to the client. If the ***lpvBuffer*** parameter is NULL, this value must be zero. If this function is called in response to a HEAD command being sent by the client, this parameter is ignored.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSendResponse** function is called within a HTTP_CLIENT_COMMAND event handler to respond to the request made by the client. This function may only be called once after a command has been received, and must be called after the **HttpReceiveRequest** function. It is only necessary for the application to call this function if it wants to implement its own custom handling for a command. It is recommended that most applications use the default command processing for standard commands such as GET and POST to ensure that the appropriate security checks are performed and the response conforms to the protocol standard.

If the HTTP_RESPONSE_HANDLE option is used to read a copy of the response data from an open file, the handle must reference a disk file that was opened using the **CreateFile** function with GENERIC_READ access. It cannot be a handle to a device or named pipe. If the *dwLength* parameter is larger than the total number of bytes available to be read from the current position in the file, the function will stop sending data to the client when it reaches the end-of-file. If the function succeeds, the file pointer is advanced by the number of bytes of response data sent to the the client. If the function fails, the file pointer is returned to its original position prior to the function being called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpSendResponseData Function

```
INT WINAPI HttpSendResponseData(  
    HSERVER hServer,  
    UINT nClientId,  
    LPBYTE lpBuffer,  
    DWORD dwLength,  
    LPDWORD lpdwResponse  
);
```

Send additional data to the client in response to a command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A pointer to a buffer that contains the response data that should be sent to the client. This parameter cannot be NULL and must point to a valid byte buffer. If the response contains non-ASCII text characters, it should be UTF-8 encoded.

dwLength

An unsigned integer that specifies the size of the response data sent to the client. This value must be greater than zero and should never exceed the number of bytes stored in the buffer specified by the *lpBuffer* parameter.

lpdwResponse

A pointer to an unsigned integer which will contain the total number of bytes successfully sent to the client in response to the request. This parameter may be NULL, in which case it is ignored.

Return Value

If the function succeeds, the return value is the number of bytes of data sent to the client. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSendResponseData** function is called within a HTTP_CLIENT_COMMAND event handler to send data to the client in response to a request. This function can only be used to send dynamically generated content after the **HttpSendResponse** function has been called. The HTTP_RESPONSE_DYNAMIC option must have been specified when responding to the client or this function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

[HttpRecieveRequest](#), [HttpSendResponse](#), [HTTPRESPONSE](#)

HttpServerAsyncNotify Function

```
BOOL WINAPI HttpServerAsyncNotify(  
    HSERVER hServer,  
    HWND hWnd,  
    UINT uMsg  
);
```

Enable or disable asynchronous notification of changes in server status.

Parameters

- hServer**
The server handle.
- hWnd**
A handle to the window whose window procedure will receive the notification message.
- uMsg**
The user-defined message that will be sent to the notification window.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **HttpGetServerError** function.

Remarks

The **HttpServerAsyncNotify** function is used by an application to enable or disable asynchronous notifications. The message window is typically the main UI window and these notifications are used signal to the application that it should update the user interface. If the **hWnd** parameter is not NULL, it must specify a valid window handle and the user-defined message must have a value of **WM_USER** or higher. The application cannot specify a notification message that is reserved by the operating system. The pseudo-handle **HWND_BROADCAST** cannot be specified as the notification window. If the **hWnd** parameter is NULL, notifications for the specified server will be disabled.

When asynchronous notifications are enabled for a server, the server will post the user-defined message to the window whenever there is a change in status or after a client has connected or disconnected from the server. The **wParam** message parameter will contain the notification message and the **lParam** message parameter will contain the handle to the server or the client ID. The following notification messages are defined:

Value	Description
HTTP_NOTIFY_STARTUP	This notification is sent when the server has started and is preparing to accept client connections. This notification is only sent once, and only if asynchronous notifications are enabled immediately after the HttpServerStart function is called. This message will not be sent once the server has begun accepting client connections or when notification messages are disabled and then subsequently re-enabled at a later time. The lParam message parameter will specify the handle to the server.
HTTP_NOTIFY_LISTEN	This notification is sent when the server is listening for client connections. This notification message may be sent to the application multiple times over the lifetime of the server. If

	the server was suspended, this notification will be sent after the application calls the HttpServerResume function to resume accepting client connections. The <i>lParam</i> message parameter will specify the handle to the server.
HTTP_NOTIFY_SUSPEND	This notification is sent when the server suspends accepting new connections because the application has called the HttpServerSuspend function. This notification message may be sent to the application multiple times over the lifetime of the server. The <i>lParam</i> message parameter will specify the handle to the server.
HTTP_NOTIFY_RESTART	This notification is sent when the server is restarted using the HttpServerRestart function. Note that the server socket handle provided by the <i>lParam</i> message parameter will specify the new socket handle of the restarted server instance, not the original socket handle. The <i>lParam</i> message parameter will specify the handle to the server.
HTTP_NOTIFY_CONNECT	This notification is sent when the server accepts a client connection and the thread that manages the client session has begun processing network events for that client. This message notification will not be sent if the client connection is rejected by the server. The <i>lParam</i> message parameter will specify the unique ID of the client that connected to the server.
HTTP_NOTIFY_DISCONNECT	This notification is sent when the client disconnects from the server and the client socket has been closed. This notification message may not occur for each client session that is forced to terminate as the result of the server being stopped using the HttpServerStop function. The <i>lParam</i> message parameter will specify the unique ID of the client that disconnected from the server.
HTTP_NOTIFY_SHUTDOWN	This notification is sent when the server thread is in the process of terminating. At the time the application processes this notification message, the server handle in <i>lParam</i> will reference the defunct server and cannot be used with other server functions. The <i>lParam</i> message parameter will specify the handle to the server.

If asynchronous notifications are enabled, you should never use those notifications as a replacement for an event handler. When an event occurs, the callback function that handles the event is invoked in the context of the thread that manages the client session. The application should exchange data with the client within that event handler and not in response to a notification message. These notification messages should only be used to update the application UI in response to changes in the status of the server.

The HTTP_NOTIFY_CONNECT and HTTP_NOTIFY_DISCONNECT notifications are different from the other server notifications because the *lParam* message parameter does not specify the server handle, but rather the unique client ID associated with the session that connected to or disconnected from the server. Use the **HttpGetClientServer** function to obtain a handle to the server that created the client session. Note that at the time the application processes the HTTP_NOTIFY_DISCONNECT notification

message, the client session will have already terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

HttpServerDisableTrace Function

BOOL WINAPI HttpServerDisableTrace();

Disable the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpServerEnableTrace](#)

HttpServerEnableTrace Function

```
BOOL WINAPI HttpServerEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

Enable the logging of network function calls to a file.

Parameters

lpszTraceFile

A pointer to a string that specifies the name of the log file. If this parameter is NULL or points to an empty string, a log file is created in the temporary directory for the current user.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_DEFAULT	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail, or return values which indicate a warning, are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call [HttpGetServerError](#).

Remarks

When trace logging is enabled, the log file is opened, appended to and closed for each socket function call. Using the same file name, you can do the same in your application to add additional information to the file if needed. This can provide an application-level context for the entries made by the library. Make sure that the file is closed after the data has been written. If a file name is not specified by the caller, a file named **cstrace.log** will be created in the temporary directory for the current user.

The TRACE_HEXDUMP option can produce very large files, since all data that is being sent and received by the application is logged. To reduce the size of the file, you can enable and disable logging around limited sections of code that you wish to analyze.

To redistribute an application that includes this debug logging functionality, the **cstrcv11.dll** library must be included as part of the installation package. This library provides the trace logging features, and if it is not available the **HttpServerEnableTrace** function will fail. Note that this is a standard Windows DLL and does not need to be registered, it only needs to be redistributed with your application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpServerDisableTrace](#)

HttpServerInitialize Function

```
BOOL WINAPI HttpServerInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **HttpServerInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**. All other functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **HttpServerInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **HttpServerUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **HttpServerInitialize** or **HttpServerUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpServerStart](#), [HttpServerStop](#), [HttpServerUninitialize](#), [INITDATA](#)

HttpServerProc Function

```
VOID CALLBACK HttpServerProc(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **HttpServerProc** function is an application-defined callback function that processes events generated by the server process.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client that has issued a request to the server.

nEventId

An unsigned integer which specifies which event occurred. For a list of events, see [Server Event Constants](#).

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero. The **HttpGetServerError** function can be used to obtain additional information about the error code.

dwParam

A user-defined integer value which was specified when the server was started. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

Return Value

None.

Remarks

The HTTP_CLIENT_COMMAND event can be used to filter commands issued by the client. If the command performs an operation on a file or directory, the **HttpGetCommandFile** function can be used to obtain the file name on the server that the client specified. It is possible for the application to change the file name using the **HttpSetCommandFile** function to direct the server to use a different file than the one specified by the client. If the file name is changed and the event handler returns a value of zero, the server will perform the default action for the command using the new file name.

The callback function will be called in the context of the thread that is currently managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within an event handler. Controls should only be modified by the same UI thread that created their window. To change the user interface in response to a server event, use the **HttpServerAsyncNotify** function to enable asynchronous notifications and update the UI in response

to the notification message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: cshtsv11.lib

See Also

[HttpServerAsyncNotify](#), [HttpServerStart](#)

HttpServerRestart Function

```
HSERVER WINAPI HttpServerRestart(  
    HSERVER hServer  
);
```

Restart the server, terminating all active client sessions.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the new handle for the specified server. If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerRestart** function will restart the specified server, terminating all active client sessions. The server handle that is returned by the function is the handle for the new server instance, and the old handle value is no longer valid. If the function is unable to restart the server for any reason, the server thread is terminated. The server retains all of the configuration parameters from the previous instance, however the statistical information (such as the number of clients, files transferred, etc.) will be reset.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **HttpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `cshtsv11.lib`

See Also

[HttpServerStart](#), [HttpServerStop](#)

HttpServerResume Function

```
BOOL WINAPI HttpServerResume(  
    HSERVER hServer  
);
```

Resume accepting client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerResume** function instructs the server to resume accepting new client connections after the **HttpServerSuspend** function has been called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpServerRestart](#), [HttpServerStart](#), [HttpServerStop](#), [HttpServerSuspend](#), [HttpServerThrottle](#)

HttpServerStart Function

```
HSERVER WINAPI HttpServerStart(  
    LPCTSTR lpszLocalHost,  
    UINT nLocalPort,  
    DWORD dwOptions,  
    LPHTTPSERVERCONFIG lpServerConfig,  
    HTTPSETPROCB lpServerProc,  
    DWORD_PTR dwServerParam,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **HttpServerStart** function begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the callback function specified by the caller.

Parameters

lpszLocalHost

A pointer to a string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is NULL or an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

nLocalPort

The port number the server should use to accept client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit TLS. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

dwOptions

An unsigned integer value that specifies the options used when creating an instance of the server. For a list of options, see [Server Option Constants](#).

lpServerConfig

A pointer to an **HTTPSERVERCONFIG** structure that specifies the configuration options for the server. If this parameter is NULL, then default configuration parameters will be used that starts the server in a restrictive mode.

lpServerProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **HttpServerProc** callback function. If this parameter is NULL, a default internal handler is used to process client commands.

dwServerParam

A user-defined integer value that is passed to the callback function. If the *lpServerProc* parameter is NULL, this value should be zero. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

lpCredentials

Pointer to a **SECURITYCREDENTIALS** structure. If this parameter is NULL, the default security credentials for the server host name will be used. If security is enabled for the server, it is recommended that you provide a pointer to this structure with specific information about the server

certificate that should be used. If the security options are not specified in the server configuration, this parameter is ignored.

Return Value

If the function succeeds, the return value is a handle to a server session. If the function fails, the return value is `INVALID_SERVER`. To get extended error information, call **HttpGetServerError**.

Remarks

In most cases, the *lpzLocalHost* parameter should be a NULL pointer or an empty string. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The handle returned by this function references the listening socket that was created when the server was started. The service is managed in another thread, and all interaction with the server and active client connections are performed inside the event handler. To disconnect all active connections, close the listening socket and terminate the server thread, call the **HttpServerStop** function.

The host UUID that is defined as part of the server configuration should be generated using the **uuidgen** utility that is included with the Windows SDK. You should not use the UUID that is provided in the example code, it is for demonstration purposes only. If no host UUID is specified in the server configuration, an ephemeral UUID will be generated automatically when the server is started.

If the server is started with security enabled, the *lpCredentials* parameter should be used to provide the server certificate information in a **SECURITYCREDENTIALS** structure. If the pointer is NULL, this function will search for a certificate that matches the hostname provided as part of the server configuration. This requires that the server certificate be installed in the personal certificate store of the current process user, and it must have a private key associated with it. To use a certificate with a different name, or one that is stored in a PFX file, a **SECURITYCREDENTIALS** structure must be defined and passed to this function.

