A null-terminated string buffer which will contain all of the matching links found in the current message part. This buffer must be large enough to contain the entire list, including the terminating null character. If you wish to determine the number of characters required to store the list, this parameter can be NULL and the ***nMaxLength*** parameter should be zero. If you are dynamically allocating memory for the list, make sure you are including additional space for the terminating null. If multiple links are found in the message contents, each link will be separated with a single space. This makes the list easy to parse using basic string functions such as the **strtok** or **Split** methods in most languages.

nMaxLength

The maximum number of characters which can be copied into the string buffer. The buffer must be large enough to store the complete list of links and the terminating null character. If this parameter is zero, the list of links are not copied to the buffer, but the function will return the number of characters required to store the complete list of links, not including the terminating null. If the ***lpszLinkList*** parameter is NULL, this parameter must be zero.

lpnLinkCount

A pointer to an integer which will contain the number of matching links extracted from the current message part. If this information is not required, this parameter can be NULL. This value will be

initialized to zero and updated with the link count if the function is successful.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer provided. If the *nMaxLength* parameter is zero, the return value specifies the number of characters required to store the list of links, not including the terminating null character. If you use this function to determine the required buffer size, allocate memory for the returned character count plus one additional character for the terminating null. If the function fails, it will return zero. To get extended error information, call **MimeGetLastError**. The last error code will be set to NO_ERROR if the parameters are valid but there are no links found in the current message part.

Remarks

The **MimeGetMessageLinks** function enables you to obtain a list of the hyperlinks which are found in the current message part. The *dwLinkTypes* parameter allows you to specify the types of links you would like to extract. The message contents are decoded and converted to UTF-8 before searching for matching links. If the message content uses HTML markup, it is possible for this function to return links in the HTML header as well as the body. Messages which are composed using Outlook will typically have links to XML namespaces like `http://www.w3.org/TR/REC-html40`. You can omit these links by not including `MIME_LINK_HTTP` in the link type bitmask.

This function can only be used to extract links from message text and cannot be used with file attachments or encoded binary data. For example, if the current message part contains encoded image data, this function will return zero. This function ignores any links that use URL schemes not listed above, such as `mailto:` or `data:`. If you have a need to find a different type of link, you can use the **MimeFindMessageText** function to search the message using a regular expression that matches your specific requirements.

When calling this function, it is generally preferable to dynamically allocate the string buffer rather than using a fixed-length buffer, which may be too small to hold all links or unnecessarily large if the message contains few or no links. This requires calling the function twice: first with *lpszLinkList* set to NULL and *nMaxLength* set to zero. The return value from this call will indicate the number of characters needed to store the list of links, excluding the terminating null character. You can then allocate a buffer of the appropriate size and call the function again to retrieve the actual list. When using this two-step approach, ensure that the *dwLinkTypes* value remains the same for both calls to avoid inconsistent results.

Example

```
hMessage = MimeOpenMessage(TEST_HTMLMSG, MIME_OPEN_DEFAULT);

if (hMessage == INVALID_MESSAGE)
{
     // Unable to open the message file
     return;
}

// Get the number of parts in a multipart message; if there is only
// one part then this is an simple RFC 822 formatted message
INT nPartCount = MimeGetMessagePartCount(hMessage);

for (INT nMessagePart = 0; nMessagePart < nPartCount; nMessagePart++)
{
    // Set the current message part
    MimeSetMessagePart(hMessage, nMessagePart);
```

```
    // If this message part is plain text or HTML, search for links
    if (MimeGetContentType(hMessage) == MIME_CONTENT_TEXT)
    {
         // Determine if there are any links in this message part and
         // how large our string buffer needs to be
         LONG cchLinkList = MimeGetMessageLinks(hMessage, MIME_LINK_HTTPS, NULL, 0,
NULL);

         // Continue to the next message part if there are no links
         if (!cchLinkList)
             continue;

         // Allocate memory for our string buffer with space for the
         // terminating null character
         LPTSTR pszLinkList = (LPTSTR)malloc((cchLinkList + 1) * sizeof(TCHAR));
         if (pszLinkList == NULL)
         {
              // Unable to allocate memory
              break;
         }

         // Return the list of links in our string buffer
         LONG nLinkCount = 0;
         cchLinkList = MimeGetMessageLinks(
                             hMessage,
                             MIME_LINK_HTTPS,
                             pszLinkList,
                             cchLinkList + 1,
                             &nLinkCount);

         if (cchLinkList > 0)
         {
            _tprintf(_T("Message part %d has %d secure links\n"), nMessagePart,
nLinkCount);

            LPTSTR pszLink = pszLinkList;
            LONG nIndex = 0;

            // Move through the list of links, replacing each space with
            // a null character to indicate the end of the link
            while (pszLink != NULL && *pszLink != '\0')
            {
                LPTSTR pszNextLink = _tcschr(pszLink, _T(' '));

                // If we found a space, what follows is the next link in the list
                if (pszNextLink != NULL)
                    *pszNextLink++ = '\0';

                _tprintf(_T("\tLink %d: %s\n"), ++nIndex, pszLink);
                pszLink = pszNextLink;
            }
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

MimeGetMessagePart Function

```
INT WINAPI MimeGetMessagePart(
   HMESSAGE hMessage
);
```

The **MimeGetMessagePart** function returns the current message part index for the specified message.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is the message part index. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

MimeGetMessagePartCount Function

```
INT WINAPI MimeGetMessagePartCount(
    HMESSAGE hMessage
);
```

The **MimeGetMessagePartCount** function returns the total number of message parts for the specified message. Each message consists of at least one part.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is the number of message parts. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

MimeGetMessageSender Function

```
INT WINAPI MimeGetMessageSender(
    HMESSAGE hMessage,
    LPCTSTR lpszSender,
    INT nMaxLength
);
```

The **MimeGetMessageSender** function returns the email address of the message sender in the specified string buffer.

Parameters

hMessage

Handle to the message.

lpszSender

A null-terminated string buffer that will contain the email address of the message sender when the function returns.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied to the string buffer, including the terminating null character. It is recommended that the maximum length be at least 64 characters.

Return Value

If the function succeeds, the return value is the number of bytes copied to the string buffer. If an error occurs, the function will return MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function attempts to determine the email address of the sender that originated the message. It will first check for the presence of a Sender or X-Sender header value. If these headers are not defined, it will use the value of the From header field. It will only return successfully if a valid email address can be found.

If the function succeeds, the string buffer that is provided will only contain an email address. It will not contain the display name of the user associated with the address or any extraneous comments that are included in quotes or parenthesis.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetMessageSize Function

```
BOOL WINAPI MimeGetMessageSize(
   HMESSAGE hMessage,
   DWORD dwOptions,
   LPDWORD lpdwMessageSize
);
```

The **MimeGetMessageSize** function returns the size of the complete message in bytes.

Parameters

hMessage

Handle to the message.

dwOptions

An unsigned integer which specifies how the size of the message should be calculated, based on what header fields should be included. These are the same options used when exporting a message to a file or memory buffer. The following values may be combined using a bitwise Or operator:

Value	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_ALLHEADERS	All headers, including the Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.

lpdwMessageSize

A pointer to an unsigned integer value which will contain the size of the message if the function succeeds, or a value of zero if the function fails. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If an error occurs, the function will return zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function returns the size of the complete message, including all headers, the message body and any attachments. It can be used to determine the minimum amount of memory that should be allocated to export the message to a memory buffer using the **ExportMessage** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeGetMessageText Function

```
LONG WINAPI MimeGetMessageText(
    HMESSAGE hMessage,
    LONG nOffset,
    LPTSTR lpszMessage,
    LONG nMaxLength
);
```

The **MimeGetMessageText** function copies the text of the current message part to the specified buffer.

Parameters

hMessage

Handle to the message.

nOffset

The byte offset from the beginning of the message. A value of zero specifies the first character in the body of the message part.

lpszMessage

The string buffer that will contain a copy of the message text when the function returns. Note that the buffer will typically contain multiple lines of text. If this parameter is NULL the function will return the number of characters that would be copied.

nMaxLength

The maximum number of bytes to copy into the buffer. The size of the buffer provided must be larger than the content length for the current message part. If this parameter is zero, the text will not be copied.

Return Value

If the function succeeds, the return value is number of bytes copied into the buffer. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

If your project targets a multi-byte character set, this function will always return the message contents as UTF-8 text, regardless of the original character set specified in the message itself. This ensures that characters in the original text are preserved, regardless of the default ANSI code page on the local system. It is recommended you build your project to use Unicode whenever possible. If your application must use ANSI, you can use the **MimeLocalizeText** method to convert the Unicode text to a specific character set.

You should not determine the maximum size of the output buffer using the **MimeGetContentLength** function. That function returns the content size in bytes as it is stored in the message, and does not account for any character encoding or Unicode conversion which may be required. The content length can be used to estimate the amount of text stored in the message part, but you should always allocate a buffer which is larger than the length specified in the message.

If the *nMaxLength* parameter does not specify a buffer size large enough to store the contents of the current message part, this function will fail and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL. Your application must ensure the buffer is large enough to contain the complete message text and a terminating null character. If you wish to determine the actual length of the decoded message text, you can specify the *lpszMessage* parameter as NULL and *nMaxLength*

as zero. This will cause the function to return the number of characters in the current message part, not including the terminating null. When allocating a buffer on the heap, make sure you include additional space for the terminating null character. See the example below.

If the current message part contains HTML markup and you want to display it as plain text to the user, you can use the **MimeFilterMessageText** function. It can remove markup from the message text, as well as remove potentially dangerous hyperlinks.

Example

```
if (MimeGetContentType(hMessage) == MIME_CONTENT_TEXT)
{
    // Get the size of the decoded/converted message text
    LONG cchMessage = MimeGetMessageText(hMessage, 0, NULL, 0);
    if (cchMessage < 1)
    {
        _tprintf(_T("Message part %d does not contain any text\n"), nMessagePart);
        return;
    }

    // Allocate a buffer for the message text +1 for the null character
    LPTSTR pszMessage = (LPTSTR)malloc((cchMessage + 1) * sizeof(TCHAR));
    if (pszMessage == NULL)
        return;

    // Copy the message contents to the buffer
    cchMessage = MimeGetMessageText(hMessage, 0, pszMessage, cchMessage + 1);
    if (cchMessage > 0)
    {
        // Write the contents of the message part to the console
        fwrite(pszMessage, sizeof(TCHAR), cchMessage, stdout);
        fflush(stdout);
    }

    // Free the memory allocated for our text buffer
    free(pszMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetMessageVersion Function

```
LPCTSTR WINAPI MimeGetMessageVersion(
    HMESSAGE hMessage
);
```

The **MimeGetMessageVersion** function returns a pointer to a string which contains the MIME version header value for the specified message.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is a pointer to the MIME version. If the version is not specified in the current message, the function will return NULL. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeGetMessageHeader, MimeSetMessageVersion

MimeGetNextMessageHeader Function

```
BOOL WINAPI MimeGetNextMessageHeader(
    HMESSAGE hMessage,
    LPTSTR lpszHeader,
    INT cchMaxHeader,
    LPTSTR lpszValue,
    INT cchMaxValue
);
```

The **MimeGetNextMessageHeader** function returns the header field name and value for the next header in the current message part. This function is typically used in conjunction with **MimeGetFirstMessageHeader** to enumerate all of the message header fields and their values in the current message part.

Parameters

hMessage

Handle to the message.

lpszHeader

The string buffer that will contain the name of the next header in the current message part when the function returns. This parameter cannot be a NULL pointer.

cchMaxHeader

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. This parameter must have a value greater than zero.

lpszValue

The string buffer that will contain the value of the next header in the current message part when the function returns. This parameter may be a NULL pointer, in which case the value of the header field is ignored.

cchMaxValue

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. If the ***lpszValue*** parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is non-zero. If no more headers exist for the current message part, or the handle to the message is invalid, the function will return zero. To get extended error information, call **MimeGetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **MimeSetMessagePart** function.

The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined, with the following exception:

If an imported message has multiple Received headers, then those headers will be returned by **MimeGetNextMessageHeader** in the order in which they appeared in the original message. Note

that if **MimeGetMessageHeader** is used to retrieve the Received header, the first Received header in the message will be returned.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetStoredMessage Function

```
HMESSAGE WINAPI MimeGetStoredMessage(
    HMESSAGESTORE hStorage,
    LONG nMessageId,
    DWORD dwOptions
);
```

The **MimeGetStoredMessage** function retrieves a message from the specified message store.

Parameters

hStorage

Handle to the message store.

nMessageId

An integer value which specifies the message number that should be retrieved. The first message in the message store has a value of one.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
A shared message handle returned by the function. The contents of this message will be overwritten each time this function is called.	
MIME_COPY_STORED_MESSAGE	A message handle is allocated for a copy of the message that is retrieved from the message store.

Return Value

If the function succeeds, the return value is a handle to the message. If the function fails, the return value is INVALID_MESSAGE. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetStoredMessage** function returns a message handle for the specified message in the message store. If no options are specified, a temporary message handle is returned that is only valid until the next message is retrieved. The application can use message handle with any function except for the **MimeCloseMessage** function because it does not own the message handle. If a multithreaded application changes the contents of the temporary message, it will change for all other threads that have obtained a message handle using this function.

If the application must have a unique copy of the message, the MIME_COPY_STORED_MESSAGE option should be specified. Instead of returning a handle to a shared message, the message is duplicated and a handle to that copy of the message is returned. If this option is used, the application must call **MimeCloseMessage** to release the memory allocated for the message.

Example

```
HMESSAGE hMessage = INVALID_MESSAGE;
LPCTSTR lpszHeader = _T("From");
LPCTSTR lpszAddress = _T("jsmith@example.com");
```

```
LONG nMessageId = 1;

// Begin searching for messages from the specified sender
while (nMessageId != MIME_ERROR)
{
    nMessageId = MimeFindStoredMessage(hStorage,
                                       nMessageId,
                                       lpszHeader,
                                       lpszAddress,
                                       MIME_SEARCH_PARTIAL_MATCH);

    if (nMessageId != MIME_ERROR)
    {
        // Get a handle to the message that was found
        hMessage = MimeGetStoredMessage(hStorage, nMessageId, 0);

        if (hMessage != INVALID_MESSAGE)
        {
            // Store the message in a file
            TCHAR szFileName[MAX_PATH];
            BOOL bExported;

            // Create a filename based on the message number
            wsprintf(szFileName, _T("msg%05ld.tmp"), nMessageId);

            // Export the message to a file
            bExported = MimeExportMessage(hMessage, szFileName);
        }

        // Increase the message ID to resume the search at the next message
        nMessageId++;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

MimeGetStoredMessageCount Function

```
LONG WINAPI MimeGetStoredMessageCount(
    HMESSAGESTORE hStorage,
    LPLONG lpnLastMessage
);
```

The **MimeGetStoredMessageCount** function returns the number of messages in the specified message store.

Parameters

hStorage

Handle to the message store.

lpnLastMessage

A pointer to an integer which will contain the message number for the last message in the storage file. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is the number of messages in the message store. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetStoredMessageCount** function returns the number of messages in the message store. It is important to note that does not count those messages which have been marked for deletion. This means that the value returned by this function will decrease as messages are deleted.

The message number returned in the ***lpnLastMessage*** parameter will specify the total number of messages in the message store, including deleted messages.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeImportMessage Function

```
BOOL WINAPI MimeImportMessage(
   HMESSAGE hMessage,
   LPCTSTR lpszFileName
);
```

The **MimeImportMessage** function reads the specified file and replaces the current message with its contents.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string which specifies the name of the text file to import.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function will delete the contents of the current message before importing the new message from the specified file. Unlike the **MimeOpenMessage** function, this function is intended to be used when you wish to replace an existing message with the contents of another MIME structured file.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeImportMessageEx Function

```
BOOL WINAPI MimeImportMessageEx(
   HMESSAGE hMessage,
   DWORD dwImportMode,
   DWORD dwImportOptions,
   LPVOID lpvMessage,
   DWORD dwMessageSize
);
```

The **MimeImportMessageEx** function imports the contents of a message from a file, string or memory handle.

Parameters

hMessage

Handle to the message.

dwImportMode

An unsigned integer which specifies how the message contents will be imported. It may be one of the following values:

Value	Description
MIME_IMPORT_DEFAULT	The default import mode. If the ***lpvMessage*** parameter is NULL, then the contents of the message will be imported from the system clipboard. Otherwise, the ***lpvMessage*** parameter is a pointer to a string which specifies the name of a file that contains the message. The ***dwMessageSize*** parameter is ignored.
MIME_IMPORT_FILE	The ***lpvMessage*** parameter is a pointer to a string which specifies the name of the file that contains the message. If the file does not exist, or is not a regular text file, an error will occur. The ***dwMessageSize*** parameter is ignored.
MIME_IMPORT_CLIPBOARD	The contents of the message is imported from the system clipboard. The ***lpvMessage*** parameter is ignored. The ***dwMessageSize*** parameter is ignored.
MIME_IMPORT_MEMORY	The contents of the message is imported from a local buffer. The ***lpvMessage*** parameter must point to a byte array which contains the message to be imported. The ***dwMessageSize*** parameter specifies the number of bytes to copy from the buffer. If this value is zero, it is assumed that the end of the message data in the buffer is terminated with a null character and the length is calculated automatically.
MIME_IMPORT_HGLOBAL	The contents of the message is imported from a global memory buffer. The ***lpvMessage*** parameter must be a global memory handle which contains the message. The ***dwMessageSize*** parameter specifies the number of bytes to copy from the buffer. If this value is zero, it is assumed that the end of the message data in the buffer is terminated with a null character and the length is calculated automatically.

dwImportOptions

An unsigned integer which specifies how the message will be imported:

Value	Description
MIME_OPTION_DEFAULT	The default import options. Currently this is the only valid value for this parameter and applications should always specify this constant.

lpvMessage

A null-terminated string, a byte buffer or a global memory handle. The ***dwImportMode*** parameter determines how this pointer is used by the function.

dwMessageSize

An unsigned integer value which specifies the size of the message to import. This parameter is only used when importing a message from a memory buffer. The message size is determined automatically when the message is imported from a file or the system clipboard.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Example

```
// Imports a message using an HGLOBAL handle which references
// a block of memory containing an email message
bResult = MimeImportMessageEx(hMessage,
                              MIME_IMPORT_HGLOBAL,
                              MIME_OPTION_DEFAULT,
                              (LPVOID)hgblMessage,
                              0);

if (bResult)
{
    // The message has been successfully imported
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeInitialize Function

```
BOOL WINAPI MimeInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **MimeInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **MimeInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **MimeUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **MimeInitialize** or **MimeUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeIsContentType Function

```
BOOL WINAPI MimeIsContentType(
   HMESSAGE hMessage,
   INT nMessagePart,
   LPCTSTR lpszContentType
);
```

The **MimeIsContentType** function checks if the content type for the message matches the specified content type.

Parameters

hMessage

Handle to the message.

nMessagePart

An integer value which specifies which part of the message to compare against the content type. A value of zero returns compares the content type against the main message header, while a value greater than zero compares the content type against the content type for a specific part of a multipart message. A value of MIME_CURRENT_PART (-1) specifies that the content type should be compared against the current message part.

lpszContentType

Pointer to a string which specifies the content type to compare against. This parameter cannot be NULL and it must specify a valid MIME media type. It is permitted to omit the media subtype, in which case the content type match will only be made against the base type. For example, both `"application/pdf"` and `"application"` are permitted as valid content types. Note that this is a prefix match, not a wildcard pattern match.

Return Value

The function will return a non-zero value if the specified content type matches the content type for the message part. If the content types do not match or one of the parameters is invalid, the function will return zero. To get extended error information, call **MimeGetLastError**. If the parameters are valid but the content types do not match, the last error code will be set to NO_ERROR.

Remarks

The **MimeIsContentType** function is used to check the content type for a specific part of a MIME-encoded message against a known media type. Multipurpose Internet Mail Extensions (MIME) defines a standard way of classifying the content of an email message or its individual parts, such as plain text, HTML, images, or file attachments.

A MIME media type, also referred to as a content type, is typically expressed in the form `type/subtype`. For example, the content type `text/plain` identifies unformatted plain text, while `text/html` identifies HTML formatted text. The content type for each message part is typically specified in its `Content-Type` header field. This function performs a case-insensitive comparison between the message part's declared content type and the type provided by the caller. It does not consider optional parameters, such as character encoding or boundary markers. For example, a content type of `"text/html; charset=UTF-8"` will match `"text/html"`.

The following table lists some of the most common MIME media types used in email messages:

Media Type	Description

`text/plain`	Plain text with no formatting
`text/html`	HTML-formatted text, commonly used for rich email content
`multipart/alternative`	Message that contains multiple representations of the same content, such as both plain text and HTML
`multipart/mixed`	Message that includes a combination of text and attachments
`multipart/related`	Message that includes related resources, such as inline images referenced by HTML content
`image/jpeg`	JPEG image
`image/png`	PNG image
`application/pdf`	PDF document
`application/octet-stream`	Generic binary data, typically used for file attachments

To obtain the full content type string for a message part, including any optional parameters, use the **MimeGetMessageHeaderEx** function with the header name `"Content-Type"`.

Example

```
// Search the message for a PDF attachment by checking the content type
// for each part of a multipart message.
//
// If the content type matches "application/pdf" then that message part
// should contain a PDF attachment. We prompt the user where to store
// the file and then exit the loop.

INT nParts = MimeGetMessagePartCount(hMessage);

for (INT nMessagePart = 1; nMessagePart < nParts; nMessagePart++)
{
    if (MimeSetMessagePart(hMessage, nMessagePart) == MIME_ERROR)
        break;

    if (MimeIsContentType(hMessage, MIME_CURRENT_PART, _T("application/pdf")))
    {
        TCHAR szAttachment[MAX_PATH] = _T("");

        // Get the name of the file attached to the message. This can be
        // useful for display purposes, but exercise caution if you want
        // to use that name to store the file locally.
        if (MimeGetAttachedFileName(hMessage, szAttachment, MAX_PATH))
        {
            _tprintf(_T("Found attachment \"%s\" in part %d\n"), szAttachment,
nMessagePart);

            // The recommended approach is to prompt your user for where
            // they would like you to store store the file attachment;
            // avoid using the remote filename directly without validating
            // or prompting the user.
            TCHAR szLocalFile[MAX_PATH] = _T("");

            OPENFILENAME ofn = {0};
            ofn.lStructSize = sizeof(OPENFILENAME);
            ofn.hwndOwner = NULL; // No owner window
```

```
            ofn.lpstrFilter = "Text Files (*.txt)\0*.txt\0All Files (*.*)\0*.*\0";
            ofn.lpstrFile = szLocalFile;
            ofn.nMaxFile = MAX_PATH;
            ofn.lpstrTitle = "Select File to Save";
            ofn.Flags = OFN_OVERWRITEPROMPT;

            // If the user cancels the dialog, we are finished
            if (!GetSaveFileName(&ofn))
                 break;

            // Extract the attachment to the file name specified by the user
            if (!MimeExtractFile(hMessage, szLocalFile))
            {
                DWORD dwError = MimeGetLastError();
                _tprintf(_T("Failed to extract file (Error 0x%08lX)\n"), dwError);
            }
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

MimeLocalizeText Function

```
LONG WINAPI MimeLocalizeText(
   UINT nCharacterSet,
   LPCTSTR lpszInput,
   LONG cchInput,
   LPBYTE lpOutput,
   LONG cbOutput
);
```

The **MimeLocalizeText** function converts a Unicode string to its ANSI equivalent using the specified character set.

Parameters

nCharacterSet

A numeric identifier which specifies the character set to use when localizing the text. A value of zero specifies the locale for the current thread should be used when localizing the text.

lpszInput

A null-terminated string which contains the Unicode text which should be localized. If the ANSI version of this function is called, the input text must be in UTF-8 format or the function will fail. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be localized. If this value is -1, the entire length of the string up to the terminating null will be decoded.

lpOutput

A buffer which will contain the localized ANSI version of the input text. This parameter cannot be a NULL pointer.

cbOutput

An integer value which specifies the maximum number of bytes which can be copied into the output buffer. The buffer must be large enough to store all of the localized text. This value must be greater than zero.

Return Value

If the input text can be successfully localized, the return value is the number of bytes copied into the output buffer. If the function returns zero, then no text was localized. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeLocalizeText** function enables the application to localize a Unicode string, returning the ANSI version of that text using the specified character set. Because library handles all text as Unicode internally, the ANSI functions in this library will always return UTF-8 encoded text. This function allows you to easily convert that UTF-8 text to another supported character set.

If the ANSI version of this function is called, the input text must use UTF-8 character encoding or the function will fail with the last error set to ST_ERROR_INVALID_CHARSET.

If the *nCharacterSet* parameter is MIME_CHARSET_DEFAULT or MIME_CHARSET_UNKNOWN the input text will be converted to the default ANSI code page for the current thread locale. If there are characters in the Unicode input text which cannot be converted to an ANSI equivalent using the

specified character set, those characters will be replaced by the default character for your locale, typically a question mark symbol. You cannot specify MIME_CHARSET_UTF16 as the character set.

This function will always attempt to ensure that the output buffer is terminated with an extra null byte so it is easier to work with as a standard C-style null-terminated string. However, if the output buffer is not large enough to accommodate the extra null byte, it will not be copied. It is always recommended that your output buffer be somewhat larger than the length of the original input text to account for multi-byte character sequences. If the output buffer is not large enough to contain the entire localized text, no bytes will be copied to the output buffer and the function will fail with the last error set to ST_ERROR_BUFFER_TOO_SMALL.

This function is only required if your application needs to localize the UTF-8 text returned by another function and convert it to a specific 8-bit ANSI character set. For example, if you have an application which calls the ANSI version of **MimeGetMessageText**, it will return the message contents as UTF-8 text. If you need to display that text as localized ANSI, you can call this function to convert the UTF-8 text to your current locale or a specific character set.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeNormalizeText Function

```
LONG WINAPI MimeNormalizeText(
    LPCTSTR lpszInput,
    LONG cchInput,
    LPTSTR lpszOutput,
    LONG nMaxLength
);
```

The **MimeNormalizeText** function normalizes the input text to replace confusable Unicode homoglyphs, remove symbols and trim whitespace.

Parameters

lpszInput

A null-terminated string which contains the Unicode text that will be normalized. The input may only contain text and cannot include non-printable control characters. If this parameter is NULL or if the input contains binary data, this function will fail. If the ANSI version of this function is called, the input string must be contain ASCII or UTF-8 encoded Unicode characters.

cchInput

An integer which specifies the number of characters in the input string. If this parameter is -1, the length of the string will be determined by counting the number of characters up to a terminating null character.

lpszOutput

A null-terminated string buffer which will contain the normalized text. The buffer must be large enough to contain the entire string and a terminating null character or the function will fail. If this parameter is NULL and the ***nMaxLength*** parameter is zero, the function will return the number of characters required to store the normalized text, not including the terminating null character.

nMaxLength

The maximum number of characters which can be copied into the ***lpszOutput*** string buffer. If this value is zero, no characters will be copied to the output buffer and the function will return the length of the filtered output, not including the terminating null character. This can be used to determine how much memory should be allocated to store the filtered text.

Return Value

If the function succeeds, it will return the number of characters copied into the output buffer, not including the terminating null character. If the ***lpszOutput*** parameter is NULL and ***nMaxLength*** is zero, the function will return the number of characters in the filtered text, not including the terminating null. If the function fails, or there is no text in the input buffer, the function will return zero.

Remarks

The **MimeNormalizeText** function performs a multi-stage normalization and cleanup of Unicode text, intended to simplify and standardize input that may contain visually similar (confusable) characters, diacritical marks, or inconsistent whitespace. It applies NFKD (Compatibility Decomposition) normalization converting characters into their canonical forms and then replaces any confusable Unicode characters with their ASCII equivalents based on an internal mapping table. This function is similar to calling the **NormalizeString** function in the Windows API, however it performs additional checks and is more strict with how the input is validated.

If the **MimeNormalizeTextA** (ANSI) version of this function is called, the input string is checked to

ensure that it only contains valid UTF-8 encoding and will reject strings which contain invalid sequences. For example, it will reject multibyte UTF-8 sequences which are over-long or truncated, invalid continuation sequences or characters outside of valid Unicode code points. You should never provide a localized ANSI string composed using the current code page. If you wish to normalize a localized string, you should convert it to Unicode using the **MultiByteToWideChar** function and then call **MimeNormalizeTextW**.

If the **MimeNormalizeTextW** (Unicode) version of this function is called, the input string is validated to ensure that it only contains valid UTF-16 encoding and will reject strings which contain invalid sequences. This includes checking to ensure there are no unpaired surrogates, invalid code points, unprintable control characters or private-use characters in the string. If the input string does not contain valid Unicode character sequences, the function will return zero and the last error code will be set to ST_ERROR_INVALID_UNICODE.

This function helps mitigate issues with characters that are visually indistinguishable from standard Latin letters, such as using the Cyrillic "a" (U+0430) instead of the Latin "a" (U+0061). It also removes symbols (such as emojis, flags and pictographs) which can confuse pattern matching and removes combining marks that can be used to visually modify characters or obscure text. Unicode whitespace is trimmed from both ends of the string, including zero-width and non-breaking spaces.

This function is particularly useful in security-sensitive applications where input normalization is critical, such as sanitizing user-provided domain names, filenames, or login credentials to prevent spoofing, phishing, or bypassing filters through the use of homoglyphs or invisible characters.

If you want a normalized version of the text in a message, you can use the **MimeFilterMessageText** function. It performs many of the same normalizations that this function does, but allows for more flexibility through options which allow you to control how the message text is processed and filtered. It is particularly useful for filtering extraneous HTML from the message, enabling you to display a version of the message that is safer for the user (such as removing unsafe links from the message contents).

This function is deliberately biased toward security rather than readability and can affect the output when applied to text containing legitimate non-Latin characters. It is intended for use on text that is expected to contain only printable ASCII characters. For example, it will filter and normalize text containing certain Greek or Cyrillic characters that could be used to spoof ASCII letters or URL delimiters. While this helps mitigate obfuscated or malicious content, it can also make legitimate text in other languages unreadable.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeOpenMessage Function

```
HMESSAGE WINAPI MimeOpenMessage(
   LPCTSTR lpszFileName,
   DWORD dwOptions
);
```

The **MimeOpenMessage** function opens and reads the specified file and returns a handle to the message.

Parameters

lpszFileName

Pointer to a string which specifies the name of the text file to open. This parameter cannot be NULL.

dwOptions

An integer which specifies options for opening the message file. This parameter is reserved for future use and should always be zero in the current implementation.

Value	Description
MIME_OPEN_DEFAULT	The default mode for opening the message file. Currently, this is the only option which should be specified.

Return Value

If the function succeeds, the return value is a handle to the message which can be used with other functions. If the function fails, the return value is INVALID_MESSAGE. To get extended error information, call **MimeGetLastError**.

Remarks

This function opens the specified file, reads the contents into memory and then parses the message. The file must be a text file which uses the standard MIME message structure. It may contain multiple parts, including file attachments and alternative representations of the same message. This function cannot be used to open messages stored in a binary format.

If the file path includes environment variables enclosed in percentage (%) symbols, those values will be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

The maximum size of an individual message is 2 GiB (approximately 2 billion characters). This limitation is implemented as a safety check to prevent opening very large files which are unlikely to contain a valid MIME formatted message. Most services impose much lower limits on the maximum size of an individual mail message.

Note: This function can only be used to open and parse messages structured according to the MIME (Multipurpose Internet Mail Extensions) standard, such as plain text `.eml` or `.txt` files. It cannot open messages stored in proprietary or binary formats used by certain email clients. For example, it does not support Microsoft Outlook message files such as `.msg` or mailbox files like `.pst` and `.ost`, nor does it support formats used by other clients such as Thunderbird's `.msf` (mail summary files) or the mbox family (`.mbx`, `.mbox`) when stored as binary containers. Attempting to open these file types will result in an error. If you need to work with messages exported from Outlook or other proprietary clients, first save or export them in the standard text format before using this function.

If you wish to create a new message rather than opening an existing message, use the **MimeComposeMessage** function. When you are finished accessing the contents of the message, use the **MimeCloseMessage** function to close the message handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeOpenMessageStore Function

```
HMESSAGESTORE WINAPI MimeOpenMessageStore(
    LPCTSTR lpszFileName,
    DWORD dwOpenMode
);
```

The **MimeOpenMessageStore** function opens the specified message storage file.

Parameters

lpszFileName

A null-terminated string which specifies the name of the storage file.

dwOpenMode

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
MIME_STORAGE_READ	The message store will be opened for read access. The contents of the message store can be accessed, but cannot be modified by the process unless it has also been opened for writing.
MIME_STORAGE_WRITE	The message store will be opened for writing. This mode also implies read access and must be specified if the application needs to modify the contents of the message store.
MIME_STORAGE_CREATE	The message store will be created if the storage file does not exist. If the file exists, it will be truncated. This mode implies read and write access.
MIME_STORAGE_LOCK	The message store will be opened so that it may only be accessed and modified by the current process.
MIME_STORAGE_COMPRESS	The contents of the message store are compressed. This option is automatically enabled if a compressed message store is opened for reading or writing.
MIME_STORAGE_MAILBOX	The message store should use the UNIX mbox format when reading and storing messages. This option is provided for backwards compatibility and is not recommended for general use.

Return Value

If the function succeeds, the return value is a handle to the message store. If the function fails, the return value is INVALID_MESSAGESTORE. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeOpenMessageStore** function opens a message storage file which contains one or more messages. If the storage file is opened for read access, the application can search the message store and extract messages but it cannot add or delete messages. To add new messages or delete existing messages from the store, it must be opened with write access.

The message store is designed to be a simple, effective way to store multiple messages together in a single file. When the message store is opened, the contents are indexed in memory. Although there is no specific limit to the number of messages that can be stored, there must be sufficient memory available to build an index of each message and its headers. If the application must store and manage a very large number of messages, it is recommended that you use a database rather than a flat-file message store.

Message Store Format

Each message is prefixed by a control sequence of five ASCII 01 characters followed by an ASCII 10 and ASCII 13 character. The messages themselves are stored unmodified in their original text format. The length of each message is calculated based on the location of the control sequence that delimits each message, and explicit message lengths are not stored in the file. This means that it is safe to manually change the message contents, as long as the message delimiters are preserved.

If the message store is compressed, the contents of the storage file are expanded when the file is opened and then re-compressed when the storage file is closed. Using the MIME_STORAGE_COMPRESS option reduces the size of the storage file and prevents the contents of the message store from being read using a text file editor. However, enabling compression will increase the amount of memory allocated by the library and can increase the amount of time that it takes to open and close the storage file.

The library also has a backwards compatibility mode where it will recognize storage files that use the UNIX mbox format. While this format is supported for accessing existing files, it is not recommended that you use it when creating new message stores or adding messages to an existing store. There are a number of different variants on the mbox format that have been used by different Mail Transfer Agents (MTAs) on the UNIX platform. For example, the mboxrd variant looks identical to the mboxcl2 variant, and they are programmatically indistinguishable from one another, but they are not compatible. For this reason, the use of the mbox format is strongly discouraged.

Example

```
HMESSAGE hMessage;

// Compose a new message
hMessage = MimeComposeMessage(lpszSender,
                              lpszRecipient,
                              NULL,
                              lpszSubject,
                              lpszMessage,
                              NULL,
                              MIME_CHARSET_DEFAULT,
                              MIME_ENCODING_DEFAULT);

if (hMessage != INVALID_MESSAGE)
{
    HMESSAGESTORE hStorage;

    // Open the message storage file
    hStorage = MimeOpenMessageStore(lpszFileName, MIME_STORAGE_WRITE);

    if (hStorage == INVALID_MESSAGESTORE)
    {
        // Close the message and return if we are unable to
        // open the storage file
        MimeCloseMessage(hMessage);
        return;
```

```
    }

    // Store a copy of the message in the message store
    nMessageId = MimeStoreMessage(hStorage, hMessage, 0);

    if (nMessageId == MIME_ERROR)
    {
        // We were unable to store the message
    }

    // Close the message store
    MimeCloseMessageStore(hStorage);

    // Close the message that was created
    MimeCloseMessage(hMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeParseAddress Function

```
INT WINAPI MimeParseAddress(
   LPCTSTR lpszString,
   LPCTSTR lpszDomain,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **MimeParseAddress** function parses a string for an email address, copying the address to the specified buffer.

Parameters

lpszString

A null-terminated string which contains the email address to parse.

lpszDomain

A null-terminated string which specifies a default domain for the address. This parameter may be NULL or point to an empty string if no default domain is required.

lpszAddress

A null-terminated string buffer which will contain the parsed email address when the function returns. It is recommended that this buffer be at least 128 characters in length.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the address. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeParseAddress** function is useful for parsing the email addresses that may be specified in various header fields in the message. In many cases, the addresses have additional comment characters which are not part of the address itself. For example, one common format used is as follows:

"User Name" <user@domain.com>

In this case, the email address is enclosed in angle brackets and the name outside of the brackets is considered to be a comment which is not part of the address itself. Another common format is:

user@domain.com (User Name)

In this case, there is the address followed by a comment which is enclosed in parenthesis. The **MimeParseAddress** function recognizes both formats, and when passed either string, would return the following address:

user@domain.com

If there was no domain specified in the address, that is just a user name was specified, then the value the *lpszDomain* parameter is added to the address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeParseDate Function

```
BOOL WINAPI MimeParseDate(
   LPCTSTR lpszDate,
   BOOL bLocalize,
   LONG *lpnSeconds,
   LONG *lpnTimezone
);
```

The **MimeParseDate** function parses a message date string, returning the number of seconds since 1 January 1970 and the difference in seconds between the specified timezone and Coordinated Universal Time.

Parameters

lpszDate

A null-terminated string which specifies the date to be parsed. The date string must be in the standard format defined by RFC 822.

bLocalize

A boolean flag which determines if the date should be localized to the current timezone, regardless of the timezone specified in the date string. A non-zero value specifies the timezone for the local system will be used, adjusted for daylight savings time if applicable.

lpnSeconds

A pointer to a long integer which is set to the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C/C++ time functions. This pointer may be NULL, in which case the parameter is ignored.

lpnTimezone

A pointer to a long integer which is set to the difference in seconds between the specified date's timezone and coordinated universal time (also known as Greenwich Mean Time). This pointer may be NULL, in which case the parameter is ignored.

Return Value

If the date could be successfully parsed, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This is not a general purpose date parsing function, and it may not be capable of parsing dates for a specific locale. The date and time should be in a standard format as outlined in RFC 822, which describes the basic structure of Internet email messages. For a description of the date string format, refer to the **MimeFormatDate** function.

If the date and time does not include any timezone information, Coordinated Universal Time (UTC) will be used by default. This is an important consideration if you use this function to parse input from a user, because in most cases they will not provide a timezone and will assume the date and time they enter is for their current timezone.

The value of the ***bLocalize*** parameter will only change the number of seconds offset by the current timezone and does not affect the value returned in the ***lpnSeconds*** parameter. If the date and time is localized, the timezone offset will be adjusted for daylight savings if it was in effect at the time.

Developers are strongly encouraged to use the **MimeParseDate64** function for all new development.

This function represents date and time values as 32-bit integers, which limits the representable range to dates before 19 January 2038 (the so-called "Year 2038 problem"). After this date, 32-bit time values will overflow, resulting in incorrect date calculations and potential failures in software that processes email message dates. By contrast, the 64-bit versions use 64-bit integer values, matching the standard **time_t** type used by modern C/C++ libraries. This not only eliminates the Year 2038 limitation but also ensures compatibility with current and future systems, allowing correct handling of dates both far in the past and well into the future. Whenever possible, applications should transition to these 64-bit functions to ensure long-term reliability and portability.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeParseDate64 Function

```
BOOL WINAPI MimeParseDate64(
   LPCTSTR lpszDate,
   BOOL bLocalize,
   LONGLONG *lpnSeconds,
   LONG *lpnTimezone
);
```

The **MimeParseDate64** function parses a message date string, returning the number of seconds since 1 January 1970 and the difference in seconds between the specified timezone and Coordinated Universal Time.

Parameters

lpszDate

A null-terminated string which specifies the date to be parsed. The date string must be in the standard format for mail messages.

bLocalize

A boolean flag which determines if the date should be localized to the current timezone, regardless of the timezone specified in the date string. A non-zero value specifies the timezone for the local system will be used, adjusted for daylight savings time if applicable.

lpnSeconds

A pointer to a 64-bit integer which is set to the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C/C++ time functions. This pointer may be NULL, in which case the parameter is ignored.

lpnTimezone

A pointer to a 32-bit integer which is set to the difference in seconds between the specified date's timezone and coordinated universal time (also known as Greenwich Mean Time). This pointer may be NULL, in which case the parameter is ignored.

Return Value

If the date could be successfully parsed, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This is not a general purpose date parsing function, and it may not be capable of parsing dates for a specific locale. The date and time should be in a standard format as outlined in RFC 822, which describes the basic structure of Internet email messages. For a description of the date string format, refer to the **MimeFormatDate64** function.

If the date and time does not include any timezone information, Coordinated Universal Time (UTC) will be used by default. This is an important consideration if you use this function to parse input from a user, because in most cases they will not provide a timezone and will assume the date and time they enter is for their current timezone.

The value of the *bLocalize* parameter will only change the number of seconds offset by the current timezone and does not affect the value returned in the *lpnSeconds* parameter. If the date and time is localized, the timezone offset will be adjusted for daylight savings if it was in effect at the time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeParseHeader Function

```
BOOL WINAPI MimeParseHeader(
   HMESSAGE hMessage,
   LPCTSTR lpszHeader
);
```

The **MimeParseHeader** function parses a line of text and adds the header and value to the current message.

Parameters

hMessage

Handle to the message.

lpszHeader

Pointer to a null-terminated string which contains the header and value to be added to the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function is used to parse a line of text that is part of a message header. The string must consist of a header name, followed by a colon, followed by the header value. The header name may only consist of printable characters, and may not contain whitespace (space, tab, carriage return or linefeed characters).

In most cases, it is recommended you use the **MimeSetMessageHeader** function to set the value of a header.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeParseText Function

```
BOOL WINAPI MimeParseText(
   HMESSAGE hMessage,
   LPCTSTR lpszText,
   INT cchText
);
```

The **MimeParseText** function parses the string buffer and adds the contents to the message.

Parameters

hMessage

Handle to the message.

lpszText

Pointer to a string buffer which contains the text to be added to the message contents.

cchText

The length of the specified buffer. If this value is -1 all of the characters in the string will be parsed up to the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function is useful when the application needs to parse an arbitrary block of text and add it to the specified message. If the string contains header fields, the values will be added to the message header. Once the end of the header block is detected, all subsequent text is added to the body of the message.

To open and parse a text file which contains a MIME structured email message, use the **MimeOpenMessage** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimePurgeMessageStore Function

```
BOOL WINAPI MimePurgeMessageStore(
   HMESSAGESTORE hStorage
);
```

The **MimePurgeMessageStore** function purges all deleted messages from the specified message store.

Parameters

hStorage

Handle to the message store.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimePurgeMessageStore** function purges all deleted messages from the message store. If the storage file has been opened in read-only mode or there are no messages marked for deletion, this function will take no action.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeCopyMessageStore, MimeFindStoredMessage, MimeGetStoredMessage, MimeDeleteStoredMessage

MimeReplaceStoredMessage Function

```
BOOL WINAPI MimeReplaceStoredMessage(
    HMESSAGESTORE hStorage,
    LONG nMessageId,
    HMESSAGE hMessage,
    DWORD dwReserved
);
```

The **MimeReplaceStoredMessage** function replaces the specified message in a message store.

Parameters

hStorage

Handle to the message store.

nMessageId

An integer value which specifies the message number that should be replaced.

hMessage

Handle to the message that will be stored.

dwReserved

A reserved parameter. This value must always be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeReplaceStoredMessage** function replaces the specified message with a new message. The message number may be a message that has been previously marked for deletion. It is important to note that the change will not be reflected in the physical storage file until it has been closed. If the application needs to replace messages in the message store, it is recommended that the file be opened for exclusive access using the MIME_STORAGE_LOCK option.

Example

```
HMESSAGE hMessage;

// Compose a new message
hMessage = MimeComposeMessage(lpszSender,
                              lpszRecipient,
                              NULL,
                              lpszSubject,
                              lpszMessage,
                              NULL,
                              MIME_CHARSET_DEFAULT,
                              MIME_ENCODING_DEFAULT);

if (hMessage != INVALID_MESSAGE)
{
    HMESSAGESTORE hStorage;
    LONG nLastMessage;
    BOOL bResult;
```

```
    // Open the message storage file
    hStorage = MimeOpenMessageStore(lpszFileName, MIME_STORAGE_WRITE);

    if (hStorage == INVALID_MESSAGESTORE)
    {
        // Close the message and return if we are unable to
        // open the storage file
        MimeCloseMessage(hMessage);
        return;
    }

    if (MimeGetStoredMessageCount(hStorage, &nLastMessage) < 1)
    {
        // No messages are stored in the file
        MimeCloseMessageStore(hStorage);
        MimeCloseMessage(hMessage);
        return;
    }

    // Replace the last message in the message store
    bResult = MimeReplaceStoredMessage(hStorage, nLastMessage, hMessage, 0);

    if (bResult == FALSE)
    {
        // We were unable to replace the message
    }

    // Close the message store
    MimeCloseMessageStore(hStorage);

    // Close the message that was created
    MimeCloseMessage(hMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeResetMessage Function

```
BOOL WINAPI MimeResetMessage(
   HMESSAGE hMessage
);
```

The **MimeResetMessage** function clears the header and body of the specified message, and deletes all message parts.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

MimeSetExportOptions Function

```
BOOL WINAPI MimeSetExportOptions(
    HMESSAGE hMessage,
    DWORD dwOptions
);
```

The **MimeSetExportOptions** function specifies a bitmask that describes current message export options.

Parameters

hMessage

Handle to the message.

dwOptions

Mask of attribute options. The mask is a combination of the following values:

Value	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

By default, the Received and Return-Path headers are not exported. In addition, the order of the headers in an exported message is undefined. This is reasonable behavior for most mail clients, but may not be appropriate for applications which need access to all of the header fields.

Example

```
MimeSetExportOptions(hMessage, MIME_EXPORT_OPTIONS_ALL |
                               MIME_EXPORT_OPTIONS_KEEP_ORDER);

if (MimeImportMessage(hMessage, lpszFileName))
{
    // Process the message and make any modifications
    // then write the message back out, preserving all
    // of the headers in their original order
    bResult = MimeExportMessage(hMessage, lpszFileName);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeSetFileContentType Function

```
BOOL WINAPI MimeSetFileContentType(
    HMESSAGE hMessage,
    UINT nContentType,
    LPCTSTR lpszSubtype,
    LPCTSTR lpszExtension
);
```

The **MimeSetFileContentType** function associates a per-message content type with a given file name extension. This association is specific to the message, and is not shared by an other messages that may be opened by the process.

Parameters

hMessage

Handle to the message.

nContentType

An identifier which specifies the primary content type. It may be one of the following values:

Value	Description
MIME_CONTENT_UNKNOWN	The default content type for the specified extension should be used. This value should only be used to delete a previously defined content type.
MIME_CONTENT_APPLICATION	The file content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
MIME_CONTENT_AUDIO	The file is an audio file in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
MIME_CONTENT_IMAGE	The file is an image file in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
MIME_CONTENT_TEXT	The file is a text file. This is also the default type for files which have an unrecognized file name extension and contain only printable text data.
MIME_CONTENT_VIDEO	The file is a video file in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.

lpszSubtype

A null-terminated string which specifies the MIME subtype. This parameter may be NULL if the content type association is being deleted.

lpszExtension

A null-terminated string which specifies the file name extension that will be associated with the MIME content type.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeSetFileContentType** function allows an application to specify a content type for a given file extension, and is typically used to define custom content types for file attachments. The content type will override any default content types associated with the extension, as well as allow new content types to be defined for application-specific files.

Example

In the following example, the file extension ".dat" is associated with a custom content type, a file is attached to the message and then the custom content type is deleted. Note that because the primary content type designates the file as an application specific (non-text) file, it will be automatically encoded when attached to a message:

```
if (MimeSetFileContentType(hMessage, MIME_CONTENT_APPLICATION, "octet-stream",
"dat"))
{
    bResult = MimeAttachFile(hMessage, lpszFileName, MIME_ATTACH_DEFAULT);
    MimeSetFileContentType(hMessage, MIME_CONTENT_UNKNOWN, NULL, "dat");
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeAttachData, MimeAttachFile, MimeGetFileContentType

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeSetLastError Function

```
VOID WINAPI MimeSetLastError(
   DWORD dwErrorCode
);
```

The **MimeSetLastError** function sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the caller. A value of zero clears the last error code.

Return Value

None.

Remarks

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_MESSAGE or MIME_ERROR. Those functions which call **MimeSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **MimeGetLastError** function. The use of **MimeGetLastError** is optional. An application can call it to find out the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

MimeSetMessageDate Function

```
BOOL WINAPI MimeSetMessageDate(
    HMESSAGE hMessage,
    LPCTSTR lpszDate,
    BOOL bLocalize
);
```

The **MimeSetMessageDate** function sets the date and time in the header for the specified message.

Parameters

hMessage

Handle to the message.

lpszDate

Pointer to a string which specifies the date and time. If this parameter specifies a zero-length string or a NULL pointer, the current date and time will be used.

bLocalize

Boolean flag that specifies the date and time should be localized for the current timezone.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The date string should be in a standard format as outlined in RFC 822, the document which describes the basic structure of Internet email messages. For a description of the date string format, refer to the **MimeFormatDate** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeSetMessageHeader Function

```
BOOL WINAPI MimeSetMessageHeader(
    HMESSAGE hMessage,
    LPCTSTR lpszHeader,
    LPCTSTR lpszValue
);
```

The **MimeSetMessageHeader** function adds or updates a header field in the specified message.

Parameters

hMessage

Handle to the message.

lpszHeader

Pointer to a string which specifies the header field that will be added or updated.

lpszValue

Pointer to a string which specifies the value for the header field. This pointer may be NULL, which causes the header field to be removed from the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeSetMessageHeaderEx Function

```
BOOL WINAPI MimeSetMessageHeaderEx(
    HMESSAGE hMessage,
    INT nMessagePart,
    LPCTSTR lpszHeader,
    LPCTSTR lpszValue,
    DWORD dwReserved
);
```

The **MimeSetMessageHeaderEx** function adds or updates a header field in the specified message.

Parameters

hMessage

Handle to the message.

nMessagePart

An integer value which specifies which part of the message the header should be set or modified in. A value of zero sets a header value in the main message header block, while a value greater than zero sets the header value in that specific part of a multipart message. A value of -1 specifies that the header value should be set in the current message part.

lpszHeader

Pointer to a string which specifies the header field that will be added or updated.

lpszValue

Pointer to a string which specifies the value for the header field. This pointer may be NULL, which causes the header field to be removed from the message.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeSetMessagePart Function

```
INT WINAPI MimeSetMessagePart(
   HMESSAGE hMessage,
   INT nNewPart
);
```

The **MimeSetMessagePart** function sets the current message part index for the specified message.

Parameters

hMessage

Handle to the message.

nNewPart

The new message part index. A value of zero specifies the main message part.

Return Value

If the function succeeds, the return value is the previous message part index. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

Multipart email messages are structured using the MIME (Multipurpose Internet Mail Extensions) standard, which allows a single email to contain multiple content types, such as plain text, HTML, and file attachments, within a single message body. These components are organized as discrete parts, each with its own headers and body, separated by unique MIME boundaries. In a typical `multipart/alternative` message, part 0 often contains the message preamble (e.g.: "This is a multipart message in MIME format"), part 1 may contain the plain text version of the message, and part 2 may contain the HTML version. However, multipart messages are not required to include both plain text and HTML content. A message may only include an HTML part and one or more attachments, or any other combination of content types. The structure and ordering of parts depends entirely on how the original sender or mail client composed the message.

To simplify navigating these multipart structures, the **MimeSetMessagePart** and **MimeGetMessagePart** functions enable you to iterate through the individual parts of a message. The message parts are zero-based, with index 0 always referring to the top-level message headers and preamble. By calling **MimeSetMessagePart**, you can change the currently selected message part, enabling functions like **MimeGetMessageHeader** or **MimeGetMessageText** to operate on that specific segment. Calling **MimeGetMessagePart** returns the current part index, which can be useful for saving and restoring state while iterating over a message.

The internal MIME parser flattens multipart messages, meaning that if a message contains nested multipart sections (such as a multipart/mixed part containing a multipart/alternative part), all leaf parts are presented in a linear sequence. This simplifies access and avoids the complexity of recursive traversal. You can determine the total number of parts using **MimeGetMessagePartCount**, and then iterate from part 0 to part N-1 to examine or extract each segment in order. This approach provides both fine-grained access to MIME message parts and an intuitive model for parsing even complex message structures.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csmsgv12.lib

MimeSetMessageText Function

```
LONG WINAPI MimeSetMessageText(
    HMESSAGE hMessage,
    LONG nOffset,
    LPCTSTR lpszText
);
```

The **MimeSetMessageText** function copies the specified text into the body of the current message part.

Parameters

hMessage

Handle to the message.

nOffset

The offset into the body of the message part. A value of -1 specifies that the text will be appended to the message body.

lpszText

A null-terminated string which specifies the text to be copied to the current message part at the given offset.

Return Value

If the function succeeds, the return value is the number of bytes copied into the message. A return value of zero indicates that no text could be copied into the current message part. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeSetMessageVersion Function

```
BOOL WINAPI MimeSetMessageVersion(
    HMESSAGE hMessage,
    LPCTSTR lpszVersion
);
```

Parameters

hMessage

Handle to the message.

lpszVersion

Pointer to a string which specifies the MIME version. A value of NULL sets the version to the default value of 1.0.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeStoreMessage Function

```
LONG WINAPI MimeStoreMessage(
   HMESSAGESTORE hStorage,
   HMESSAGE hMessage,
   DWORD dwReserved
);
```

The **MimeStoreMessage** function stores the specified message in a message store.

Parameters

hStorage

Handle to the message store.

hMessage

Handle to the message that will be stored.

dwReserved

A reserved parameter. This value must always be zero.

Return Value

If the function succeeds, the return value is the message number for the message that was just stored. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeStoreMessage** function will always append the specified message to the storage file. If you want to replace a message in the message store, you should use the **MimeReplaceStoredMessage** function.

Example

```
HMESSAGE hMessage;

// Compose a new message
hMessage = MimeComposeMessage(lpszSender,
                              lpszRecipient,
                              NULL,
                              lpszSubject,
                              lpszMessage,
                              NULL,
                              MIME_CHARSET_DEFAULT,
                              MIME_ENCODING_DEFAULT);

if (hMessage != INVALID_MESSAGE)
{
    HMESSAGESTORE hStorage;

    // Open the message storage file
    hStorage = MimeOpenMessageStore(lpszFileName, MIME_STORAGE_WRITE);

    if (hStorage == INVALID_MESSAGESTORE)
    {
        // Close the message and return if we are unable to
        // open the storage file
```

```
        MimeCloseMessage(hMessage);
        return;
    }

    // Store a copy of the message in the message store
    nMessageId = MimeStoreMessage(hStorage, hMessage, 0);

    if (nMessageId == MIME_ERROR)
    {
        // We were unable to store the message
    }

    // Close the message store
    MimeCloseMessageStore(hStorage);

    // Close the message that was created
    MimeCloseMessage(hMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

MimeUninitialize Function

```
VOID WINAPI MimeUninitialize();
```

The **MimeUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **MimeInitialize** call before it can call any of the other the library functions. When it has finished using the library, the application must call **MimeUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **MimeUninitialize** for every successful call to **MimeInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

Message Character Sets

Value	Name	Code Page	Description
MIME_CHARSET_USASCII	us-ascii	20127	A character set which defines 7-bit printable characters with values ranging from 20h to 7Eh. An application that uses this character set has the broadest compatibility with most mail servers (MTAs) because it does not require the server to handle 8-bit characters correctly when the message is delivered.
MIME_CHARSET_ISO8859_1	iso-8859-1	28591	A character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin-1. This character set is similar to Windows code page 1252 (Windows-1252), however there are differences such as the Euro symbol.
MIME_CHARSET_ISO8859_2	iso-8859-2	28592	A character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin-2. This character set is similar to Windows code page 1250, however the characters are arranged differently.
MIME_CHARSET_ISO8859_3	iso-8859-3	28593	A character set for southern European languages such as Maltese and Esperanto. This character set was also used with the Turkish language, but it was superseded by ISO 8859-9 which is the preferred character set for Turkish. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
MIME_CHARSET_ISO8859_4	iso-8859-4	28594	A character set for northern European languages such as Latvian, Lithuanian and Greenlandic. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead.
MIME_CHARSET_ISO8859_5	iso-8859-5	28595	A character set for Cyrillic languages such as Russian, Bulgarian and Serbian. This character set was never widely adopted and most mail messages use

			either KOI8 or UTF-8 encoding.
MIME_CHARSET_ISO8859_6	iso-8859-6	28596	A character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	iso-8859-7	28597	A character set for the Greek language. This character set is also commonly referred to as Latin/Greek. This character set is no longer widely used and has largely been replaced with UTF-8 which provides more complete coverage of the Greek alphabet.
MIME_CHARSET_ISO8859_8	iso-8859-8	28598	A character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English. In most cases it is recommended that you use UTF-8 instead of this character set.
MIME_CHARSET_ISO8859_9	iso-8859-9	28599	A character set for the Turkish language. This character set is also commonly referred to as Latin-5. This character set is nearly identical to ISO 8859-1, except that it replaces certain Icelandic characters with Turkish characters.
MIME_CHARSET_ISO8859_10	iso-8859-10	28600	A character set for the Danish, Icelandic, Norwegian and Swedish languages. This character set is also commonly referred to as Latin-6 and is similar to ISO 8859-4.
MIME_CHARSET_ISO8859_13	iso-8859-13	28603	A character set for Baltic languages. This character set is also commonly referred to as Latin-7. This character set is similar to ISO 8859-4, except it adds certain Polish characters and does not support Nordic languages.
MIME_CHARSET_ISO8859_14	iso-8859-14	28604	A character set for Gaelic languages such as Irish, Manx and Scottish Gaelic. This character set is also commonly

			referred to as Latin-8. This character set replaced ISO 8859-12 which was never fully implemented.
MIME_CHARSET_ISO8859_15	iso-8859-15	28605	A character set for western European languages. This character set is also commonly referred to as Latin-9 and is nearly identical to ISO8859-1 except that it replaces lesser-used symbols with the Euro sign and some letters.
MIME_CHARSET_ISO2022_JP	iso-2022-jp	50220	A multi-byte character encoding for Japanese that is widely used with mail messages. This is a 7-bit encoding where all characters start with ASCII and uses escape sequences to switch to the double-byte character sets.
MIME_CHARSET_ISO2022_KR	iso-2022-kr	50225	A multi-byte character encoding for Korean which encodes both ASCII and Korean double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
MIME_CHARSET_ISO2022_CN	x-cp50227	50227	A multi-byte character encoding for Simplified Chinese which encodes both ASCII and Chinese double-byte characters. This is a 7-bit encoding which uses the shift in and shift out control characters to switch to the double-byte character set.
MIME_CHARSET_KOI8R	koi8-r	20866	A character set for Russian using the Cyrillic alphabet. This character set also covers the Bulgarian language. Most mail messages in the Russian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
MIME_CHARSET_KOI8U	koi8-u	21866	A character set for Ukrainian using the Cyrillic alphabet. This character set is similar to the KOI8-R character set, but replaces certain symbols with Ukrainian letters. Most mail messages in the Ukrainian language use this character set or UTF-8 instead of ISO 8859-5, which was never widely adopted.
MIME_CHARSET_GB2312	x-cp20936	20936	A multi-byte character encoding which can represent ASCII and simplified Chinese characters. It has been superseded by GB18030, however it

			remains widely used in China.
MIME_CHARSET_GB18030	gb18030	54936	A Unicode transformation format which can represent all Unicode code points and supports both simplified and traditional Chinese characters. It is backwards compatible with GB2312 and supersedes that character set.
MIME_CHARSET_BIG5	big5	950	A multi-byte character set that supports both ASCII characters and traditional Chinese characters. It is widely used in Taiwan, Hong Kong and Macau. It is no longer commonly used in China, which has developed GB18030 as a standard encoding. Microsoft's implementation of Big5 on Windows does not support all of the extensions and is missing certain code points.
MIME_CHARSET_UTF7	utf-7	65000	A Unicode transformation format that uses variable-length character encoding to represent Unicode text as a stream of ASCII characters that are safe to transport between mail servers that only support 7-bit printable characters. It is primarily used as an alternative to UTF-8 when quoted-printable or base64 encoding is not desired.
MIME_CHARSET_UTF8	utf-8	65001	A Unicode transformation format that uses multi-byte character sequences to represent Unicode text. It is backwards compatible with the ASCII character set, however because it uses 8-bit text, it is recommended that you use either quoted-printable or base64 encoding to ensure compatibility with mail servers that do not support 8-bit characters.
MIME_CHARSET_UTF16	utf-16le	N/A	A 16-bit Unicode format that represents each character as a 16-bit value in little endian byte order. This character set is not widely used in mail messages and it is recommended that you use UTF-8 instead. UTF-16 characters in big endian byte order are not supported.

Remarks

When composing a new message, it is recommended that you always use UTF-8 as the character set encoding which ensures broad compatibility with most applications. The other character sets are primarily used when parsing messages generated by other applications. Internally, all message headers and text are processed as UTF-8. If you use the ANSI version of these functions, header values

and message text will always be returned to your application as UTF-8 encoded Unicode, regardless of the original character set used in the message.

In addition to the character sets listed above, the library will recognize additional character sets which correspond to specific Windows code pages, as well several variants. These additional character sets are included for compatibility with other applications; they are not defined because they should not be used when composing new messages.

It is important to note that while certain Windows character sets are similar to standard ISO character sets, they are not identical. For example, although the Windows-1252 character set is nearly identical to ISO 8859-1, they are not interchangeable. Some legacy applications make the error of representing Windows ANSI character sets as 8-bit ISO character sets, which can result in errors when converting them to Unicode. This is something to be aware of when encoding and decoding text generated by older applications. Before the widespread adoption of UTF-8, it was particularly common for legacy Windows mail clients to default to using Windows-1252 for text and label it as using ISO 8859-1.

Although the library supports UTF-16, it is recommended you use UTF-8 instead. Text which uses UTF-16 will always be base64 encoded, and some mail clients may not recognize it as a valid character set. If the message does not specify if big endian or little endian byte order is used, the library will default to little endian. When UTF-16 is used when composing a new message, it will always use little endian byte order.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Network News Transfer Protocol Library

Download and submit articles to a news server.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSNWSV12.DLL
Version	12.0.3024.1286
LibID	C11CFCC7-8D02-4CB5-B3D2-003BD1D65C40
Import Library	CSNWSV12.LIB
Dependencies	None
Standards	RFC 977, RFC 2980

Overview

The Network News Transfer Protocol (NNTP) is used with servers that provide news services. This is similar in functionality to bulletin boards or message boards, where topics are organized hierarchically into groups, called newsgroups. Users can browse and search for messages, called news articles, which have been posted by other users. On many servers, they can also post their own articles which can be read by others. The largest collection of public newsgroups available is called USENET, a world-wide distributed discussion system. In addition, there are a large number of smaller news servers. For example, Catalyst Development operates a news server which functions as a forum for technical questions and announcements.