Example

```
HSERVER hServer;  
HTTPSERVERCONFIG httpConfig;  
  
// Initialize the server configuration  
ZeroMemory(&httpConfig, sizeof(HTTPSERVERCONFIG));  
httpConfig.dwSize = sizeof(httpConfig);  
httpConfig.nMaxClients = 100;  
httpConfig.nMaxClientsPerAddress = 8;  
httpConfig.nMaxRequests = 5;  
httpConfig.nLogFormat = HTTP_LOGFILE_EXTENDED;  
httpConfig.nLogLevel = 5;  
httpConfig.lpszIdentity = _T("MyProgram");
```

```
httpConfig.lpszHostName = _T("server.company.com");
httpConfig.lpszHostUuid = _T("10000000-1000-1000-1000-100000000000");
httpConfig.lpszDirectory = _T("%ProgramData%\\MyProgram\\Files");
httpConfig.lpszLogFile = _T("%ProgramData%\\MyProgram\\Server.log");

// Start the server
hServer = HttpServerStart(lpszLocalHost,
                          HTTP_PORT_DEFAULT,
                          HTTP_SERVER_DEFAULT,
                          &httpConfig,
                          lpEventHandler,
                          0,
                          NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpServerStop Function

```
BOOL WINAPI HttpServerStop(  
    HSERVER hServer  
);
```

Stop the server, terminating all active client sessions and releasing the resources that were allocated for the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **HttpServerStop** function instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the server handle to be opaque and never depend on it being a specific value.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **HttpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpServerRestart](#), [HttpServerStart](#)

HttpServerSuspend Function

```
BOOL WINAPI HttpServerSuspend(  
    HSERVER hServer  
);
```

Suspend the server and reject new client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerSuspend** function instructs the server to suspend accepting new client connections. Any incoming client connections will be rejected with an error message indicating that the server is currently unavailable. To resume accepting client connections, call the **HttpServerResume** function. Suspending the server will have no effect on clients that have already established a connection with the server.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **HttpServerThrottle** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpServerRestart](#), [HttpServerResume](#), [HttpServerStart](#), [HttpServerStop](#), [HttpServerThrottle](#)

HttpServerThrottle Function

```
BOOL WINAPI HttpServerThrottle(  
    HSERVER hServer,  
    UINT nMaxClients,  
    UINT nMaxClientsPerAddress,  
    DWORD dwConnectionRate  
);
```

The **HttpServerThrottle** function limits the number of active client connections, connections per address and connection rate.

Parameters

hServer

Handle to the server.

nMaxClients

A value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

nMaxClientsPerAddress

A value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is a limit of four client connections per address.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerThrottle** function is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **HttpServerStart** function is called with the maximum number of clients set to 100, and then **HttpServerThrottle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would

limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

It is recommended that you always specify conservative connection limits for your server application based on expected usage. Allowing an unlimited number of client connections can potentially expose the system to denial-of-service attacks and should never be done for servers that are accessible over the Internet.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpServerRestart](#), [HttpServerResume](#), [HttpServerStart](#), [HttpServerSuspend](#)

HttpServerUninitialize Function

```
VOID WINAPI HttpServerUninitialize();
```

The **HttpServerUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **HttpServerInitialize** call before it can call any of the other library functions. When it has completed the use of library, the application must call **HttpServerUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **HttpServerUninitialize** for every successful call to **HttpServerInitialize** made by a process. Operations for all threads in the server are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpServerInitialize](#), [HttpServerStart](#), [HttpServerStop](#)

HttpSetClientAccess Function

```
BOOL WINAPI HttpSetClientAccess(  
    HSERVER hServer,  
    UINT nClientId,  
    DWORD dwUserAccess  
);
```

Change the access rights associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see [User and File Access Constants](#).

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **HttpSetClientAccess** function can change the multiple access rights for a client session. The **HttpEnableClientAccess** function can be used to grant or revoke a specific permission for the client session.

If the *dwUserAccess* parameter has a value of HTTP_ACCESS_DEFAULT, then default permissions will be granted to the client session based on the configuration of the server. This is the recommended value for most clients. It is important to consider the implications of changing the access permissions granted to a client session. For example, if you do not grant clients HTTP_ACCESS_READ permission, it can effectively disable the site because the server will return 403 Forbidden errors for all GET and HEAD requests.

This function should typically be called in the HTTP_CLIENT_CONNECT event handler to assign general permissions to the client, or in the HTTP_CLIENT_COMMAND event handler after the client has issued a request and provided any authentication credentials that are required.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpAuthenticateClient](#), [HttpEnableClientAccess](#), [HttpGetClientAccess](#)

HttpSetClientHeader Function

```
BOOL WINAPI HttpSetClientHeader(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nHeaderType,  
    LPCTSTR lpszHeaderName,  
    LPCTSTR lpszHeaderValue  
);
```

Create or change the value of a request or response header for the client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header to create or modify. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Change a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Change a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A pointer to a string that specifies the name of the header that should be created or modified. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszHeaderValue

A pointer to a string that specifies the new value of the header. If this parameter is a NULL pointer or an empty string, it has the same effect as deleting the header value from the list of request or response headers.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpSetClientHeader** function will change the value of a request or response header for the specified client session. If the *lpszHeaderName* value matches an existing header field, its value will be replaced. If the header name is not defined, then a new header will be created with the given value. You should not change the value of most standard response header values unless you are certain of

the impact that it would have on the normal operation of the client.

If you wish to define a custom header value that would be included in the response to a client request, you should prefix the header name with "X-" to avoid potential conflicts with the standard response headers. For example, if you wanted to identify a customer, you could create a header field with the name "X-Customer-ID" and set the value to the customer ID number. The client application would receive this custom header value as part of the response to its request for a document.

Refer to [Hypertext Transfer Protocol Headers](#) for a list of common request and response headers that are used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

HttpSetClientIdleTime Function

```
UINT WINAPI HttpSetClientIdleTime(  
    HSERVER hServer,  
    UINT nClientId,  
    UINT nTimeout  
);
```

Change the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nTimeout

An unsigned integer value that specifies the number of seconds that the client may remain idle. If this value is zero, the default idle timeout period for the server will be used.

Return Value

If the function succeeds, the return value is the previous client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpSetClientIdleTime** function will change the number of seconds that the client may remain idle before being automatically disconnected by the server. The minimum timeout period for a client is 10 seconds, the maximum is 300 seconds (5 minutes). The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed.

If the value INFINITE is specified as the timeout period, the client activity timer will be refreshed, extending the idle timeout period for the session. This is typically done inside an event handler to prevent the client from being disconnected due to inactivity.

To obtain the current idle timeout period for a client, along with the amount of time the client has been idle, use the **HttpGetClientIdleTime** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

See Also

[HttpGetClientIdleTime](#)

HttpSetClientVariable Function

```
BOOL WINAPI HttpSetClientVariable(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszName,  
    LPCTSTR lpszValue  
);
```

Create or change the value of a CGI environment variable for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszName

A pointer to a string that specifies the name of the environment variable that should be created or modified. Environment variables are not case-sensitive and should not include the equal sign which acts as a delimiter that separates the variable name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszValue

A pointer to a string that specifies the new value of the environment variable. If this parameter is a NULL pointer or an empty string, it has the same effect as deleting the variable from the environment block for the client session.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpSetClientVariable** function will change the value of a environment variable for the specified client session. If the *lpszName* value matches an existing variable, its value will be replaced. If the variable is not defined, then a new variable will be created with the given value. The value of an environment variable can be obtained using the **HttpGetClientVariable** function.

The server will automatically create a number of different environment variables that will be passed to a program or script executed by the server. These variables are defined in RFC 3875 as part of the Common Gateway Interface (CGI) 1.1 specification. The following variables are defined by the server and should not be modified directly by the application:

Variable Name	Description
AUTH_TYPE	The authorization scheme used by the server to authenticate the client session
CONTENT_LENGTH	The length of the request data provided by the client
CONTENT_TYPE	The MIME type that identifies the type of content provided by the client
DOCUMENT_ROOT	The full path to the local document root directory on the server

GATEWAY_INTERFACE	The version of the Common Gateway Interface that is being used by the server
PATH_INFO	The resource or sub-resource that is to be returned by the program or script
PATH_TRANSLATED	The path information mapped to the server root document directory structure
QUERY_STRING	The URL encoded query parameters passed to the program or script
REMOTE_ADDR	The network address of the client sending the request to the server
REMOTE_HOST	The same value as the REMOTE_ADDR variable
REMOTE_USER	The username specified as part of the authentication credentials provided by the client
REQUEST_METHOD	The method used by the client to request the resource
REQUEST_URI	The URI for the script provided by the client
SCRIPT_FILENAME	The full path to the program or script on the server
SCRIPT_NAME	The path to the program or script specified by the client
SERVER_NAME	The hostname or IP address of the server that the client connected to
SERVER_PORT	The port number that the client used to connect to the server
SERVER_PORT_SECURE	This variable has a value of "1" if the client connection to the server is secure
SERVER_PROTOCOL	The version of the server protocol used
SERVER_SOFTWARE	The server identity string which specifies the application name and version

In addition to the environment variables listed, the server will also create variables that are prefixed with "HTTP_" that are set to the value of request headers that are not otherwise defined. For example, the HTTP_USER_AGENT variable will be set to the value of the User-Agent header provided by the client as part of the request.

Calling the **HttpSetClientVariable** function in response to an HTTP_CLIENT_EXECUTE event notification will have no effect because it occurs after the CGI program or script has completed execution. To create or modify environment variables for the client session, it should be done in response to the HTTP_CLIENT_COMMAND event notification.

This function will not change the environment block for the server process. Each client session is allocated its own private environment block which is inherited by the CGI program. When the client session terminates, the memory allocated for its environment is released.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetClientVariable](#)

HttpSetCommandFile Function

```
BOOL WINAPI HttpSetCommandFile(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszFileName  
);
```

Change the name of the local file or directory that is the target of the current command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A pointer to a string that specifies the new file name. This parameter may be NULL to specify that the original file or directory name should be used.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpSetCommandFile** function is used by the application to change the target file or directory name for the current command from within an HTTP_EVENT_COMMAND event handler. This can be used to effectively redirect the client to use a different file than the one that was actually requested. For example, if the client issues the GET command to download a file from the server, this function can be used to redirect the command to use a different file name. To obtain the full path to the file or directory that is the target of the current command, use the **HttpGetCommandFile** function.

The *lpszFileName* parameter specifies the path to the new file or directory name. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the root directory for the client session. Because the root document directory for the client can depend on the hostname that the client used when connecting to the server, it is recommended that you always use an absolute path. The full path to this file is not limited to the server root directory or its subdirectory, it can specify a file anywhere on the local system. If this parameter is a NULL pointer, or points to an empty string, then the server will revert to using the actual file or directory name specified by the command. This enables the application to effectively undo a previous call to this function to change the target file name.

Typically this function would be used to redirect a client to a file or directory that it may not normally have access to. Exercise caution when using this function to provide access to data that is stored outside of the server root directory. Incorrect use of this function could expose the server to security risks or cause unpredictable behavior by client applications. In most cases it is preferable to use the **HttpAddVirtualPath** function to create a virtual path or file name on the server, or the **HttpRedirectRequest** function to request the client use a different URL to access the resource.

This function should only be called within the context of the HTTP_EVENT_COMMAND event, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, this function will return zero and the last error code will be set to

ST_ERROR_INVALID_COMMAND.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

HttpSetServerError Function

```
VOID WINAPI HttpSetServerError(  
    HSERVER hServer,  
    DWORD dwError  
);
```

Set the last error code for the specified server session.

Parameters

hServer

The server handle.

dwError

An unsigned integer that specifies an error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each server session. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or HTTP_ERROR.

If the *hServer* parameter is specified as INVALID_SERVER, this function will set the last error code for the current thread, but will not change the error code associated with any server session. This should only be done if the application does not have access to a valid server handle.

If the *dwError* parameter is specified with a value of zero, this effectively clears the error code for the last function that failed. Those functions which clear the last error code when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **HttpGetServerError** function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

[HttpGetCommandResult](#), [HttpGetServerError](#), [HttpSendResponse](#)

HttpSetServerIdentity Function

```
BOOL WINAPI HttpSetServerIdentity(  
    HSERVER hServer,  
    LPCTSTR lpszIdentity  
);
```

Change the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A pointer to a string that identifies the server. If this parameter is NULL or specifies an empty string, the current identity for the server is reset to a default value. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **HttpSetClientIdentity** function changes a string value used by the server to identify itself to clients. The identity string does not have any standard format and is used for informational purposes only. Typically it consists of the application name and a version number. Changing the server identity has no effect on the operation of the server. To obtain the identity string currently associated with the server, use the **HttpGetServerIdentity** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetServerIdentity](#)

HttpSetServerLogFile Function

```
BOOL WINAPI HttpSetServerLogFile(  
    HSERVER hServer,  
    UINT nLogFormat,  
    UINT nLogLevel,  
    LPCTSTR lpszFileName  
);
```

Change the current log format, level of detail and file name.

Parameters

hServer

The server handle.

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Value	Description
HTTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about GET, PUT and POST requests.
HTTP_LOGFILE_COMBINED	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session. This format typically generates the largest logfiles.

nLogLevel

An integer value that specifies the level of detail that should generated in the log file. The minimum value is 1 and the maximum value is 10. If this parameter is zero, it is the same as specifying a log file format of HTTP_LOGFILE_NONE and will disable logging by the server.

lpszFileName

A pointer to a string that specifies the name of the log file that should be created or appended to. If the server was configured with logging enabled and this parameter is NULL or an empty string, the current log file name will not be changed. If the log file does not exist, it will be created. If it does exist, the contents of the log file will be appended to.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero.

Remarks

The **HttpSetServerLogFile** function can be used to change the current log file name, the format of the log file or the level of detail recorded in the log file. In some situations it may be desirable to delete the current log file contents when changing the format or ensure that a new log file is created. To do this, combine the *nLogFormat* parameter with the constant HTTP_LOGFILE_DELETE.

The higher the value of the *nLogLevel* parameter, the greater the level of detail that is recorded by the server. A log level of 1 instructs the server to only record GET, POST and PUT requests, while a level of 10 instructs the server to record all commands processed by the server. Because a higher level of logging detail can negatively impact the performance of the server, it is recommended that you do not exceed a level of 5 for most applications. A log level of 10 should only be used for debugging purposes.

Example

```
UINT nLogFormat = HTTP_LOGFILE_NONE;
UINT nLogLevel = 0;
UINT nNewLevel = 5;
BOOL bChanged = FALSE;

// Change the level of detail for the current log file if logging
// has been enabled and the current level is a lower value

if (HttpGetServerLogFile(hServer, &nLogFormat, &nLogLevel, NULL, 0))
{
    if (nLogFormat != HTTP_LOGFILE_NONE && nLogLevel < nNewLevel)
        bChanged = HttpSetServerLogFile(hServer, nLogFormat, nNewLevel, NULL);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetServerLogFile](#), [HttpRenameServerLogFile](#)

HttpSetServerName Function

```
BOOL WINAPI HttpSetServerName(  
    HSERVER hServer,  
    UINT nClientId,  
    LPCTSTR lpszHostName  
);
```

Change the host name assigned to the specified server or client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A pointer to a string that specifies the new host name assigned to the server or client session. If this value is NULL or points to an empty string, the current host name will be changed to use the default host name.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will change the host name assigned to the specified client session. If the *nClientId* parameter has a value of zero, the function will change default host name that was assigned to the server as part of the server configuration. If the *nClientId* parameter specifies a valid client session and the *lpszHostName* parameter is NULL, the host name associated with the client session will be changed to the current host name assigned to the server.