The SocketTools library provides a comprehensive interface for accessing newsgroups, retrieving articles and posting new articles. In combination with the Mail Message library to process the news articles, SocketTools can be used to integrate newsgroup access with an existing email application, or you can implement your own full-featured newsgroup client.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of

Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Network News Transfer Protocol Functions

Function	Description
NntpAsyncConnect	Establish an asynchronous connection to the specified server
NntpAttachThread	Attach the specified client handle to another thread
NntpAuthenticate	Authenticate the specified user on the news server
NntpCancel	Cancel the current blocking operation
NntpCloseArticle	Close the article being posted to the current newsgroup
NntpCommand	Send a command to the server
NntpConnect	Connect to the specified server
NntpCreateArticle	Create a new article in the current newsgroup
NntpCreateSecurityCredentials	Create a new security credentials structure
NntpDeleteSecurityCredentials	Delete a previously created security credentials structure
NntpDisableEvents	Disable asynchronous event notification
NntpDisableTrace	Disable logging of network function calls
NntpDisconnect	Disconnect from the current server
NntpEnableEvents	Enable asynchronous event notification
NntpEnableTrace	Enable logging of network function calls to a file
NntpEventProc	Callback function that processes events generated by the client
NntpFreezeEvents	Suspend asynchronous event processing
NntpGetArticle	Retrieve an article from the server and store the contents in a local buffer
NntpGetArticleEx	Retrieve an article from the server with support for large article IDs
NntpGetArticleByMessageId	Retrieve an article from the server using a message ID and store the contents in a local buffer
NntpGetArticleHeaders	Return the contents of the specified article header
NntpGetArticleHeadersEx	Return the contents of the specified article header with support for large article IDs
NntpGetArticleMessageId	Return the message identifier for the specified article
NntpGetArticleMessageIdEx	Return the message identifier for the specified article with support for large article IDs
NntpGetArticleRange	Return the first and last article number for the current group
NntpGetArticleRangeEx	Return the first and last article number for the current group with support for large article IDs
NntpGetArticleSize	Return the size of the specified news article in bytes
NntpGetArticleSizeEx	Return the size of the specified article with support for large article IDs
NntpGetCurrentArticle	Return the current article number for the selected group
NntpGetCurrentArticleEx	Return the current article number for the selected group with support for large article IDs
NntpGetCurrentDate	Return the current date and time
NntpGetErrorString	Return a description for the specified error code
NntpGetFirstArticle	Return the first available article in the currently selected newsgroup
NntpGetFirstArticleEx	Return the first available article in the currently selected newsgroup with support for large article IDs
NntpGetFirstGroup	Return the first available newsgroup from the server
NntpGetFirstGroupEx	Return the first available newsgroup from the server with support for large article IDs
NntpGetGroupName	Return the name of the currently selected newsgroup
NntpGetGroupTitle	Return a description of the currently selected newsgroup

NntpGetLastError	Return the last error code
NntpGetMessageIdArticle	Return the article number for the specified message identifier
NntpGetMessageIdArticleEx	Return the article number for the specified message with support for large article IDs
NntpGetMultiLine	Return the client multi-line output flag
NntpGetNextArticle	Return the next available article from the current newsgroup
NntpGetNextArticleEx	Return the next available article from the current newsgroup with support for large article IDs
NntpGetNextGroup	Return the next available newsgroup from the server
NntpGetNextGroupEx	Return the next available newsgroup from the server with support for large article IDs
NntpGetResultCode	Return the result code from the previous command
NntpGetResultString	Return the result string from the previous command
NntpGetSecurityInformation	Return security information about the current client connection
NntpGetStatus	Return the current client status
NntpGetTimeout	Return the number of seconds until an operation times out
NntpGetTransferStatus	Return data transfer statistics
NntpGetTransferStatusEx	Return data transfer statistics with support for large article IDs
NntpInitialize	Initialize the library and validates the specified license key at runtime
NntpIsBlocking	Determine if the client is blocked, waiting for information
NntpIsConnected	Determine if the client is connected to the server
NntpIsReadable	Determine if data can be read from the server
NntpIsWritable	Determine if data can be written to the server
NntpListArticles	Return a list of articles in the currently selected newsgroup
NntpListArticlesEx	Return a list of articles in the currently selected newsgroup with support for large article IDs
NntpListGroups	Return a list of newsgroups maintained by the server
NntpListNewGroups	Return a list of newsgroups created since a specified date
NntpOpenArticle	Open the specified article in the current newsgroup
NntpOpenArticleEx	Open the specified article in the current newsgroup with support for large article IDs
NntpOpenArticleByMessageId	Open the specified article by message ID in the current newsgroup
NntpOpenNextArticle	Open the next available article
NntpOpenPreviousArticle	Open the previous article
NntpPostArticle	Post a new article to the news server
NntpRead	Read data returned by the news server
NntpRegisterEvent	Register an event callback function
NntpReset	Reset the client
NntpSelectGroup	Select the specified newsgroup to retrieve articles from
NntpSetLastError	Set the last error code
NntpSetMultiLine	Set the client multi-line output flag
NntpSetTimeout	Set the number of seconds until an operation times out
NntpStoreArticle	Retrieve an article and store the contents in a local file
NntpStoreArticleEx	Retrieve an article and store the contents in a local file with support for large article IDs
NntpUninitialize	Terminate use of the library by the application
NntpWrite	Write data to the news server

NntpAsyncConnect Function

```
HCLIENT WINAPI NntpAsyncConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **NntpAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **NntpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
NNTP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
NNTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
NNTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection

	will always be permitted. This option only affects connections using the TLS protocol.
NNTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
NNTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
NNTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
NNTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This parameter is only used if the NNTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **NntpGetLastError**.

Remarks

The ***dwOptions*** argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle.

The ownership of the handle may be transferred from one thread to another using the **NntpAttachThread** function.

Specifying the NNTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
NNTP_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_LISTARTICLE	The client is retrieving a list of articles from the server and information about another article has been processed. The client should use this event to retrieve the next available article from the server.
NNTP_EVENT_LASTARTICLE	The client is retrieving a list of articles from the server and all of the available articles have been processed. This event is generated when there are no further articles.
NNTP_EVENT_LISTGROUP	The client is retrieving a list of newsgroups from the server and

	information about another group has been processed. The client should use this event to retrieve the next available newsgroup from the server.
NNTP_EVENT_LASTGROUP	The client is retrieving a list of newsgroups from the server and all of the available groups have been processed. This event is generated when there are no further newsgroups.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

To cancel asynchronous notification and return the client to a blocking mode, use the **NntpDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

NntpAttachThread Function

```
DWORD WINAPI NntpAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **NntpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **NntpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **NntpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **NntpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **NntpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpConnect, NntpDisconnect, NntpUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpAuthenticate Function

```
INT WINAPI NntpAuthenticate(
   HCLIENT hClient,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

The **NntpAuthenticate** function is used to authenticate access to the news server. Not all news servers require authentication by the client.

Parameters

hClient

Handle to the client session.

lpszUserName

Pointer to a string which specifies the user name required for authentication on the news server.

lpszPassword

Pointer to a string which specifies the password required for authentication on the news server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function should only be called if the server requires authentication. Two authentication methods, "original" and "simple" authentication, are recognized by the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

NntpConnect, NntpListArticles, NntpListGroups

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpCancel Function

```
INT WINAPI NntpCancel(
   HCLIENT hClient
);
```

The **NntpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

When the **NntpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpCloseArticle Function

```
INT WINAPI NntpCloseArticle(
    HCLIENT hClient
);
```

The **NntpCloseArticle** function closes the current article that has been opened or created.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

If an article is being created, this function actually submits the article to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpCommand Function

```
INT WINAPI NntpCommand(
   HCLIENT hClient,
   LPCTSTR lpszCommand,
   LPCTSTR lpszParameter
);
```

The **NntpCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the function succeeds, the return value is the result code returned by the server. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpConnect Function

```
HCLIENT WINAPI NntpConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **NntpConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
NNTP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
NNTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
NNTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
NNTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
NNTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will

	allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
NNTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
NNTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This parameter is only used if the NNTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **NntpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **NntpConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The ***dwOptions*** argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **NntpAttachThread** function.

Specifying the NNTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpCreateArticle Function

```
INT WINAPI NntpCreateArticle(
    HCLIENT hClient
);
```

The **NntpCreateArticle** function creates a new article in the current newsgroup.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function sends the POST command to the news server. Not all servers permit clients to post articles. The client application is responsible for generating the message headers as well as the body of the message. News articles conform to the same general characteristics of an email message.

The **NntpCloseArticle** function must be called once the contents of the article has been written to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpCreateSecurityCredentials Function

```
BOOL WINAPI NntpCreateSecurityCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **NntpCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **NntpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **NntpGetLastError** function.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **NntpConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
NntpCreateSecurityCredentials(SECURITY_PROTOCOL_DEFAULT,
                              0,
                              NULL,
                              NULL,
                              lpszCertStore,
                              lpszCertName,
                              NULL,
                              &lpSecCred);

hClient = NntpConnect(lpszHostName,
                      NNTP_PORT_SECURE,
                      NNTP_TIMEOUT,
                      NNTP_OPTION_SECURE,
                      lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpDeleteSecurityCredentials Function

```
VOID WINAPI NntpDeleteSecurityCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **NntpDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)
    NntpDeleteSecurityCredentials(&lpSecCred);

NntpUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpCreateSecurityCredentials, NntpUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpDisableEvents Function

```
INT WINAPI NntpDisableEvents(
    HCLIENT hClient
);
```

The **NntpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpDisableTrace Function

```
BOOL WINAPI NntpDisableTrace();
```

The **NntpDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpDisconnect Function

```
INT WINAPI NntpDisconnect(
   HCLIENT hClient
);
```

The **NntpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpConnect, NntpUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpEnableEvents Function

```
INT WINAPI NntpEnableEvents(
   HCLIENT hClient,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **NntpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **NntpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the ***hEventWnd*** parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
NNTP_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.

NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_LISTARTICLE	The client is retrieving a list of articles from the server and information about another article has been processed. The client should use this event to retrieve the next available article from the server.
NNTP_EVENT_LASTARTICLE	The client is retrieving a list of articles from the server and all of the available articles have been processed. This event is generated when there are no further articles.
NNTP_EVENT_LISTGROUP	The client is retrieving a list of newsgroups from the server and information about another group has been processed. The client should use this event to retrieve the next available newsgroup from the server.
NNTP_EVENT_LASTGROUP	The client is retrieving a list of newsgroups from the server and all of the available groups have been processed. This event is generated when there are no further newsgroups.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

NntpEnableTrace Function

```
BOOL WINAPI NntpEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **NntpEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpEventProc Function

```
VOID CALLBACK NntpEventProc(
   HCLIENT hClient,
   UINT nEvent,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **NntpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **NntpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **NntpRegisterEvent** function. The **NntpEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpFreezeEvents Function

```
INT WINAPI NntpFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **NntpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

NntpGetArticle Function

```
INT WINAPI NntpGetArticle(
   HCLIENT hClient,
   LONG nArticleId,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwReserved
);
```

The **NntpGetArticle** function retrieves the specified article and copies the contents to a local buffer.

Parameters

hClient

Handle to the client session.

nArticleId

Number of article to retrieve from the server. This value must be greater than zero.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticle** function is used to retrieve an article from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the article. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvBuffer*** parameter point to a global memory handle which will contain the article data when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the complete article has been retrieved, a timeout occurs or the operation is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **NntpEnableEvents**, or by registering a callback

function using the **NntpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **NntpGetTransferStatus** function. If you need to retrieve an article based on its message ID rather than the article number, use the **NntpGetArticleByMessageId** function.

Your application should use the **NntpGetArticleEx** function if the server uses 64-bit article IDs.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the article into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = NntpGetArticle(hClient,
                         nArticleId,
                         &hgblBuffer,
                         &cbBuffer,
                         0);

if (nResult != NNTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // article text
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpGetArticleByMessageId Function

```
INT WINAPI NntpGetArticleByMessageId(
    HCLIENT hClient,
    LPCTSTR lpszMessageId,
    LPVOID lpvBuffer,
    LPDWORD lpdwLength,
    DWORD dwReserved
);
```

The **NntpGetArticleByMessageId** function retrieves an article using the specified message ID and copies the contents to a local buffer.

Parameters

hClient

Handle to the client session.

lpszMessageId

A null-terminated string which specifies the message ID of the article that you want to retrieve. If this parameter is a NULL pointer or specifies a zero-length string, an error will be returned.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticleByMessageId** function is used to retrieve an article from the server and copy it into a local buffer. This function is identical to the **NntpGetArticle** function except that a message ID string is used to identify the article, rather than an article number. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the article. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvBuffer*** parameter point to a global memory handle which will contain the article data when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the complete article has been retrieved, a timeout occurs or the operation is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **NntpEnableEvents**, or by registering a callback function using the **NntpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **NntpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the article into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = NntpGetArticleByMessageId(hClient,
                                    lpszMessageId,
                                    &hgblBuffer,
                                    &cbBuffer,
                                    0);

if (nResult != NNTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // article text
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

NntpGetArticleHeaders Function

```
INT WINAPI NntpGetArticleHeaders(
    HCLIENT hClient,
    LONG nArticleId,
    LPVOID lpvHeaders,
    LPDWORD lpdwLength
);
```

The **NntpGetArticleHeaders** function retrieves the headers for the specified article from the server.

Parameters

hClient

Handle to the client session.

nArticleId

Number of article to retrieve from the server. This value must be greater than zero.

lpvHeaders

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvHeaders*** parameter. If the ***lpvHeaders*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticleHeaders** function is used to retrieve an article header block from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the ***lpvHeaders*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvHeaders*** parameter point to a global memory handle which will contain the message headers when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

This function will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the NNTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **NntpEnableEvents**, or by registering a callback function using the **NntpRegisterEvent** function.

Your application should use the **NntpGetArticleHeadersEx** function if the server uses 64-bit article IDs.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpGetArticleHeadersEx Function

```
INT WINAPI NntpGetArticleHeadersEx(
    HCLIENT hClient,
    ULONGLONG nArticleId,
    LPVOID lpvHeaders,
    LPDWORD lpdwLength
);
```

The **NntpGetArticleHeadersEx** function retrieves the headers for the specified article from the server.

Parameters

hClient

Handle to the client session.

nArticleId

Number of article to retrieve from the server.

lpvHeaders

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvHeaders*** parameter. If the ***lpvHeaders*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticleHeadersEx** function is used to retrieve an article header block from the server and copy it into a local buffer. This function provides support for servers which use 64-bit article IDs. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the ***lpvHeaders*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

NntpGetArticleMessageId Function

```
INT WINAPI NntpGetArticleMessageId(
    HCLIENT hClient,
    LONG nArticleId,
    LPTSTR lpszMessageId,
    INT cbMessageId
);
```

The **NntpGetArticleMessageId** function returns the message identifier for the specified article in the current newsgroup.

Parameters

hClient

Handle to the client session.

nArticleId

Article number to retrieve the message identifier for. The value may be zero, in which case the current article number is used.

lpszMessageId

Pointer to a string buffer which will contain the message identifier for the specified article.

cbMessageId

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the message identifier string. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The message identifier is a string which can uniquely identify the message on the news server. This value may be used to retrieve the contents of the article. Your application should use the **NntpGetArticleMessageIdEx** function if the server uses 64-bit article IDs.

NntpGetArticleMessageIdEx Function

```
INT WINAPI NntpGetArticleMessageIdEx(
    HCLIENT hClient,
    ULONGLONG nArticleId,
    LPTSTR lpszMessageId,
    INT cbMessageId
);
```

The **NntpGetArticleMessageIdEx** function returns the message identifier for the specified article in the current newsgroup.

Parameters

hClient

Handle to the client session.

nArticleId

Article number to retrieve the message identifier for. The value may be zero, in which case the current article number is used.

lpszMessageId

Pointer to a string buffer which will contain the message identifier for the specified article.

cbMessageId

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the message identifier string. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The message identifier is a string which can uniquely identify the message on the news server. This value may be used to retrieve the contents of the article. This function provides support for servers which use 64-bit article IDs.

NntpGetArticleRange Function

```
LONG WINAPI NntpGetArticleRange(
   HCLIENT hClient,
   LPLONG lpnFirstArticle,
   LPLONG lpnLastArticle
);
```

The **NntpGetArticleRange** function returns the first and last article numbers for the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpnFirstArticle

Pointer to a long integer that will contain the first article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnLastArticle

Pointer to a long integer that will contain the last article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

Return Value

If the function succeeds, the return value is number of articles in the selected newsgroup. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. If the server uses 64-bit article IDs, your application should use the **NntpGetArticleRangeEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpGetArticleRangeEx Function

```
BOOL WINAPI NntpGetArticleRangeEx(
   HCLIENT hClient,
   ULONGLONG *lpnFirstArticle,
   ULONGLONG *lpnLastArticle,
   ULONGLONG *lpnArticleCount
);
```

The **NntpGetArticleRangeEx** function returns the first and last article numbers for the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpnFirstArticle

Pointer to an unsigned 64-bit integer that will contain the first article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnLastArticle

Pointer to an unsigned 64-bit integer that will contain the last article number in the currently selected newsgroup. If this parameter is NULL, it will be ignored.

lpnArticleCount

Pointer to an unsigned 64-bit integer that will contain the total number of articles in the selected newsgroup. If this parameter is NULL, it will be ignored.

Return Value

If the function succeeds, the return value will be non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. This function provides support for servers which use 64-bit article IDs.

The **NntpGetArticleRangeEx** function returns a BOOL (a signed 32-bit integer) to indicate success or failure, and the article count is returned in a variable that is passed by reference to the function. If you are updating your code to use this function, make sure you also change how you check the return value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpGetArticleSize Function

```
DWORD WINAPI NntpGetArticleSize(
    HCLIENT hClient,
    LONG nArticleId
);
```

The **NntpGetArticleSize** function returns the size of the specified article.

Parameters

hClient

Handle to the client session.

nArticleId

An integer value that identifies the article. The value may be zero, in which case the current article number is used.

Return Value

If the function succeeds, the return value is the size of the article in bytes. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticleSize** function sends the XOVER command to the server to request the size of the specified article. If the server uses 64-bit article IDs, your application should use the **NntpGetArticleSizeEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

NntpGetArticleSizeEx Function

```
DWORD WINAPI NntpGetArticleSizeEx(
    HCLIENT hClient,
    ULONGLONG nArticleId
);
```

The **NntpGetArticleSize** function returns the size of the specified article.

Parameters

hClient

Handle to the client session.

nArticleId

An unsigned 64-bit integer value that identifies the article. The value may be zero, in which case the current article number is used.

Return Value

If the function succeeds, the return value is the size of the article in bytes. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetArticleSizeEx** function sends the XOVER command to the server to request the size of the specified article. This function provides support for servers which use 64-bit article IDs.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpGetCurrentArticle Function

```
LONG WINAPI NntpGetCurrentArticle(
    HCLIENT hClient
);
```

The **NntpGetCurrentArticle** function returns the current article number for the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the current article number. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpGetCurrentArticleEx Function

```
BOOL WINAPI NntpGetCurrentArticleEx(
    HCLIENT hClient,
    ULONGLONG *lpnArticleId
);
```

The **NntpGetCurrentArticle** function returns the current article number for the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpnArticleId

Pointer to an unsigned 64-bit integer that will contain the current article number in the selected newsgroup. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetCurrentArticleEx** function returns a BOOL (a signed 32-bit integer) to indicate success or failure, and the article ID is returned in a variable that is passed by reference to the function. This function provides support for servers which use 64-bit article IDs. If you are updating your code to use this function, make sure you also change how you check the return value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpGetCurrentDate Function

```
INT WINAPI NntpGetCurrentDate(
    LPTSTR lpszDate,
    INT nMaxLength
);
```

The **NntpGetCurrentDate** function copies the current date and time to the specified buffer in a format that is commonly used in news articles. This date format should be used in all date-related fields in the message header.

Parameters

lpszDate

Pointer to a string buffer that will contain the current date and time when the function returns.

nMaxLength

The maximum number of characters that can be copied into the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null-terminator. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The date value that is returned is adjusted for the local timezone.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetErrorString Function

```
INT WINAPI NntpGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **NntpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **NntpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetFirstArticle Function

```
BOOL WINAPI NntpGetFirstArticle(
   HCLIENT hClient,
   LPNEWSARTICLE lpArticle
);
```

The **NntpGetFirstArticle** function returns information about the first article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpArticle

A pointer to a NEWSARTICLE structure which will contain information about the first article in the currently selected directory.

Return Value

If the function succeeds, the return value is non-zero. If there are no articles in the current newsgroup, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetFirstArticle** function returns information about the first article in the currently selected newsgroup. This function is used in conjunction with the **NntpGetNextArticle** function to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **NntpGetArticle** function cannot be called while inside a loop calling **NntpGetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NttpGetArticle** for each article number to retrieve the article text.

The date and time that the article was posted is returned in the ***stPosted*** member of the NEWSARTICLE structure. This value is returned in Universal Coordinated Time (UTC) and can be converted to local time using the **SystemTimeToTzSpecificLocalTime** function.

If the server uses 64-bit article IDs, your application should use the **NntpGetFirstArticleEx** and **NntpGetNextArticleEx** functions.

Example

```
NEWSARTICLE newsArticle;
BOOL bResult;
INT nResult;

// List all articles in the current group
nResult = NntpListArticles(hClient, -1L, -1L);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();
```

```
    NntpGetErrorString(dwError, szError, ASTRING);
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);
    return;
}

// Get each article in the current newsgroup, printing the article
// number and the subject of the article
bResult = NntpGetFirstArticle(hClient, &newsArticle);

while (bResult)
{
    _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticle(hClient, &newsArticle);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetFirstArticleEx Function

```
BOOL WINAPI NntpGetFirstArticleEx(
   HCLIENT hClient,
   LPNEWSARTICLEEX lpArticleEx
);
```

The **NntpGetFirstArticleEx** function returns information about the first article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpArticleEx

A pointer to a NEWSARTICLEEX structure which will contain information about the first article in the currently selected directory.

Return Value

If the function succeeds, the return value is non-zero. If there are no articles in the current newsgroup, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetFirstArticleEx** function returns information about the first article in the currently selected newsgroup. This function is used in conjunction with the **NntpGetNextArticleEx** function to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access. This function provides support for servers which use 64-bit article IDs.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **NntpGetArticleEx** function cannot be called while inside a loop calling **NntpGetNextArticleEx**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NttpGetArticleEx** for each article number to retrieve the article text.

The date and time that the article was posted is returned in the ***stPosted*** member of the NEWSARTICLE structure. This value is returned in Universal Coordinated Time (UTC) and can be converted to local time using the **SystemTimeToTzSpecificLocalTime** function.

Example

```
NEWSARTICLEEX newsArticle;
BOOL bResult;
INT nResult;

// List all articles in the current group
nResult = NntpListArticlesEx(hClient, (ULONGLONG)-1, (ULONGLONG)-1);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();

    NntpGetErrorString(dwError, szError, ASTRING);
```

```
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);
    return;
}

// Get each article in the current newsgroup, printing the article
// number and the subject of the article
bResult = NntpGetFirstArticleEx(hClient, &newsArticle);

while (bResult)
{
    _tprintf(_T("%I64u %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticleEx(hClient, &newsArticle);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetFirstGroup Function

```
BOOL WINAPI NntpGetFirstGroup(
   HCLIENT hClient,
   LPNEWSGROUP lpGroup
);
```

The **NntpGetFirstGroup** function returns information about the first available newsgroup.

Parameters

hClient

Handle to the client session.

lpGroup

A pointer to a NEWSGROUP structure which will contain information about the first available newsgroup.

Return Value

If the function succeeds, the return value is non-zero. If there are no newsgroups available, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetFirstGroup** function returns information about the first newsgroup on the server. This function is used in conjunction with the **NntpGetNextGroup** function to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Note that if no newsgroups are returned by the server, it may indicate that it requires the client to authenticate itself prior to requesting a list of groups or articles.

If the server uses 64-bit article IDs, your application should use the **NntpGetFirstGroupEx** and **NntpGetNextGroupEx** functions.

Example

```
NEWSGROUP newsGroup;
BOOL bResult;
INT nResult;

// List all available newsgroups
nResult = NntpListGroups(hClient);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();

    NntpGetErrorString(dwError, szError, ASTRING);
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);
    return;
}
```

```
// Get each newsgroup, printing the article range and
// the name of the group
bResult = NntpGetFirstGroup(hClient, &newsGroup);

while (bResult)
{
    _tprintf(_T("%ld %ld %s\n"), newsGroup.nFirstArticle,
                                 newsGroup.nLastArticle,
                                 newsGroup.szName);

    bResult = NntpGetNextGroup(hClient, &newsGroup);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetFirstGroupEx Function

```
BOOL WINAPI NntpGetFirstGroupEx(
   HCLIENT hClient,
   LPNEWSGROUPEX lpGroupEx
);
```

The **NntpGetFirstGroupEx** function returns information about the first available newsgroup.

Parameters

hClient

Handle to the client session.

lpGroupEx

A pointer to a NEWSGROUPEX structure which will contain information about the first available newsgroup.

Return Value

If the function succeeds, the return value is non-zero. If there are no newsgroups available, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetFirstGroupEx** function returns information about the first newsgroup on the server. This function is used in conjunction with the **NntpGetNextGroupEx** function to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. This function provides support for servers which use 64-bit article IDs.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Note that if no newsgroups are returned by the server, it may indicate that it requires the client to authenticate itself prior to requesting a list of groups or articles.

Example

```
NEWSGROUPEX newsGroup;
BOOL bResult;
INT nResult;

// List all available newsgroups
nResult = NntpListGroups(hClient);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();
    NntpGetErrorString(dwError, szError, ASTRING);
    fprintf(stderr, "Error %08x: %s\n", dwError, szError);
    return;
}

// Get each newsgroup, printing the article range and
// the name of the group
```

```
bResult = NntpGetFirstGroupEx(hClient, &newsGroup);
while (bResult)
{
    printf("%I64u %I64u %s\n", newsGroup.nFirstArticle,
                               newsGroup.nLastArticle,
                               newsGroup.szName);

    bResult = NntpGetNextGroupEx(hClient, &newsGroup);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetGroupName Function

```
INT WINAPI NntpGetGroupName(
   HCLIENT hClient,
   LPTSTR lpszGroupName,
   INT nMaxLength
);
```

The **NntpGetGroupName** function returns the name of the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpszGroupName

Pointer to a string buffer that will contain the name of the currently selected newsgroup.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the newsgroup name. If no newsgroup has been selected, the function will return a value of zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetGroupTitle Function

```
INT WINAPI NntpGetGroupTitle(
   HCLIENT hClient,
   LPTSTR lpszGroupTitle,
   INT nMaxLength
);
```

The **NntpGetGroupTitle** function returns a description of the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpszGroupTitle

Pointer to a string buffer that will contain a description of the currently selected newsgroup.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the description. If no newsgroup has been selected, the function will return a value of zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The news server must support the XGTITLE command so that the group description can be obtained when the newsgroup is selected. If this command is not recognized, then no description will be returned.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetLastError Function

```
DWORD WINAPI NntpGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **NntpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **NntpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **NntpSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or NNTP_ERROR. Those functions which call **NntpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpGetMessageIdArticle Function

```
LONG WINAPI NntpGetMessageIdArticle(
    HCLIENT hClient,
    LPCTSTR lpszMessageId
);
```

The **NntpGetMessageIdArticle** function returns the article number associated with a message identifier in the current newsgroup.

Parameters

hClient

Handle to the client session.

lpszMessageId

A pointer to a message identifier string.

Return Value

If the function succeeds, the return value is the article number. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

If the server uses 64-bit article IDs, your application should use the **NntpGetMessageIdArticleEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetMessageIdArticleEx Function

```
BOOL WINAPI NntpGetMessageIdArticleEx(
    HCLIENT hClient,
    LPCTSTR lpszMessageId
    ULONGLONG *lpnArticleId
);
```

The **NntpGetMessageIdArticleEx** function returns the article number associated with a message identifier in the current newsgroup.

Parameters

hClient

Handle to the client session.

lpszMessageId

A pointer to a message identifier string.

lpnArticleId

A pointer to an unsigned 64-bit integer which will contain the article ID. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetMessageIdArticleEx** function returns a BOOL (a signed 32-bit integer) to indicate success or failure, and the article count is returned in a variable that is passed by reference to the function. If you are updating your code to use this function, make sure you also change how you check the return value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

NntpGetMultiLine Function

```
INT WINAPI NntpGetMultiLine(
   HCLIENT hClient,
   LPBOOL lpbMultiLine
);
```

The **NntpGetMultiLine** function returns the value of the client multi-line flag in the specified boolean parameter.

Parameters

hClient

Handle to the client session.

lpbMultiLine

A pointer to a boolean variable. This variable will be set to the current value of the client's internal multi-line flag.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The multi-line flag is used by the library to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpGetNextArticle Function

```
BOOL WINAPI NntpGetNextArticle(
   HCLIENT hClient,
   LPNEWSARTICLE lpArticle
);
```

The **NntpGetNextArticle** function returns information about the next article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpArticle

A pointer to a NEWSARTICLE structure which will contain information about the next available article in the currently selected directory.

Return Value

If the function succeeds, the return value is non-zero. If there are no more articles in the current newsgroup, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetNextArticle** function returns information about the next available article in the currently selected newsgroup. This function is used in conjunction with the **NntpGetFirstArticle** function to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **NntpGetArticle** function cannot be called while inside a loop calling **NntpGetNextArticle**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NttpGetArticle** for each article number to retrieve the article text.

If the server uses 64-bit article IDs, your application should use the **NntpGetFirstArticleEx** and **NntpGetNextArticleEx** functions.

Example

```
NEWSARTICLE newsArticle;
BOOL bResult;
INT nResult;

// List all articles in the current group
nResult = NntpListArticles(hClient, -1L, -1L);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();

    NntpGetErrorString(dwError, szError, ASTRING);
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);
    return;
```

```
}

// Get each article in the current newsgroup, printing the article
// number and the subject of the article
bResult = NntpGetNextArticle(hClient, &newsArticle);

while (bResult)
{
    _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticle(hClient, &newsArticle);
}
```

Requirements

NntpGetNextArticleEx Function

```
BOOL WINAPI NntpGetNextArticleEx(
   HCLIENT hClient,
   LPNEWSARTICLEEX lpArticleEx
);
```

The **NntpGetNextArticleEx** function returns information about the next article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

lpArticle

A pointer to a NEWSARTICLEEX structure which will contain information about the next available article in the currently selected directory.

Return Value

If the function succeeds, the return value is non-zero. If there are no more articles in the current newsgroup, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetNextArticleEx** function returns information about the next available article in the currently selected newsgroup. This function is used in conjunction with the **NntpGetFirstArticleEx** function to enumerate all of the articles in the newsgroup. Typically this is used to provide the user with a list of articles to access. This function provides support for servers which use 64-bit article IDs.

While the articles in the newsgroup are being listed, the client cannot retrieve the contents of a specific article. For example, the **NntpGetArticleEx** function cannot be called while inside a loop calling **NntpGetNextArticleEx**. The client should store those articles which it wants to retrieve in an array, and then once all of the articles have been listed, it can begin calling **NttpGetArticleEx** for each article number to retrieve the article text.

Example

```
NEWSARTICLEEX newsArticle;
BOOL bResult;
INT nResult;

// List all articles in the current group
nResult = NntpListArticlesEx(hClient, (ULONGLONG)-1, (ULONGLONG)-1);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();

    NntpGetErrorString(dwError, szError, ASTRING);
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);
    return;
}
```

```
// Get each article in the current newsgroup, printing the article
// number and the subject of the article
bResult = NntpGetNextArticleEx(hClient, &newsArticle);

while (bResult)
{
    _tprintf(_T("%I64u %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticleEx(hClient, &newsArticle);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

NntpGetArticleEx, NntpGetFirstArticleEx, NntpGetFirstGroupEx, NntpGetNextGroupEx, NntpListArticlesEx, NntpListGroups, NntpListNewGroups, NntpSelectGroup, NEWSARTICLEEX, NEWSGROUPEX

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpGetNextGroup Function

```
BOOL WINAPI NntpGetNextGroup(
   HCLIENT hClient,
   LPNEWSGROUP lpGroup
);
```

The **NntpGetNextGroup** function returns information about the next available newsgroup.

Parameters

hClient

Handle to the client session.

lpGroup

A pointer to a NEWSGROUP structure which will contain information about the next available newsgroup.

Return Value

If the function succeeds, the return value is non-zero. If there are no more newsgroups available, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetNextGroup** function returns information about the next newsgroup on the server. This function is used in conjunction with the **NntpGetFirstGroup** function to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

If the server uses 64-bit article IDs, your application should use the **NntpGetFirstGroupEx** and **NntpGetNextGroupEx** functions.

Example

```
NEWSGROUP newsGroup;
BOOL bResult;
INT nResult;

// List all available newsgroups
nResult = NntpListGroups(hClient);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();

    NntpGetErrorString(dwError, szError, ASTRING);
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);
    return;
}

// Get each newsgroup, printing the article range and
// the name of the group
```

```
bResult = NntpGetFirstGroup(hClient, &newsGroup);

while (bResult)
{
    _tprintf(_T("%ld %ld %s\n"), newsGroup.nFirstArticle,
                                 newsGroup.nLastArticle,
                                 newsGroup.szName);

    bResult = NntpGetNextGroup(hClient, &newsGroup);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetNextGroupEx Function

```
BOOL WINAPI NntpGetNextGroupEx(
   HCLIENT hClient,
   LPNEWSGROUPEX lpGroupEx
);
```

The **NntpGetNextGroupEx** function returns information about the next available newsgroup.

Parameters

hClient

Handle to the client session.

lpGroup

A pointer to a NEWSGROUPEX structure which will contain information about the next available newsgroup.

Return Value

If the function succeeds, the return value is non-zero. If there are no more newsgroups available, or the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetNextGroupEx** function returns information about the next newsgroup on the server. This function is used in conjunction with the **NntpGetFirstGroupEx** function to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. This function provides support for servers which use 64-bit article IDs.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
NEWSGROUPEX newsGroup;
BOOL bResult;
INT nResult;

// List all available newsgroups
nResult = NntpListGroups(hClient);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();

    NntpGetErrorString(dwError, szError, ASTRING);
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);
    return;
}

// Get each newsgroup, printing the article range and
// the name of the group
bResult = NntpGetFirstGroupEx(hClient, &newsGroup);
```

```
while (bResult)
{
    _tprintf(_T("%I64u %I64u %s\n"), newsGroup.nFirstArticle,
                                     newsGroup.nLastArticle,
                                     newsGroup.szName);

    bResult = NntpGetNextGroup(hClient, &newsGroup);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetResultCode Function

```
INT WINAPI NntpGetResultCode(
    HCLIENT hClient
);
```

The **NntpGetResultCode** function reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpGetResultString Function

```
INT WINAPI NntpGetResultString(
    HCLIENT hClient,
    LPTSTR lpszResult,
    INT nMaxLength
);
```

The **NntpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

The buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **NntpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetSecurityInformation Function

```
BOOL WINAPI NntpGetSecurityInformation(
   HCLIENT hClient,
   LPSECURITYINFO lpSecurityInfo
);
```

The **NntpGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;

securityInfo.dwSize = sizeof(SECURITYINFO);
if (NntpGetSecurityInformation(hClient, &securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
```

```
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpGetStatus Function

```
INT WINAPI NntpGetStatus(
   HCLIENT hClient
);
```

The **NntpGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
NNTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
NNTP_STATUS_CONNECT	The client is establishing a connection with the server.
NNTP_STATUS_READ	The client is reading data from the server.
NNTP_STATUS_WRITE	The client is writing data to the server.
NNTP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpGetTimeout Function

```
INT WINAPI NntpGetTimeout(
   HCLIENT hClient
);
```

The **NntpGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpGetTransferStatus Function

```
INT WINAPI NntpGetTransferStatus(
   HCLIENT hClient,
   LPNNTPTRANSFERSTATUS lpStatus
);
```

The **NntpGetTransferStatus** function returns information about the current news article transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an NNTPTRANSFERSTATUS structure which contains information about the status of the current article transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetTransferStatus** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If no article is currently being retrieved or submitted to the server, this function will return the status of the last successful data transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the server uses 64-bit article IDs, your application should use the **NntpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpGetTransferStatusEx Function

```
INT WINAPI NntpGetTransferStatusEx(
   HCLIENT hClient,
   LPNNTPTRANSFERSTATUSEX lpStatusEx
);
```

The **NntpGetTransferStatusEx** function returns information about the current news article transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an NNTPTRANSFERSTATUSEX structure which contains information about the status of the current article transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpGetTransferStatusEx** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. This function provides support for servers which use 64-bit article IDs. If no article is currently being retrieved or submitted to the server, this function will return the status of the last successful data transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

NntpInitialize Function

```
BOOL WINAPI NntpInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **NntpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **NntpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **NntpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **NntpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **NntpInitialize** or **NntpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

NntpConnect, NntpDisconnect, NntpUninitialize

NntpIsBlocking Function

```
BOOL WINAPI NntpIsBlocking(
   HCLIENT hClient
);
```

The **NntpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **NntpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpCancel, NntpCommand, NntpIsConnected, NntpIsReadable, NntpIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpIsConnected Function

```
BOOL WINAPI NntpIsConnected(
    HCLIENT hClient
);
```

The **NntpIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpIsBlocking, NntpIsReadable, NntpIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpIsReadable Function

```
BOOL WINAPI NntpIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **NntpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpGetStatus, NntpIsBlocking, NntpIsConnected, NntpIsWritable, NntpRead

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpIsWritable Function

```
BOOL WINAPI NntpIsWritable(
   HCLIENT hClient,
   INT nTimeout
);
```

The **NntpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpGetStatus, NntpIsBlocking, NntpIsConnected, NntpIsReadable, NntpWrite

NntpListArticles Function

```
INT WINAPI NntpListArticles(
   HCLIENT hClient,
   LONG nFirstArticle,
   LONG nLastArticle
);
```

The **NntpListArticles** function returns a list of articles in the currently selected newsgroup, within the specified article range.

Parameters

hClient

Handle to the client session.

nFirstArticle

The first newsgroup article to be returned in the list. If this value is -1, the list will begin with the first available article in the newsgroup.

nLastArticle

The last newsgroup article to be returned in the list. If the value is -1, the list will end with the last available article in the newsgroup.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

It is possible that there will be gaps in the articles within the range of the first and last articles in the newsgroup. This may be due to a message being canceled or expired. Use the **NntpGetFirstArticle** and **NntpGetNextArticle** functions to read the list of articles returned by the server.

If the server uses 64-bit article IDs, your application should use the **NntpListArticlesEx** function.

Example

```
NEWSARTICLE newsArticle;
BOOL bResult;
INT nResult;

// List all articles in the current group
nResult = NntpListArticles(hClient, -1L, -1L);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();

    NntpGetErrorString(dwError, szError, ASTRING);
    _ftprintf(stderr, _T("Error %08x: %s\n"), dwError, szError);
    return;
}

// Get each article in the current newsgroup, printing the article
// number and the subject of the article
```

```
bResult = NntpGetNextArticle(hClient, &newsArticle);
while (bResult)
{
    _tprintf(_T("%ld %s\n"), newsArticle.nArticleId, newsArticle.szSubject);
    bResult = NntpGetNextArticle(hClient, &newsArticle);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpGetArticleRange, NntpGetCurrentArticle, NntpGetFirstArticle, NntpGetNextArticle, NntpListGroups, NntpListArticlesEx, NntpListNewGroups

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpListGroups Function

```
INT WINAPI NntpListGroups(
   HCLIENT hClient
);
```

The **NntpListGroups** function instructs the server to begin sending a list of newsgroups back to the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpListGroups** function is used in conjunction with the **NntpGetFirstGroup** and **NntpGetNextGroup** functions to enumerate all of the available newsgroups. Typically this is used to provide the user with a list of newsgroups to select. To list only those newsgroups which have been added since a certain date, use the **NntpListNewGroups** function.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
NEWSGROUP newsGroup;
BOOL bResult;
INT nResult;

// List all available newsgroups
nResult = NntpListGroups(hClient);

if (nResult == NNTP_ERROR)
{
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();
    NntpGetErrorString(dwError, szError, ASTRING);
    fprintf(stderr, "Error %08x: %s\n", dwError, szError);
    return;
}

// Get each newsgroup, printing the article range and
// the name of the group
bResult = NntpGetFirstGroup(hClient, &newsGroup);
while (bResult)
{
    printf("%ld %ld %s\n", newsGroup.nFirstArticle,
                           newsGroup.nLastArticle,
                           newsGroup.szName);
    bResult = NntpGetNextGroup(hClient, &newsGroup);
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpListNewGroups Function

```
INT WINAPI NntpListNewGroups(
   HCLIENT hClient,
   LPCTSTR lpszLastUpdated,
   BOOL bLocalTime
);
```

The **NntpListNewGroups** function instructs the server to begin sending a list of newsgroups that were created since the specified date.

Parameters

hClient

Handle to the client session.

lpszLastUpdated

Pointer to a string which specifies the date and time that the list of newsgroups were last retrieved from the server. This parameter may be NULL or an empty string, in which case all available newsgroups will be listed by the server.

bLocalTime

A boolean value which indicates if the time specified in the ***lpszLastUpdated*** parameter is for the current timezone. If the value is non-zero, the time is assumed to be in the local timezone. If the value is zero, the time is assumed to be in Coordinated Universal Time (UTC).

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpListNewGroups** function is used in conjunction with the **NntpGetFirstGroup** and **NntpGetNextGroup** functions to enumerate all of the newsgroups that were added to the server since a specific date and time. Typically this is used to provide the user with a list of updated newsgroups to select. To list all of the newsgroups available on the server, use the **NntpListGroups** function.

While the newsgroups are being listed, the client cannot select a newsgroup or retrieve the contents of a specific article. The client should store those newsgroups which it wants to retrieve articles from, and then once all of the newsgroups have been listed, it can then select each newsgroup and retrieve the available articles from that group.

Example

```
NEWSGROUP newsGroup;
LPCTSTR lpszUpdated = _T("1/1/2004 12:00 AM");
BOOL bResult;
INT nResult;

// List all newsgroups that were added after a
// specific date
nResult = NntpListNewGroups(hClient, lpszUpdated, TRUE);

if (nResult == NNTP_ERROR)
{
```

```
    TCHAR szError[ASTRING];
    DWORD dwError = NntpGetLastError();
    NntpGetErrorString(dwError, szError, ASTRING);
    fprintf(stderr, "Error %08x: %s\n", dwError, szError);
    return;
}

// Get each newsgroup, printing the article range and
// the name of the group
bResult = NntpGetFirstGroup(hClient, &newsGroup);
while (bResult)
{
    printf("%ld %ld %s\n", newsGroup.nFirstArticle,
                           newsGroup.nLastArticle,
                           newsGroup.szName);
    bResult = NntpGetNextGroup(hClient, &newsGroup);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpOpenArticle Function

```
INT WINAPI NntpOpenArticle(
   HCLIENT hClient,
   LONG nArticleId
);
```

The **NntpOpenArticle** function opens the specified article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

nArticleId

An integer value that specifies which article in the current newsgroup to retrieve. This value may be zero, which specifies that the current article should be opened.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpOpenArticle** function sends a request to begin returning the contents of the specified article. The **NntpRead** function is used to read the article contents after it has been opened. When the complete article has been read, the **NntpCloseArticle** function must be called to close the article and complete the request.

It is recommended most applications use the **NntpGetArticle** function, which will retrieve the complete article in a single function call. This function is typically only used if the application needs to modify the contents of the article as it is being read. If you wish to download an article and store it in a file on the local system, use the **NntpStoreArticle** function.

If the server uses 64-bit article IDs, your application should use the **NntpOpenArticleEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpOpenArticleEx Function

```
INT WINAPI NntpOpenArticleEx(
   HCLIENT hClient,
   ULONGLONG nArticleId
);
```

The **NntpOpenArticle** function opens the specified article in the currently selected newsgroup.

Parameters

hClient

Handle to the client session.

nArticleId

An unsigned 64-bit integer that specifies which article in the current newsgroup to retrieve. This value may be zero, which specifies that the current article should be opened.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpOpenArticleEx** function sends a request to begin returning the contents of the specified article. This function provides support for servers which use 64-bit article IDs. The **NntpRead** function is used to read the article contents after it has been opened. When the complete article has been read, the **NntpCloseArticle** function must be called to close the article and complete the request.

It is recommended most applications use the **NntpGetArticleEx** function, which will retrieve the complete article in a single function call. This function is typically only used if the application needs to modify the contents of the article as it is being read. If you wish to download an article and store it in a file on the local system, use the **NntpStoreArticleEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpOpenArticleByMessageId Function

```
INT WINAPI NntpOpenArticleByMessageId(
    HCLIENT hClient,
    LPCTSTR lpszMessageId
);
```

The **NntpOpenArticleByMessageId** function opens the article specified by the message identifier string.

Parameters

hClient

Handle to the client session.

lpszMessageId

Pointer to a string which contains the message identifier for the article in the current newsgroup.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NntpOpenNextArticle Function

```
INT WINAPI NntpOpenNextArticle(
    HCLIENT hClient
);
```

The **NntpOpenNextArticle** function opens the next available article in the current newsgroup.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpOpenPreviousArticle Function

```
INT WINAPI NntpOpenPreviousArticle(
    HCLIENT hClient
);
```

The **NntpOpenPreviousArticle** function opens the previous article in the current newsgroup.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NntpPostArticle Function

```
INT WINAPI NntpPostArticle(
   HCLIENT hClient,
   LPCTSTR lpBuffer,
   DWORD dwLength,
   DWORD dwReserved
);
```

The **NntpPostArticle** function post the contents of the specified buffer to the server as a new article in the current newsgroup.

Parameters

hClient

Handle to the client session.

lpBuffer

A pointer to a character buffer which contains the article to be posted to the currently selected newsgroup.

dwLength

Specifies the length of the string which contains the article. If this parameter is -1, the actual length of the string is calculated by searching the buffer for a terminating null byte.

dwReserved

Reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpPostArticle** function is used to post the contents of the specified buffer to the server as a new article in the current newsgroup. Not all newsgroups permit new articles to be posted, and some newsgroups may require that you email the article to a moderator for approval instead of posting directly to the group. It may be required that the client authenticate itself using the **NntpAuthenticate** function prior to posting the article.

A news article is similar to an email message in that it contains one or more header fields, followed by an empty line, followed by the body of the article. Each line of text should be terminated by a carriage return/linefeed sequence of characters. The Mail Message library can be used to compose a message if needed. Note that the article header must contain a header field named "Newsgroups" with a value that specifies the newsgroup or newsgroups the article is being posted to. If this header field is missing, the news server will reject the article.

This function will cause the current thread to block until the transfer has completed, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **NntpEnableEvents**, or by registering a callback function using the **NntpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **NntpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

NntpGetTransferStatus, NntpIsBlocking, NntpIsWritable, NntpRead, NntpReset, NntpWrite

NntpRead Function

```
INT WINAPI NntpRead(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **NntpRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

When **NntpRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpRegisterEvent Function

```
INT WINAPI NntpRegisterEvent(
  HCLIENT hClient,
  UINT nEvent,
  NNTPEVENTPROC lpEventProc,
  DWORD_PTR dwParam
);
```

The **NntpRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
NNTP_EVENT_CONNECT	The connection to the server has completed.
NNTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
NNTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
NNTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
NNTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
NNTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
NNTP_EVENT_LISTARTICLE	The client is retrieving a list of articles from the server and information about another article has been processed. The

	client should use this event to retrieve the next available article from the server.
NNTP_EVENT_LASTARTICLE	The client is retrieving a list of articles from the server and all of the available articles have been processed. This event is generated when there are no further articles.
NNTP_EVENT_LISTGROUP	The client is retrieving a list of newsgroups from the server and information about another group has been processed. The client should use this event to retrieve the next available newsgroup from the server.
NNTP_EVENT_LASTGROUP	The client is retrieving a list of newsgroups from the server and all of the available groups have been processed. This event occurs when there are no further newsgroups.
NNTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **NntpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpRegisterEvent** function associates a callback function with a specific event. The event handler is an **NntpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a news article is being uploaded or downloaded. The NNTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one NNTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpReset Function

```
INT WINAPI NntpReset(
   HCLIENT hClient
);
```

The **NntpReset** function resets the client state and resynchronizes with the server. This function is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The client cannot be reset while it is in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpCancel, NntpIsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpSelectGroup Function

```
INT WINAPI NntpSelectGroup(
   HCLIENT hClient,
   LPCTSTR lpszGroupName
);
```

The **NntpSelectGroup** function selects the specified newsgroup from which articles will be retrieved.

Parameters

hClient

Handle to the client session.

lpszGroupName

Pointer to a string which specifies the newsgroup to be selected. This value may be NULL, in which case the current newsgroup is unchanged, but the article count is updated.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

This function selects the newsgroup and obtains a description and the first and last article numbers for that group.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

NntpGetGroupName, NntpGetGroupTitle, NntpListGroups, NntpListNewGroups

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpSetLastError Function

```
VOID WINAPI NntpSetLastError(
    DWORD dwErrorCode
);
```

The **NntpSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or NNTP_ERROR. Those functions which call **NntpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **NntpGetLastError** function. The use of **NntpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpGetErrorString, NntpGetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpSetMultiLine Function

```
INT WINAPI NntpSetMultiLine(
   HCLIENT hClient,
   BOOL bMultiLine
);
```

The **NntpSetMultiLine** function sets the client multi-line flag into the specified value.

Parameters

hClient

Handle to the client session.

bMultiLine

A boolean flag which determines if the client is processing multiple lines of data as the result of a command.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The multi-line flag is used by the library to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

The **NntpSetMultiLine** function should only be used in conjunction with the **NntpCommand** function. If a command is issued which would result in multiple lines of output, the multi-line flag must be set TRUE. The multi-line flag must be set after each command, since it is reset to FALSE with each command that is sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpCommand, NntpGetMultiLine, NntpGetResultCode, NntpGetResultString

NntpSetTimeout Function

```
INT WINAPI NntpSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **NntpSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

See Also

NntpConnect, NntpGetTimeout

NntpStoreArticle Function

```
INT WINAPI NntpStoreArticle(
   HCLIENT hClient,
   LONG nArticleId,
   LPCTSTR lpszFileName
);
```

The **NntpStoreMessage** function retrieves an article from the current newsgroup and stores it in a local file.

Parameters

hClient

Handle to the client session.

nArticleId

An integer value that specifies the article to be downloaded.

lpszFileName

Pointer to a string which specifies the file that the article will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the article.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpStoreArticle** function provides a method of retrieving and storing an article on the local system. The contents of the article is stored as a text file, using the specified file name. This function always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode. If you wish to download the article to memory rather than a file, use the **NntpGetArticle** function.

If event handling is enabled, the NNTP_EVENT_PROGRESS event will fire periodically during the transfer of the article to the local system. An application can determine how much of the article has been retrieved by calling the **NntpGetTransferStatus** function.

If the server uses 64-bit article IDs, your application should use the **NntpStoreArticleEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpStoreArticleEx Function

```
INT WINAPI NntpStoreArticleEx(
   HCLIENT hClient,
   ULONGLONG nArticleId,
   LPCTSTR lpszFileName,
   DWORD dwReserved
);
```

The **NntpStoreMessageEx** function retrieves an article from the current newsgroup and stores it in a local file.

Parameters

hClient

Handle to the client session.

nArticleId

An unsigned 64-integer value which specifies the article to be downloaded.

lpszFileName

Pointer to a string which specifies the file that the article will be stored in. If the file does not exist, it will be created. If the file does exist, it will be overwritten with the contents of the article.

dwReserved

Number of the article to retrieve. This value must be greater than zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The **NntpStoreArticleEx** function provides a method of retrieving and storing an article on the local system. This function provides support for servers which use 64-bit article IDs.

The contents of the article is stored as a text file, using the specified file name. This function always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode. If you wish to download the article to memory rather than a file, use the **NntpGetArticle** function.

If event handling is enabled, the NNTP_EVENT_PROGRESS event will fire periodically during the transfer of the article to the local system. An application can determine how much of the article has been retrieved by calling the **NntpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

NntpGetArticleEx, NntpGetArticleHeadersEx, NntpGetTransferStatusEx

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NntpUninitialize Function

```
VOID WINAPI NntpUninitialize();
```

The **NntpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **NntpInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **NntpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **NntpUninitialize** for every successful call to **NntpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

NntpWrite Function

```
INT WINAPI NntpWrite(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **NntpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is NNTP_ERROR. To get extended error information, call **NntpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the NNTP_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

NEWSARTICLE

This structure is used by the **NntpGetFirstArticle** and **NntpGetNextArticle** functions to return information about news articles.

```
typedef struct _NEWSARTICLE
{
    LONG        nArticleId;
    LONG        nBytes;
    LONG        nLines;
    TCHAR       szSubject[NNTP_MAXSUBJLEN];
    TCHAR       szAuthor[NNTP_MAXAUTHLEN];
    TCHAR       szMessageId[NNTP_MAXMSGIDLEN];
    TCHAR       szReferences[NNTP_MAXREFLEN];
    SYSTEMTIME  stPosted;
} NEWSARTICLE, *LPNEWSARTICLE;
```

Members

nArticleId

A long integer which specifies the article number.

nBytes

The length of the news article in bytes.

nLines

The length of the news article specified as the number of lines of text.

szSubject

A null-terminated string which specifies the subject of the article.

szAuthor

A null-terminated string which specifies the email address of the user who posted the article.

szMessageId

A null-terminated string which specifies the message ID for the article.

szReferences

A null-terminated string which specifies references to the article.

stPosted

A SYSTEMTIME structure which specifies when the article was posted in Universal Coordinated Time (UTC).

Remarks

If the server uses 64-bit article IDs your application should use the NEWSARTICLEEX structure and related functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

NEWSARTICLEEX

This structure is used by the **NntpGetFirstArticleEx** and **NntpGetNextArticleEx** functions to return information about news articles.

```
typedef struct _NEWSARTICLEEX
{
    ULONGLONG   nArticleId;
    ULONG       nBytes;
    ULONG       nLines;
    TCHAR       szSubject[NNTP_MAXSUBJLEN];
    TCHAR       szAuthor[NNTP_MAXAUTHLEN];
    TCHAR       szMessageId[NNTP_MAXMSGIDLEN];
    TCHAR       szReferences[NNTP_MAXREFLEN];
    SYSTEMTIME  stPosted;
} NEWSARTICLEEX, *LPNEWSARTICLEEX;
```

Members

nArticleId

An unsigned 64-bit integer which specifies the article number.

nBytes

The length of the news article in bytes.

nLines

The length of the news article specified as the number of lines of text.

szSubject

A null-terminated string which specifies the subject of the article.

szAuthor

A null-terminated string which specifies the email address of the user who posted the article.

szMessageId

A null-terminated string which specifies the message ID for the article.

szReferences

A null-terminated string which specifies references to the article.

stPosted

A SYSTEMTIME structure which specifies when the article was posted in Universal Coordinated Time (UTC).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NEWSGROUP

This structure is used by the **NntpGetFirstGroup** and **NntpGetNextGroup** functions to return information about the available newsgroups.

```
typedef struct _NEWSGROUP
{
    LONG        nFirstArticle;
    LONG        nLastArticle;
    DWORD       dwAccess;
    TCHAR       szName[NNTP_MAXGRPNAMLEN];
} NEWSGROUP, *LPNEWSGROUP;
```

Members

nFirstArticle

A long integer which specifies the article number of the first available article in the newsgroup.

nLastArticle

A long integer which specifies the article number of the last available article in the newsgroup. Note that posted articles may not be contiguous in the range between the first and last article numbers. Some servers may assign numbers in a different order than the articles were posted, or there may be gaps where articles have been removed.

dwAccess

An unsigned integer which specifies the access mode for the group. It may be one of the following values:

Value	Description
NNTP_GROUP_READONLY	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
NNTP_GROUP_READWRITE	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
NNTP_GROUP_MODERATED	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

szName

A null-terminated string which specifies the name of the newsgroup.

Remarks

If the server uses 64-bit article IDs your application should use the NEWSGROUPEX structure and related functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnwsv12.lib

Unicode: Implemented as Unicode and ANSI versions

```
typedef struct _NEWSGROUPEX
{
    ULONGLONG   nFirstArticle;
    ULONGLONG   nLastArticle;
    DWORD       dwAccess;
    TCHAR       szName[NNTP_MAXGRPNAMLEN];
} NEWSGROUP, *LPNEWSGROUP;
```

Members

nFirstArticle

An unsigned 64-bit integer which specifies the article number of the first available article in the newsgroup.

nLastArticle

An unsigned 64-bit integer which specifies the article number of the last available article in the newsgroup. Note that posted articles may not be contiguous in the range between the first and last article numbers. Some servers may assign numbers in a different order than the articles were posted, or there may be gaps where articles have been removed.

dwAccess

An unsigned integer which specifies the access mode for the group. It may be one of the following values:

Value	Description
NNTP_GROUP_READONLY	The group is read-only and cannot be modified. Attempts to post articles to the newsgroup will result in an error.
NNTP_GROUP_READWRITE	Articles can be posted to the newsgroup. Even though a newsgroup is read-write, it may require that the client authenticate before being given permission to post articles to the server.
NNTP_GROUP_MODERATED	The newsgroup is moderated and articles can only be posted by the group moderator. To request that an article be posted to the newsgroup, you must email the message to the moderator.

szName

A null-terminated string which specifies the name of the newsgroup.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

NNTPTRANSFERSTATUS

This structure is used by the **NntpGetTransferStatus** function to return information about an article transfer in progress. If the server uses 64-bit article IDs your application should use the NNTPTRANSFERSTATUSEX structure and related functions.

```
typedef struct _NNTPTRANSFERSTATUS
{
   LONG    nArticleId;
   DWORD   dwBytesTotal;
   DWORD   dwBytesCopied;
   DWORD   dwBytesPerSecond;
   DWORD   dwTimeElapsed;
   DWORD   dwTimeEstimated;
} NNTPTRANSFERSTATUS, *LPNNTPTRANSFERSTATUS;
```

Members

nArticleId

A signed integer that specifies the article ID of the current article that is being transferred. If an article is being posted, this value will be zero.

dwBytesTotal

An unsigned integer that specifies the total number of bytes that will be transferred. If the article is being copied from the server to the local host, this is the size of the article on the server. If the article is being posted to the server, it is the size of article on the local system. If the article size cannot be determined, this value will be zero.

dwBytesCopied

An unsigned integer that specifies the total number of bytes that have been copied.

dwBytesPerSecond

An unsigned integer that specifies the average number of bytes that have been copied per second.

dwTimeElapsed

An unsigned integer that specifies the number of seconds that have elapsed since the transfer started.

dwTimeEstimated

An unsigned integer that specifies the estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

NNTPTRANSFERSTATUSEX

This structure is used by the **NntpGetTransferStatusEx** function to return information about an article transfer in progress. This structure is intended for use with servers that return 64-bit article IDs.

```
typedef struct _NNTPTRANSFERSTATUSEX
{
   ULONGLONG nArticleId;
   DWORD     dwBytesTotal;
   DWORD     dwBytesCopied;
   DWORD     dwBytesPerSecond;
   DWORD     dwTimeElapsed;
   DWORD     dwTimeEstimated;
} NNTPTRANSFERSTATUSEX, *LPNNTPTRANSFERSTATUSEX;
```

Members

nArticleId

An unsigned 64-bit integer that specifies the article ID of the current article that is being transferred. If an article is being posted, this value will be zero.

dwBytesTotal

An unsigned integer that specifies the total number of bytes that will be transferred. If the article is being copied from the server to the local host, this is the size of the article on the server. If the article is being posted to the server, it is the size of article on the local system. If the article size cannot be determined, this value will be zero.

dwBytesCopied

An unsigned integer that specifies the total number of bytes that have been copied.

dwBytesPerSecond

An unsigned integer that specifies the average number of bytes that have been copied per second.

dwTimeElapsed

An unsigned integer that specifies the number of seconds that have elapsed since the transfer started.

dwTimeEstimated

An unsigned integer that specifies the estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Network Time Protocol Library

Query a network time server for the current date and time.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSTIMV12.DLL
Version	12.0.3024.1286
LibID	79C32362-35E2-4115-9F08-043C7F982BB8
Import Library	CSTIMV12.LIB
Dependencies	None
Standards	RFC 868, RFC 5905

Overview

The Network Time Protocol library provides an interface for obtaining the current date and time from a server. The time is returned in Coordinated Universal Time (UCT) and can be adjusted for the local host's timezone. The time value is returned as the number of seconds which have elapsed since midnight, January 1, 1900. The library supports the Network Time Protocol (NTP) as specified in RFC 5905 and the TIME protocol described in RFC 868.

It is recommended you update your applications to call the functions which use 64-bit integer time values and use the NTP v4 protocol, which is supported in the current version of this API. To use NTP v4, provide the name of a valid NTP server and specify port 123. Although the API continues to support the TIME protocol on port 37, its use has been deprecated and applications should be updated to use NTP which is considered a more reliable method for obtaining the current time over the Internet.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy

development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Network Time Protocol Functions

Function	Description
ConvertNetworkTime	Convert 32-bit network time to system time
ConvertNetworkTime64	Convert a 64-bit network time to system time
ConvertSystemTime	Convert system time to a 32-bit network time
ConvertSystemTime64	Convert system time to a 64-bit network time
FormatNetworkTime	Return the specified 32-bit network time as a string formatted for the current locale.
FormatNetworkTime64	Return the specified 64-bit network time as a string formatted for the current locale.
GetNetworkTime	Return the current 32-bit network time from the server
GetNetworkTime64	Return the current 64-bit network time from the server
QueryNetworkTime	Query the server for the network time
ReadNetworkTime	Read the network time returned by the server
ReadNetworkTime64	Read the 64-bit network time returned by the server
TimeDisableTrace	Disable logging of network function calls
TimeEnableTrace	Enable logging of network function calls to a file
TimeGetErrorString	Return a description for the specified error code
TimeGetLastError	Return the last error code
TimeInitialize	Initialize the library and validates the specified license key at runtime
TimeSetLastError	Set the last error code
TimeUninitialize	Terminate use of the library by the application
UpdateLocalTime	Update the local system time with a 32-bit network time
UpdateLocalTime64	Update the local system time with a 64-bit network time

ConvertNetworkTime Function

```
BOOL WINAPI ConvertNetworkTime(
   DWORD dwNetworkTime,
   LPSYSTEMTIME lpSystemTime,
   BOOL bLocalTime
);
```

The **ConvertNetworkTime** function converts the specified network time, adjusting for the local timezone if required. The network time is a 32-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Parameters

dwNetworkTime

An unsigned 32-bit integer value which specifies the network time. This value should specify the number of seconds since midnight, January 1, 1900 UTC.

lpSystemTime

A pointer to a SYSTEMTIME structure which will be modified for the specified network time.

bLocalTime

A boolean flag that is used to specify if the network time should be adjusted for the local timezone.

Return Value

If the network time could be converted, the function returns a non-zero value. If the network time cannot be converted, or the pointer to the SYSTEMTIME structure is invalid, the function will return zero.

Remarks

This function is included for backwards compatibility and should not be used with new applications. The 32-bit network time value can only represent a date and time up to the year 2036. Use the **ConvertNetworkTime64** function which accepts a 64-bit integer and avoids potential problems with the 32-bit value rolling over.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

ConvertNetworkTime64 Function

```
BOOL WINAPI ConvertNetworkTime64(
   ULONGLONG ulNetworkTime,
   LPSYSTEMTIME lpSystemTime,
   BOOL bLocalTime
);
```

The **ConvertNetworkTime64** function converts the specified network time, adjusting for the local timezone if required. The network time is a 64-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Parameters

ulNetworkTime

An unsigned 64-bit integer value which specifies the network time. This value should specify the number of seconds since midnight, January 1, 1900 UTC.

lpSystemTime

A pointer to a SYSTEMTIME structure which will be modified for the specified network time.

bLocalTime

A boolean flag that is used to specify if the network time should be adjusted for the local timezone.

Return Value

If the network time could be converted, the function returns a non-zero value. If the network time cannot be converted, or the pointer to the SYSTEMTIME structure is invalid, the function will return zero.

Remarks

This version of the function supports 64-bit network time values which can represent a date and time beyond the year 2036.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

ConvertNetworkTime, ConvertSystemTime64

ConvertSystemTime Function

```
DWORD WINAPI ConvertSystemTime(
   LPSYSTEMTIME lpSystemTime
);
```

The **ConvertSystemTime** function converts the specified system time to network time. The network time value is a 32-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Parameters

lpSystemTime

A pointer to a SYSTEMTIME structure which will be modified for the specified network time.

Return Value

If the system time could be converted, the function returns the number of seconds since midnight, 1 January 1900 UTC. If the pointer to the SYSTEMTIME structure is invalid, or the structure contains invalid data, the function will return zero.

Remarks

This function is included for backwards compatibility and should not be used with new applications. The 32-bit network time value can only represent a date and time up to the year 2036. Use the **ConvertSystemTime64** function which returns a 64-bit integer and avoids potential problems with the 32-bit value rolling over.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

ConvertSystemTime64 Function

```
ULONGLONG WINAPI ConvertSystemTime64(
   LPSYSTEMTIME lpSystemTime
);
```

The **ConvertSystemTime64** function converts the specified system time to network time. The network time value is a 64-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Parameters

lpSystemTime

A pointer to a SYSTEMTIME structure which will be modified for the specified network time.

Return Value

If the system time could be converted, the function returns the number of seconds since midnight, 1 January 1900 UTC. If the pointer to the SYSTEMTIME structure is invalid, or the structure contains invalid data, the function will return zero.

Remarks

This version of the function supports 64-bit network time values which can represent a date and time beyond the year 2036.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

FormatNetworkTime Function

```
INT WINAPI FormatNetworkTime(
   DWORD dwNetworkTime,
   LPTSTR lpszDateTime,
   INT nMaxLength,
   BOOL bLocalTime
);
```

The **FormatNetworkTime** function converts a 32-bit network time value to a string which contains the date and time formatted for the current locale.

Parameters

dwNetworkTime

An unsigned 32-bit integer value which specifies the network time. This value should specify the number of seconds since midnight, January 1, 1900 UTC.

lpszDateTime

A null-terminated string buffer which will contain the formatted date and time. This buffer must be large enough to store both date and time values, including the terminating null character. The date is formatted using the current system locale's short date format. The time is formatted to use a 24-hour clock and includes the seconds value.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character. If the buffer is not large enough to contain the entire date and time string, the function will fail and return a value of zero.

bLocalTime

An integer boolean value which specifies if the network time should be adjusted for the local timezone. If this parameter is zero, the date and time are formatted using Coordinated Universal Time (UTC). If this parameter is non-zero, the network time value will be adjusted for the current timezone and will return a localized time value. The current timezone is determined by the configuration of the local system.

Return Value

If successful, the function returns the number of characters copied into the string buffer, not including the terminating null character. If the function fails, it returns a value of zero. Call the **TimeGetLastError** function for more information about the cause of the failure.

Remarks

The **FormatNetworkTime** function is a convenient way to convert a numeric network time value to a string value which can be displayed to the user. The actual format of the string is determined by the local system configuration and locale. For example, in North America the date string will be returned using a month/day/year format, while European locales may return the date in a day/month/year format.

This function is included for backwards compatibility and should not be used with new applications. The 32-bit network time value can only represent a date and time up to the year 2036. Use the **FormatNetworkTime64** function which accepts a 64-bit integer and avoids potential problems with the 32-bit value rolling over.

Example

```
// Request the time from a server and write it to standard output
DWORD dwNetworkTime = GetNetworkTime(_T("time.nist.gov"), TIME_PORT_DEFAULT,
TIME_TIMEOUT);

if (dwNetworkTime != 0)
{
    TCHAR szDateTime[64];
    INT nLength = FormatNetworkTime(dwNetworkTime, szDateTime, 64, TRUE);

    if (nLength > 0)
        _tprintf(_T("The local date and time is %s\n"), szDateTime);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

FormatNetworkTime64 Function

```
INT WINAPI FormatNetworkTime64(
   ULONGLONG ulNetworkTime,
   LPTSTR lpszDateTime,
   INT nMaxLength,
   BOOL bLocalTime
);
```

The **FormatNetworkTime64** function converts a 64-bit network time value to a string which contains the date and time formatted for the current locale.