When a client connects to the server, it can specify the host name that it used to establish the connection by sending the HOST command. This is typically used with virtual hosting, where one server may accept client connections for multiple domains. The **HttpGetServerName** function will return the host name specified by the client, and **HttpSetServerName** can be used by the application to either explicitly assign a different host name to the client session, or override the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Unicode: Implemented as Unicode and ANSI versions

[HttpGetServerAddress](#), [HttpGetServerName](#)

HttpSetServerPriority Function

```
INT WINAPI HttpSetServerPriority(  
    HSERVER hServer,  
    INT nPriority  
);
```

Change the priority assigned to the specified server.

Parameters

hServer

The server handle.

nPriority

An integer value which specifies the new priority for the server. It may be one of the following values:

Value	Description
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
HTTP_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority assigned to the server. If the function fails, the return value is HTTP_PRIORITY_INVALID. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSetServerPriority** function can be used to change the current priority assigned to the specified server. Client connections that are accepted after this function is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

HttpSetServerStackSize Function

```
BOOL WINAPI HttpSetServerStackSize(  
    SOCKET hServer,  
    DWORD dwStackSize  
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSetServerStackSize** function changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change the stack size unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: cshtsv11.lib

Hypertext Transfer Protocol Server Data Structures

- HTTPCLIENTCREDENTIALS
- HTTPREQUEST
- HTTPRESPONSE
- HTTPSERVERCONFIG
- HTTPSERVERTRANSFER
- INITDATA
- SECURITYCREDENTIALS

HTTPCLIENTCREDENTIALS

The **HTTPCLIENTCREDENTIALS** structure defines the credentials used to authenticate a specific user.

```
typedef struct _HTTPCLIENTCREDENTIALS
{
    DWORD dwSize;
    DWORD dwFlags;
    UINT  nAuthType;
    UINT  nHostPort;
    TCHAR szHostName[HTTP_MAXHOSTNAME];
    TCHAR szUserName[HTTP_MAXUSERNAME];
    TCHAR szPassword[HTTP_MAXPASSWORD];
} HTTPCLIENTCREDENTIALS, *LPHTTPCLIENTCREDENTIALS;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value is reserved for future use. This value will always be zero.

nAuthType

An unsigned integer value that identifies the authentication method.

nHostPort

The server port number.

szHostName

A pointer to a string that specifies the server host name.

szUserName

A pointer to a string that specifies the user name.

szPassword

A pointer to a string that specifies the user password.

Remarks

When an instance of this structure is passed to the **HttpGetClientCredentials** function, this member must be initialized to the size of the structure and all other members must be initialized with a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

[HttpGetClientCredentials](#)

HTTPREQUEST

The **HTTPREQUEST** structure provides information about the request made by the client.

```
typedef struct _HTTPREQUEST
{
    DWORD    dwSize;
    DWORD    dwFlags;
    DWORD    dwVersion;
    DWORD    dwAccess;
    DWORD    dwLength;
    DWORD    dwReserved;
    UINT     nHostId;
    UINT     nHostPort;
    LPCSTR   lpszCommand;
    LPCSTR   lpszHostName;
    LPCSTR   lpszUserName;
    LPCSTR   lpszPassword;
    LPCSTR   lpszResource;
    LPCSTR   lpszParameters;
    LPCSTR   lpszDirectory;
    LPCSTR   lpszPathInfo;
    LPCSTR   lpszProgram;
    LPCSTR   lpszScriptFile;
    LPCSTR   lpszLocalFile;
    LPCSTR   lpszMediaType;
} HTTPREQUEST, *LPHTTPREQUEST;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value that provides additional information about the request. It may be one or more of the following values:

Value	Description
HTTP_REQUEST_FLAG_PROTECTED	The resource that the client has requested is protected. The client should only be permitted to access the resource if the client session has been authenticated.
HTTP_REQUEST_FLAG_PROGRAM	The resource that the client has requested is a CGI program or an executable script. The output from the program or script should be returned to the client in the response. If this flag is specified, the <i>lpszProgram</i> member of the structure specifies the name of the program that should be executed.
HTTP_REQUEST_FLAG_SCRIPT	The resource that the client has requested is an executable script. This flag is set when the request URL is mapped to a registered script handler. The <i>lpszProgram</i> member specifies the name of the program that is responsible for executing the script, and the <i>lpszScriptFile</i> parameter specifies the full

path to the script itself.

dwVersion

An unsigned integer value that specifies the protocol version used. It may be one of the following values:

Value	Description
HTTP_VERSION_09	The client issued a GET command without specifying a protocol version.
HTTP_VERSION_10	The client issued a command that specified version 1.0 of the protocol.
HTTP_VERSION_11	The client issued a command that specified version 1.1 of the protocol.

dwAccess

An unsigned integer value that specifies the access permissions that were assigned to the resource. For a list of file access permissions, see [User and File Access Constants](#).

dwLength

An unsigned integer value that will specify the number of bytes of request data provided by the client. If the client did not submit any data with the request, this member will have a value of zero.

dwReserved

An unsigned integer value that is reserved for future use.

nHostId

An integer value that identifies the virtual host that was specified by the client. This is based on the value of the Host request header included in the request. This value will be zero if a host name is not specified by the client, or does not match one of the virtual hosts that have been created.

nHostPort

An integer value that specifies the port number that the client used to establish the connection. This will be the same port number that was used when starting the server.

lpszCommand

A pointer to a string that specifies the command that was issued by the client. The command will always be in upper case. Refer to [Hypertext Transfer Protocol Commands](#) for a list of standard commands.

lpszHostName

A pointer to a string that identifies the hostname or IP address that the client used to establish the connection. This will typically correspond to the hostname assigned to the server, or to one of the virtual hosts that have been created.

lpszUserName

A pointer to a string that specifies the username provided with the request. This member is only set if the client has included authentication credentials as part of the request. If the client has not provided any credentials, this member will be NULL.

lpszPassword

A pointer to a string that specifies the password provided with the request. This member is only set if the client has included authentication credentials as part of the request. If the client has not provided any credentials, this member will be NULL.

lpSzResource

A pointer to a string that specifies the URL path provided by the client.

lpSzParameters

A pointer to a string that specifies any query parameters that were included in the request made by the client. If the URL did not include any query parameters, this member will be NULL.

lpSzDirectory

A pointer to a string that specifies the full path to the root directory for the virtual host.

lpSzPathInfo

A pointer to a string that specifies additional path information provided by the client when referencing an executable CGI program or script in the URL. For example, if a program is mapped to the virtual path "/orders/invoice" and the client requests "/orders/invoice/pdf/10001" this member will be the string "/pdf/10001". If there is no path information associated with the request, this member will be NULL.

lpSzProgram

A pointer to a string that specifies the local path to the CGI program that should be executed to process the request made by the client. If this member is NULL, it indicates that the client has provided a URL that maps to a local file or directory.

lpSzScriptFile

A pointer to a string that specifies the local path to the script file that will be executed by the handler. If this member is NULL, it indicates that the request URL was not mapped to registered script handler.

lpSzLocalFile

A pointer to a string that specifies the local path to the directory or file name referenced by the URL. If the *lpSzPathInfo* member is not NULL, then this member will point to a local file name based the path information appended to the root directory for the virtual host.

lpSzMediaType

A pointer to a string that identifies the request data using the standard Internet media types defined in RFC 2046. It is used to designate the format for various types of content and has two parts, a primary and secondary media type separated by a forward slash. Common examples are "text/plain", "text/html" and "application/octet-stream". If the client did not submit any data with the request, this member will be NULL.

Remarks

This structure is used with the **HttpReceiveRequest** function and all members should be initialized to a value of zero, except for the *dwSize* member which should be initialized to size of the structure. Failure to properly initialize the structure will cause the function call to fail.

The value of the *lpSzLocalFile* member depends on whether the client has requested a static document, or if the URL is mapped to a registered program or script handler. If the request is for a static document, then the *dwFlags* member will not have the HTTP_REQUEST_FLAG_PROGRAM bit flag set and the *lpSzLocalFile* member will be the full path to the document. If the URL is mapped to a registered program or script, then the *lpSzLocalFile* member will be the full path to the server root directory. If the request URL included additional path information, that will be appended to the root directory.

The value of the *lpSzScriptFile* member is only defined if the *dwFlags* member has the HTTP_REQUEST_FLAG_SCRIPT bit flag set. This indicates that the request URL references a file that is an executable script with a handler that was registered using the **HttpRegisterHandler** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpReceiveRequest](#), [HttpSendResponse](#), [HTTPRESPONSE](#)

HTTPRESPONSE

The **HTTPRESPONSE** structure provides additional information about the response to the client.

```
typedef struct _HTTPRESPONSE
{
    DWORD    dwSize;
    DWORD    dwFlags;
    DWORD    dwVersion;
    DWORD    dwReserved;
    UINT     nExpires;
    UINT     nResultCode;
    LPCTSTR  lpszReason;
    LPCTSTR  lpszMediaType;
} HTTPRESPONSE, *LPHTTPRESPONSE;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value that specifies one or more response flags. This member is reserved for future use and should always have a value of zero.

dwVersion

An unsigned integer value that specifies the protocol version used. It may be one of the following values:

Value	Description
HTTP_VERSION_DEFAULT	The server should respond to the client using the same version specified in the request.
HTTP_VERISON_10	The server should respond to the client using version 1.0 of the protocol.
HTTP_VERSION_11	The server should respond to the client using version 1.1 of the protocol.

dwReserved

An unsigned integer value that is reserved for future use.

nExpires

An integer value that specifies the number of seconds until the client should consider any cached response data to be stale. If this value is zero, the default cache expiration time for the server will be used. The default cache expiration time is 7200 seconds (2 hours). The value of this structure member is ignored if the HTTP_RESPONSE_NOCACHE option is specified when the response is sent to the client.

nResultCode

An integer value that specifies the result code that should be sent in response to the client request. The result code is a three-digit number that indicates success or failure. For more information, refer to the **HttpGetCommandResult** function.

lpszReason

A string that describes the result code sent to the client. The description should be brief and

should not contain any formatting characters or HTML markup. This parameter may be NULL, in which case a default description of the result code will be used.

lpzMediaType

A string that specifies the Internet media type for the data that is being sent to the client as defined in RFC 2046. The format for the content type string consists of two parts, a primary and secondary media type separated by a forward slash. Common examples are "text/plain", "text/html" and "application/octet-stream". If this member is NULL, the library will attempt to automatically determine the appropriate media type.

Remarks

This structure is used with the **HttpSendResponse** function and the *dwSize* member must be initialized to size of the structure. Failure to properly initialize the structure will cause the function call to fail.

Requirements

HTTPSERVERCONFIG

The **HTTPSERVERCONFIG** structure provides the configuration information used to create an instance of an HTTP server.

```
typedef struct _HTTPSERVERCONFIG
{
    DWORD    dwSize;
    UINT     nMaxClients;
    UINT     nMaxClientsPerAddress;
    UINT     nMaxRequests;
    UINT     nMaxPostSize;
    UINT     nLogFormat;
    UINT     nLogLevel;
    UINT     nCacheTime;
    UINT     nIdleTime;
    UINT     nExecTime;
    LPCTSTR  lpszIdentity;
    LPCTSTR  lpszHostUuid;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszRootPath;
    LPCTSTR  lpszTempPath;
    LPCTSTR  lpszLogFile;
} HTTPSERVERCONFIG, *LPHTTPSERVERCONFIG;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

nMaxClients

An integer value that specifies the maximum number of active client connections that will be accepted by the server. If the maximum number of clients is reached, any further connections are rejected by the server until one or more clients close their connection to the server or are disconnected. A value of zero specifies the default configuration value of 100 connections should be used.

nMaxClientsPerAddress

An integer value that specifies the maximum number of active client connections per IP address that will be accepted by the server. If the maximum number of clients from the same IP address is reached, any further connections are rejected until one of the clients closes its connection to the server. A value of zero specifies the default configuration value of 8 connections per address should be used.

nMaxRequests

An integer value that specifies the maximum number of a requests a client may make per connection. When a client reaches the maximum number of requests, the server will close the connection and the client must establish a new connection to send another request. If this member has a value of zero, the server will allow 5 requests per connection. The minimum value is 1 and the maximum is 100.

nMaxPostSize

An integer value that specifies the maximum size of the request data that may be submitted by a client with a POST command. If the amount of request data submitted to the server exceeds this limit, the server will return a 413 error to the client and the connection will be closed. If this member has a value of zero, the server will permit the client to submit up to 4 MB (4,194,304 bytes) of data.

The minimum value is 100 KB (102,400 bytes) and the maximum value is 100 MB (104,857,600 bytes).

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Value	Description
HTTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
HTTP_LOGFILE_COMBINED	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

nLogLevel

An integer value that specifies the level of detail that should be generated in the log file. The minimum value is 1 and the maximum value is 10. If the ***nLogFormat*** member specifies a valid log file format and this value is zero, a default level of detail will be selected based on the format. The common log file format generally contains less information by default, only logging the data transfers between the client and server. The W3C extended log file format defaults to a higher level of detail that includes additional information about the client session. The higher the level of detail, the larger the log file will be.

nCacheTime

An integer value that specifies the amount of time that the client should store a document in its cache before requesting it from the server again. A value of zero specifies that the default value of 7200 seconds (2 hours) should be used.

nIdleTime

An integer value that specifies the maximum number of seconds that a client session may be idle before the server closes the control connection to the client. A value of zero specifies the default value of 60 seconds. If the value is non-zero, the minimum value is 10 seconds and the maximum value is 300 seconds (5 minutes). This value is used to initialize the default idle timeout period for each client session. The server determines if a client is idle based on the time the last command was issued and whether or not a file transfer is in progress.

nExecTime

An unsigned integer value that specifies the maximum number of seconds that an external CGI program is permitted to run on the server. Programs are registered using the **HttpRegisterProgram** function, and are executed when the client sends a request for a resource that is associated with the program. If this value is zero, the default timeout period of 5 seconds will be used. The minimum execution time is 1 second and the maximum time limit is 30 seconds.

lpzIdentity

A pointer to a string that identifies the server. It is used for informational purposes only and has no effect on the operation of the server. If this member is not initialized to a value, then a default identity will be used. The server identity is provided when a client establishes the initial connection and when the client sends the STAT or CSID commands. If this member is defined, it is recommended that you only use printable ASCII characters.

lpzHostUuid

A pointer to a string that specifies a Universally Unique Identifier (UUID) that is used to uniquely identify the server. This value can be used when storing information about the server, and should be generated using a utility such as **uuidgen** which is included with Visual Studio. This structure member may be initialized to an empty string, in which case a temporary UUID will be randomly generated.

lpzHostName

A pointer to a string that specifies the fully-qualified host name for the server. If this structure member is initialized with an empty string, the local host name assigned to the Windows system will be used. This value does not need to correspond to the actual host name associated with the server's IP address. This value is used for informational purposes only and has no effect on the operation of the server.

lpzRootPath

A pointer to a string that specifies the path to the root directory for the server. If this structure member is initialized with an empty string, the current working directory for the process will be used as the root directory. It is recommended that you provide a full path to an existing directory and do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpzTempPath

A pointer to a string that specifies the path to the temporary directory for the server. If this structure member is initialized with an empty string, the current temporary directory for the process will be used. The temporary directory cannot be the same as the root directory, and it is strongly recommended that you do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpzLogFile

A pointer to a string that specifies the name of the server log file to create, if a logging format has been specified. If logging is enabled and this member is an empty string, then a default log file name will be created. If the file name does not include a path, then the file is created in the server log directory. If the file name includes a path, the log file will be created using that specific name. If the server is in multi-user mode, then the default location for log files will be the Logs subdirectory in the server root directory. If the server is not in multi-user mode, the default location for log files will be the temporary directory for the current process.

Remarks

When an instance of this structure is passed to the **HttpServerStart** function, the **dwSize** member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the configuration is invalid.

The **nMaxClients** member limits the total number of client connections and the **nMaxClientsPerAddress** member limits the number of simultaneous connections can originate from the same address. If either client limit is exceeded, the server will automatically close the connection. For more control over how the server accepts client connections, use the **HttpServerThrottle**

function. It is not recommended that you set the maximum clients per address below a value of 4. Lower values can negatively impact the performance of some clients, particularly web browsers.

The ***nMaxPostSize*** member limits the amount of data that a client can submit to the server using a POST command. The default limit is 4 MB which should be sufficient for most applications. One situation where you may need to increase this value is if you expect the client to upload large files using the POST command. Increasing this limit will potentially increase the amount of virtual memory that the server will allocate. Note that this value does not limit amount of data that can be uploaded using the PUT command.

When specifying the root directory for the server configuration, it is important to consider that a client's default access to files on the system will be limited to these directories and any subdirectories. If a root directory is not specified, then one will be created using the current working directory for the process. The root directory path may include environment variables surrounded by % symbols and these will be expanded.

For servers that are publicly accessible, or where you want files to be accessible across multiple server sessions, you should always populate the ***szHostUuid*** member with a valid UUID string, and the ***lpszRootPath*** member should specify an absolute path to an existing directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Unicode: Implemented as Unicode and ANSI versions

See Also

[HttpServerStart](#), [HttpServerStop](#), [HttpServerThrottle](#)

HTTPSERVERTRANSFER

The **HTTPSERVERTRANSFER** structure provides information about the last file transfer performed by a client.

```
typedef struct _HTTPSERVERTRANSFER
{
    DWORD          dwSize;
    DWORD          dwReserved;
    DWORD          dwFileAccess;
    DWORD          dwTimeElapsed;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szFileName[MAX_PATH];
} HTTPSERVERTRANSFER, *LPHTTPSERVERTRANSFER;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

dwFileAccess

An unsigned integer value that specifies the how the local file was accessed. It can be one of the following values:

Value	Description
HTTP_FILE_READ	The file was opened for reading. This mode indicates that the client issued the GET command to download the contents of a file from the server to the client system. The <i>szFileName</i> member specifies the name of the local file on the server that was downloaded by the client.
HTTP_FILE_WRITE	The file was opened for writing. This mode indicates that the client issued the PUT command to upload the contents of a file from the client system to server. The <i>szFileName</i> member specifies the name of the local file on the server that was created by the client. If a file already existed with the name name, it was replaced.

dwTimeElapsed

The amount of time that it took for the file transfer to complete in milliseconds. This value is limited to the resolution of the system timer, which is typically in the range of 10 to 16 milliseconds. This value may be zero if the transfer occurred over a local network or on the same host using a loopback address.

uiBytesCopied

A 64-bit integer value that specifies the total number of bytes copied during the file transfer. This value is represented by a ULARGE_INTEGER union which provides support for those programming languages that do not have intrinsic support for 64-bit integers. For more information, refer to the Windows SDK documentation. The application should not make the assumption that this is the actual size of the file.

szFileName

A pointer to a string value that will contain the full path to the local file that was transferred. The *dwFileAccess* member determines whether the file name represents a file that was downloaded by

the client, or uploaded from the client and stored on the server.

Remarks

When an instance of this structure is passed to the **HttpGetServerTransferInfo** function, the *dwSize* member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the parameter is invalid. All other members should be initialized to a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD        dwSize;
    DWORD        dwVersionMajor;
    DWORD        dwVersionMinor;
    DWORD        dwVersionBuild;
    DWORD        dwOptions;
    DWORD_PTR    dwReserved1;
    DWORD_PTR    dwReserved2;
    TCHAR        szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify the security protocol and server certificate when accepting a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

- dwSize*

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.
- dwProtocol*

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A pointer to a null terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A pointer to a null terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A pointer to a null terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A pointer to a null terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* member should be set to CREDENTIAL_STORE_FILENAME and the *lpCertStore* member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the *lpPassword* member or the library will be unable to access the certificate.

Note that the *lpUserName* and *lpPassword* members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Internet Control Message Protocol Library

Determine if a remote host is reachable and how packets of data are routed to that system.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSICMV11.DLL
Version	11.0.2218.1855
LibID	861142C8-68FD-4BC5-BAA9-25B33F15DD07
Import Library	CSICMV11.LIB
Dependencies	None
Standards	RFC 792

Overview

The Internet Control Message Protocol (ICMP) is commonly used to determine if a remote host is reachable and how packets of data are routed to that system. Users are most familiar with this protocol as it is implemented in the ping and traceroute command line utilities. The ping command is used to check if a system is reachable and the amount of time that it takes for a packet of data to make a round trip from the local system, to the remote host and then back again. The traceroute command is used to trace the route that a packet of data takes from the local system to the remote host, and can be used to identify potential problems with overall throughput and latency. The library can be used to build in this type of functionality in your own applications, giving you the ability to send and receive ICMP echo datagrams in order to perform your own analysis.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be

registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Internet Control Message Protocol Functions

Function	Description
IcmpCancel	Cancel the current blocking operation
IcmpCloseHandle	Close the current client session
IcmpCreateHandle	Create a new handle for the current client session
IcmpDisableEvents	Disable asynchronous event notification
IcmpDisableTrace	Disable logging of socket-level calls to the trace log
IcmpEcho	Send one or more echo datagrams to the specified host
IcmpEnableEvents	Enable asynchronous event notification
IcmpEnableTrace	Enable logging of network function calls to a file
IcmpEventProc	Callback function that processes events generated by the client
IcmpFormatAddress	Convert a numeric IP address to a string
IcmpFreezeEvents	Suspend or resume event handling by the calling process
IcmpGetErrorString	Return a description for the specified error code
IcmpGetHostAddress	Return the current host IP address
IcmpGetHostName	Return the current host name
IcmpGetLastError	Return the last error code
IcmpGetPacketSize	Return the ICMP datagram packet size
IcmpGetRecvCount	Return the number of packets received
IcmpGetSendCount	Return the number of packets sent
IcmpGetSequenceId	Return the current sequence identifier
IcmpGetTimeout	Return the number of milliseconds until an operation times out
IcmpGetTimeToLive	Return the current time-to-live for the ICMP datagram
IcmpGetTripTime	Return the current trip time statistics
IcmpInitialize	Initialize the library and validate the specified license key at runtime
IcmpIsBlocking	Determine if the client is blocked, waiting for information
IcmpRecvEcho	Read an ICMP datagram returned by the remote host
IcmpRegisterEvent	Register an event callback function
IcmpReset	Reset the current client state
IcmpResolveAddress	Resolve an IP address into a fully qualified host name
IcmpSendEcho	Send an ICMP datagram to the specified host
IcmpSetHostAddress	Set the IP address of the host to receive the next datagram
IcmpSetHostName	Set the name of the host to receive the next datagram

IcmpSetLastError	Set the last error code
IcmpSetPacketSize	Set the ICMP datagram packet size
IcmpSetSequenceId	Set the sequence identifier for the next datagram
IcmpSetTimeout	Set the number of milliseconds until an operation times out
IcmpSetTimeToLive	Set the time-to-live for the next datagram
IcmpTraceRoute	Trace the route from the local system to a remote host
IcmpUninitialize	Terminate use of the library by the application

IcmpCancel Function

```
INT WINAPI IcmpCancel(  
    HCLIENT hClient  
);
```

The **IcmpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

When the **IcmpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

[IcmpIsBlocking](#)

IcmpCloseHandle Function

```
INT WINAPI IcmpCloseHandle(  
    HCLIENT hClient  
);
```

The **IcmpCloseHandle** function closes the socket and releases the memory allocated for the client session.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

[IcmpCreateHandle](#), [IcmpInitialize](#), [IcmpUninitialize](#)

IcmpCreateHandle Function

```
HCLIENT WINAPI IcmpCreateHandle(  
    UINT nPacketSize,  
    UINT nTimeToLive,  
    DWORD dwTimeout,  
    DWORD dwReserved,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **IcmpCreateHandle** function creates a client handle for sending and receiving ICMP echo datagrams. If an event notification window is specified, the client will be notified when a network event occurs.

Parameters

nPacketSize

An unsigned integer which specifies the default packet size used when generating ICMP echo datagrams. The minimum packet size is 32 bytes and the maximum size is 65,535 bytes.

nTimeToLive

An unsigned integer which specifies the default time-to-live for ICMP echo datagrams. This determines the maximum number of times that a packet will be routed from one system to another while en route to its destination. The minimum time-to-live value is 1, the maximum is 255. The recommend value for this parameter is 255, and typical applications should use a time-to-live value of at least 30.

dwTimeout

An unsigned integer which specifies the maximum number of milliseconds to wait before the current operation times out.

dwReserved

A reserved parameter. This value should always be zero.

hEventWnd

The handle to an asynchronous notification window. This window receives messages which notify the client when asynchronous network events occur. If asynchronous event notification is not required, this parameter may be NULL.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the *hEventWnd* parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to the client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpCreateHandle** function creates a client handle that is used with subsequent calls to the library. This library uses a special type of socket called a raw socket, which is created to send and receive ICMP echo datagrams. Raw socket support is optional under the Windows Sockets specification, and may not be available if a non-standard networking libraries are used or may only be

available to privileged accounts.

If the *hEventWnd* parameter is not NULL, the client operates in asynchronous mode and messages will be posted to the notification window when a network event occurs. When a message is posted to the window, the low word of the *lParam* parameter contains the event identifier. The high word of *lParam* contains the low word of the error code, if an error has occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation.
ICMP_EVENT_CANCEL	The current operation has been canceled. The client application may attempt to retry the operation or close the handle.

To cancel asynchronous notification and return the client to a blocking mode, use the **IcmpDisableEvents** function.

The ability to create and send ICMP echo datagrams is limited to privileged users. Non-administrator users will receive an error if they attempt to create a client handle. On Windows NT it is possible to disable this security check by creating or modifying the system registry. Microsoft Knowledge Base article 195445 has additional information and instructions for making this change.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

[IcmpCloseHandle](#), [IcmpInitialize](#), [IcmpUninitialize](#)

IcmpDisableEvents Function

```
INT WINAPI IcmpDisableEvents(  
    HCLIENT hClient  
);
```

The **IcmpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

[IcmpEnableEvents](#), [IcmpFreezeEvents](#), [IcmpRegisterEvent](#)

IcmpDisableTrace Function

```
BOOL WINAPI IcmpDisableTrace();
```

The **IcmpDisableTrace** function disables the logging of socket function calls to the trace log file.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

[IcmpEnableTrace](#)

IcmpEcho Function

```
INT WINAPI IcmpEcho(  
    LPCTSTR lpszHostName,  
    UINT nIterations,  
    UINT nPacketSize,  
    DWORD dwTimeout,  
    DWORD dwReserved,  
    LPICMP_TIME lpTime  
);
```

The **IcmpEcho** function sends one or more ICMP echo datagrams, collecting information about the reliability and latency of a connection between the local and remote host.

Parameters

lpszHostName

A pointer to a string which specifies the fully qualified domain name of the remote host, or the IP address in dotted notation.

nIterations

An unsigned integer value which specifies the number of echo datagrams that will be sent to the remote host. The minimum value for this parameter is 1 and the maximum value is 512.

nPacketSize

An unsigned integer value which specifies the size of the echo datagram in bytes. The minimum size is 1 byte and the maximum size is 65,535 bytes. It is recommended that most applications use the minimum size of 32 bytes for this parameter.

dwTimeout

An unsigned integer which specifies the number of milliseconds the function will wait for a response to an echo datagram.

dwReserved

A reserved parameter. This value should always be zero.

lpTime

A pointer to an [ICMP_TIME](#) structure which will contain the minimum, maximum and average round trip times for the echo datagrams sent and received.

Return Value

If the function succeeds, the return value is the number of replies received from the remote host. If the function fails, the return value is `ICMP_ERROR`. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpEcho** function sends a series of ICMP echo datagrams to the specified host, providing a simplified interface for pinging a remote system. If the function returns the same value as the number of iterations, then replies were received for all of the echo datagrams that were sent. This would typically indicate that the client can establish a reliable connection to the server; the values returned in the `ICMP_TIME` structure provide information on the latency between the two hosts. Higher average time values would indicate greater latency and reduced throughput between the systems. If the function returns a value less than the specified number of iterations, this indicates that replies were not received for one or more of the echo datagrams. This may indicate that there are problems routing

data between the local and remote host. A return value of zero indicates that there was no response to the echo datagrams. The remote host may not exist or may not be available.

The failure for a host to respond to an ICMP echo datagram may not indicate a problem with the remote system. In some cases, a router between the local and remote host may be malfunctioning or discarding the datagrams. Systems can also be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of Denial of Service attacks.

The ability to send ICMP datagrams may be restricted to users with administrative privileges, depending on the policies and configuration of the local system. If you are unable to send or receive any ICMP datagrams, it is recommended that you check the firewall settings and any third-party security software that could impact the normal operation of this component.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

IcmpEnableEvents Function

```
INT WINAPI IcmpEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **IcmpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **IcmpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

- hClient**
Handle to the client session.
- hEventWnd**
Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.
- uEventMsg**
An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the **lParam** parameter contains the event identifier. The high word of **lParam** contains the low word of the error code, if an error has occurred. The **wParam** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation.
ICMP_EVENT_CANCEL	The current operation has been canceled. The client application may attempt to retry the operation or close the handle.