Parameters

ulNetworkTime

An unsigned 64-bit integer value which specifies the network time. This value should specify the number of seconds since midnight, January 1, 1900 UTC.

lpszDateTime

A null-terminated string buffer which will contain the formatted date and time. This buffer must be large enough to store both date and time values, including the terminating null character. The date is formatted using the current system locale's short date format. The time is formatted to use a 24-hour clock and includes the seconds value.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character. If the buffer is not large enough to contain the entire date and time string, the function will fail and return a value of zero.

bLocalTime

An integer boolean value which specifies if the network time should be adjusted for the local timezone. If this parameter is zero, the date and time are formatted using Coordinated Universal Time (UTC). If this parameter is non-zero, the network time value will be adjusted for the current timezone and will return a localized time value. The current timezone is determined by the configuration of the local system.

Return Value

If successful, the function returns the number of characters copied into the string buffer, not including the terminating null character. If the function fails, it returns a value of zero. Call the **TimeGetLastError** function for more information about the cause of the failure.

Remarks

The **FormatNetworkTime64** function is a convenient way to convert a numeric network time value to a string value which can be displayed to the user. The actual format of the string is determined by the local system configuration and locale. For example, in North America the date string will be returned using a month/day/year format, while European locales may return the date in a day/month/year format.

Example

```
// Request the time from a server and write it to standard output
ULONGLONG ulNetworkTime = GetNetworkTime64(_T("pool.ntp.org"), TIME_PORT_DEFAULT,
TIME_TIMEOUT);
```

```
if (ulNetworkTime != 0)
{
    TCHAR szDateTime[64];
    INT nLength = FormatNetworkTime64(ulNetworkTime, szDateTime, 64, TRUE);

    if (nLength > 0)
        _tprintf(_T("The local date and time is %s\n"), szDateTime);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetNetworkTime Function

```
DWORD WINAPI GetNetworkTime(
   LPCTSTR lpszHostName,
   UINT nHostPort,
   UINT nTimeout
);
```

The **GetNetworkTime** function returns the network time from the specified host. The network time is a 32-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Parameters

lpszHostName

The name of the server. The host must be running a time server that complies with the Network Time Protocol (NTP) specification outlined in RFC 5905.

nHostPort

The port the time server is running on. A value of zero indicates that the default port number for the NTP service should be used. If the application specifies port 37, the library will attempt to use the legacy TIME protocol defined in RFC 868. Support for this protocol is deprecated and is only provided for backwards compatibility.

nTimeout

The number of seconds that the function will wait for a response from the server.

Return Value

If the function succeeds, it returns the number of seconds since midnight, 1 January 1900 UTC. If the function was unable to obtain the time from the specified host, it returns zero.

Remarks

This function is included for backwards compatibility and should not be used with new applications. The 32-bit network time value can only represent a date and time up to the year 2036. Use the **GetNetworkTime64** function which returns a 64-bit integer and avoids potential problems with the 32-bit value rolling over.

This function will cause the calling thread to block until the time is returned by the server, or the operation times out. If you do not want the current thread to block, you can create a worker thread and call this function from within that thread. The blocking network call in the worker thread will not interefere with any other threads in your application.

In most cases, it is preferable to use the NTP pool servers which distribute requests over a number of different servers:

- **pool.ntp.org** is a global load-balanced pool of time servers
- **us.pool.ntp.org** servers are located in the United States
- **eu.pool.ntp.org** servers are located in Europe
- **asia.pool.ntp.org** servers are located in Asia

There are also load balanced pools of time servers available in specific countries prefixed by their country code. For example, the **de.pool.ntp.org** servers are located in Germany and the **uk.pool.ntp.org** servers are located in the United Kingdom. Regardless of their location, the time values they return are always in Coordinated Universal Time (UTC) and are not localized based on the

physical location of the server.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time. The following table lists the current host names and addresses:

Server Name	IP Address	Location
time-a-g.nist.gov	129.6.15.28	Gaithersburg, Maryland
time-b-g.nist.gov	129.6.15.29	Gaithersburg, Maryland
time-nw.nist.gov	131.107.13.100	Redmond, Washington
time-a-b.nist.gov	132.163.96.1	Boulder, Colorado
time-b-b.nist.gov	132.163.96.2	Boulder, Colorado
time-c-b.nist.gov	132.163.96.3	Boulder, Colorado

Time servers are also commonly maintained by government agencies and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they support the standard time service available on port 123.

If you are requesting the time from a public server, you should ensure that your application does not send too many requests over a short period of time. In most cases, you should not query a time server more than once per minute. Most public time servers will block the IP addresse of a client which sends too many requests.

It is important to note that the network time value is not the same as the UNIX time value used with the standard C runtime library. The **time()** function returns the number of seconds since January 1, 1970 which is commonly referred to as the UNIX epoch. NTP servers return the time as the number of seconds since January 1, 1900.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetNetworkTime64 Function

```
ULONGLONG WINAPI GetNetworkTime64(
    LPCTSTR lpszHostName,
    UINT nHostPort,
    UINT nTimeout
);
```

The **GetNetworkTime64** function returns the network time from the specified host. The network time is a 64-bit number, represented as the number of seconds since midnight, 1 January 1900 UTC.

Parameters

lpszHostName

The name of the server. The host must be running a time server that complies with the Network Time Protocol (NTP) specification outlined in RFC 5905.

nHostPort

The port the time server is running on. A value of zero indicates that the default port number for the NTP service should be used. If the application specifies port 37, the library will attempt to use the legacy TIME protocol defined in RFC 868. Support for this protocol is deprecated and is only provided for backwards compatibility.

nTimeout

The number of seconds that the function will wait for a response from the server.

Return Value

If the function succeeds, it returns the number of seconds since midnight, 1 January 1900 UTC. If the function was unable to obtain the time from the specified host, it returns zero.

Remarks

The **GetNetworkTime64** function will cause the calling thread to block until the time is returned by the server, or the operation times out. If you do not want the current thread to block, you can create a worker thread and call this function from within that thread. The blocking network call in the worker thread will not interefere with any other threads in your application.

In most cases, it is preferable to use the NTP pool servers which distribute requests over a number of different servers:

- **pool.ntp.org** is a global load-balanced pool of time servers
- **us.pool.ntp.org** servers are located in the United States
- **eu.pool.ntp.org** servers are located in Europe
- **asia.pool.ntp.org** servers are located in Asia

There are also load balanced pools of time servers available in specific countries prefixed by their country code. For example, the **de.pool.ntp.org** servers are located in Germany and the **uk.pool.ntp.org** servers are located in the United Kingdom. Regardless of their location, the time values they return are always in Coordinated Universal Time (UTC) and are not localized based on the physical location of the server.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time. The following table lists the current host names and addresses:

Server Name	IP Address	Location
time-a-g.nist.gov	129.6.15.28	Gaithersburg, Maryland
time-b-g.nist.gov	129.6.15.29	Gaithersburg, Maryland
time-nw.nist.gov	131.107.13.100	Redmond, Washington
time-a-b.nist.gov	132.163.96.1	Boulder, Colorado
time-b-b.nist.gov	132.163.96.2	Boulder, Colorado
time-c-b.nist.gov	132.163.96.3	Boulder, Colorado

Time servers are also commonly maintained by government agencies and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they support the standard time service available on port 123.

If you are requesting the time from a public server, you should ensure that your application does not send too many requests over a short period of time. In most cases, you should not query a time server more than once per minute. Most public time servers will block the IP addresse of a client which sends too many requests.

It is important to note that the network time value is not the same as the UNIX time value used with the standard C runtime library. The **time()** function returns the number of seconds since January 1, 1970 which is commonly referred to as the UNIX epoch. NTP servers return the time as the number of seconds since January 1, 1900.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

QueryNetworkTime Function

```
HCLIENT WINAPI QueryNetworkTime(
    LPCTSTR lpszHostName,
    UINT nHostPort,
    HWND hEventWnd,
    UINT uEventMsg
);
```

The **QueryNetworkTime** function connects to the specified server and issues a request for the current network time. The handle is passed as a parameter to the **ReadNetworkTime64** function to read the value returned by the server.

Parameters

lpszHostName

The name of the server. The host must be running a time server that complies with the Network Time Protocol (NTP) specification outlined in RFC 5905.

nHostPort

The port the time server is running on. A value of zero indicates that the default port number for the NTP service should be used. If the application specifies port 37, the library will attempt to use the legacy TIME protocol defined in RFC 868. Support for this protocol is deprecated and is only provided for backwards compatibility.

hEventWnd

A handle to the window that will receive the notification that the network time has been returned by the server.

uEventMsg

The notification message that will be sent to the window, indicating that the client has received the network time from the server.

Return Value

If the function succeeds, it returns a handle which can be used with the obtain the network time. If the function fails, it returns INVALID_CLIENT. To get extended error information, call **TimeGetLastError**.

Remarks

The **QueryNetworkTime** function creates an asynchronous datagram socket which sends a request to the time server for the current time. Use the **ReadNetworkTime64** function to read the response from the server and return the time as a 64-bit value which specifies the number of seconds elapsed since midnight, January 1, 1900. Typically this would be done in response to a TIME_EVENT_REPLY event message.

It is important to note the event notifications are sent as Windows messages which requires a window handle and the application must have a message pump. For console applications, you should use the **GetNetworkTime64** function instead. If you do not want to block the main thread while waiting for a response, you can create a background worker thread and send the request from within that thread. The blocking network call in the worker thread will not interefere with any other threads in your application.

In most cases, it is preferable to use the NTP pool servers which distribute requests over a number of different servers:

- **pool.ntp.org** is a global load-balanced pool of time servers
- **us.pool.ntp.org** servers are located in the United States
- **eu.pool.ntp.org** servers are located in Europe
- **asia.pool.ntp.org** servers are located in Asia

There are also load balanced pools of time servers available in specific countries prefixed by their country code. For example, the **de.pool.ntp.org** servers are located in Germany and the **uk.pool.ntp.org** servers are located in the United Kingdom. Regardless of their location, the time values they return are always in Coordinated Universal Time (UTC) and are not localized based on the physical location of the server.

In the United States, the National Institute of Standards and Technology (NIST) hosts a number of public servers which can be used to obtain the current time. The following table lists the current host names and addresses:

Server Name	IP Address	Location
time-a-g.nist.gov	129.6.15.28	Gaithersburg, Maryland
time-b-g.nist.gov	129.6.15.29	Gaithersburg, Maryland
time-nw.nist.gov	131.107.13.100	Redmond, Washington
time-a-b.nist.gov	132.163.96.1	Boulder, Colorado
time-b-b.nist.gov	132.163.96.2	Boulder, Colorado
time-c-b.nist.gov	132.163.96.3	Boulder, Colorado

Time servers are also commonly maintained by government agencies and universities. If you are unable to obtain the time from a server, contact the system administrator to determine if they support the standard time service available on port 123.

If you are requesting the time from a public server, you should ensure that your application does not send too many requests over a short period of time. In most cases, you should not query a time server more than once per minute. Most public time servers will block the IP addresse of a client which sends too many requests.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
TIME_EVENT_QUERY	The connection to the server has completed and the request for the time has been sent. The client should wait for the response from the server.
TIME_EVENT_REPLY	The server has replied to the request for the time. The client should call the ReadNetworkTime function to read the value returned by the server.
TIME_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TIME_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or

	refuse to accept further commands from the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

ReadNetworkTime Function

```
DWORD WINAPI ReadNetworkTime(
    HCLIENT hClient
);
```

The **ReadNetworkTime** function returns a 32-bit network time value sent from the server.

Parameters

hClient

The client handle.

Return Value

If the function succeeds, it returns the number of seconds since midnight, 1 January 1900 UTC. If the function was unable to read the time from the specified host, it returns zero.

Remarks

The **ReadNetworkTime** function reads 32-bit the time value returned by the server using the handle returned by the **QueryNetworkTime** function. This function is included for backwards compatibility and should not be used with new applications. The 32-bit network time value can only represent a date and time up to the year 2036. Use the **ReadNetworkTime64** function which returns a 64-bit integer and avoids potential problems with the 32-bit value rolling over. To obtain the time from a server synchronously, use the **GetNetworkTime64** function instead.

It is important to note that the network time value is not the same as the UNIX time value used with the standard C runtime library. The **time()** function returns the number of seconds since January 1, 1970 which is commonly referred to as the UNIX epoch. NTP servers return the time as the number of seconds since January 1, 1900.

To convert the 32-bit time value to a SYSTEMTIME structure, use the **ConvertNetworkTime** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

ReadNetworkTime64 Function

```
ULONGLONG WINAPI ReadNetworkTime64(
    HCLIENT hClient
);
```

The **ReadNetworkTime64** function returns a 64-bit network time value sent from the server.

Parameters

hClient

The client handle.

Return Value

If the function succeeds, it returns the number of seconds since midnight, 1 January 1900 UTC. If the function was unable to read the time from the specified host, it returns zero.

Remarks

The **ReadNetworkTime64** function reads the 64-bit time value returned by the server using the handle returned by the **QueryNetworkTime** function. To obtain the time from a server synchronously, use the **GetNetworkTime64** function.

It is important to note that the network time value is not the same as the UNIX time value used with the standard C runtime library. The **time()** function returns the number of seconds since January 1, 1970 which is commonly referred to as the UNIX epoch. NTP servers return the time as the number of seconds since January 1, 1900.

To convert the 64-bit time value to a SYSTEMTIME structure, use the **ConvertNetworkTime64** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

TimeAttachThread Function

```
DWORD WINAPI TimeAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **TimeAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is TIME_ERROR. To get extended error information, call **TimeGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **TimeAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **TimeAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **TimeCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **TimeUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

TimeDisableEvents Function

```
INT WINAPI TimeDisableEvents(
    HCLIENT hClient
);
```

The **TimeDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TIME_ERROR. To get extended error information, call **TimeGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

TimeEnableEvents, TimeFreezeEvents, TimeRegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TimeDisableTrace Function

```
BOOL WINAPI TimeDisableTrace();
```

The **TimeDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

TimeEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TimeEnableEvents Function

```
INT WINAPI TimeEnableEvents(
   HCLIENT hClient,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **TimeEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **TimeRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TIME_ERROR. To get extended error information, call **TimeGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
TIME_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
TIME_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TIME_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TIME_EVENT_WRITE	The client can now write data. This notification is sent after a

	connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TIME_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TIME_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **TimeDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

TimeEnableTrace Function

```
BOOL WINAPI TimeEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **TimeEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

TimeEventProc Function

```
VOID CALLBACK TimeEventProc(
   HCLIENT hClient,
   UINT nEventId,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **TimeEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hClient

The handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **TimeRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **TimeRegisterEvent** function. The **TimeEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

TimeDisableEvents, TimeEnableEvents, TimeFreezeEvents, TimeRegisterEvent

TimeFreezeEvents Function

```
INT WINAPI TimeFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **TimeFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TIME_ERROR. To get extended error information, call **TimeGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

TimeGetErrorString Function

```
INT WINAPI TimeGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **TimeGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **TimeGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

TimeGetLastError, TimeSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TimeGetLastError Function

```
DWORD WINAPI TimeGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **TimeSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **TimeGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **TimeSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TIME_ERROR. Those functions which call **TimeSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

TimeGetErrorString, TimeSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TimeGetStatus Function

```
INT WINAPI TimeGetStatus(
   HCLIENT hClient
);
```

The **TimeGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is TIME_ERROR. To get extended error information, call **TimeGetLastError**.

Remarks

The **TimeGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
TIME_STATUS_IDLE	The client is current idle and not sending or receiving data.
TIME_STATUS_CONNECT	The client is establishing a connection with the server.
TIME_STATUS_READ	The client is reading data from the server.
TIME_STATUS_WRITE	The client is writing data to the server.
TIME_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

QueryNetworkTime, ReadNetworkTime

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TimeInitialize Function

```
BOOL WINAPI TimeInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **TimeInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TimeGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **TimeInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **TimeUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **TimeInitialize** or **TimeUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetNetworkTime, QueryNetworkTime, TimeUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TimeRegisterEvent Function

```
INT WINAPI TimeRegisterEvent(
   HCLIENT hClient,
   UINT nEventId,
   INETEVENTPROC lpfnEvent,
   DWORD_PTR dwParam
);
```

The **TimeRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One or more of the following values may be used:

Value	Description
TIME_EVENT_CONNECT	The connection to the server has completed.
TIME_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TIME_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TIME_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TIME_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TIME_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpfnEvent

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **TimeEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86

(32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TIME_ERROR. To get extended error information, call **TimeGetLastError**.

Remarks

The **TimeRegisterEvent** function associates a callback function with a specific event. The event handler is an **TimeEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

TimeDisableEvents, TimeEnableEvents, TimeEventProc, TimeFreezeEvents

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TimeSetLastError Function

```
VOID WINAPI TimeSetLastError(
   DWORD dwErrorCode
);
```

The **TimeSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TIME_ERROR. Those functions which call **TimeSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **TimeGetLastError** function. The use of **TimeGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

TimeGetErrorString, TimeGetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TimeUninitialize Function

```
VOID WINAPI TimeUninitialize();
```

The **TimeUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **TimeInitialize** call before it can call any of the other the library functions. When it has finished using the library, the application must call **TimeUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **TimeUninitialize** for every successful call to **TimeInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

See Also

TimeInitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

UpdateLocalTime Function

```
BOOL WINAPI UpdateLocalTime(
   DWORD dwNetworkTime
);
```

The **UpdateLocalTime** function sets the local system clock to the specified date and time.

Parameters

dwNetworkTime

The date and time the system clock should be set to, represented as the number of seconds since midnight, 1 January 1900.

Return Value

If the function is able to update the local time, it returns a non-zero value. If the specified time is invalid, or the user does not have the access rights to change the system clock, the function returns zero.

Remarks

The **UpdateLocalTime** function updates the local system clock to the specified date and time. The user must have the appropriate privileges to change the system clock, otherwise an error will be returned. This typically requires the application to execute with elevated privileges. Because Windows systems are usually configured to automatically synchronize the system clock with a time server using the Windows Time service (W32Time), most applications should not use this function.

This function is included for backwards compatibility and should not be used with new applications. The 32-bit network time value can only represent a date and time up to the year 2036. Use the **UpdateLocalTime64** function which accepts a 64-bit integer time value.

It is important to note that the network time value is not the same as the UNIX time value used with the standard C runtime library. The **time()** function returns the number of seconds since January 1, 1970 which is commonly referred to as the UNIX epoch.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstimv12.lib

UpdateLocalTime64 Function

```
BOOL WINAPI UpdateLocalTime64(
   ULONGLONG ulNetworkTime
);
```

The **UpdateLocalTime64** function sets the local system clock to the specified date and time.

Parameters

ulNetworkTime

The date and time the system clock should be set to, represented as the number of seconds since midnight, 1 January 1900.

Return Value

If the function is able to update the local time, it returns a non-zero value. If the specified time is invalid, or the user does not have the access rights to change the system clock, the function returns zero.

Remarks

The **UpdateLocalTime64** function updates the local system clock to the specified date and time. The user must have the appropriate privileges to change the system clock, otherwise an error will be returned. This typically requires the application to execute with elevated privileges. Because Windows systems are usually configured to automatically synchronize the system clock with a time server using the Windows Time service (W32Time), most applications should not use this function.

It is important to note that the network time value is not the same as the UNIX time value used with the standard C runtime library. The **time()** function returns the number of seconds since January 1, 1970 which is commonly referred to as the UNIX epoch.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

News Feed Library

Retrieve and process the contents of a syndicated news feed.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSRSSV12.DLL
Version	12.0.3024.1286
LibID	B8830D80-2618-4202-9C9C-9C3AD511E9D0
Import Library	CSRSSV12.LIB
Dependencies	None

Overview

Really Simple Syndication (RSS) is a collection of standardized formats that are used to publish information about content that is frequently changed. A news feed is published in XML format, which contains one or more items that includes summary text, hyperlinks to source content and additional metadata that is used to describe the item. News feeds can be used for a variety of purposes, including providing updates for weblogs, news headlines, video and audio content. RSS can also be used for other purposes, such as a software updates, where new updates are listed as items in the feed.

News feeds can be accessed remotely from a web server, or locally as an XML formatted text file. The source of the feed is determined by the URI scheme that is specified. If the http or https scheme is specified, then the feed is retrieved from a web server. If the file scheme is used, the feed is considered to be local and is accessed from the disk or local network. The News Feed library provides an API that enables you to open a feed by URL and iterate through each of the items in the feed or search for a specific feed item. The API also provides a function that can be used to parse a string that contains XML data in RSS format, where the feed may have been retrieved from other sources such as a database.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

News Feed Functions

Function	Description
RssCloseFeed	Close the specified news feed and release memory allocated for the channel
RssDisableTrace	Disable logging of network function calls
RssEnableTrace	Enable logging of network function calls to a text file
RssFindItem	Find a specific news feed item using its unique identifier (GUID) property
RssGetErrorString	Return a description for the specified error code
RssGetFirstItem	Return information about the first item in the news feed channel
RssGetItem	Return information about the specified news feed item
RssGetItemCount	Return the number of news feed items in the channel
RssGetItemProperty	Return the value of the specified news feed item property or attribute
RssGetItemText	Return the text description of the specified news feed item
RssGetLastError	Return the last error code
RssGetNextItem	Return information about the next item in the news feed channel
RssInitialize	Initialize the library and validates the specified license key at runtime
RssOpenFeed	Open the specified news feed and return information about the channel
RssParseFeed	Parse the contents of a string and return information about the channel
RssRefreshFeed	Refresh the specified news feed, updating the items in the channel
RssSetLastError	Set the last error code
RssStoreFeed	Store the contents of the specified news feed in an XML formatted text file
RssUninitialize	Terminate use of the library by the application
RssValidateFeed	Validate the contents of the specified news feed, returning the number of items in the feed

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssCloseFeed Function

```
INT WINAPI RssCloseFeed(
   HCHANNEL hChannel
);
```

The **RssCloseFeed** function closes the specified news feed and releases memory allocated for the channel.

Parameters

hChannel

Handle to the news feed channel.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Remarks

The **RssCloseFeed** function must be called whenever the application has completed processing the news feed. It is important to note that the memory allocated for the channel will be released when this function is called, which means that any data referenced in the RSSCHANNEL and RSSCHANNELITEM structures will no longer be valid and must not be used by the application after the feed has been closed.

This function can fail if the feed is currently being updated, such as when the **RssRefreshFeed** function is called. In this case, the channel handle will not be released and the application must attempt to close the feed at a later time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

RssOpenFeed RssParseFeed RssStoreFeed

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssDisableTrace Function

```
BOOL WINAPI RssDisableTrace();
```

The **RssDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

RssEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssEnableTrace Function

```
BOOL WINAPI RssEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **RssEnableTrace** function enables the logging of network function calls to a text file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

RssFindItem Function

```
INT WINAPI RssFindItem(
   HCHANNEL hChannel,
   LPCTSTR lpszValue,
   DWORD dwOptions,
   LPRSSCHANNELITEM lpItem
);
```

The **RssFindItem** function searches for an item in the news feed channel which matches the unique identifier (GUID) value and returns information about that item.

Parameters

hChannel

Handle to the news feed channel.

lpszValue

A null-terminated string which specifies the value of the item being searched for. This value should uniquely identify the item in the feed, and this parameter cannot be an empty string or NULL pointer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
RSS_FIND_GUID	Search the feed for items with a matching GUID property value. This is the default option, and is the only item property that is guaranteed to be unique in the feed. The search is case-sensitive, requiring that the ***lpszValue*** parameter match the property value exactly.
RSS_FIND_LINK	Search the feed for items with a matching link property value. For feeds that do not specify a GUID property, this is the recommended option for searching for an item. The search is not case-sensitive.
RSS_FIND_TITLE	Search the feed for items with a matching title. This option should not be used if you must ensure that the item returned is unique in the feed because there may be multiple items with the same title in the feed. The search is not case-sensitive.
RSS_FIND_PUBDATE	Search the feed for items with a matching publishing date. This option should not be used if you must ensure that the item returned is unique in the feed because more than one item may have the same publishing date. The format of the date string must match the standard format used with the RSS protocol and the match is not case-sensitive.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the specified item in the news feed. This structure is initialized by the function and the parameter can never be specified as a NULL pointer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Remarks

It is recommended that you use the RSS_FIND_GUID option with news feeds that are using version 2.0 or later of the RSS specification. If the feed uses an earlier version, items may not include a GUID property. It is also possible that a feed may omit the GUID property even though it is considered a requirement for the current RSS specification. For the broadest compatibility with all news feeds, an application should not depend on being able to search for a specific news feed item by its GUID.

Only the GUID property is guaranteed to be unique in the feed. If the feed does not specify GUIDs for the news items, the application must use an alternate criteria such as the item hyperlink or publishing date. If there are multiple items that match the ***lpszValue*** value, the first matching item will be returned.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RssGetErrorString Function

```
INT WINAPI RssGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **RssGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **RssGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RssGetLastError, RssSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssGetFirstItem Function

```
BOOL WINAPI RssGetFirstItem(
   HCHANNEL hChannel,
   LPRSSCHANNELITEM lpItem
);
```

The **RssGetFirstItem** function returns information about the first item in the specified news feed channel.

Parameters

hChannel

Handle to the news feed channel.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the first item in the news feed. This structure is initialized by the function and the parameter can never be specified as a NULL pointer.

Return Value

If the function succeeds, it returns a non-zero value. If the function fails, the return value is zero. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetFirstItem** function is used in conjunction with the **RssGetNextItem** function to enumerate the available items in the specified news feed channel. If this function fails, it typically indicates that the channel does not contain any valid news items or that the format of the news feed is invalid.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RssFindItem, RssGetItem, RssGetItemProperty, RssGetItemText, RssGetNextItem, RSSCHANNELITEM

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssGetItem Function

```
BOOL WINAPI RssGetItem(
   HCHANNEL hChannel,
   UINT nItemId,
   LPRSSCHANNELITEM lpItem
);
```

The **RssGetItem** function returns information about the specified item in the news feed channel.

Parameters

hChannel

Handle to the news feed channel.

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this function will fail.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the specified item in the news feed. This structure is initialized by the function and the parameter can never be specified as a NULL pointer.

Return Value

If the function succeeds, it returns a value of zero. If the function fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetItem** function is used to return information about a specific item in the news feed. If this function fails, it typically indicates that the item ID is invalid or that the feed does not contain any valid news items. The **RssGetItemCount** function can be used to determine the number of items contained in the feed channel.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RssFindItem, RssGetFirstItem, RssGetItemCount, RssGetItemProperty, RssGetItemText, RssGetNextItem, RSSCHANNELITEM

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssGetItemCount Function

```
INT WINAPI RssGetItemCount(
   HCHANNEL hChannel
);
```

The **RssGetItemCount** function returns the number of items in the news feed channel.

Parameters

hChannel

Handle to the news feed channel.

Return Value

If the function succeeds, the return value is the number of items in the news feed. A value of zero indicates that the feed channel is empty. If the function fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetItemCount** function is used to determine the number of items that are contained in the news feed channel, and therefore determine the maximum value of the item identifier which can be used to reference a specific item in the feed. This value is the same as the value specified by the *nItemCount* member of the **RSSCHANNEL** structure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

RssFindItem, RssGetItem, RssGetItemProperty, RssGetItemText, RSSCHANNEL

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssGetItemProperty Function

```
INT WINAPI RssGetItemProperty(
   HCHANNEL hChannel,
   UINT nItemId,
   DWORD dwReserved,
   LPCTSTR lpszProperty,
   LPCTSTR lpszAttribute,
   LPTSTR lpszValue,
   INT nMaxLength
);
```

The **RssGetItemProperty** function is used to return the value of a property for the specified item in the news feed channel.

Parameters

hChannel

Handle to the news feed channel.

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this function will fail.

dwReserved

A parameter reserved for future use. This value should always be zero.

lpszProperty

A null-terminated string which specifies the name of the item property. This parameter cannot point to an empty string or specify a NULL pointer.

lpszAttribute

A null-terminated string which specifies the name of an attribute for the property. If this parameter is an empty string or NULL pointer, the function will return the value of the property, rather than an attribute of the specified property.

lpszValue

A null-terminated string buffer which will contain the value of the specified item property or attribute. This string should be large enough to contain the property value. If this parameter is a NULL pointer, it will be ignored and the function will only return the length of value for the specified property.

nMaxLength

The maximum number of characters that may be copied into the property value buffer. If the value of this parameter is zero, then the ***lpszValue*** parameter is ignored and the function will only return the length of the value for the specified property.

Return Value

If the function succeeds, the return value is the length of the property value string. A return value of zero indicates that the property does not contain any value. If the function fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetItemProperty** function is primarily used with custom item properties that may be used with extensions to the news feed. The standard properties for an item such as the title, link and description can be obtained using **RssGetItem** and related functions. However, if items in the feed contain custom properties that are not part of the standard RSS format, this function can be used to obtain those values.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RssGetItemText Function

```
INT WINAPI RssGetItemText(
   HCHANNEL hChannel,
   UINT nItemId,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **RssGetItemText** function is used to return a copy of an item's description.