To cancel asynchronous notification and return the client to a blocking mode, use the

IcmpDisableEvents function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

[IcmpDisableEvents](#), [IcmpFreezeEvents](#), [IcmpRegisterEvent](#)

IcmpEnableTrace Function

```
BOOL WINAPI IcmpEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **IcmpEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

A pointer to a string which specifies the name of the trace log file. If this parameter is NULL or an empty string, the default file name **cstrace.log** is used. The file is stored in the directory specified by the TEMP environment variable, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the tracing library **cstrcv11.dll** cannot be loaded on the local system.

Remarks

When trace logging is enabled, the file is opened, appended to and closed for each socket function call. This makes it possible for an application to append its own logging information, however care should be taken to ensure that the file is closed before the next network operation is performed. To limit the size of the log files, enable and disable logging only around those sections of code that you wish to trace.

Note that the TRACE_HEXDUMP trace level generates very large log files since it includes all of the data exchanged between your application and the remote host.

Trace function logging is managed on a per-thread basis, not for each client handle. This means that all SocketTools libraries and components share the same settings in the current thread. If you are using multiple SocketTools libraries or components in your application, you only need to enable logging once.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

IcmpEventProc Function

```
VOID CALLBACK IcmpEventProc(  
    HCLIENT hClient,  
    UINT nEventId,  
    DWORD dwError,  
    DWORD_PTR dwParam  
);
```

The **IcmpEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hClient

The handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **IcmpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **IcmpRegisterEvent** function. The **IcmpEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

IcmpFormatAddress Function

```
INT WINAPI IcmpFormatAddress(  
    DWORD dwAddress,  
    LPTSTR lpszAddress,  
    INT nMaxLength  
);
```

The **IcmpFormatAddress** function converts a numeric IP address to a string.

Parameters

dwAddress

A unsigned 32-bit integer which specifies the IP address to be converted into a string.

lpszAddress

A pointer to a null-terminated array of characters which will contain the converted IP address in dot-notation. This string should be at least 16 characters in length.

nMaxLength

The maximum number of characters which may be copied in to the string buffer.

Return Value

If the function succeeds, the return value is the length of the string buffer. If the function fails, the return value is zero. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[IcmpGetHostAddress](#), [IcmpGetHostName](#), [IcmpResolveAddress](#)

IcmpFreezeEvents Function

```
INT WINAPI IcmpFreezeEvents(  
    HCLIENT hClient,  
    BOOL bFreeze  
);
```

The **IcmpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

IcmpGetErrorString Function

```
INT WINAPI IcmpGetErrorString(  
    DWORD dwErrorCode,  
    LPTSTR lpszDescription,  
    INT cbDescription  
);
```

The **IcmpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **IcmpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

A pointer to the buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

cbDescription

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

Unicode: Implemented as Unicode and ANSI versions

IcmpGetHostAddress Function

```
INT WINAPI IcmpGetHostAddress(  
    HCLIENT hClient,  
    LPTSTR lpszHostAddress,  
    INT cbHostAddress  
);
```

The **IcmpGetHostAddress** copies the IP address of the current host into the specified buffer as a string using dot-notation.

Parameters

hClient

A handle to the client session.

lpszHostAddress

A pointer to the buffer that will contain the IP address of the current remote host in dot-notation. This buffer should be at least 16 characters in length.

cbHostAddress

The maximum number of characters that may be copied into the buffer, including the terminating null character character.

Return Value

If the function succeeds, the return value is the length of the address string. If the return value is zero, this indicates that no remote host has been specified. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[IcmpSetHostName](#)

IcmpGetHostName Function

```
INT WINAPI IcmpGetHostName(  
    HCLIENT hClient,  
    LPTSTR lpszHostName,  
    INT cbHostName  
);
```

The **IcmpGetHostName** copies the name of the current host into the specified buffer.

Parameters

hClient

A handle to the client session.

lpszHostName

A pointer to the buffer that will contain the name of the current remote host. This buffer should be at least 64 characters in length.

cbHostName

The maximum number of characters that may be copied into the buffer, including the terminating null character character.

Return Value

If the function succeeds, the return value is the length of the host name string. If the return value is zero, this indicates that no remote host has been specified. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

Unicode: Implemented as Unicode and ANSI versions

[IcmpSetHostName](#)

IcmpGetLastError Function

DWORD WINAPI IcmpGetLastError();

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **IcmpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **IcmpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **IcmpSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or ICMP_ERROR. Those functions which call **IcmpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

IcmpGetPacketSize Function

```
UINT WINAPI IcmpGetPacketSize(  
    HCLIENT hClient  
);
```

The **IcmpGetPacketSize** function returns the size of the ICMP echo datagram that will be sent to the remote host. The minimum packet size is 1 byte, the maximum packet size is 65,535 bytes.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the size of the datagram. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpGetRecvCount Function

```
INT WINAPI IcmpGetRecvCount(  
    HCLIENT hClient  
);
```

The **IcmpGetRecvCount** function returns the number of replies sent to the client from the remote host.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the number of replies. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpGetSendCount Function

```
INT WINAPI IcmpGetSendCount(  
    HCLIENT hClient  
);
```

The **IcmpGetSendCount** function returns the number of datagrams sent to the remote host by the client.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the number of datagrams sent by the client. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpGetSequenceId Function

```
INT WINAPI IcmpGetSequenceId(  
    HCLIENT hClient  
);
```

The **IcmpGetSequenceId** function returns the sequence identifier for the last ICMP echo datagram received by the client.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the sequence identifier. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpGetTimeout Function

```
DWORD WINAPI IcmpGetTimeout(  
    HCLIENT hClient  
);
```

The **IcmpGetTimeout** function returns the number of milliseconds the client will wait for a response from the remote host. Once the specified number of milliseconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in milliseconds. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

[IcmpIsBlocking](#), [IcmpSetTimeout](#)

IcmpGetTimeToLive Function

```
INT WINAPI IcmpGetTimeToLive(  
    HCLIENT hClient  
);
```

The **IcmpGetTimeToLive** function returns the time-to-live for the last ICMP echo datagram received by the client.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the time-to-live for the last datagram. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The time-to-live (TTL) value is specified in the IP header of a datagram, and is used to control the number of routers that the datagram is passed through. Each router that handles the datagram decrements the TTL value by one. When it drops to zero, a datagram is returned to the sender, specifying that the TTL has been exceeded. The default value is 255.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpGetTripTime Function

```
INT WINAPI IcmpGetTripTime(  
    HCLIENT hClient,  
    LPICMP_TIME lpIcmpTime  
);
```

The **IcmpGetTripTime** returns round-trip statistics for the datagrams sent to the current remote host.

Parameters

hClient

A handle to the client session.

lpIcmpTime

A pointer to an [ICMP_TIME](#) data structure which will contain the round-trip statistics for the current remote host.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is `ICMP_ERROR`. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: `cstools11.h`

Import Library: `csicmv11.lib`

See Also

IcmpInitialize Function

```
BOOL WINAPI IcmpInitialize(  
    LPCTSTR lpszLicenseKey,  
    LPINITDATA lpData  
);
```

The **IcmpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpData

Pointer to an INITDATA data structure. This parameter may be NULL if the initialization data for the library is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **IcmpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must insure that this function is called with a valid license key.

If the *lpData* argument is specified, it must point to an INITDATA structure which has been initialized by setting the *dwSize* member to the size of the structure. All other structure members should be set to zero. If the function is successful, then the INITDATA structure will be filled with identifying information about the library.

Although it is only required that **IcmpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **IcmpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **IcmpInitialize** or **IcmpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[IcmpCloseHandle](#), [IcmpCreateHandle](#), [IcmpUninitialize](#)

IcmpIsBlocking Function

```
BOOL WINAPI IcmpIsBlocking(  
    HCLIENT hClient  
);
```

The **IcmpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IcmpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csicmv11.lib

See Also

[IcmpCancel](#)

IcmpRecvEcho Function

```
INT WINAPI IcmpRecvEcho(  
    HCLIENT hClient  
);
```

The **IcmpRecvEcho** function reads the reply to an ICMP echo datagram generated by the client. This function should only be called by asynchronous client sessions in response to an event notification that a datagram has been received.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

[IcmpGetRecvCount](#), [IcmpGetSequenceId](#), [IcmpGetTimeToLive](#), [IcmpSendEcho](#)

IcmpRegisterEvent Function

```
INT WINAPI IcmpRegisterEvent(
    HCLIENT hClient,
    UINT nEventId,
    INETEVENTPROC LpfnEvent,
    DWORD_PTR dwParam
);
```

The **IcmpRegisterEvent** function registers a callback function for the specified event.

Parameters

- hClient**
Handle to client session.
- nEventId**
An unsigned integer which specifies which event should be registered with the specified callback function. One or more of the following values may be used:
- | Value | Description |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ICMP_EVENT_ECHO | The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender. |
| ICMP_EVENT_REPLY | The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information. |
| ICMP_EVENT_TIMEOUT | The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation. |
| ICMP_EVENT_CANCEL | The current operation has been canceled. The client application may attempt to retry the operation or close the handle. |
- lpfnEvent**
Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **IcmpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.
- dwParam**
A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpRegisterEvent** function associates a callback function with a specific event. The event handler is an **IcmpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will

be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

IcmpReset Function

```
INT WINAPI IcmpReset(  
    HCLIENT hClient  
);
```

The **IcmpReset** function resets the client session, clearing the packet trip statistics, time-to-live, sequence identifier, send and receive counts.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

[IcmpSetHostAddress](#), [IcmpSetHostName](#), [IcmpSetSequenceId](#), [IcmpSetTimeToLive](#)

IcmpResolveAddress Function

```
INT WINAPI IcmpResolveAddress(  
    DWORD dwAddress,  
    LPTSTR lpszHostName,  
    INT nMaxLength  
);
```

The **IcmpResolveAddress** function resolves a numeric IP address into a fully qualified domain name.

Parameters

dwAddress

The IP address to be resolved, specified as an unsigned 32-bit integer in network byte order.

lpszHostName

A pointer to a buffer that will contain a null-terminated string that specifies the fully qualified domain name for the host. It is recommended that this buffer be at least 64 characters in length.

nMaxLength

The maximum number of characters that can be copied into the string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the host name. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpResolveAddress** function is used to perform a reverse DNS lookup, converting a numeric IP address into a fully qualified domain name. This is useful for functions like **IcmpTraceRoute**, which return host addresses as numeric values in network byte order. If the reverse DNS lookup fails because there is no PTR record for the given IP address, a printable form of the address in dotted notation will be returned in the string buffer.

Calling this function will cause the thread to block until the IP address is resolved, or until the DNS query times out because there is no reverse record for the address. In some cases, a reverse lookup can take several seconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

IcmpSendEcho Function

```
INT WINAPI IcmpSendEcho(  
    HCLIENT hClient  
);
```

The **IcmpSendEcho** function sends an ICMP echo datagram to the remote host.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

For asynchronous client sessions, this function returns immediately. Otherwise, the client enters a blocking state and waits for a reply from the remote host. The function returns when a reply has been received, or the operation times-out.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpSetHostAddress Function

```
INT WINAPI IcmpSetHostAddress(  
    HCLIENT hClient,  
    DWORD dwAddress  
);
```

The **IcmpSetHostAddress** function specifies the IP address of the host to receive an ICMP echo datagram. If the address specifies a new host, the current client statistics are reset.

Parameters

hClient

A handle to the client session.

dwAddress

The IP address of the remote host as a 32-bit integer value, specified in network byte order.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

To specify a remote host name or an IP address as a string in dot notation, use the **IcmpSetHostName** function instead.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpSetHostName Function

```
INT WINAPI IcmpSetHostName(  
    HCLIENT hClient,  
    LPCTSTR lpszHostName  
);
```

The **IcmpSetHostName** function specifies the name of the host to receive an ICMP echo datagram. If the name specifies a new host, the current client statistics are reset.

Parameters

hClient

A handle to the client session.

lpszHostName

A pointer to a string which specifies the name, or IP address in dot-notation, of the remote host.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

IcmpSetLastError Function