Parameters

hChannel

Handle to the news feed channel.

nItemId

An integer value which identifies the news feed item. The first item identifier in the news feed has a value of one, and that value is incremented for each additional item in the feed. If this parameter is zero or specifies a value larger than the number of items in the feed, this function will fail.

lpszBuffer

A null-terminated string buffer which will contain the value of the item description. If this parameter is a NULL pointer, it will be ignored and the function will only return the length of the item description.

nMaxLength

The maximum number of characters that may be copied into the description buffer. If the value of this parameter is zero, then the ***lpszValue*** parameter is ignored and the function will only return the length of the item description.

Return Value

If the function succeeds, the return value is the length of the item description. A return value of zero indicates that the item does not have a description. If the function fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetItemText** function is used to obtain a copy of the string that describes the specified item. Typically this is text that provides a summary of the news feed item and is used in conjunction with the item's title and hyperlink to additional content.

The content of an item description is typically either plain text or HTML formatted text. It is the responsibility of the application to display the content in a format is appropriate for the end-user.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

RssGetLastError Function

```
DWORD WINAPI RssGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **RssSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **RssGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **RssSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CHANNEL or RSS_ERROR. Those functions which call **RssSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

RssGetNextItem Function

```
BOOL WINAPI RssGetNextItem(
  HCHANNEL hChannel,
  LPRSSCHANNELITEM lpItem
);
```

The **RssGetNextItem** function returns information about the next item in the specified news feed channel.

Parameters

hChannel

Handle to the news feed channel.

lpItem

A pointer to a **RSSCHANNELITEM** structure which contains information about the next item in the news feed. This structure is initialized by the function and the parameter can never be specified as a NULL pointer.

Return Value

If the function succeeds, it returns a non-zero value. If the function fails, the return value is zero. To get extended error information, call **RssGetLastError**.

Remarks

The **RssGetNextItem** function is used in conjunction with the **RssGetFirstItem** function to enumerate the available items in the specified news feed channel. If this function fails, it typically indicates that there are no more items in the news feed channel.

The data referenced in the **RSSCHANNELITEM** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssInitialize Function

```
BOOL WINAPI RssInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **RssInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **RssGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **RssInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **RssUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **RssInitialize** or **RssUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssOpenFeed Function

```
HCHANNEL WINAPI RssOpenFeed(
   LPCTSTR lpszFeedUrl,
   UINT nTimeout,
   DWORD dwOptions,
   LPRSSCHANNEL lpChannel
);
```

The **RssOpenFeed** function is used to open a news feed and return a handle which can be used to access the individual news items in the feed.

Parameters

lpszFeedUrl

A null-terminated string which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be specified. To access a file on the local system or network share, a file name or file URL may be specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation. This parameter is ignored if the ***lpszFeedUrl*** parameter specifies a local file name or URL.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
RSS_OPTION_NONE	No additional options are specified and the news feed is processed using relaxed rules when checking the validity of the feed. The library will attempt to automatically compensate for a feed that is malformed or does not strictly conform to the RSS standard.
RSS_OPTION_STRICT	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the function. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the function succeeds, the return value is a handle to the news feed channel. If the function fails, the return value is INVALID_CHANNEL. To get extended error information, call **RssGetLastError**.

Remarks

A news feed may be local or remote, depending on the URL that is specified. If a local file name or file URL is specified for the feed, then it is opened locally and no network access is required. If an http or https URL is specified, then **RssOpenFeed** will attempt to download the feed from the server and

store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs.

Although the **RssOpenFeed** function will meet the needs of most applications, if you require more complex functionality such as retrieving the feed asynchronously in the background or event notifications for large transfers, you can use the SocketTools Hypertext Transfer Protocol API to download the news feed and then use the **RssParseFeed** function to parse the contents.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

RssParseFeed Function

```
HCHANNEL WINAPI RssParseFeed(
   LPCTSTR lpszFeedXml,
   DWORD dwOptions,
   LPRSSCHANNEL lpChannel
);
```

The **RssParseFeed** function is used to parse the contents of a news feed, returning a handle which can be used to access the individual news items in the feed.

Parameters

lpszFeedXml

A null-terminated string which contains the contents of the news feed. The string must contain XML formatted data that conforms to the RSS standard specification. This parameter cannot specify an empty string or a NULL pointer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
RSS_OPTION_NONE	No additional options are specified.
RSS_OPTION_STRICT	The news feed content should be processed using strict rules to ensure that the feed meets the appropriate RSS standard specification and all feed property values are case-sensitive. By default, relaxed rules are used which allows the application to open a feed that may not strictly conform to the standard specification.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the function. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the function succeeds, the return value is a handle to the news feed channel. If the function fails, the return value is INVALID_CHANNEL. To get extended error information, call **RssGetLastError**.

Remarks

The **RssParseFeed** function is an alternative to the **RssOpenFeed** function, enabling the application to process a news feed from alternative sources such as a database or compressed file. It is important to note that the string which contains the news feed XML must be properly formatted and conform to the RSS standard specification.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. Not all members of the structure may contain valid values, in which case those members will either have a value of zero or will specify NULL pointers. When the feed is closed, the members of this structure will no longer be valid, and therefore should never be stored by the application. If the application needs to store or modify this information, it should create its own private copy of the data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RssCloseFeed, RssInitialize, RssOpenFeed, RssRefreshFeed, RssStoreFeed, RssUninitialize, RSSCHANNEL

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssRefreshFeed Function

```
INT WINAPI RssRefreshFeed(
   HCHANNEL hChannel,
   LPRSSCHANNEL lpChannel
);
```

The **RssRefreshFeed** function reloads the news feed and updates the items in the channel.

Parameters

hChannel

Handle to the news feed channel.

lpChannel

A pointer to an **RSSCHANNEL** structure which contains information about the news feed channel such as the feed title, hyperlink and description. If the parameter is not NULL, the structure is initialized by the function. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Remarks

When the **RssRefreshFeed** function is called, the news feed is reloaded from the original source and the items in the channel are updated. For news feeds that are frequently updated, the *nTimeToLive* member of the **RSSCHANNEL** structure can provide a hint to the application as to how frequently the feed should be refreshed.

If the news feed was originally opened using an http or https URL, this function will download the updated feed from the server and store it temporarily on the local system. Accessing a remote feed requires that the application has permission to establish a connection with the server and will cause the application to block until the feed has been downloaded, the operation times out or an error occurs. The same timeout period and options will be used as when the feed was originally opened.

The **RssRefreshFeed** function should only be used if the feed was opened using the **RssOpenFeed** function, otherwise the function will fail with an error indicating that the operation is not supported.

The data referenced in the **RSSCHANNEL** structure should be considered read-only and never modified by the application. The members of this structure returned by previous calls to either the **RssOpenFeed** or **RssRefreshFeed** functions will no longer be valid and should not be referenced. Likewise, the members of an **RSSCHANNELITEM** structure will no longer be valid after this function returns.

It is important that the application does not make any assumptions about the number of news items in the channel, or the content associated with those items after the **RssRefreshFeed** function has been called. For example, never assume that the number of items in the channel remains the same, or that the item IDs for each item remains the same. If you need to find a specific item in the news feed, use the **RssFindItem** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

RssSetLastError Function

```
VOID WINAPI RssSetLastError(
   DWORD dwErrorCode
);
```

The **RssSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSS_ERROR. Those functions which call **RssSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **RssGetLastError** function. The use of **RssGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

RssGetErrorString, RssGetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssStoreFeed Function

```
INT WINAPI RssStoreFeed(
   HCHANNEL hChannel,
   LPCTSTR lpszFileName,
   DWORD dwReserved
);
```

The **RssStoreFeed** function stores the contents of the news feed in an XML formatted text file.

Parameters

hChannel

Handle to the news feed channel.

lpszFileName

A null-terminated string which specifies the name of the file on the local system. The contents of the news feed will be stored in this file. If the file does not exist, it will be created; otherwise it will overwrite the contents of the file.

dwReserved

A reserved parameter for future use. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RssOpenFeed, RssParseFeed

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RssUninitialize Function

```
VOID WINAPI RssUninitialize();
```

The **RssUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **RssInitialize** call before it can call any of the other the library functions. When it has finished using the library, the application must call **RssUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **RssUninitialize** for every successful call to **RssInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib

See Also

RssValidateFeed Function

```
INT WINAPI RssValidateFeed(
   LPCTSTR lpszFeedUrl,
   UINT nTimeout,
   DWORD dwOptions,
   LPSYSTEMTIME lpstModified
);
```

The **RssValidateFeed** function is used to validate a news feed, returning the number of items in the feed and the date it was last modified.

Parameters

lpszFeedUrl

A null-terminated string which specifies the URL for the news feed. To access a news feed on a web server, a standard http or https URL may be specified. To access a file on the local system or network share, a file name or file URL may be specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation. This parameter is ignored if the *lpszFeedUrl* parameter specifies a local file name or URL.

dwOptions

An unsigned integer that specifies one or more options. This parameter is reserved for future use an should always have a value of zero.

lpstModified

A pointer to a **SYSTEMTIME** structure which will specify the date that the feed was last modified when the function returns. If the parameter is NULL, it is ignored and no information is returned.

Return Value

If the function succeeds, the return value is the number of items in the news feed channel. If the function fails, the return value is RSS_ERROR. To get extended error information, call **RssGetLastError**.

Remarks

The **RssValidateFeed** function can be used to check that a news feed exists and is properly formatted. If the contents of the feed are valid, the function will return the number of items in the feed and the date that it was last modified. This can be useful for applications that want to periodically check a news feed and determine if the contents have changed.

The **SYSTEMTIME** structure that is populated by the function specifies the date when the feed was last modified. The function first checks the value of the lastBuildDate property of the feed channel. If that property is not defined, then it will use the value of the pubDate property. If neither are defined, then the structure members will have a value of zero.

The validation process imposes strict checks on the structure of the news feed and requires that it conform to the RSS specification. For example, the feed must have a title, link and description. Each item in the feed must have either a title or description, and the hyperlinks specified in the feed must be valid. If the feed XML is malformed, or a required property of the feed is invalid or missing, this function will fail.

If a news feed cannot be validated, it still may be possible to open the feed using the **RssOpenFeed**

function. By default, relaxed rules are used when parsing the contents of the feed and it does not check to ensure all required properties are defined and have valid values.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrssv12.lib
Unicode: Implemented as Unicode and ANSI versions

News Feed Data Structures

- RSSCHANNEL
- RSSCHANNELITEM
- SYSTEMTIME

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RSSCHANNEL

The **RSSCHANNEL** structure contains information about the properties of the news feed channel.

```
typedef struct _RSSCHANNEL
{
    UINT        nItemCount;
    UINT        nTimeToLive;
    WORD        wVersionMajor;
    WORD        wVersionMinor;
    DWORD       dwFlags;
    DWORD       dwReserved;
    LPCTSTR     lpszTitle;
    LPCTSTR     lpszLink;
    LPCTSTR     lpszDescription;
    LPCTSTR     lpszCategory;
    LPCTSTR     lpszLanguage;
    LPCTSTR     lpszCopyright;
    LPCTSTR     lpszEditor;
    LPCTSTR     lpszWebmaster;
    LPCTSTR     lpszGenerator;
    LPCTSTR     lpszImageLink;
    LPCTSTR     lpszImageTitle;
    LPCTSTR     lpszImageUrl;
    SYSTEMTIME  stPublished;
    SYSTEMTIME  stLastBuild;
}  RSSCHANNEL, *LPRSSCHANNEL;
```

Members

nItemCount

An integer value which specifies number of news items in the channel.

nTimeToLive

An integer value which specifies the frequency in seconds at which the feed should be refreshed to obtain updated information. Not all feeds specify a time-to-live, in which case this member will have a value of zero.

wVersionMajor

A word value which specifies the major version number for the news feed.

wVersionMinor

A word value which specifies the minor version number for the news feed.

dwFlags

A value which specifies one or more option flags for the news feed channel. Currently there are no option flags defined and this member is reserved for future expansion.

dwReserved

A value reserved for future expansion.

lpszTitle

A null-terminated string which specifies the name of the channel. If the content of the news feed corresponds to a website, this is typically the same as the title of the website. If a title has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a title.

lpszLink

A null-terminated string which specifies a URL to the website corresponding to the channel. Note

that this is not the URL of the news feed itself. Typically it is a link to the home page of the site which owns the news feed. If a link has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a valid link URL.

lpszDescription

A null-terminated string which describes the channel. This provides an overview of the news feed and the type of information that is provided. If a description of the feed has not been specified, this member will be NULL. Note that a strictly conforming news feed requires a description.

lpszCategory

A null-terminated string which defines the category or categories that the channel belongs to. This property is optional and the category names themselves are user-defined. If a category has not been specified, this member will be NULL.

lpszLanguage

A null-terminated string which defines the language the channel is written in, using the standard language codes. This property is optional and if this member is NULL, the English language is typically presumed to be the default.

lpszCopyright

A null-terminated string which specifies a copyright notice for the content. If a copyright has not been specified, this member will be NULL.

lpszEditor

A null-terminated string which identifies the person responsible for managing the content of the news feed. If this property is defined, it is typically the name and email address of the feed editor. If an editor has not been specified, this member will be NULL.

lpszWebmaster

A null-terminated string which identifies the person responsible for technical issues related to the news feed. If this property is defined, it is typically the name and email address of a system administrator. If a webmaster has not been specified, this member will be NULL.

lpszGenerator

A null-terminated string which identifies the application that was used to create the news feed. If the application that generated the feed has not been specified, this member will be NULL.

lpszImageLink

A null-terminated string which specifies a URL to the website corresponding to the channel. In most cases, this is the same URL that is specified by the ***lpszLink*** member. If an image link has not been specified, this member will be NULL.

lpszImageTitle

A null-terminated string which identifies the image associated with the channel. This is usually a brief description of the image, and may be the same as the value specified by the ***lpszTitle*** member. If an image title has not been specified, this member will be NULL.

lpszImageUrl

A null-terminated string which specifies a URL for the image associated with the channel. An application can download this image and display it with the contents of the news feed. If an image URL has not been specified, this member will be NULL.

stPublished

The date that the news feed was published. For example, a feed that is associated with a weekly print publication may update this value once per week. Note that this is not necessarily the date that

the feed was last modified. If the channel does not specify the publish date, this structure will contain all zeroes.

stLastBuild

The date that the content of the channel was last modified. If the channel does not specify the build date, this structure will contain all zeroes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RSSCHANNELITEM

The **RSSCHANNELITEM** structure contains information about the properties of an item in a news feed channel.

```
typedef struct _RSSCHANNELITEM
{
    UINT        nItemId;
    DWORD       dwFlags;
    DWORD       dwReserved;
    LPCTSTR     lpszTitle;
    LPCTSTR     lpszLink;
    LPCTSTR     lpszText;
    LPCTSTR     lpszGuid;
    LPCTSTR     lpszAuthor;
    LPCTSTR     lpszSource;
    LPCTSTR     lpszComments;
    LPCTSTR     lpszEnclosure;
    SYSTEMTIME  stPublished;
}  RSSCHANNELITEM, *LPRSSCHANNELITEM;
```

Members

nItemId

An integer which identifies this item in the channel.

dwFlags

A value which specifies one or more option flags for the item. Currently there are no option flags defined and this member is reserved for future expansion.

dwReserved

A value reserved for future expansion.

lpszTitle

A null-terminated string which specifies the title of the item. If a title for the item has not been specified, this member will be NULL.

lpszLink

A null-terminated string which specifies a URL that typically links to additional information related to the item. If a link for the item has not been specified, this member will be NULL.

lpszText

A null-terminated string which specifies a summary or description of the item. This may contain either plain text or HTML formatted text, and there is no fixed limit to the length of the text. If no text has been specified for the item, this member will be NULL.

lpszGuid

A null-terminated string which uniquely identifies the item in the channel. If this property is defined, it is guaranteed to be a unique, persistent value. It is important to note that this string does not have to be a standard GUID reference number, it can be any unique string. In many cases it is the same value as the item hyperlink specified by the ***lpszLink*** member, although an application should never depend on this behavior. If there is no unique identifier associated with the item, this member will be NULL.

lpszAuthor

A null-terminated string which identifies the author of the item. If this property is defined, it is

typically the name and email address of the person who created the content that the item links to. If the author is not specified, this member will be NULL.

lpszSource

A null-terminated string which identifies the source of the item, specified as a URL for the original news feed that contained it. This typically used to propagate credit for items that are aggregated by a third-party and re-published in their own channel. If the source is not specified, this member will be NULL.

lpszComments

A null-terminated string which specifies a URL that links to further discussion about the item. Typically this is a link to the comment area of a weblog or a forum topic specific to the item. If a comment link is not specified, this member will be NULL.

lpszEnclosure

A null-terminated string which specifies a URL that links to a file related to the item. This is similar to an attachment in an email message, however instead of the item containing the contents of the attached file, it only specifies a link to the file. Enclosures are most commonly used with podcasting where an item is linked to an audio or video file, however the link may reference any type of file. If there is no enclosure specified for the item, this member will be NULL.

stPublished

The date that the item was published. If the item does not specify the publish date, this structure will contain all zeroes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Post Office Protocol Library

List and retrieve email messages from a mail server.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSPOPV12.DLL
Version	12.0.3024.1286
LibID	33EB8402-9A5F-4ADD-B520-9C24EC56F1A1
Import Library	CSPOPV12.LIB
Dependencies	None
Standards	RFC 1939

Overview

The Post Office Protocol (POP3) provides access to a user's new email messages on a mail server. Functions are provided for listing available messages and then retrieving those messages, storing them either in files or in memory. Once a user's messages have been downloaded to the local system, they are typically removed from the server. The library provides a complete interface for managing a user's mailbox and is typically used in conjunction with the Mail Message library, which is used to parse the messages retrieved from the server.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or

later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Post Office Protocol Functions

Function	Description
PopAsyncConnect	Connect asynchronously to the specified server
PopAttachThread	Attach the specified client handle to another thread
PopCancel	Cancel the current blocking operation
PopChangePassword	Change the specified mail account password
PopCommand	Send a command to the server
PopConnect	Connect to the specified server
PopCreateSecurityCredentials	Allocate a structure to establish client security credentials
PopDeleteMessage	Delete the specified message from the mailbox
PopDeleteSecurityCredentials	Delete the specified client security credentials
PopDisableEvents	Disable the event notification mechanism
PopDisableTrace	Disable logging of network function calls
PopDisconnect	Disconnect from the current server
PopEnableEvents	Enable the client event notification mechanism
PopEnableTrace	Enable logging of network function calls to a file
PopEventProc	Callback function that processes events generated by the client
PopFreezeEvents	Suspend and resume event handling by the client
PopGetErrorString	Return a description for the specified error code
PopGetHeaderValue	Return the value of the specified header field
PopGetLastError	Return the last error code
PopGetMessage	Retrieve the specified message from the server
PopGetMessageCount	Return the number of messages available in the mailbox
PopGetMessageCountEx	Return the number of messages available in the mailbox
PopGetMessageHeaders	Retrieve the specified message header from the server
PopGetMessageId	Return the message ID string for the specified message
PopGetMessageSender	Return the address of the message sender
PopGetMessageSize	Return the size of the specified message
PopGetMessageUid	Return the unique identifier for the specified message
PopGetMultiLine	Return the client multi-line output flag
PopGetResultCode	Return the result code from the previous command
PopGetResultString	Return the result string from the previous command
PopGetSecurityInformation	Return security information about the current client connection

PopGetStatus	Return the current status of the client
PopGetTimeout	Return the number of seconds until an operation times out
PopGetTransferStatus	Return data transfer statistics
PopInitialize	Initialize the library and validates the specified license key at runtime
PopIsBlocking	Determine if the client is blocked, waiting for information
PopIsConnected	Determine if the client is connected to the server
PopIsReadable	Determine if data can be read from the server
PopIsWritable	Determine if data can be written to the server
PopLogin	Login to the server
PopOpenMessage	Open the specified message for reading on the server
PopRead	Read data returned by the server
PopRegisterEvent	Register an event handler for the specified event
PopReset	Reset the client and return to a command state
PopSendMessage	Send a message through the mail server
PopSetLastError	Set the last error code
PopSetMultiLine	Set the client multi-line output flag
PopSetTimeout	Set the number of seconds until an operation times out
PopStoreMessage	Store the contents of a message in the specified file
PopUninitialize	Terminate use of the library by the application
PopWrite	Write data to the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopAsyncConnect Function

```
HCLIENT WINAPI PopAsyncConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **PopAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **PopConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 110. For secure connections, the default port number is 995. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
POP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
POP_OPTION_LINEBREAK	Message data that is received from the server is read as individual lines of text terminated by a carriage return and linefeed control sequence. This option can be useful for applications that need to use the lower level network I/O functions and must process the message text on a line-by-line basis. This option is not recommended for most applications because it can have a negative impact on performance when

	retrieving large messages from the server.
POP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
POP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
POP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option is the same as specifying POP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STLS command.
POP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the STLS command.
POP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit TLS connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.
POP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
POP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
POP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is

	synchronized across multiple threads.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which is used to establish the client credentials for a secure connection to the server. The function **PopCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur. If this parameter is NULL, a blocking connection is established with the server.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **PopGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
POP_EVENT_CONNECT	The connection to the server has completed. The high word of the lParam parameter should be checked, since this notification message will be posted if an error has occurred.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
POP_EVENT_CANCEL	The client has canceled the current operation.
POP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response

	to the command. The high word of the lParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
POP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

To cancel asynchronous notification and return the client to a blocking mode, use the **PopDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **PopAttachThread** function.

Specifying the POP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

PopAttachThread Function

```
DWORD WINAPI PopAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **PopAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **PopAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **PopAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **PopCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **PopUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopConnect, PopDisconnect, PopUninitialize

PopCancel Function

```
INT WINAPI PopCancel(
   HCLIENT hClient
);
```

The **PopCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

When the **PopCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopIsBlocking, PopReset

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopChangePassword Function

```
BOOL WINAPI PopChangePassword(
   HCLIENT hClient,
   LPCTSTR lpszUserName,
   LPCTSTR lpszOldPassword,
   LPCTSTR lpszNewPassword
);
```

The **PopChangePassword** function changes the account password for the specified user.

Parameters

hClient

Handle to the client session.

lpszUserName

Pointer to a string which specifies the user name of the account who's password will be changed. It is not required that this be the same user name that was used to login to the mail server.

lpszOldPassword

Pointer to a string which specifies the current account password.

lpszNewPassword

Pointer to a string which specifies the new account password. When the function returns, the user's mailbox password will be set to this value.

Return Value

If the function succeeds, it will return a non-zero value. If the function fails, it will return zero. To get extended error information, call **PopGetLastError**.

Remarks

The **PopChangePassword** function is used to change the password associated with the specified account on the server. The function establishes a connection to a separate service running on the server, and does not use the POP3 protocol. For this function to succeed, the server must be configured to allow password changes using the "poppass" service, running on port 106.

Because passwords are sent over the network as clear text, this service is considered to be insecure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopConnect, PopLogin

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopCloseMessage Function

```
INT WINAPI PopCloseMessage(
   HCLIENT hClient
);
```

The **PopCloseMessage** function closes the current message that has been opened or created.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

If an message is being created, this function actually submits the message to the server. Note that the client application is responsible for generating the message headers as well as the body of the message. News messages conform to the same general characteristics of an email message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopOpenMessage, PopRead

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopCommand Function

```
BOOL WINAPI PopCommand(
   HCLIENT hClient,
   LPCTSTR lpszCommand,
   LPCTSTR lpszParameter
);
```

The **PopCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the command was successful, the function returns a non-zero value. If the command failed, the function returns zero. To get extended error information, call **PopGetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

PopConnect Function

```
HCLIENT WINAPI PopConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **PopConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 110. For secure connections, the default port number is 995. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
POP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
POP_OPTION_LINEBREAK	Message data that is received from the server is read as individual lines of text terminated by a carriage return and linefeed control sequence. This option can be useful for applications that need to use the lower level network I/O functions and must process the message text on a line-by-line basis. This option is not recommended for most applications because it can have a negative impact on performance when retrieving large messages from the server.
POP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.

POP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
POP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option is the same as specifying POP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STLS command.
POP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the STLS command.
POP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. It should only be used when the server expects an implicit TLS connection or does not implement RFC 2595 where the STLS command is used to negotiate a secure connection with the server.
POP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
POP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
POP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which is used to establish the client credentials for a secure connection to the server. The function **PopCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **PopGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **PopConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **PopAttachThread** function.

Specifying the POP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopDisconnect, PopInitialize, PopLogin, PopUninitialize

PopCreateSecurityCredentials Function

```
BOOL WINAPI PopCreateSecurityCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **PopCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This value should always be zero for connections using SSH. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **PopDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **PopGetLastError** function.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **PopConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
PopCreateSecurityCredentials(SECURITY_PROTOCOL_DEFAULT,
                             0,
                             NULL,
                             NULL,
                             lpszCertStore,
                             lpszCertName,
                             NULL,
                             &lpSecCred);

hClient = PopConnect(lpszHostName,
                     POP_PORT_SECURE,
                     POP_TIMEOUT,
                     POP_OPTION_SECURE,
                     lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

PopDeleteMessage Function

```
INT WINAPI PopDeleteMessage(
   HCLIENT hClient,
   UINT nMessage
);
```

The **PopDeleteMessage** function marks the specified message for deletion from the mailbox.

Parameters

hClient

Handle to the client session.

nMessage

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

This function only marks the message for deletion. The message is not actually deleted until the user disconnects from the server. To prevent one or more marked messages from actually being deleted from the mailbox, call the **PopReset** function to reset the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopDeleteSecurityCredentials Function

```
VOID WINAPI PopDeleteSecurityCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **PopDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)
    PopDeleteSecurityCredentials(&lpSecCred);

PopUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

PopDisableEvents Function

```
INT WINAPI PopDisableEvents(
    HCLIENT hClient
);
```

The **PopDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopDisableTrace Function

```
BOOL WINAPI PopDisableTrace();
```

The **PopDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopEnableTrace

PopDisconnect Function

```
INT WINAPI PopDisconnect(
   HCLIENT hClient
);
```

The **PopDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopEnableEvents Function

```
INT WINAPI PopEnableEvents(
   HCLIENT hClient,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **PopEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **PopRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the ***hEventWnd*** parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
POP_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.

POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
POP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
POP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
POP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopEnableTrace Function

```
BOOL WINAPI PopEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **PopEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

PopEventProc Function

```
VOID CALLBACK PopEventProc(
   HCLIENT hClient,
   UINT nEvent,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **PopEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **PopRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **PopRegisterEvent** function. The **PopEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopDisableEvents, PopEnableEvents, PopFreezeEvents, PopRegisterEvent

PopFreezeEvents Function

```
INT WINAPI PopFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **PopFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopGetErrorString Function

```
INT WINAPI PopGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **PopGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **PopGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopGetLastError, PopSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopGetHeaderValue Function

```
INT WINAPI PopGetHeaderValue(
   HCLIENT hClient,
   UINT nMessageId,
   LPCTSTR lpszHeader,
   LPTSTR lpszValue,
   INT nMaxLength
);
```

The **PopGetHeaderValue** function returns the value of a header field in the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszHeader

Pointer to a string which specifies the message header to retrieve. The colon should not be included in this string.

lpszValue

Pointer to a string buffer that will contain the value of the specified message header.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the function returns the length of the header field value. If the header field is not present in the message, the function will return a value of zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetHeaderValue** function returns the value of a header field from the specified message. This allows an application to be able to easily determine the value of a header (such as the sender, or the subject of the message) without downloading the entire header block or contents of the message.

This function uses the XTND XLST command, which is an extension to the POP3 protocol. Not all servers support the use of this command. If this command is not supported by the server, the function will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this function even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopGetMessageHeaders, PopGetMessageId, PopGetMessageSender

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopGetLastError Function

```
DWORD WINAPI PopGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **PopSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **PopGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **PopSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or POP_ERROR. Those functions which call **PopSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopGetMessage Function

```
INT WINAPI PopGetMessage(
   HCLIENT hClient,
   LONG nMessageId,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwReserved
);
```

The **PopGetMessage** function retrieves the specified message and copies the contents to a local buffer.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessage** function is used to retrieve an message from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the message. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvBuffer*** parameter point to a global memory handle which will contain the message data when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the complete message has been retrieved, a timeout occurs or the operation is canceled. During the transfer, the POP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event

notification must be enabled, either by calling **PopEnableEvents**, or by registering a callback function using the **PopRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **PopGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the message into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = PopGetMessage(hClient,
                        nMessageId,
                        &hgblBuffer,
                        &cbBuffer,
                        0);

if (nResult != POP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // message text
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopGetMessageCount Function

```
INT WINAPI PopGetMessageCount(
    HCLIENT hClient
);
```

The **PopGetMessageCount** function returns the number of mail messages that are currently available in the mailbox.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, it returns the number of messages that are currently available. If no messages are available, either because the mailbox is empty or all of the messages have been deleted, this function will return zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopGetMessageCountEx Function

```
INT WINAPI PopGetMessageCountEx(
   HCLIENT hClient,
   UINT *lpnLastMessage,
   DWORD *lpdwMailboxSize
);
```

The **PopGetMessageCountEx** function returns the number of mail messages that are currently available in the mailbox.

Parameters

hClient

Handle to the client session.

lpnLastMessage

Address of a variable that receives the number of the last valid message in the mailbox. If a NULL value is specified, this argument is ignored.

lpdwMailboxSize

Address of a variable that receives the current size of the mailbox. This value will decrease as messages are deleted. If a NULL value is specified, this argument is ignored.

Return Value

If the function succeeds, it returns the number of messages that are currently available. If no messages are available, either because the mailbox is empty or all of the messages have been deleted, this function will return zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageCountEx** function returns the number of messages available in the mailbox, the last valid message number in the mailbox and the current size of the mailbox in bytes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopGetMessageHeaders Function

```
INT WINAPI PopGetMessageHeaders(
    HCLIENT hClient,
    LONG nMessageId,
    LPVOID lpvHeaders,
    LPDWORD lpdwLength
);
```

The **PopGetMessageHeaders** function retrieves the headers for the specified message from the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero.

lpvHeaders

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvHeaders*** parameter. If the ***lpvHeaders*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageHeaders** function is used to retrieve an message header block from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the ***lpvHeaders*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvHeaders*** parameter point to a global memory handle which will contain the message headers when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

This function will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the POP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **PopEnableEvents**, or by registering a callback function using the **PopRegisterEvent** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopGetHeaderValue, PopGetMessage, PopGetMessageId, PopOpenMessage

PopGetMessageId Function

```
INT WINAPI PopGetMessageId(
   HCLIENT hClient,
   UINT nMessageId,
   LPTSTR lpszMessageId,
   INT nMaxLength
);
```

The **PopGetMessageId** function returns the message identifier for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageId

Address of a string buffer to receive the message identifier. This should be at least 64 bytes in length.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the length of the unique identifier string. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageId** function returns the message identifier from the Message-ID header of the specified message. The returned value is a typically a string which specifies the domain, date and timestamp for the message that is created when the message is submitted to the mail server for delivery. To obtain a unique identifier for the message in the mailbox, it is recommended that you use the **PopGetMessageUid** function instead.

This function uses the XTND XLST command to obtain the value of the "Message-ID" header field. If this command is not supported by the server, the function will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this function even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopGetHeaderValue, PopGetMessage, PopGetMessageHeaders, PopGetMessageSender, PopGetMessageUid

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopGetMessageSender Function

```
INT WINAPI PopGetMessageSender(
   HCLIENT hClient,
   UINT nMessageId,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **PopGetMessageSender** function returns the sender's address for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszAddress

Pointer to a string buffer that will contain the address of the message sender.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the function returns the length of the address. If the sender cannot be determined, the function will return a value of zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageSender** function returns the email address of the user who sent the specified message. This allows an application to be able to easily determine the sender, without downloading the entire header block or contents of the message.