```
VOID WINAPI IcmpSetLastError(  
    DWORD dwErrorCode  
);
```

The **IcmpSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or ICMP_ERROR. Those functions which call **IcmpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **IcmpGetLastError** function. The use of **IcmpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpSetPacketSize Function

```
UINT WINAPI IcmpSetPacketSize(  
    HCLIENT hClient,  
    UINT nPacketSize  
);
```

The **IcmpSetPacketSize** function sets the size of the ICMP datagram packet that is sent to the remote host.

Parameters

hClient

Handle to the client session.

nPacketSize

Size of the ICMP datagram packet in bytes. The minimum packet size is 1 byte and the maximum packet size is 65,535 bytes.

Return Value

If the function succeeds, the return value is the previous ICMP datagram packet size. If the function fails, the return value is zero. To get extended error information, call **IcmpGetLastError**.

Remarks

Note that packet sizes over 512 bytes may not be supported by your networking software or configuration. It is recommended that most applications use the minimum packet size of 32 bytes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpSetSequenceId Function

```
INT WINAPI IcmpSetSequenceId(  
    HCLIENT hClient,  
    INT nSequenceId  
);
```

The **IcmpSetSequenceId** function sets the sequence identifier for the next ICMP echo datagram sent by the client. The default sequence identifier for the first datagram is one.

Parameters

hClient

A handle to the client session.

nSequenceId

The sequence identifier for the next datagram sent by the client.

Return Value

If the function succeeds, the return value is the previous sequence identifier. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

IcmpSetTimeout Function

```
DWORD WINAPI IcmpSetTimeout(  
    HCLIENT hClient,  
    DWORD dwTimeout  
);
```

The **IcmpSetTimeout** function sets the number of milliseconds the client will wait for a response from the remote host. Once the specified number of milliseconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

dwTimeout

The number of milliseconds until a blocking operation fails.

Return Value

If the function succeeds, the return value is the value of the timeout before the function was called. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

[IcmpCreateHandle](#), [IcmpGetTimeout](#)

IcmpSetTimeToLive Function

```
INT WINAPI IcmpSetTimeToLive(  
    HCLIENT hClient,  
    INT nTimeToLive  
);
```

The **IcmpSetTimeToLive** function sets the maximum time-to-live for the next ICMP datagram sent by the client.

Parameters

hClient

A handle to the client session.

nTimeToLive

The time-to-live value for the next ICMP echo datagram.

Return Value

If the function succeeds, the return value is the previous time-to-live value. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The time-to-live (TTL) value is specified in the IP header of a datagram, and is used to control the number of routers that the datagram is passed through. Each router that handles the datagram decrements the TTL value by one. When it drops to zero, a datagram is returned to the sender, specifying that the TTL has been exceeded.

Calling this function changes the default TTL value for all subsequent ICMP datagrams sent by the library, with the default value being 255. Note that not all Windows Sockets implementations support setting the time-to-live value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

See Also

IcmpTraceRoute Function

```
INT WINAPI IcmpTraceRoute(  
    LPCTSTR lpszHostName,  
    UINT nMaxHops,  
    DWORD dwTimeout,  
    DWORD dwReserved,  
    LPICMPTRACE lpTrace,  
    LPDWORD lpdwSize  
);
```

The **IcmpTraceRoute** function sends a series of ICMP echo datagrams to trace the route taken from the local system to the remote host.

Parameters

lpszHostName

A pointer to a string which specifies the fully qualified domain name of the remote host, or the IP address in dotted notation.

nMaxHops

An unsigned integer which specifies the maximum number of routers the datagram will be forwarded through (the number of hops) to the remote host. The minimum value is 1 and the maximum value is 255. It is recommended that most applications specify a value of at least 30.

dwTimeout

An unsigned integer which specifies the number of milliseconds the function will wait for a response to an echo datagram.

dwReserved

A reserved parameter. This value should always be zero.

lpTrace

A pointer to an array of [ICMPTRACE](#) structures which will contain information about each intermediate host between the local and remote system. The number of structures must be at least the same as the maximum number of hops specified by the *nMaxHops* parameter. To determine the total number of bytes that must be allocated for the structure array, this parameter can be passed as NULL and the total size will be returned in the *lpdwSize* parameter.

lpdwSize

A pointer to an unsigned integer which should be initialized to the size of the ICMPTRACE array passed to the function. If the *lpTrace* parameter is NULL, the function will calculate the size of the array buffer that must be allocated and return that value. If both the *lpTrace* and *lpdwSize* parameters are NULL, no statistical information about the intermediate hosts will be collected.

Return Value

If the function succeeds, the return value is the number of intermediate hosts between the local and remote system. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpTraceRoute** function sends a series of ICMP echo datagrams to the specified host, adjusting the time-to-live value to determine the intermediate hosts that route the packet. The function returns the number of hops to the remote host.

It is important to note that the failure of an intermediate host to respond to an ICMP echo datagram may not indicate a problem with the remote system. Systems can be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of Denial of Service attacks.

The ability to send ICMP datagrams may be restricted to users with administrative privileges, depending on the policies and configuration of the local system. If you are unable to send or receive any ICMP datagrams, it is recommended that you check the firewall settings and any third-party security software that could impact the normal operation of this component.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

Unicode: Implemented as Unicode and ANSI versions

IcmpUninitialize Function

```
VOID WINAPI IcmpUninitialize();
```

The **IcmpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **IcmpInitialize** call before it can call any of the other the library functions. When it has completed the use of library, the application must call **IcmpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There must be a call to **IcmpUninitialize** for every successful call to **IcmpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csicmv11.lib

Internet Control Message Protocol Data Structures

- [ICMPTIME](#)
- [ICMPTRACE](#)
- [INITDATA](#)
- [INTERNET_ADDRESS](#)
- [SYSTEMTIME](#)

ICMPTIME

This structure is used by the [IcmpGetTripTime](#) function to return the round-trip times of an ICMP datagram.

```
typedef struct _ICMPTIME {  
    DWORD dwTripAverage;  
    DWORD dwTripMaximum;  
    DWORD dwTripMinimum;  
    DWORD dwTripTime;  
} ICMPTIME, *LPICMPTIME;
```

Members

dwTripAverage

The average round-trip time in milliseconds for all datagrams sent to the current host.

dwTripMaximum

The maximum round-trip time in milliseconds for all datagrams sent to current host.

dwTripMinimum

The minimum round-trip time in milliseconds for all datagrams sent to the current host.

dwTripTime

The current round-trip time in milliseconds for the last datagram sent to the current host.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

ICMPTRACE

This structure is used by the [IcmpTraceRoute](#) function to return the route of an ICMP datagram.

```
typedef struct _ICMPTRACE
{
    UINT          nDistance;
    DWORD         dwHostAddress;
    DWORD         dwTripAverage;
    DWORD         dwTripMaximum;
    DWORD         dwTripMinimum;
} ICMPTRACE, *LPICMPTRACE;
```

Members

nDistance

The distance from the local host to the remote host for this route.

dwHostAddress

An unsigned integer which specifies the IP address of the remote host in network byte order.

dwTripAverage

The average round-trip time in milliseconds for all datagrams sent to the specified host.

dwTripMaximum

The maximum round-trip time in milliseconds for all datagrams sent to specified host.

dwTripMinimum

The minimum round-trip time in milliseconds for all datagrams sent to the specified host.

dwTripTime

The current round-trip time in milliseconds for the last datagram sent to the specified host.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

This structure contains information about the SocketTools library when the initialization function returns.

```
typedef struct _INITDATA
{
    DWORD      dwSize;
    DWORD      dwVersionMajor;
    DWORD      dwVersionMinor;
    DWORD      dwVersionBuild;
    DWORD      dwOptions;
    DWORD_PTR  dwReserved1;
    DWORD_PTR  dwReserved2;
    TCHAR      szDescription[128];
} INITDATA, *LPINITDATA;
```

Members

dwSize

Size of this structure. This structure member must be set to the size of the structure prior to calling the initialization function. Failure to do so will cause the function to fail.

dwVersionMajor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the major version number for the library.

dwVersionMinor

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the minor version number for the library.

dwVersionBuild

This member must be initialized to a value of zero prior to calling the initialization function. When the function returns, it will contain the build number for the library.

dwOptions

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved1

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

dwReserved2

This member must be initialized to a value of zero prior to calling the initialization function. This member is reserved for future use.

szDescription

A null terminated string which describes the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Unicode: Implemented as Unicode and ANSI versions

INTERNET_ADDRESS

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
    INT    ipFamily;
    BYTE   ipNumber[16];
} INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the <i>ipNumber</i> array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the <i>ipNumber</i> array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the <i>ipNumber</i> array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the *ipNumber* array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the *ipFamily* member first to make sure that it is actually an IPv4 address.

Requirements

- Minimum Desktop Platform:** Windows 7 Service Pack 1
- Minimum Server Platform:** Windows Server 2008 R2 Service Pack 1
- Header File:** ctools11.h

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: windows.h.

Internet Message Access Protocol Library

Manage email messages and mailboxes on a mail server.

Reference

- [Functions](#)
- [Data Structures](#)
- [Error Codes](#)

Library Information

File Name	CSMAPV11.DLL
Version	11.0.2218.1855
LibID	FFDFB6F8-6CBE-49EF-8C0F-093254490868
Import Library	CSMAPV11.LIB
Dependencies	None
Standards	RFC 3501

Overview

The Internet Message Access Protocol (IMAP) is an application protocol which is used to access a user's email messages which are stored on a mail server. However, unlike the Post Office Protocol (POP) where messages are downloaded and processed on the local system, the messages on an IMAP server are retained on the server and processed remotely. This is ideal for users who need access to a centralized store of messages or have limited bandwidth. For example, traveling salesmen who have notebook computers or mobile users on a wireless network would be ideal candidates for using IMAP.

The SocketTools IMAP library implements the current standard for this protocol, and provides functions to retrieve messages, or just certain parts of a message, create and manage mailboxes, search for specific messages based on certain criteria and so on. The API is designed as a superset of the Post Office Protocol API, so developers who are used to working with the POP3 library will find the IMAP library very easy to integrate into an existing application.

This library supports secure connections using the standard SSL and TLS protocols.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). If you are using Visual C++ 6.0 it is required that you have Service Pack 6 (SP6) installed. You should install all updates for your development tools and have the current Windows SDK installed. The minimum recommended version of Visual Studio is Visual Studio 2010.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are using Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. It is recommended that you install the current service pack and all critical updates available for your version of the operating system.

This product includes both 32-bit and 64-bit libraries. Native 64-bit CPU support requires the 64-bit version of Windows 7 or later versions of the Windows operating system.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Internet Message Access Protocol Functions

Function	Description
ImapAsyncConnect	Connect asynchronously to the specified server
ImapAttachThread	Attach the specified client handle to another thread
ImapCancel	Cancel the current blocking operation
ImapCheckMailbox	Check the current mailbox for new messages
ImapCloseMessage	Close the current message
ImapCommand	Send a command to the server
ImapConnect	Connect to the specified server
ImapCopyMessage	Copy a message from the current mailbox to another mailbox
ImapCreateMailbox	Create a new mailbox on the server
ImapCreateMessage	Create a new message in the specified mailbox
ImapCreateSecurityCredentials	Allocate a structure to establish client security credentials
ImapDecodeMailboxName	Decode a UTF-7 encoded mailbox name using the specified code page
ImapDeleteMailbox	Delete the specified mailbox from the server
ImapDeleteMessage	Delete the specified message from the mailbox
ImapDeleteSecurityCredentials	Delete the specified client security credentials
ImapDisableEvents	Disable the event notification mechanism
ImapDisableTrace	Disable logging of network function calls to the trace log
ImapDisconnect	Disconnect from the current server
ImapEnableEvents	Enable the client event notification mechanism
ImapEnableTrace	Enable logging of network function calls to a file
ImapEncodeMailboxName	Encode a mailbox name using modified UTF-7 encoding
ImapEnumMessages	Enumerate the messages in the current mailbox
ImapEventProc	Callback function that processes events generated by the client
ImapExamineMailbox	Select the specified mailbox in read-only mode
ImapExpungeMailbox	Remove messages that have been marked for deletion from the current mailbox
ImapFreezeEvents	Suspend and resume event handling by the client
ImapGetCapability	Return a string which identifies the capabilities of the server
ImapGetCurrentMailbox	Return the name of the currently selected mailbox
ImapGetDeletedMessages	Return the messages that have been marked for deletion
ImapGetErrorString	Return a description for the specified error code
ImapGetFirstMailbox	Return the first mailbox according to specified criteria
ImapGetHeaderValue	Return the value of the specified header field
ImapGetHeaderValueEx	Return the value of a header field in the specified message part

ImapGetIdleThreadId	Return the ID of the thread created to monitor the client session
ImapGetLastError	Return the last error code
ImapGetMailboxDelimiter	Get the path delimiter for the specified mailbox hierarchy
ImapGetMailboxSize	Return the size of the specified mailbox
ImapGetMailboxStatus	Return the status of the specified mailbox
ImapGetMailboxUid	Return the unique identifier for the specified mailbox
ImapGetMessage	Retrieve the specified message from the server
ImapGetMessageCount	Return the number of messages available in the mailbox
ImapGetMessageCountEx	Return the number of messages available in the mailbox
ImapGetMessageFlags	Return the status flags for the specified message
ImapGetMessageHeaders	Retrieve the specified message header from the server
ImapGetMessageHeadersEx	Retrieve the specified message header, UID and flags from the server
ImapGetMessageId	Return the message ID string for the specified message
ImapGetMessageParts	Return the number of MIME message parts in the specified message
ImapGetMessageSender	Return the address of the message sender
ImapGetMessageSize	Return the size of the specified message
ImapGetMessageUid	Return the unique identifier for the specified message
ImapGetNewMessages	Return a list of the new messages in the current mailbox
ImapGetNextMailbox	Return the next mailbox name on the server
ImapGetResultCode	Return the result code from the previous command
ImapGetResultString	Return the result string from the previous command
ImapGetSecurityInformation	Return security information about the current client connection
ImapGetStatus	Return the current status of the client
ImapGetTimeout	Return the number of seconds until an operation times out
ImapGetTransferStatus	Return data transfer statistics
ImapGetUnseenMessages	Return a list of messages from the current mailbox that have not been read
ImapIdle	Enables mailbox status monitoring for the client session
ImapIdleProc	Callback function that receives update notifications from the server
ImapInitialize	Initialize the library and validate the specified license key at runtime
ImapIsBlocking	Determine if the client is blocked, waiting for information
ImapIsConnected	Determine if the client is connected to the server
ImapIsReadable	Determine if data can be read from the server
ImapIsWritable	Determine if data can be written to the server
ImapLogin	Login to the server
ImapOpenMessage	Open the specified message for reading on the server
ImapOpenMessageEx	Open the specified message for reading on the server, with additional options

ImapRead	Read data returned by the server
ImapRegisterEvent	Register an event handler for the specified event
ImapRenameMailbox	Rename the specified mailbox
ImapReselectMailbox	Reselect the current mailbox and return updated status information
ImapSearchMailbox	Search the mailbox according to specified criteria
ImapSelectMailbox	Select the specified mailbox in read-write mode
ImapSetLastError	Set the last error code for the current thread
ImapSetMessageFlags	Set one or more status flags for the specified message
ImapSetTimeout	Set the number of seconds until an operation times out
ImapStoreMessage	Store the contents of a message to the specified file
ImapSubscribeMailbox	Subscribe to the specified mailbox
ImapUndeleteMessage	Undelete the specified message from the current mailbox
ImapUninitialize	Terminate use of the library by the application
ImapUnselectMailbox	Unselect the current mailbox and expunge any deleted messages
ImapUnsubscribeMailbox	Unsubscribe from the specified mailbox
ImapWrite	Write data to the server

ImapAsyncConnect Function

```
HCLIENT WINAPI ImapAsyncConnect(  
    LPCTSTR lpszHostName,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **ImapAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **ImapConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

- lpszHostName***
A pointer to a null terminated string which specifies the host name or IP address of the IMAP server.
- nRemotePort***
The port number the client should use to establish the connection. A value of zero specifies that default port 143 should be used, which is the standard port number assigned to the IMAP service. If the secure port number is specified, an implicit TLS connection will be established by default.
- nTimeout***
The number of seconds that the client will wait for a response from the server before failing the current operation
- dwOptions***
An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
IMAP_OPTION_IDENTIFY	This option specifies the client should identify itself to the server. If enabled, the client will send the ID command to the server as defined in RFC 2971. This option has no effect if the server does not support the ID command.
IMAP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior

	of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
IMAP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
IMAP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option is the same as specifying IMAP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STARTTLS command.
IMAP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the STARTTLS command.
IMAP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
IMAP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
IMAP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which is used to establish the client credentials for a secure connection to the server. The function **ImapCreateSecurityCredentials** can be used to

create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

hEventWnd

The handle to the asynchronous notification window. This window receives messages which notify the client of various asynchronous client events that occur. Specifying this parameter and a message identifier causes the connection to be non-blocking. If this parameter is NULL, then a blocking connection is established.

uEventMsg

The message identifier that is used when an asynchronous client event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **ImapGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
IMAP_EVENT_CONNECT	The connection to the server has completed. The high word of the <i>lParam</i> parameter should be checked, since this notification message will be posted if an error has occurred.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
IMAP_EVENT_CANCEL	The client has canceled the current operation.
IMAP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the <i>lParam</i> parameter should be checked, since this notification message will also be posed if the command cannot be executed.
IMAP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking

	operations, such as retrieving a complete message from the server.
--	--------------------------------------------------------------------

To cancel asynchronous notification and return the client to a blocking mode, use the **ImapDisableEvents** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **ImapAttachThread** function.

Specifying the IMAP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

ImapAttachThread Function

```
DWORD WINAPI ImapAttachThread(  
    HCLIENT hClient  
    DWORD dwThreadId  
);
```

The **ImapAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **ImapAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **ImapAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **ImapCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **ImapUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

See Also

[ImapConnect](#), [ImapDisconnect](#), [ImapUninitialize](#)

ImapCancel Function

```
INT WINAPI ImapCancel(  
    HCLIENT hClient  
);
```

The **ImapCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When the **ImapCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapv11.lib

See Also

[ImapIsBlocking](#)

ImapCheckMailbox Function

```
INT WINAPI ImapCheckMailbox(  
    HCLIENT hClient,  
    UINT *LpnMessages,  
    UINT *LpnUnseen  
);
```

The **ImapCheckMailbox** function requests that the server create a checkpoint of the currently selected mailbox, and returns the current number of messages and unseen messages.

Parameters

hClient

Handle to the client session.

lpnMessages

A pointer to an unsigned integer value which will contain the number of messages in the currently selected mailbox when the function returns.

lpnUnseen

A pointer to an unsigned integer value which will contain the number of unseen messages in the currently selected mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When the client requests a checkpoint, the server may perform implementation-dependent housekeeping for that mailbox, such as updating the mailbox on disk with the current state of the mailbox in memory. On some systems this command has no effect other than to update the client with the current number of messages in the mailbox.

This function actually sends two IMAP commands. The first is the CHECK command, followed by the NOOP command to poll for any new messages that have arrived. In addition to polling the server for new messages, this command can also be used to ensure the idle timer on the server does not expire and force a disconnect from the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csmapv11.lib

ImapCloseMessage Function

```
INT WINAPI ImapCloseMessage(  
    HCLIENT hClient  
);
```

The **ImapCloseMessage** function closes the current message.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapCloseMessage** function closes the current message. If there is any remaining data left to be read from the message, it will be read and discarded.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

ImapCommand Function

```
INT WINAPI ImapCommand(  
    HCLIENT hClient,  
    LPCTSTR lpszCommand,  
    LPCTSTR lpszParameter  
);
```

The **ImapCommand** function sends a command to the server. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the function succeeds, it returns an IMAP result code. If the command was successful, it returns IMAP_RESULT_OK. A return value of IMAP_RESULT_CONTINUE indicates the command was accepted and the caller should proceed with the next command. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. The current version of the protocol which is supported by this library is version 4rev1 as defined in RFC 3501.

Use the **ImapGetResultCode** function to determine the result of the command that was sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

Unicode: Implemented as Unicode and ANSI versions

ImapConnect Function

```
HCLIENT WINAPI ImapConnect(  
    LPCTSTR lpszHostName,  
    UINT nRemotePort,  
    UINT nTimeout,  
    DWORD dwOptions,  
    LPSECURITYCREDENTIALS lpCredentials  
);
```

The **ImapConnect** function is used to establish a connection with the server.

Parameters

lpszHostName

A pointer to a null terminated string which specifies the host name or IP address of the IMAP server.

nRemotePort

The port number the client should use to establish the connection. A value of zero specifies that default port 143 should be used, which is the standard port number assigned to the IMAP service. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
IMAP_OPTION_IDENTIFY	This option specifies the client should identify itself to the server. If enabled, the client will send the ID command to the server as defined in RFC 2971. This option has no effect if the server does not support the ID command.
IMAP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
IMAP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
IMAP_OPTION_SECURE	This option specifies that a secure connection should

	be established with the server and requires that the server support the TLS protocol. This option is the same as specifying IMAP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STARTTLS command.
IMAP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
IMAP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
IMAP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
IMAP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
IMAP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

A pointer to a [SECURITYCREDENTIALS](#) structure which is used to establish the client credentials for a secure connection to the server. The function **ImapCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **ImapGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should

create a background worker thread and establish a connection by calling **ImapConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **ImapAttachThread** function.

Specifying the IMAP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

Unicode: Implemented as Unicode and ANSI versions

[ImapDisconnect](#), [ImapInitialize](#), [ImapLogin](#)

ImapCopyMessage Function

```
INT WINAPI ImapCopyMessage(  
    HCLIENT hClient,  
    UINT nMessageId,  
    LPCTSTR lpszMailbox  
);
```

The **ImapCopyMessage** function copies a message from the current mailbox to the specified mailbox. The message is appended to the mailbox, and the message flags and internal date are preserved.

Parameters

hClient

Handle to the client session.

nMessageId

The message identifier which specifies which message is to be copied to the mailbox. This value must be greater than zero and specify a valid message number.

lpszMailbox

A pointer to a string which specifies the name of the mailbox that the message will be copied to. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

Return Value

If the function succeeds, it returns a value of zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the mailbox does not exist, the function will fail. To create a new mailbox, use the **ImapCreateMailbox** function. A message can be copied within the same mailbox, in which case the server may flag it as a new message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[ImapCreateMailbox](#), [ImapGetResultCode](#), [ImapGetResultString](#)

ImapCreateMailbox Function

```
INT WINAPI ImapCreateMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox  
);
```

The **ImapCreateMailbox** function creates a new mailbox on the server.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a null terminated string which specifies the new mailbox to be created.

Return Value

If the function succeeds, it returns a value of zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the mailbox name is suffixed with the server's hierarchy delimiter, this indicates to the server that the client intends to create mailbox names under the specified name in the hierarchy. If superior hierarchical names are specified in the mailbox name, then the server may automatically create them as needed. For example, if the mailbox name "Mail/Office/Projects" is specified and "Mail/Office" does not exist, it may be automatically created by the server.

The special mailbox name INBOX is reserved, and cannot be created. It is recommended that mailbox names only consist of printable ASCII characters, and the special characters "*" and "%" should be avoided.

If you need to create a mailbox which contains Unicode characters or symbols, it is recommended you always use the Unicode version of this function. The mailbox name will automatically be converted to modified UTF-7 encoding as defined by the IMAP4 standard. The ANSI version of this function will only accept mailbox names using either modified UTF-7 encoding or UTF-8 encoding.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapv11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[ImapDecodeMailboxName](#), [ImapDeleteMailbox](#), [ImapEncodeMailboxName](#), [ImapGetFirstMailbox](#), [ImapGetNextMailbox](#), [ImapRenameMailbox](#)

ImapCreateMessage Function

```
INT WINAPI ImapCreateMessage(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox,  
    DWORD dwReserved,  
    LPVOID lpMessage,  
    DWORD dwMessageSize,  
    DWORD dwFlags  
);
```

The **ImapCreateMessage** function creates a message, appending it to the contents of the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a string which specifies the name of the mailbox that the message will be created in. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

dwReserved

A reserved parameter. This value should always be zero.

lpMessage

A pointer to the buffer which contains the message to be created.

dwMessageSize

An unsigned integer value which specifies the size of the message in bytes. If this value is zero, then it is assumed that the *lpMessage* parameter points to a string.

dwFlags

An unsigned integer that specifies one or more message flags. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_FLAG_NONE	No value.
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DRAFT	The message is not completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message is flagged for urgent or special attention.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the mailbox does not exist, the function will fail. To create a new mailbox, use the **ImapCreateMailbox** function. If the message is created in the mailbox that is currently selected, the server may flag it as recent.

This function is typically used by applications to store messages which have already been sent to a user. After a message has been delivered using the SMTP protocol, that same message may be created in a mailbox on the IMAP server so that the user has access to those messages.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[ImapCopyMessage](#), [ImapDeleteMessage](#), [ImapGetMessageFlags](#), [ImapSetMessageFlags](#)

ImapCreateSecurityCredentials Function

```
BOOL WINAPI ImapCreateSecurityCredentials(  
    DWORD dwProtocol,  
    DWORD dwOptions,  
    LPCTSTR lpszUserName,  
    LPCTSTR lpszPassword,  
    LPCTSTR lpszCertStore,  
    LPCTSTR lpszCertName,  
    LPVOID lpvReserved,  
    LPSECURITYCREDENTIALS *LppCredentials  
);
```

The **ImapCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpzUserName

A pointer to a string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpzPassword

A pointer to a string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpzCertStore

A pointer to a string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A pointer to a null terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **ImapDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **ImapConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify

the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpzCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpzPassword* parameter or the library will be unable to access the certificate.

Note that the *lpzUserName* and *lpzPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
ImapCreateSecurityCredentials(SEcurity_PROTOCOL_DEFAULT,
                             0,
                             NULL,
                             NULL,
                             lpzCertStore,
                             lpzCertName,
                             NULL,
                             &lpSecCred);

hClient = ImapConnect(lpzHostName,
                     IMAP_PORT_SECURE,
                     IMAP_TIMEOUT,
                     IMAP_OPTION_SECURE,
                     lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[ImapConnect](#), [ImapDeleteSecurityCredentials](#), [ImapGetSecurityInformation](#), [SECURITYCREDENTIALS](#)

ImapDecodeMailboxName Function

```
INT WINAPI ImapDecodeMailboxName(  
    INT nCodePage,  
    LPCSTR lpszMailboxName,  
    LPTSTR lpszDecodedName,  
    INT nMaxLength  
);
```

The **ImapDecodeMailboxName** function decodes a UTF-7 encoded mailbox name using the specified code page.

Parameters

nCodePage

An integer value which specifies the code page which should be used when decoding the mailbox name. If the ANSI version of this function is called, this parameter can be any valid code page, or the constant CP_ACP which specifies the current active code page for the locale. If the Unicode version of this function is called, this parameter should always be zero.

lpszMailboxName

A pointer to a null terminated string which contains the UTF-7 encoded name of the mailbox. The encoded string must use the modified UTF-7 format defined in the IMAP4 protocol standard. This parameter cannot be a NULL pointer or an empty string.

lpszDecodedName

A pointer to a string buffer which will contain the decoded mailbox name. This parameter cannot be NULL and must be large enough to contain the entire name.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the *lpszDecodedName* string buffer. This value must be greater than zero and the buffer must be large enough to store the entire name.

Return Value

If the function succeeds, it returns the number of characters in the decoded mailbox name. If an error occurs, the function returns zero. To get extended error information, call **ImapGetLastError**.

Remarks

Mailbox names which contain non-ASCII characters must be converted to a modified version of UTF-7 encoding as defined by the IMAP4 protocol. This encoding allows applications to reference mailbox names which contain Unicode characters and provides support for languages other than English. This function is used to convert a UTF-7 encoded mailbox name using the current locale, primarily for display purposes.