This function uses the XSENDER command, which is an extension to the POP3 protocol, to determine the address of the authenticated sender of the message. If the command is not supported, or the server was unable to authenticate the sender, the function will use the XTND XLST command to obtain the value of the "From" header field. If this command is not supported by the server, the function will attempt to retrieve the entire message header and return the value for the specified header field. This enables an application to use this function even if the server does not support command extensions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

PopGetMessageSize Function

```
DWORD WINAPI PopGetMessageSize(
    HCLIENT hClient,
    UINT nMessageId
);
```

The **PopGetMessageSize** function returns the size of the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve size of. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is the size of the specified message in bytes. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopGetMessageUid Function

```
INT WINAPI PopGetMessageUid(
   HCLIENT hClient,
   UINT nMessageId,
   LPTSTR lpszMessageUID,
   INT nMaxLength
);
```

The **PopGetMessageUid** function returns the unique identifier (UID) for the specified message in the current mailbox.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageUID

Address of a string buffer to receive the unique identifier for the specified message. This should be at least 64 bytes in length.

nMaxLength

The maximum length of the string buffer for the message UID.

Return Value

If the function succeeds, it returns a non-zero value. If no unique identifier is assigned to the message, the function will return zero. If an error occurs, the function returns POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetMessageUid** function returns the unique message identifier for the specified message. The returned value is a string which can be used to uniquely identify a specific message in the mailbox across multiple client sessions. This is commonly used by mail clients to determine if they have already retrieved a message from the server in a previous session. The UID can also be used as a key or component of the file name to reference the message after it has been stored on the local system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopGetMultiLine Function

```
INT WINAPI PopGetMultiLine(
   HCLIENT hClient,
   LPBOOL lpbMultiLine
);
```

The **PopGetMultiLine** function returns the value of the client multi-line flag in the specified boolean parameter.

Parameters

hClient

Handle to the client session.

lpbMultiLine

A pointer to a boolean variable. This variable will be set to the current value of the client's internal multi-line flag.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The multi-line flag is used by the library to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopCommand, PopGetResultCode, PopGetResultString, PopSetMultiLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopGetResultCode Function

```
BOOL WINAPI PopGetResultCode(
    HCLIENT hClient
);
```

The **PopGetResultCode** function reads the result code returned by the server in response to a command. The result code is a boolean value, and indicates if the operation succeeded or failed.

Parameters

hClient

Handle to the client session.

Return Value

If the previous command was successful, the function returns a non-zero value. If the previous command failed, the function returns zero. To get extended error information, call **PopGetLastError**.

Remarks

Unlike most other Internet application protocols, the Post Office Protocol does not return numeric result codes to indicate success or failure. If a command is successful, the server will respond with the string "+OK" and this is indicated by the **PopGetResultCode** function returning a non-zero value. If the command fails, the server will respond with the string "-ERR" along with a description of the error, and this is indicated by the function returning a value of zero. The description of the error returned by the server can be obtained by calling the **PopGetResultString** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopCommand, PopGetResultString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopGetResultString Function

```
INT WINAPI PopGetResultString(
   HCLIENT hClient,
   LPTSTR lpszResult,
   INT nMaxLength
);
```

The **PopGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

The buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **PopGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

PopGetSecurityInformation Function

```
BOOL WINAPI PopGetSecurityInformation(
   HCLIENT hClient,
   LPSECURITYINFO lpSecurityInfo
);
```

The **PopGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The ***dwSize*** member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **PopGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the ***dwProtocol*** structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Notifies the user if the connection is secure or not
SECURITYINFO securityInfo;

securityInfo.dwSize = sizeof(SECURITYINFO);
if (PopGetSecurityInformation(hClient, &securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopConnect, PopDisconnect, SECURITYINFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopGetStatus Function

```
INT WINAPI PopGetStatus(
   HCLIENT hClient
);
```

The **PopGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
POP_STATUS_IDLE	The client is current idle and not sending or receiving data.
POP_STATUS_CONNECT	The client is establishing a connection with the server.
POP_STATUS_READ	The client is reading data from the server.
POP_STATUS_WRITE	The client is writing data to the server.
POP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopGetTimeout Function

```
INT WINAPI PopGetTimeout(
   HCLIENT hClient
);
```

The **PopGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopConnect, PopIsReadable, PopIsWritable, PopRead, PopSetTimeout

PopGetTransferStatus Function

```
INT WINAPI PopGetTransferStatus(
   HCLIENT hClient,
   LPPOPTRANSFERSTATUS lpStatus
);
```

The **PopGetTransferStatus** function returns information about the current file transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an POPTRANSFERSTATUS structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopGetTransferStatus** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopEnableEvents, PopGetStatus, PopRegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopInitialize Function

```
BOOL WINAPI PopInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **PopInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **PopGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **PopInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **PopUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **PopInitialize** or **PopUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopIsBlocking Function

```
BOOL WINAPI PopIsBlocking(
   HCLIENT hClient
);
```

The **PopIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **PopIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopIsConnected Function

```
BOOL WINAPI PopIsConnected(
   HCLIENT hClient
);
```

The **PopIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopIsBlocking, PopIsReadable, PopIsWritable

PopIsReadable Function

```
BOOL WINAPI PopIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **PopIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopIsWritable Function

```
BOOL WINAPI PopIsWritable(
   HCLIENT hClient,
   INT nTimeout
);
```

The **PopIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopLogin Function

```
INT WINAPI PopLogin(
   HCLIENT hClient,
   UINT nAuthType,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

The **PopLogin** function authenticates the specified user in on the server. This function must be called after the connection has been established, and before attempting to retrieve messages or perform any other function on the server.

Parameters

hClient

Handle to the client session.

nAuthType

Identifies the type of authentication that should be used when the client logs in to the mail server. The following authentication methods are supported:

Value	Description
POP_AUTH_DEFAULT	The default authentication scheme which sends the username and password as cleartext to the server. Because the user credentials are not encrypted, this method should only be used over a secure connection. This is the same as specifying POP_AUTH_PASS as the authentication method.
POP_AUTH_PASS	The username and password is sent to the server using the USER and PASS commands. This authentication method is supported by most servers and is the default authentication type. The credentials are not encrypted and this method should only be used over secure connections.
POP_AUTH_APOP	The APOP authentication method which uses an MD5 digest of the password. This method has been deprecated is not supported by all servers. It should only be used if required by legacy mail servers which do not support the SASL authentication methods.
POP_AUTH_LOGIN	This authentication type will use the LOGIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted and should only be used over a secure connection. The server must support the Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4422.
POP_AUTH_PLAIN	This authentication type will use the PLAIN method to authenticate the client session. This encodes the username and password in a specific format, but the credentials are not encrypted and should only be used over a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.

POP_AUTH_XOAUTH2	This authentication type will use the XOAUTH2 method to authenticate the client session. This authentication method does not require the user password, instead the *lpszPassword* parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.
POP_AUTH_BEARER	This authentication type will use the OAUTHBEARER method to authenticate the client session as defined in RFC 7628. This authentication method does not require the user password, instead the *lpszPassword* parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.

lpszUserName

A null-terminated string which specifies the user name to be used to authenticate the current client session. For many service providers, the user name is the full email address of the user which owns the mailbox. In some cases, this may only be the portion of their email address before the domain name.

lpszPassword

A null-terminated string which specifies the password to be used when authenticating the current client session. If you are using the POP_AUTH_XOAUTH2 or POP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the OAuth 2.0 bearer token provided by the mail service.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The POP_AUTH_LOGIN and POP_AUTH_PLAIN authentication methods require the mail server support the Simple Authentication and Security Layer (SASL) AUTH command as defined in RFC 5034. Most modern mail servers do support one or both of these methods, and they are generally preferred over the POP_AUTH_PASS method when possible. However, for backwards compatibility with legacy servers, the API will default to using POP_AUTH_PASS for client authentication.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The POP_AUTH_XOAUTH2 and POP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify

offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

PopOpenMessage Function

```
INT WINAPI PopOpenMessage(
   HCLIENT hClient,
   UINT nMessageId,
   DWORD dwReserved
);
```

The **PopOpenMessage** function opens the specified message for reading.

Parameters

hClient

Handle to the client session.

nMessageId

Number that specifies which message to open. This value must be greater than zero. The first message in the mailbox is message one.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopOpenMessage** function is used to begin the process of reading the contents of a message from the from the server. Similar to how a file is opened and read, this method is followed by one or more calls to the **PopRead** method. When the entire contents of the message has been read, the **PopCloseMessage** method is used to close the message, completing the transaction on the server.

This is a lower-level function which enables the application to process the message as the contents are being returned by the server. In general, it is recommended that most applications use the **PopGetMessage** method instead, which provides a simpler method for retrieving the contents of a message.

It is important to note that you cannot use this function to read the partial contents of a message. Opening a message on the server begins a process where the entire message contents must be read and the message closed before the next command can be issued to the server. If you only want to obtain the headers for a message, use the **PopGetMessageHeaders** function instead.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopCloseMessage, PopGetMessage, PopGetMessageHeaders, PopIsReadable, PopRead

PopRead Function

```
INT WINAPI PopRead(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **PopRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that there is no more data available to be read. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

When **PopRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopRegisterEvent Function

```
INT WINAPI PopRegisterEvent(
   HCLIENT hClient,
   UINT nEvent,
   POPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **PopRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
POP_EVENT_CONNECT	The connection to the server has completed.
POP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
POP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
POP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
POP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
POP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
POP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
POP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so

	that the client can update any user interface components such as a status control or progress bar.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **PopEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopRegisterEvent** function associates a callback function with a specific event. The event handler is an **PopEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a message is being retrieved. The POP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one POP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopReset Function

```
BOOL WINAPI PopReset(
   HCLIENT hClient
);
```

The **PopReset** function resets the client state and resynchronizes with the server. This function is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **PopGetLastError**.

Remarks

This function will prevent any messages marked for deletion from actually being deleted from the mailbox. The client cannot be reset while the client is in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopSendMessage Function

```
INT WINAPI PopSendMessage(
   HCLIENT hClient,
   LPVOID lpMessage,
   DWORD dwMessageSize,
   DWORD dwReserved
);
```

The **PopSendMessage** function sends a message to the specified recipients.

Parameters

hClient

Handle to the client session.

lpMessage

Pointer to a buffer which contains the message to be submitted to the mail server for delivery.

dwMessageSize

The length of the buffer in bytes. This specifies the number of bytes to be written to the mail server. This value must be greater than zero.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopSendMessage** function sends a message through the POP3 server using the XTND XMIT command. The specified file must be in the standard format as described in RFC 822, with the recipient addresses specified in the To: and Cc: header fields. Some servers may support blind carbon copies by using addresses specified in a Bcc: header field, and then removing those addresses from the header before delivering the message.

Note that not all POP3 servers support this command, and it is recommended that you use the Simple Mail Transfer Protocol (SMTP) for general mail delivery purposes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopGetMessage, PopStoreMessage

PopSetLastError Function

```
VOID WINAPI PopSetLastError(
   DWORD dwErrorCode
);
```

The **PopSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or POP_ERROR. Those functions which call **PopSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **PopGetLastError** function. The use of **PopGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

PopSetMultiLine Function

```
INT WINAPI PopSetMultiLine(
   HCLIENT hClient,
   BOOL bMultiLine
);
```

The **PopSetMultiLine** function sets the client multi-line flag into the specified value.

Parameters

hClient

Handle to the client session.

bMultiLine

A boolean flag which determines if the client is processing multiple lines of data as the result of a command.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The multi-line flag is used by the library to determine if multiple lines of data will be returned by the server as the result of a command. Unlike a single line response, which consists of a result code and result string, a multi-line response consists of one or more lines of text, terminated by a special end-of-data marker.

The **PopSetMultiLine** function should only be used in conjunction with the **PopCommand** function. If a command is issued which would result in multiple lines of output, the multi-line flag must be set TRUE. The multi-line flag must be set after each command, since it is reset to FALSE with each command that is sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopSetTimeout Function

```
INT WINAPI PopSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **PopSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopStoreMessage Function

```
INT WINAPI PopStoreMessage(
   HCLIENT hClient,
   UINT nMessageId,
   LPCTSTR lpszFileName
);
```

The **PopStoreMessage** function stores a message in the specified file.

Parameters

hClient

Handle to the client session.

nMessageId

Number of the message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

lpszFileName

Pointer to a string which specifies the file that the message will be stored in. If an empty string or NULL pointer is passed as an argument, the message is copied to the system clipboard.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The **PopStoreMessage** function provides a method of retrieving and storing a message on the local system. The contents of the message is stored as a text file, using the specified file name. This function always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

PopGetMessage, PopGetMessageHeaders, PopGetTransferStatus, PopSendMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopUninitialize Function

```
VOID WINAPI PopUninitialize();
```

The **PopUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **PopInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **PopUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **PopUninitialize** for every successful call to **PopInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

See Also

PopDisconnect, PopInitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

PopWrite Function

```
INT WINAPI PopWrite(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **PopWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is POP_ERROR. To get extended error information, call **PopGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the POP_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cspopv12.lib

Post Office Protocol Data Structures

- POPTRANSFERSTATUS
- SECURITYCREDENTIALS
- SECURITYINFO
- SYSTEMTIME

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

POPTRANSFERSTATUS

This structure is used by the PopGetTransferStatus function to return information about a message transfer in progress.

```
typedef struct _POPTRANSFERSTATUS
{
   UINT    nMessageId;
   DWORD   dwBytesTotal;
   DWORD   dwBytesCopied;
   DWORD   dwBytesPerSecond;
   DWORD   dwTimeElapsed;
   DWORD   dwTimeEstimated;
} POPTRANSFERSTATUS, *LPPOPTRANSFERSTATUS;
```

Members

nMessageId

The message ID of the current message that is being transferred.

dwBytesTotal

The total number of bytes that will be transferred. If the message is being copied from the server to the local host, this is the size of the message on the server. If the message is being posted to the server, it is the size of message on the local system. If the message size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Remote Command Protocol Library

Execute commands on a server or establish an interactive terminal session.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSRSHV12.DLL
Version	12.0.3024.1286
LibID	BA9EA46F-9835-474A-90B1-535762F4E993
Import Library	CSRSHV12.LIB
Dependencies	None
Standards	RFC 1282

Overview

The Remote Command protocol is used to execute a command on a server and return the output of that command to the client. This is most commonly used with UNIX based servers, although there are implementations of remote command servers for the Windows operating system. The library supports both the rcmd and rshell remote execution protocols and provides methods which can be used to search the data stream for specific sequences of characters. This makes it extremely easy to write Windows applications which serve as light-weight client interfaces to commands being executed on a UNIX server or another Windows system. The library can also be used to establish a remote terminal session using the rlogin protocol, which is similar to the Telnet protocol.

The Remote Shell (rsh/rcmd) protocol is deprecated, insecure, and should never be used. This protocol transmits user credentials and command data in plaintext, making it vulnerable to interception, spoofing, and other network-based attacks. Support for this protocol will be removed in a future release. For secure remote command execution and interactive terminal sessions, it is recommended you use the Secure Shell library.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum

required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Remote Command Protocol Functions

Function	Description
RshAsyncExecute	Execute a command on the specified server
RshAsyncLogin	Establish an asynchronous login session with the specified server
RshAttachThread	Attach the specified client handle to another thread
RshCancel	Cancel the current blocking operation
RshDisableEvents	Disable asynchronous event notification
RshDisableTrace	Disable logging of network function calls
RshDisconnect	Disconnect from the current server
RshEnableEvents	Enable asynchronous event notification
RshEnableTrace	Enable logging of network function calls to a file
RshEventProc	Callback function that processes events generated by the client
RshExecute	Execute a command on the server
RshFreezeEvents	Suspend asynchronous event processing
RshGetErrorString	Return a description for the specified error code
RshGetLastError	Return the last error code
RshGetStatus	Return the current client status
RshGetTimeout	Return the number of seconds until an operation times out
RshInitialize	Initialize the library and validates the specified license key at runtime
RshIsBlocking	Determine if the client is blocked, waiting for information
RshIsConnected	Determine if the client is connected to the server
RshIsReadable	Determine if data can be read from the server
RshIsWritable	Determine if data can be written to the server
RshLogin	Establish a login session with the specified server
RshRead	Read data returned by the server
RshRegisterEvent	Register an event callback function
RshSearch	Search for a specific character sequence in the data stream
RshSetLastError	Set the last error code
RshSetTimeout	Set the number of seconds until an operation times out
RshUninitialize	Terminate use of the library by the application
RshWrite	Write data to the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RshAsyncExecute Function

```
HCLIENT WINAPI RshAsyncExecute(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCommand,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **RshAsyncExecute** function is used to establish a connection with the server and execute the specified command.

The application should create a background worker thread and establish a connection by calling **RshExecute** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. One of the following values should be used:

Value	Description
RSH_PORT_REXEC	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
RSH_PORT_RSHELL	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the server considers the client to be equivalent to itself, and as long as the specified user exists on the server, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
RSH_OPTION_RESERVEDPORT	This option specifies that a reserved port should be used to establish the connection. Reserved ports are those port numbers which are less than 1024. This option should be

	specified when connecting on the RSH_PORT_RSHELL port.
RSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
RSH_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpszUserName

A null-terminated string which specifies the username used to authenticate the client session.

lpszPassword

A null-terminated string which specifies the password used to authenticate the client session. This parameter is only used when connecting to the RSH_PORT_REXEC port. If the password is not required, this parameter may be NULL.

lpszCommand

A null-terminated string which specifies the command to execute on the server.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this parameter is NULL, then a synchronous (blocking) connection will be established with the server.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **RshGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.

RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **RshDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **RshAttachThread** function.

Specifying the RSH_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RshAsyncLogin, RshDisconnect, RshExecute, RshInitialize, RshLogin, RshUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RshAsyncLogin Function

```
HCLIENT WINAPI RshAsyncLogin(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwReserved,
   LPCTSTR lpszUserName,
   LPCTSTR lpszTerminal,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **RshAsyncLogin** function is used to establish a connection with the server.

The application should create a background worker thread and establish a connection by calling **RshLogin** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwReserved

A reserved parameter. This value should always be zero.

lpszUserName

A null-terminated string which specifies the username used to authenticate the client session.

lpszTerminal

A null-terminated string which specifies the terminal type which the client will be identified as using during the session. If no particular terminal emulation is required, this parameter may be NULL.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this parameter is NULL, then a synchronous (blocking) connection will be established with the server.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **RshGetLastError**.

Remarks

This function uses host equivalence, where the client is permitted to login without requiring a password. Host equivalence must be configured by the server administrator and it is typically restricted to specific users. Note that if configured improperly, host equivalence can introduce a significant security loophole. Refer to your UNIX system documentation for more information about host equivalence and the various remote command services.

On UNIX based systems, the terminal name specified by the ***lpszTerminal*** parameter corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this parameter may be ignored and the server will assume that the client is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this parameter is passed as NULL pointer or an empty string, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal Type	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is a using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.

xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **RshDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

RshAsyncExecute, RshDisconnect, RshExecute, RshInitialize, RshLogin, RshUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RshAttachThread Function

```
DWORD WINAPI RshAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **RshAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **RshAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **RshAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **RshCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **RshUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

RshCancel Function

```
INT WINAPI RshCancel(
   HCLIENT hClient
);
```

The **RshCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero.

If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

When the **RshCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshDisableEvents Function

```
INT WINAPI RshDisableEvents(
    HCLIENT hClient
);
```

The **RshDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshEnableEvents, RshFreezeEvents, RshRegisterEvent

RshDisableTrace Function

```
BOOL WINAPI RshDisableTrace();
```

The **RshDisableTrace** function disables the logging of network function calls file.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RshDisconnect Function

```
INT WINAPI RshDisconnect(
   HCLIENT hClient
);
```

The **RshDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshEnableEvents Function

```
INT WINAPI RshEnableEvents(
   HCLIENT hClient,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **RshEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RshRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
RSH_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a

	connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **RshDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

RshEnableTrace Function

```
BOOL WINAPI RshEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **RshEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

RshEventProc Function

```
VOID CALLBACK RshEventProc(
   HCLIENT hClient,
   UINT nEventId,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **RshEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hClient

The handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **RshRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **RshRegisterEvent** function. The **RshEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshExecute Function

```
HCLIENT WINAPI RshExecute(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCommand
);
```

The **RshExecute** function is used to establish a connection with the server and execute the specified command.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. One of the following values should be used:

Value	Description
RSH_PORT_REXEC	A connection is established with the server using port 512, the rexec service. This service requires that the client provide a username and password to execute the specified command.
RSH_PORT_RSHELL	A connection is established with the server using port 514, the rshell service. This service uses host equivalence to authenticate the user. With host equivalence, the server considers the client to be equivalent to itself, and as long as the specified user exists on the server, the client is permitted to execute commands on behalf of the user without requiring a password. Host equivalence is configured by the server administrator.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
RSH_OPTION_RESERVEDPORT	This option specifies that a reserved port should be used to establish the connection. Reserved ports are those port numbers which are less than 1024. This option should be specified when connecting on the RSH_PORT_RSHELL port.
RSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an

	IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
RSH_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpszUserName

A null-terminated string which specifies the username used to authenticate the client session.

lpszPassword

A null-terminated string which specifies the password used to authenticate the client session. This parameter is only used when connecting to the RSH_PORT_REXEC port. If the password is not required, this parameter may be NULL.

lpszCommand

A null-terminated string which specifies the command to execute on the server.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **RshGetLastError**.

Remarks

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **RshAttachThread** function.

Specifying the RSH_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

RshFreezeEvents Function

```
INT WINAPI RshFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **RshFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

RshGetErrorString Function

```
INT WINAPI RshGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **RshGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **RshGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RshGetLastError, RshSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RshGetLastError Function

```
DWORD WINAPI RshGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **RshSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **RshGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **RshSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSH_ERROR. Those functions which call **RshSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

RshGetStatus Function

```
INT WINAPI RshGetStatus(
   HCLIENT hClient
);
```

The **RshGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The **RshGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
RSH_STATUS_IDLE	The client is current idle and not sending or receiving data.
RSH_STATUS_CONNECT	The client is establishing a connection with the server.
RSH_STATUS_READ	The client is reading data from the server.
RSH_STATUS_WRITE	The client is writing data to the server.
RSH_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshGetTimeout Function

```
INT WINAPI RshGetTimeout(
   HCLIENT hClient
);
```

The **RshGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshSetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RshInitialize Function

```
BOOL WINAPI RshInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **RshInitialize** function initializes the library and validates the specified license key at runtime.

The Remote Shell (rsh/rcmd) protocol is deprecated, insecure, and should never be used. This protocol transmits user credentials and command data in plaintext, making it vulnerable to interception, spoofing, and other network-based attacks. Support for this protocol will be removed in a future release. For secure remote command execution and interactive terminal sessions, it is recommended you use the Secure Shell library.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **RshGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The ***lpvReserved*** parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **RshInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **RshUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **RshInitialize** or **RshUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

RshIsBlocking Function

```
BOOL WINAPI RshIsBlocking(
   HCLIENT hClient
);
```

The **RshIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns TRUE. If the client is not performing a blocking operation, or the client handle is invalid, the function returns FALSE.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **RshIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshCancel, RshGetStatus, RshIsConnected, RshIsReadable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RshIsConnected Function

```
BOOL WINAPI RshIsConnected(
   HCLIENT hClient
);
```

The **RshIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshGetStatus, RshIsBlocking, RshIsReadable, RshIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RshIsReadable Function

```
BOOL WINAPI RshIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **RshIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

RshIsWritable Function

```
BOOL WINAPI RshIsWritable(
   HCLIENT hClient,
   INT nTimeout
);
```

The **RshIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

RshLogin Function

```
HCLIENT WINAPI RshLogin(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwReserved,
   LPCTSTR lpszUserName,
   LPCTSTR lpszTerminal
);
```

The **RshLogin** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwReserved

A reserved parameter. This value should always be zero.

lpszUserName

A null-terminated string which specifies the username used to authenticate the client session.

lpszTerminal

A null-terminated string which specifies the terminal type which the client will be identified as using during the session. If no particular terminal emulation is required, this parameter may be NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **RshGetLastError**.

Remarks

This function uses host equivalence, where the client is permitted to login without requiring a password. Host equivalence must be configured by the server administrator and it is typically restricted to specific users. Note that if configured improperly, host equivalence can introduce a significant security loophole. Refer to your UNIX system documentation for more information about host equivalence and the various remote command services. Note that if there is no host equivalence for the local host and the user account requires a password, the system will prompt for a password.

This protocol should not be used when connecting to a server on a public network because the user credentials are sent as unencrypted text. For secure remote command execution and interactive terminal sessions, it is recommended you use the Secure Shell (SSH) library.

On UNIX based systems, the terminal name specified by the ***lpszTerminal*** parameter corresponds to a termcap or terminfo entry as set in the TERM environment variable. On Windows based systems which implement the rlogin service, this parameter may be ignored and the server will assume that the client

is capable of displaying ANSI escape sequences. On VMS systems, the terminal name should correspond to the terminal type used with the SET TERMINAL/DEVICE command.

If this parameter is passed as NULL pointer or an empty string, a default terminal type named "unknown" will be used. On most UNIX and VMS systems this defines a terminal which is not capable of cursor positioning using control or escape sequences. This terminal type may not be recognized and an error may be displayed when the user logs in indicating that the terminal type is invalid.

Refer to the documentation for the server system to determine what terminal type names are available to you. Remember that on UNIX systems, the terminal type is case-sensitive. Some of the more common terminal types are:

Terminal Type	Description
ansi	This terminal type is usually available on UNIX based servers. This specifies that the client is capable of displaying standard ANSI escape sequences for cursor control.
dumb	This terminal type typically specifies a terminal display which does not support control or escape sequences for cursor positioning. If you do not want escape sequences embedded in the data stream and the server returns an error if the terminal type is not specified, try using this terminal type.
pcansi	This terminal type is usually available on UNIX based servers. This specifies that the client is a using a PC terminal emulator that supports basic ANSI escape sequences for cursor control. This may also enable escape sequences which can set the display colors.
vt100	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT100. This specifies that the client is capable of emulating a DEC VT100 terminal. The VT100 supports many of the same cursor control sequences as an ANSI terminal.
vt220	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT220. This specifies that the client is capable of emulating a DEC VT220 terminal, which is a later version of the VT100.
vt320	This terminal type is usually available on UNIX and VMS based servers. On some VMS systems this string may need to be specified as DEC-VT320. This specifies that the client is capable of emulating a DEC VT320 terminal, which is similar to the VT100 and VT220 and provides advanced features such as the ability to set display colors.
xterm	This terminal type is may be available on UNIX based servers which have X Windows installed. This specifies that the client is a using the X Windows xterm emulator which supports standard ANSI escape sequences for cursor control.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

RshRead Function

```
INT WINAPI RshRead(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **RshRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

When **RshRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

RshRegisterEvent Function

```
INT WINAPI RshRegisterEvent(
   HCLIENT hClient,
   UINT nEventId,
   INETEVENTPROC lpfnEvent,
   DWORD_PTR dwParam
);
```

The **RshRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One or more of the following values may be used:

Value	Description
RSH_EVENT_CONNECT	The connection to the server has completed.
RSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
RSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
RSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
RSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpfnEvent

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **RshEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86

(32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The **RshRegisterEvent** function associates a callback function with a specific event. The event handler is an **RshEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshSearch Function

```
BOOL WINAPI RshSearch(
   HCLIENT hClient,
   LPCTSTR lpszString,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwReserved
);
```

The **RshSearch** function searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

hClient

Handle to the client session.

lpszString

A null-terminated string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpvBuffer

A buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the function returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the ***lpvBuffer*** parameter is NULL, this parameter should also be NULL.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds and the character sequences was found in the data stream, the return value is non-zero. If the function fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **RshGetLastError**.

Remarks

The **RshSearch** function searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as executing a command and processing the output. The function collects the output from the server and stores it in the buffer specified by the ***lpvBuffer*** parameter. When the function returns, the buffer will contain everything sent by the server up to and including the search string.

The ***lpvBuffer*** parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the ***lpvBuffer*** parameter point to a global memory handle which will contain the output when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib
Unicode: Implemented as Unicode and ANSI versions

RshSetLastError Function

```
VOID WINAPI RshSetLastError(
   DWORD dwErrorCode
);
```

The **RshSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or RSH_ERROR. Those functions which call **RshSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **RshGetLastError** function. The use of **RshGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

RshSetTimeout Function

```
INT WINAPI RshSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **RshSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshGetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

RshUninitialize Function

```
VOID WINAPI RshUninitialize();
```

The **RshUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **RshInitialize** call before it can call any of the other the library functions. When it has finished using the library, the application must call **RshUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **RshUninitialize** for every successful call to **RshInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

See Also

RshWrite Function

```
INT WINAPI RshWrite(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **RshWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is RSH_ERROR. To get extended error information, call **RshGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the RSH_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csrshv12.lib

Secure Shell Protocol Library

Establish an interactive terminal session with an SSH server and execute remote commands.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSTSHV12.DLL
Version	12.0.3024.1286
LibID	758D7F52-CE33-4C44-B404-EBF1F15875E8
Import Library	CSTSHV12.LIB
Dependencies	None
Standards	RFC 4251

Remarks

The Secure Shell (SSH) protocol API is used to establish a secure connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The library provides an interface for establishing the connection and handling the standard I/O functions needed by the program.

Standard password and private key authentication methods are supported. The library will automatically select the strongest cipher suite available to both the client and server, providing support for AES-256 encryption and elliptical curve key exchance algorithms like ECDH and Curve25519. The control also supports some legacy algortithms for backwards compatibility with older servers but will only use them if no other options are available. If the server you are connecting with is based on OpenSSH, we recommend using OpenSSH 7.0 or later. Earlier versions of OpenSSH may request the use of encryption algorithms which are no longer considered secure.

The library also provides functions that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write lightweight client interfaces to applications running on the server. This library can be combined with the Terminal Emulation library to provide terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Important: The Secure Shell (SSH) API provides a secure, encrypted alternative to legacy protocols such as Remote Shell (rsh/rcmd), Remote Login (rlogin), and Telnet. Unlike those older protocols, SSH uses strong authentication and end-to-end encryption to protect user credentials, command input, and output data from interception or tampering. SSH is the recommended protocol for remote command execution and interactive terminal sessions, particularly when connecting over public or untrusted networks. It ensures confidentiality and integrity of data in transit, and is widely supported on modern operating systems and network infrastructure. If you are currently using Telnet or Remote Shell in your applications, you are strongly encouraged to migrate to the Secure Shell API. These older protocols are inherently insecure and should not be used in any context where data security matters.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Secure Shell Protocol Functions

Function	Description
SshAsyncConnect	Connect asynchronously to the specified server
SshAttachThread	Attach the specified client handle to another thread
SshCancel	Cancel the current blocking operation
SshConnect	Connect to the specified server
SshControl	Send a control sequence to the server
SshCreateSecurityCredentials	Create a new security credentials structure
SshDeleteSecurityCredentials	Delete a previously created security credentials structure
SshDisableEvents	Disable asynchronous event notification
SshDisableTrace	Disable logging of network function calls
SshDisconnect	Disconnect from the current server
SshEnableEvents	Enable asynchronous event notification
SshEnableTrace	Enable logging of network function calls to a file
SshEventProc	Callback function that processes events generated by the client
SshExecute	Execute a command on a server and return the output in the specified buffer
SshFreezeEvents	Suspend asynchronous event processing
SshGetErrorString	Return a description for the specified error code
SshGetExitCode	Return the exit code from the remote program
SshGetLastError	Return the last error code
SshGetLineMode	Return the current mode used to send end-of-line character sequences
SshGetSecurityInformation	Return security information about the current client connection
SshGetStatus	Return the current client status
SshGetTimeout	Return the number of seconds until an operation times out
SshInitialize	Initialize the library and validates the specified license key at runtime
SshIsBlocking	Determine if the client is blocked, waiting for information
SshIsConnected	Determine if the client is connected to the server
SshIsReadable	Determine if data can be read from the server
SshIsWritable	Determine if data can be written to the server
SshPeek	Read data returned by the server, but do not remove it from the receive buffer
SshRead	Read data returned by the server
SshReadLine	Read a line of text from the server and return it in a string buffer
SshRegisterEvent	Register an event callback function
SshSearch	Search for a specific character sequence in the data stream

SshSetLastError	Set the last error code
SshSetLineMode	Change how end-of-line character sequences are sent to the server
SshSetTimeout	Set the number of seconds until an operation times out
SshUninitialize	Terminate use of the library by the application
SshWrite	Write data to the server
SshWriteLine	Write a line of text to the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshAsyncConnect Function

```
HCLIENT WINAPI SshAsyncConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   UINT nTimeout,
   DWORD dwOptions,
   LPSSHOPTIONDATA lpOptions,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **SshAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **SshConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

A null-terminated string which specifies the name of the server to connect to. This may either be a fully-qualified domain name or an IP address. This parameter cannot be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A null-terminated string which specifies the user name which will be used to authenticate the client session. This parameter must specify a valid user name and cannot be NULL or an empty string.

lpszPassword

A null-terminated string which specifies the password which will be used to authenticate the client session. If the user does not have a password, this parameter can be NULL or an empty string.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.