For example, if the *lpszMailboxName* parameter specifies the string "&A5QDvw06A7kDvA0u-", this function will convert it to the Greek word "Δοκιμή" and return that value in the *lpszDecodedName* buffer. It is recommended you use the Unicode version of this function whenever possible to ensure the mailbox name is decoded correctly.

The ANSI version of this function should only be used with legacy applications which do not support Unicode. The decoded mailbox name will be converted using the code page specified by the *nCodePage* parameter. If the code page does not support the characters used in the mailbox name, this can result in an incorrect conversion. Using the previous example, the mailbox name will always

decode correctly if the Unicode version of the function is used, but the ANSI version of the function will only decode it correctly if the code page is specified as 1253 (Greek).

This function should not be used to convert strings between Unicode and UTF-7. The encoding format is specifically intended for use with the IMAP4 protocol and should never be used for general purpose encoding or decoding. If you need to convert a UTF-7 encoded string to Unicode, use the Win32 API function **MultiByteToWideChar**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib.h

Import Library: cstdlib.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[ImapCreateMailbox](#), [ImapEncodeMailboxName](#), [ImapGetFirstMailbox](#), [ImapGetNextMailbox](#),
[ImapRenameMailbox](#)

ImapDeleteMailbox Function

```
INT WINAPI ImapDeleteMailbox(  
    HCLIENT hClient,  
    LPCTSTR lpszMailbox  
);
```

The **ImapDeleteMailbox** function deletes a mailbox on the server.

Parameters

hClient

Handle to the client session.

lpszMailbox

A pointer to a null terminated string which specifies the mailbox to be deleted.

Return Value

If the function succeeds, it returns value of zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

A mailbox cannot be deleted if it contains inferior hierarchical names and has the IMAP_FLAG_NOSELECT attribute. On most systems this is the case when the mailbox name references a directory on the server, and that directory contains other subdirectories or mailboxes. To remove the mailbox, you must first delete any child mailboxes that exist.

If the mailbox that is deleted is the currently selected mailbox, it will be automatically unselected and any messages marked for deletion will be expunged before the mailbox is removed. If the delete operation fails, the client will remain in an unselected state until either the **ImapExamineMailbox** or **ImapSelectMailbox** function is called.

The special mailbox name INBOX is reserved, and cannot be deleted.

If you need to delete a mailbox which contains Unicode characters or symbols, it is recommended you always use the Unicode version of this function. The mailbox name will automatically be converted to modified UTF-7 encoding as defined by the IMAP4 standard. The ANSI version of this function will accept mailbox names using either modified UTF-7 encoding or UTF-8 encoding.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csmapi11.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

[ImapCreateMailbox](#), [ImapGetFirstMailbox](#), [ImapGetNextMailbox](#), [ImapRenameMailbox](#)

ImapDeleteMessage Function

```
INT WINAPI ImapDeleteMessage(  
    HCLIENT hClient,  
    UINT nMessageId  
);
```

The **ImapDeleteMessage** function marks the specified message for deletion from the current mailbox.

Parameters

hClient

Handle to the client session.

nMessage

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

This function only marks the message for deletion. The message is not actually deleted until the mailbox is expunged or another mailbox is selected. This function will return an error if the current mailbox is in read-only mode, such as if it was selected using the **ImapExamineMailbox** function.

It is important to note that unlike the POP3 protocol, a message that is marked for deletion is still accessible on the IMAP server until the mailbox is expunged. This means, for example, that a deleted message can still be retrieved using the **ImapGetMessage** function.

To determine if a message has been marked for deletion, use the **ImapGetMessageFlags** function and check if the IMAP_FLAG_DELETED bit flag has been set. To list all of the deleted messages in the current mailbox, use the **ImapGetDeletedMessages** function.

To remove the deletion flag from the message, use the **ImapUndeleteMessage** function. To prevent all messages in the current mailbox from being expunged, use the **ImapReselectMailbox** function to reset the current mailbox state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

ImapDeleteSecurityCredentials Function

```
VOID WINAPI ImapDeleteSecurityCredentials(  
    LPSECURITYCREDENTIALS *lppCredentials  
);
```

The **ImapDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an [LPSECURITYCREDENTIALS](#) pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)  
    ImapDeleteSecurityCredentials(&lpSecCred);  
  
ImapUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

Unicode: Implemented as Unicode and ANSI versions

ImapDisableEvents Function

```
INT WINAPI ImapDisableEvents(  
    HCLIENT hClient  
);
```

The **ImapDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapDisableEvents** function is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this function has been called.

This function is automatically called if the client has event notification enabled, and the **ImapDisconnect** function is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

ImapDisableTrace Function

```
BOOL WINAPI ImapDisableTrace();
```

The **ImapDisableTrace** function disables the logging of socket function calls to the trace log.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csmapi11.lib

See Also

[ImapEnableTrace](#)

ImapDisconnect Function

```
INT WINAPI ImapDisconnect(  
    HCLIENT hClient  
);
```

The **ImapDisconnect** function terminates the connection with the server, releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If a mailbox is selected at the time that **ImapDisconnect** is called, the current mailbox will be unselected and any messages that are marked for deletion will be expunged. To prevent any deleted messages from being removed from the mailbox, use the **ImapUnselectMailbox** function to unselect the current mailbox prior to disconnecting from the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: ctools11.h

Import Library: csmapi11.lib

ImapEnableEvents Function

```
INT WINAPI ImapEnableEvents(  
    HCLIENT hClient,  
    HWND hEventWnd,  
    UINT uEventMsg  
);
```

The **ImapEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **ImapRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

- hClient**
Handle to the client session.
- hEventWnd**
Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.
- uEventMsg**
The message that is received when a client event occurs. To avoid conflict with standard Windows messages, this value must be greater than WM_USER (1024) or an error will be returned. If the **hEventWnd** parameter is NULL, this value should be WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapEnableEvents** function is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer. The client must create a window message handler, which processes the various events. The **wParam** argument will contain the client handle, the low word of the **lParam** argument will contain the event identifier, and the high word will contain any error code. If no error has occurred, the high word will have a value of zero. The following events may be generated:

Value	Description
IMAP_EVENT_CONNECT	The connection to the server has completed. The high word of the lParam parameter should be checked, since this notification message will be posted if an error has occurred.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is

	only generated if the calling process is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
IMAP_EVENT_CANCEL	The client has canceled the current operation.
IMAP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the IParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
IMAP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

It is not required that the client be placed in asynchronous (non-blocking) mode in order to receive event notifications, except for the connect, disconnect, read and write events. To disable event notification, call the **ImapDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csmapi11.lib

ImapEnableTrace Function

```
BOOL WINAPI ImapEnableTrace(  
    LPCTSTR lpszTraceFile,  
    DWORD dwTraceFlags  
);
```

The **ImapEnableTrace** function enables the logging of socket function calls to a file.

Parameters

lpszTraceFile

Name of the trace log file. If this parameter is NULL or empty, the file CSTRACE.LOG is used. The directory for CSTRACE.LOG is given by the TEMP environment variable, if it is defined; otherwise, the directory given by the TMP environment variable is used, if it is defined; otherwise, the current working directory is used.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_DEFAULT	All function calls and return values are written to the trace file. The actual data being sent or received will not be logged. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file. Those errors which are not fatal and only indicate a warning will not be logged.
TRACE_WARNING	Only those function calls which fail, or return values which indicate a warning, are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

When trace logging is enabled, the logfile is opened, appended to and closed for each socket function call. Using the same logfile name, you can do the same in your application to add additional information to the logfile if needed. This can provide an application-level context for the entries made by the library. Make sure that the logfile is closed after the data has been written.

The TRACE_HEXDUMP option can produce very large logfiles, since all data that is being sent and received by the application is logged. To reduce the size of the file, you can enable and disable logging around limited sections of code that you wish to analyze.

All of the SocketTools networking components that use the Windows Sockets API support logging. If you are using multiple components, you only need to enable tracing once in your application or once per thread in a multithreaded application.

To redistribute an application that includes logging functionality, the **cstrcv11.dll** library must be

included as part of the installation package. This library provides the trace logging features, and if it is not available the **ImapEnableTrace** function will fail. Note that the trace logging library is a standard Windows DLL and does not need to be registered, it only needs to be redistributed with your application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools11.h

Import Library: csmapi11.lib

Unicode: Implemented as Unicode and ANSI versions

[ImapDisableTrace](#)

ImapEncodeMailboxName Function

```
INT WINAPI ImapEncodeMailboxName(  
    INT nCodePage,  
    LPCTSTR lpszMailboxName,  
    LPTSTR lpszEncodedName,  
    INT nMaxLength  
);
```

The **ImapEncodeMailboxName** function encodes a mailbox name using modified UTF-7 encoding.

Parameters

nCodePage

An integer value which specifies the code page which should be used when converting the mailbox name to Unicode. If the ANSI version of this function is called, this parameter can be any valid code page or a value of zero, which specifies the current active code page for the locale. If the Unicode version of this function is called, no conversion is required and this parameter should always be zero.

lpszMailboxName

A pointer to a null terminated string which contains the name of the mailbox. If the ANSI version of this function is called, this string is automatically converted to Unicode using the code page specified by the *nCodePage* parameter. This parameter cannot be a NULL pointer or an empty string.

lpszEncodedName

A pointer to a string buffer which will contain the UTF-7 encoded mailbox name. This parameter cannot be NULL and must be large enough to contain the entire name. The string will be null terminated and will only contain printable ASCII characters.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the *lpszEncodedName* string buffer. This value must be greater than zero and the buffer must be large enough to store the entire name.

Return Value

If the function succeeds, it returns the number of characters in the encoded mailbox name. If an error occurs, the function returns zero. To get extended error information, call **ImapGetLastError**.

Remarks

Mailbox names which contain non-ASCII characters must be converted to a modified version of UTF-7 encoding as defined by the IMAP4 protocol. This encoding allows applications to reference mailbox names which contain Unicode characters and provides support for languages other than English. This function is used to convert a mailbox name which contains non-ASCII characters to the UTF-7 encoded format required by IMAP servers.

For example, if the *lpszMailboxName* parameter specifies the string "Δοκίμή", this function will encode it as "&A5QDvwO6A7kDvA0u-" and return that value in the *lpszEncodedName* buffer. It is recommended you use the Unicode version of this function whenever possible to ensure the mailbox name is encoded correctly.

The ANSI version of this function should only be used with legacy applications which do not support Unicode. The mailbox name will be converted to Unicode using the code page specified by the

nCodePage parameter. If the code page does not support the characters used in the mailbox name, this can result in an incorrect conversion. Using the previous example, the mailbox name will always encode correctly if the Unicode version of the function is used, but the ANSI version of the function will only encode it correctly if the code page is specified as 1253 (Greek).

If the ANSI version of this function is used and the **nCodePage** parameter is zero, this function will attempt to determine if the **lpszMailboxName** parameter specifies UTF-8 text as the mailbox name. If it does, the name will be converted from UTF-8 to modified UTF-7; otherwise, the name will be encoded as modified UTF-7 using the current active code page for the process.

This function should not be used to convert strings between Unicode and UTF-7. The encoding format is specifically intended for use with the IMAP4 protocol and should never be used for general purpose encoding or decoding. If you need to convert a Unicode string to UTF-7, use the Win32 API function **WideCharToMultiByte**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstdlib11.h

Import Library: csmapi11.lib

Unicode: Implemented as Unicode and ANSI versions

ImapEnumMessages Function

```
INT WINAPI ImapEnumMessages(  
    HCLIENT hClient,  
    UINT nFirstMessageId,  
    UINT nLastMessageId,  
    DWORD dwMessageFlags,  
    DWORD dwReserved,  
    LPIMAPMESSAGE lpMessageList,  
    INT nMaxMessages  
);
```

The **ImapEnumMessages** function enumerates the messages in the current mailbox, populating an array of IMAPMESSAGE structures which contain information about each message.

Parameters

hClient
Handle to the client session.

nFirstMessageId
An unsigned integer value which specifies the first message to enumerate. This value must be greater than zero and specify a valid message identifier. The first message in the mailbox has a value of one.

nLastMessageId
An unsigned integer value which specifies the last message to enumerate. This value must be greater than or equal to the value of the *nFirstMessageId* parameter. A special value of 0xFFFFFFFF can be used to specify the last message in the mailbox.

dwMessageFlags
This parameter is used to determine which messages are enumerated. If the value is zero, then all applicable messages will be enumerated. If the value is non-zero, only those messages which have at least one of the specified flags will be returned. More than one flag can be specified by using a bitwise operator.

Value	Description
IMAP_FLAG_ANSWERED	Return only those messages which have been answered.
IMAP_FLAG_DELETED	Return only those messages which have been marked for deletion.
IMAP_FLAG_DRAFT	Return only those messages which have been marked as draft copies.
IMAP_FLAG_URGENT	Return only those messages which have been flagged for urgent or special attention.
IMAP_FLAG_RECENT	Return only those messages which have been recently added to the mailbox.
IMAP_FLAG_SEEN	Return only those messages which have been read.

dwReserved
A reserved parameter. This value should always be set to zero.

lpMessageList

A pointer to an array of [IMAPMESSAGE](#) structures which will contain information about each of the messages returned by the server. This parameter cannot be NULL.

nMaxMessages

An integer value which specifies the maximum size of the IMAPMESSAGE array that was passed to the function. This value must be at least one.

Return Value

If the function succeeds, the return value is the number of messages that were enumerated. If no messages match the specified criteria, the function will return a value of zero. If an error is encountered, the function returns IMAP_ERROR. To get extended error information, call

ImapGetLastError.

Remarks

If the message UID is being stored locally by the client to identify the message over multiple sessions, it must also store the mailbox UID. Only the combination of the mailbox name, mailbox UID and message UID can be used to uniquely identify a given message on the server. Although IMAP server implementations are encouraged to maintain persistent message UIDs, they are not required to do so and those values may change if the mailbox UID changes.

Requirements