SSH_OPTION_KEEPALIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for an extended period of time. The actual client idle timeout period is determined by the server configuration.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the SSH_OPTION_COMMAND option has been specified. This option should never be used with interactive client sessions.
SSH_OPTION_NOSHELL	This option specifies that a command shell should not be used when executing a command on the server. You should not use this option unless you require the command to execute without the normal shell environment. In most cases you should not use this option because it may cause commands to fail unexpectedly.
SSH_OPTION_TERMINAL	This option specifies the client session will use terminal emulation and the SSHOPTIONDATA structure specifies the characteristics of the virtual terminal. This enables the caller to specify the dimensions of the virtual display (in columns and rows) and the type of terminal that will be emulated. If this option is omitted, the session will default to a virtual display that is 80 columns, 25 rows.
SSH_OPTION_COMMAND	This option specifies the client session will be used to issue a command that is executed on the server, and the output will be returned to the caller. If this option is specified, the session will not be interactive and no pseudoterminal is created for the client. The szCommandLine member of the SSHOPTIONDATA structure specifies the command string that will be sent to the server.
SSH_OPTION_PROXYSERVER	This option specifies the client should establish a connection through a proxy server. The two protocols that are supported are SSH_PROXY_HTTP and SSH_PROXY_TELNET, which specifies the protocol that the proxy connection is created through. The proxy-related members of the SSHOPTIONDATA structure should be set to the appropriate values.
SSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SSH_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread

	which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpOptions

A pointer to a SSHOPTIONDATA structure which specifies additional information for one or more options. If no optional data is required, a NULL pointer may be specified.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which specifies additional security-related information required to establish the connection. This parameter may be NULL, in which case default values will be used. Note that the ***dwSize*** member must be initialized to the size of the **SECURITYCREDENTIALS** structure that is being passed to the function. You can use the **SshCreateSecurityCredentials** function to create this structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **SshGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
SSH_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.

SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **SshDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create worker threads for each additional session if more than one active client session is required.

By default, the client session will be authenticated using standard password authentication. If you prefer to authenticate using a private key file, you must create a SECURITYCREDENTIALS structure which specifies the path to the private key and optionally the password used when creating it. The private key file must be in the standard PEM format defined in RFC 1422. Both the standard RSA private key format and the proprietary OpenSSH format are supported. To determine how the private key was created, you can open the file in a text editor and the first line of the file will identify the format.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **SshAttachThread** function.

Specifying the SSH_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
// Define the asynchronous event notification message ID
#define WM_CLIENT_EVENTS (WM_APP + 1)

HCLIENT hClient;
SSHOPTIONDATA sshOptions;

// Initialize the SSHOPTIONDATA structure and specify the
// command that should be executed on the server
ZeroMemory(&sshOptions, sizeof(sshOptions));
lstrcpyn(sshOptions.szCommandLine, lpszCommand, SSH_MAXCOMMANDLEN);

// Establish a connection with the SSH server

hClient = SshAsyncConnect(lpszHostName,
                          SSH_PORT_DEFAULT,
                          lpszUserName,
                          lpszPassword,
                          SSH_TIMEOUT,
                          SSH_OPTION_COMMAND,
                          &sshOptions,
                          NULL,
                          hAppWnd,
                          WM_CLIENT_EVENTS);
```

```
// If the connection attempt fails, then get a description of
// the error and display it in a message box

if (hClient == INVALID_CLIENT)
{
    DWORD dwError;
    TCHAR szError[128];

    dwError = SshGetLastError();
    if (dwError > 0)
    {
        SshGetErrorString(dwError, szError, 128);
        MessageBox(NULL, szError, _T("Error"), MB_ICONEXCLAMATION);
    }

    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

SshAttachThread Function

```
DWORD WINAPI SshAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **SshAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **SshAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **SshAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **SshCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **SshUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshConnect, SshDisconnect, SshUninitialize

SshCancel Function

```
INT WINAPI SshCancel(
   HCLIENT hClient
);
```

The **SshCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

When the **SshCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

SshConnect Function

```
HCLIENT WINAPI SshConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   UINT nTimeout,
   DWORD dwOptions,
   LPSSHOPTIONDATA lpOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **SshConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

A null-terminated string which specifies the name of the server to connect to. This may either be a fully-qualified domain name or an IP address. This parameter cannot be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A null-terminated string which specifies the user name which will be used to authenticate the client session. This parameter must specify a valid user name and cannot be NULL or an empty string.

lpszPassword

A null-terminated string which specifies the password which will be used to authenticate the client session. If the user does not have a password, this parameter can be NULL or an empty string.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.
SSH_OPTION_KEEPALIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for an extended period of time. The actual client idle timeout period is determined by the server configuration.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is automatically set if the SSH_OPTION_COMMAND option has been specified. This option should never be used with interactive

	client sessions.
SSH_OPTION_NOSHELL	This option specifies that a command shell should not be used when executing a command on the server. You should not use this option unless you require the command to execute without the normal shell environment. In most cases you should not use this option because it may cause commands to fail unexpectedly.
SSH_OPTION_TERMINAL	This option specifies the client session will use terminal emulation and the SSHOPTIONDATA structure specifies the characteristics of the virtual terminal. This enables the caller to specify the dimensions of the virtual display (in columns and rows) and the type of terminal that will be emulated. If this option is omitted, the session will default to a virtual display that is 80 columns, 25 rows.
SSH_OPTION_COMMAND	This option specifies the client session will be used to issue a command that is executed on the server, and the output will be returned to the caller. If this option is specified, the session will not be interactive and no pseudoterminal is created for the client. The szCommandLine member of the SSHOPTIONDATA structure specifies the command string that will be sent to the server.
SSH_OPTION_PROXYSERVER	This option specifies the client should establish a connection through a proxy server. The two protocols that are supported are SSH_PROXY_HTTP and SSH_PROXY_TELNET, which specifies the protocol that the proxy connection is created through. The proxy-related members of the SSHOPTIONDATA structure should be set to the appropriate values.
SSH_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SSH_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpOptions

A pointer to a SSHOPTIONDATA structure which specifies additional information for one or more options. If no optional data is required, a NULL pointer may be specified.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which specifies additional security-related

information required to establish the connection. This parameter may be NULL, in which case default values will be used. Note that the *dwSize* member must be initialized to the size of the **SECURITYCREDENTIALS** structure that is being passed to the function. You can use the **SshCreateSecurityCredentials** function to create this structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **SshGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **SshConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

By default, the client session will be authenticated using standard password authentication. If you prefer to authenticate using a private key file, you must create a SECURITYCREDENTIALS structure which specifies the path to the private key and optionally the password used when creating it. The private key file must be in the standard PEM format defined in RFC 1422. Both the standard RSA private key format and the proprietary OpenSSH format are supported. To determine how the private key was created, you can open the file in a text editor and the first line of the file will identify the format.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **SshAttachThread** function.

Specifying the SSH_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
HCLIENT hClient;
SSHOPTIONDATA sshOptions;

// Initialize the SSHOPTIONDATA structure and specify the
// command that should be executed on the server
ZeroMemory(&sshOptions, sizeof(sshOptions));
lstrcpyn(sshOptions.szCommandLine, lpszCommand, SSH_MAXCOMMANDLEN);

// Establish a connection with the SSH server

hClient = SshConnect(lpszHostName,
                     SSH_PORT_DEFAULT,
                     lpszUserName,
                     lpszPassword,
                     SSH_TIMEOUT,
                     SSH_OPTION_COMMAND,
                     &sshOptions,
```

```
                    NULL);

// If the connection attempt fails, then get a description of
// the error and display it in a message box

if (hClient == INVALID_CLIENT)
{
    DWORD dwError;
    TCHAR szError[128];

    dwError = SshGetLastError();
    if (dwError > 0)
    {
        SshGetErrorString(dwError, szError, 128);
        MessageBox(NULL, szError, _T("Error"), MB_ICONEXCLAMATION);
    }

    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

SshControl Function

```
INT WINAPI SshControl(
   HCLIENT hClient
   DWORD dwControlCode,
   LPVOID lpvReserved,
   DWORD dwReserved
);
```

The **SshControl** function sends a control message to the server.

Parameters

hClient

Handle to the client session.

dwControlCode

A numeric control code which specifies the control message which should be sent to the server. This may be one of the following values:

Value	Description
SSH_CONTROL_BREAK	Sends a control message to the server which simulates a break signal on a physical terminal. This is used by some operating systems as an instruction to enter a privileged configuration mode. Note that this is not the same as sending an interrupt character such as Ctrl+C to the server. This control code is ignored for SSH 1.0 sessions.
SSH_CONTROL_NOOP	Sends a control message to the server, but it does not perform any operation. This is typically used by clients to prevent the server from automatically closing a session that has been idle for a long period of time.
SSH_CONTROL_EOF	Sends a control message to the server indicating that the client has finished sending data. Note that this option is normally not used with interactive terminal sessions, and should only be used when required by the server.
SSH_CONTROL_PING	Sends a control message to the server which is used to test whether or not the server is responsive to the client. This is typically used by clients to attempt to detect if the connection to the server is still active.
SSH_CONTROL_REKEY	Sends a control message to the server requesting that the key exchange be performed again. This control code is ignored for SSH 1.0 sessions.

lpvReserved

A reserved parameter which should always be specified as NULL.

dwReserved

A reserved parameter which should always be specified as a value of 0.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshControl** function enables an application to send control messages to the server, which can cause it to take specific actions such as simulate a terminal break or request that the key exchanged be performed again. Some control messages are not supported by the SSH 1.0 protocol, in which case the control message is ignored.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshCancel, SshIsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshCreateSecurityCredentials Function

```
BOOL WINAPI SshCreateSecurityCredentials(
   DWORD dwProtocol,
   DWORD dwOptions,
   LPCTSTR lpszKeyFile,
   LPCTSTR lpszPassword,
   LPVOID lpvReserved,
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **SshCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols.

Value	Description
SECURITY_PROTOCOL_SSH2	Version 2.0 of the protocol will be used when establishing the connection. Currently, this is the only supported protocol option for SSH connections. In older versions of SocketTools, you had the option of selecting either version 1.0 or 2.0; however, version 1.0 is no longer considered secure and is not supported.

dwOptions

This parameter is reserved for future use and should always be a value of zero.

lpszKeyFile

A null-terminated string which specifies the name of a private key file that used when authenticating the client connection. The private key file must be in the standard PEM format defined in RFC 1422. Both the standard RSA private key format and the proprietary OpenSSH format are supported.

lpszPassword

A null-terminated string which specifies the password for the private key file. A value of NULL specifies that no password is required.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **SshDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

This function is only required if you wish to authenticate the client session using a private key file instead of an account password.

The ***lpszKeyFile*** path can use environment variables enclosed in percent symbols, and the path to the

private key file will be normalized. It is recommended you always use an absolute path to the private key file. If you do not include a path, it will use the current working directory for the process. This can produce inconsistent results with multithreaded applications because the current working directory for a process is a global value and it can be changed by any thread at any time.

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **SshConnect** function.

It is safe to call **SshDeleteSecurityCredentials** after the connection has been established. An internal copy of the credentials are created during the connection process and the pointer to the credentials structure allocated by this function are no longer needed.

Example

```
HCLIENT hClient = INVALID_CLIENT;
LPSECURITYCREDENTIALS lpCredentials = NULL;

// Define the security credentials
SshCreateSecurityCredentials(SECURITY_PROTOCOL_SSH2,
                             SSH_OPTION_NONE,
                             _T("%USERPROFILE%\\.ssh\\id_rsa.pem"),
                             NULL,
                             &lpCredentials);

if (lpCredentials == NULL)
{
    // Something went wrong
    return;
}

// Establish a connection with the SSH server on port 22
hClient = SshConnect(lpszHostName,
                     SSH_PORT_DEFAULT,
                     lpszUserName,
                     NULL, // No password, using a private key file
                     SSH_TIMEOUT,
                     SSH_OPTION_COMMAND,
                     NULL,
                     lpCredentials);

// Delete the credentials
SshDeleteSecurityCredentials(&lpCredentials);

if (hClient == INVALID_CLIENT)
{
    DWORD dwError;
    TCHAR szError[128];

    dwError = SshGetLastError();
    if (dwError > 0)
    {
        SshGetErrorString(dwError, szError, 128);
        MessageBox(NULL, szError, _T("Error"), MB_ICONEXCLAMATION);
    }
```

```
    return;
}
```

In this example, the path to the private key file will be expanded to an absolute path because the USERPROFILE environment variable defines the home directory for the current user. The path must resolve to a normal file which that can be read by the current process. If the file does not exist, or it does not specify a PEM formatted file which contains an RSA or OpenSSH private key, the connection will fail and the last error code will be set to `ST_ERROR_INVALID_PRIVATE_KEY`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

SshDeleteSecurityCredentials Function

```
VOID WINAPI SshDeleteSecurityCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **SshDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Remarks

This function releases the memory allocated for the client credentials created by the **SshCreateSecurityCredentials** function. It is safe to call this function immediately after the connection has been established. An internal copy of the credentials are allocated during the connection process and the pointer to the credentials structure is no longer needed.

You should never call this function using a pointer to a credentials structure you have not explicitly allocated using the **SshCreateSecurityCredentials** function. Attempting to do so will corrupt the process heap and in most cases will throw an unhandled exception, causing your application to terminate.

Example

```
HCLIENT hClient = INVALID_CLIENT;
LPSECURITYCREDENTIALS lpCredentials = NULL;

// Define the security credentials using a private key file
SshCreateSecurityCredentials(SECURITY_PROTOCOL_SSH2,
                             SSH_OPTION_NONE,
                             _T("%USERPROFILE%\\.ssh\\id_rsa.pem"),
                             NULL,
                             &lpCredentials);

if (lpCredentials == NULL)
{
    // Something went wrong
    return;
}

// Establish a connection with the SSH server on port 22
hClient = SshConnect(lpszHostName,
                     SSH_PORT_DEFAULT,
                     lpszUserName,
                     NULL, // No password, using a private key file
                     SSH_TIMEOUT,
                     SSH_OPTION_COMMAND,
                     NULL,
                     lpCredentials);
```

```
// Delete the credentials
SshDeleteSecurityCredentials(&lpCredentials);

if (hClient == INVALID_CLIENT)
{
    DWORD dwError;
    TCHAR szError[128];

    dwError = SshGetLastError();
    if (dwError > 0)
    {
        SshGetErrorString(dwError, szError, 128);
        MessageBox(NULL, szError, _T("Error"), MB_ICONEXCLAMATION);
    }

    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

SshDisableEvents Function

```
INT WINAPI SshDisableEvents(
    HCLIENT hClient
);
```

The **SshDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshEnableEvents, SshFreezeEvents, SshRegisterEvent

SshDisableTrace Function

```
BOOL WINAPI SshDisableTrace();
```

The **SshDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

SshDisconnect Function

```
INT WINAPI SshDisconnect(
   HCLIENT hClient
);
```

The **SshDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

SshEnableEvents Function

```
INT WINAPI SshEnableEvents(
   HCLIENT hClient,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **SshEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **SshRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the ***hEventWnd*** parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
SSH_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a

	connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

SshEnableTrace Function

```
BOOL WINAPI SshEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **SshEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

SshEventProc Function

```
VOID CALLBACK SshEventProc(
   HCLIENT hClient,
   UINT nEvent,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **SshEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **SshRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **SshRegisterEvent** function. The **SshEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshExecute Function

```
INT WINAPI SshExecute(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCommandLine,
   UINT nTimeout,
   DWORD dwOptions,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **SshExecute** function executes a command on the server and returns the output in the specified buffer.

Parameters

lpszRemoteHost

A null-terminated string which specifies the name of the server. This may either be a fully-qualified domain name, or an IP address. This parameter cannot be NULL.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 22 should be used.

lpszUserName

A null-terminated string which specifies the user name which will be used to authenticate the client session.

lpszPassword

A null-terminated string which specifies the password which will be used to authenticate the client session.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SSH_OPTION_NONE	No options specified. A standard terminal session will be established with the default terminal type.
SSH_OPTION_KEEPALIVE	This option specifies the library should attempt to maintain an idle client session for long periods of time. This option is only necessary if you expect that the connection will be held open for more than two hours.
SSH_OPTION_NOPTY	This option specifies that a pseudoterminal (PTY) should not be created for the client session. This option is

	automatically set if the SSH_OPTION_COMMAND option has been specified.
SSH_OPTION_NOSHELL	This option specifies that a command shell should not be used when executing a command on the server.
SSH_OPTION_NOAUTHRSA	This option specifies that RSA authentication should not be used with SSH-1 connections. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOPWDNULL	This option specifies the user password cannot be terminated with a null character. This option is ignored with SSH-2 connections and should only be specified if required by the server.
SSH_OPTION_NOREKEY	This option specifies the client should never attempt a repeat key exchange with the server. Some SSH servers do not support rekeying the session, and this can cause the client to become non-responsive or abort the connection after being connected for an hour.
SSH_OPTION_COMPATSID	This compatibility option changes how the session ID is handled during public key authentication with older SSH servers. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.
SSH_OPTION_COMPATHMAC	This compatibility option changes how the HMAC authentication codes are generated. This option should only be specified when connecting to servers that use OpenSSH 2.2.0 or earlier versions.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which specifies additional security-related information required to establish the connection. This parameter may be NULL, in which case default values will be used. Note that the ***dwSize*** member must be initialized to the size of the **SECURITYCREDENTIALS** structure that is being passed to the function.

Return Value

If the function succeeds, the return value is the exit code from the program that was executed on the server. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshExecute** function is used to execute a command on a server, read the output from that command and copy it into a local buffer. This function cannot be used if the connection to the server must be established through a proxy server; if a proxy server must be used, then you should use the **SshConnect** function to establish the connection, and then use either the **SshRead** or **SshReadLine** functions to read the output.

This function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the command output. In this case, the *lpvBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the output when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

When the command output is being read from the server, this function will automatically convert the data to match the end-of-line convention used on the Windows platform. This is useful when executing a command on a UNIX based system where the end-of-line is indicated by a single linefeed, while on Windows it is a carriage-return and linefeed pair. If the output contains embedded nulls or escape sequences, then this conversion will not be performed.

This function will cause the current thread to block until the command completes or a timeout occurs.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Execute a command on the server and return the data into block
// of global memory allocated by the GlobalAlloc function; the handle
// to this memory will be returned in the hgblBuffer parameter
nResult = SshExecute(lpszHostName,
                     SSH_PORT_DEFAULT,
                     lpszUserName,
                     lpszPassword,
                     lpszCommandLine,
                     SSH_TIMEOUT,
                     SSH_OPTION_NONE,
                     &hgblBuffer,
                     &cbBuffer,
                     NULL);

if (nResult != SSH_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

SshFreezeEvents Function

```
INT WINAPI SshFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **SshFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshGetErrorString Function

```
INT WINAPI SshGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **SshGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **SshGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SshGetLastError, SshSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshGetExitCode Function

```
INT WINAPI SshGetExitCode(
   HCLIENT hClient
);
```

The **SshGetExitCode** function returns the exit code for the remote session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the numeric exit code. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

This function should only be called after the command has completed and the **SshRead** function has returned a value of zero. In most cases, an exit code value of zero indicates success, while any other value indicates an error condition.

Note that the actual value is application dependent and is only meaningful in the context of that particular program. A program may choose or use exit codes in a non-standard way, such as having certain non-zero values indicate success.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshGetStatus

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshGetLastError Function

```
DWORD WINAPI SshGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SshSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **SshGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **SshSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SSH_ERROR. Those functions which call **SshSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshGetErrorString, SshSetLastError

SshGetLineMode Function

```
INT WINAPI SshGetLineMode(
   HCLIENT hClient
);
```

The **SshGetLineMode** function returns the current line mode.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the current line mode. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshGetLineMode** function returns an integer value that specifies how end-of-line character sequences are sent to the server. For more information about how newlines are processed by the library and the available options, refer to the **SshSetLineMode** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

SshGetSecurityInformation Function

```
BOOL WINAPI SshGetSecurityInformation(
   HCLIENT hClient,
   LPSECURITYINFO lpSecurityInfo
);
```

The **SshGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The ***dwSize*** member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the ***dwProtocol*** structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Get the server fingerprint
SECURITYINFO securityInfo;

securityInfo.dwSize = sizeof(SECURITYINFO);
if (SshGetSecurityInformation(hClient, &securityInfo))
{
    if (securityInfo.lpszFingerprint != NULL)
    {
        TCHAR szMessage[256];
        wsprintf(szMessage, _T("The fingerprint is %s",
securityInfo.lpszFingerprint);
        MessageBox(NULL, szMessage, "Connection", MB_OK);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SshConnect, SshDisconnect, SECURITYINFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshGetStatus Function

```
INT WINAPI SshGetStatus(
   HCLIENT hClient
);
```

The **SshGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
SSH_STATUS_IDLE	The client is current idle and not sending or receiving data.
SSH_STATUS_CONNECT	The client is establishing a connection with the server.
SSH_STATUS_AUTHENTICATE	The client is authenticating the session with the server.
4	SSH_STATUS_READ	The client is reading data from the server.
SSH_STATUS_WRITE	The client is writing data to the server.
SSH_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

SshGetTimeout Function

```
INT WINAPI SshGetTimeout(
   HCLIENT hClient
);
```

The **SshGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshSetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshInitialize Function

```
BOOL WINAPI SshInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **SshInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **SshInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **SshUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **SshInitialize** or **SshUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

SshIsBlocking Function

```
BOOL WINAPI SshIsBlocking(
   HCLIENT hClient
);
```

The **SshIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **SshIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action such as warning the user that they must wait for the operation to complete.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshCancel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshIsConnected Function

```
BOOL WINAPI SshIsConnected(
   HCLIENT hClient
);
```

The **SshIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

SshIsReadable Function

```
BOOL WINAPI SshIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **SshIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations on different versions of Windows, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshIsWritable Function

```
BOOL WINAPI SshIsWritable(
   HCLIENT hClient,
   INT nTimeout
);
```

The **SshIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshPeek Function

```
INT WINAPI SshPeek(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **SshPeek** function reads the specified number of bytes from the server and copies them into the buffer, but it does not remove the data from the internal receive buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that there is no data available to be read at that time. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The **SshPeek** function can be used to examine the data that is available to be read from the internal receive buffer. If there is no data in the receive buffer at that time, a value of zero is returned. It should be noted that this differs from the **SshRead** function, where a return value of zero indicates that there is no more data available to be read and the connection has been closed. The **SshPeek** function will never cause the client to block, and so may be safely used with asynchronous connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshIsReadable, SshRead, SshSearch, SshWrite

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshRead Function

```
INT WINAPI SshRead(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **SshRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

When **SshRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshIsReadable, SshPeek, SshReadLine, SshSearch, SshWrite, SshWriteLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshReadLine Function

```
BOOL WINAPI SshReadLine(
   HCLIENT hClient,
   LPTSTR lpszBuffer,
   LPINT lpnLength
);
```

The **SshReadLine** function reads up to a line of data and returns it in a string buffer.

Parameters

hClient

Handle to the client session.

lpszBuffer

Pointer to the string buffer that will contain the data when the function returns. The string will be terminated with a null byte, and will not contain the end-of-line characters.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the function returns, its value will updated with the actual length of the string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

The **SshReadLine** function reads data sent by the server and copies it into a specified string buffer. Unlike the **SshRead** function which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **SshReadLine**. The function should only be used to read text, never binary data. In particular, the function will discard nulls, linefeed and carriage return control characters. The Unicode version of this function will return a Unicode string, however this function does not support reading raw Unicode data from the server. The data is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This function will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the connection. If this function is called with asynchronous events enabled, it will automatically switch the client into a blocking mode, read the data and then restore the client to asynchronous operation. If another client operation is attempted while **SshReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this function only be used with blocking (synchronous) client connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **SshRead** and **SshReadLine** function calls can be intermixed, however be aware that **SshRead** will consume any data that has already been buffered by the **SshReadLine** function and this may have unexpected results.

Unlike the **SshRead** function, it is possible for data to be returned in the buffer even if the return value is zero. Applications should also check the value of the *lpnLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the function is waiting for more data to arrive, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Example

```
TCHAR szBuffer[MAXBUFLEN];
INT nLength;
BOOL bResult;

do
{
    nLength = sizeof(szBuffer);
    bResult = SshReadLine(hSocket, szBuffer, &nLength);

    if (nLength > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = SshGetLastError();
if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The server has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

SshRegisterEvent Function

```
INT WINAPI SshRegisterEvent(
   HCLIENT hClient,
   UINT nEvent,
   SSHEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **SshRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
SSH_EVENT_CONNECT	The connection to the server has completed.
SSH_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SSH_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SSH_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
SSH_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SshEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86

(32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **SshRegisterEvent** function associates a callback function with a specific event. The event handler is an **SshEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

SshSearch Function

```
BOOL WINAPI SshSearch(
   HCLIENT hClient,
   LPCTSTR lpszString,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwReserved
);
```

The **SshSearch** function searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

hClient

Handle to the client session.

lpszString

A null-terminated string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpvBuffer

A buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the function returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the ***lpvBuffer*** parameter is NULL, this parameter should also be NULL.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds and the character sequences was found in the data stream, the return value is non-zero. If the function fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

The **SshSearch** function searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server. The function collects the output from the server and stores it in the buffer specified by the ***lpvBuffer*** parameter. When the function returns, the buffer will contain everything sent by the server up to and including the matching string.

The ***lpvBuffer*** parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the output when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Example

```
LPCTSTR lpszCommand = _T("/bin/ls -l\r\n");
LPCTSTR lpszPrompt = _T("$ ");
HGLOBAL hgblOutput = NULL;
DWORD cbOutput = 0;
BOOL bResult;

// Search for a command prompt issued by the server

bResult = SshSearch(hClient,
                    lpszPrompt,
                    NULL,
                    NULL,
                    0);

// If the shell prompt was found, issue the command
// and capture the output into the hgblBuffer global
// memory buffer; the cbBuffer variable will contain
// the actual number of bytes in the buffer when the
// function returns

if (bResult)
{
    SshWrite(hClient,
            (LPBYTE)lpszCommand,
            lstrlen(lpszCommand));

    bResult = SshSearch(hClient,
                        lpszPrompt,
                        &hgblOutput,
                        &cbOutput,
                        0);
}

// Write the contents of the output buffer to the
// standard output stream

if (bResult)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    if (lpBuffer)
        fwrite(lpBuffer, 1, cbBuffer, stdout);

    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

SshSetLastError Function

```
VOID WINAPI SshSetLastError(
   DWORD dwErrorCode
);
```

The **SshSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SSH_ERROR. Those functions which call **SshSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **SshGetLastError** function. The use of **SshGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshGetErrorString, SshGetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshSetLineMode Function

```
INT WINAPI SshSetLineMode(
   HCLIENT hClient,
   INT nLineMode
);
```

The **SshSetLineMode** function changes the current line mode for the client session.

Parameters

hClient

Handle to the client session.

nLineMode

An integer value which specifies how the newlines are sent by the library. It must be one of the following values:

Value	Description
SSH_NEWLINE_DEFAULT	There are no changes to how data is sent to the server. Any carriage return or linefeed characters that are sent using the **SshWrite** function will be sent as-is. The **SshWriteLine** function will terminate each line of text with a carriage return and linefeed (CRLF) sequence. This is the default line mode that is set when a new connection is established.
SSH_NEWLINE_CR	A carriage return is used as the end-of-line character. Any data sent using the **SshWrite** function that contains only a linefeed (LF) character or a carriage return and linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a carriage return (CR) character. The **SshWriteLine** function will terminate each line of text with a single carriage return character.
SSH_NEWLINE_LF	A linefeed is used as the end-of-line character. Any data sent using the **SshWrite** function that contains only a carriage return (CR) character or a carriage return an linefeed (CRLF) sequence to indicate the end-of-line will be replaced by a linefeed (LF) character. The **SshWriteLine** function will terminate each line of text with a single linefeed character.
SSH_NEWLINE_CRLF	A carriage return and linefeed (CRLF) character sequence is used to indicate the end-of-line. Any data sent using the **SshWrite** function that contains only a carriage return (CR) or linefeed (LF) will be replaced by a carriage return and linefeed. The **SshWriteLine** function will terminate each line of text with a carriage return and linefeed sequence.

Return Value

If the function succeeds, the return value is the previous line mode for the client session. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

When a connection is initially established with the server, it determines what characters are used to

indicate the end-of-line and how they are displayed. On UNIX based systems, this is controlled by the settings for the pseudo-terminal that is allocated for the client session, and can be changed using the **stty** command. In most cases, the client line mode can be left at the default. However, in some cases you may need to change the line mode, particularly if you intend to send data from a Windows text file or copied from the clipboard.

Windows uses a carriage return and linefeed (CRLF) sequence to indicate the end-of-line and a UNIX based server may interpret that as multiple newlines. To prevent this, use the **SshSetLineMode** function to change the current line mode to **SSH_NEWLINE_CR** and the CRLF sequence in the text will be replaced by a single carriage return.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

SshSetTimeout Function

```
INT WINAPI SshSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **SshSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshGetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshUninitialize Function

```
VOID WINAPI SshUninitialize();
```

The **SshUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **SshInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **SshUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **SshUninitialize** for every successful call to **SshInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

See Also

SshWrite Function

```
INT WINAPI SshWrite(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **SshWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is SSH_ERROR. To get extended error information, call **SshGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the SSH_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SshWriteLine Function

```
BOOL WINAPI SshWriteLine(
   HCLIENT hClient,
   LPCTSTR lpszBuffer,
   LPINT lpnLength
);
```

The **SshWriteLine** function sends a line of text to the server, terminated by a carriage-return and linefeed.

Parameters

hClient

Handle to the client session.

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the server. All characters up to, but not including, the terminating null character will be written to the server. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the server.

lpnLength

A pointer to an integer value which will contain the number of characters written to the server, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SshGetLastError**.

Remarks

The **SshWriteLine** function writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **SshWrite** function which writes arbitrary bytes of data to the server, this function is specifically designed to write a single line of text data from a string.

If the ***lpszBuffer*** string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the ***lpnLength*** parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **SshWriteLine**. The function should only be used to send text, never binary data. In particular, the function will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this function will accept a Unicode string, however this function does not support sending raw Unicode data to the server. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written as a stream of bytes.

This function will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this function is called with asynchronous events enabled, it will automatically switch the client into a blocking mode, send the data and then

restore the client to asynchronous operation. If another network operation is attempted while **SshWriteLine** is blocked sending data to the server, an error will occur. It is recommended that this function only be used with blocking (synchronous) connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **SshWrite** and **SshWriteLine** function calls can be safely intermixed.

Unlike the **SshWrite** function, it is possible for data to have been written to the server if the return value is zero. For example, if a timeout occurs while the function is waiting to send more data to the server, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the ***lpnLength*** argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstshv12.lib
Unicode: Implemented as Unicode and ANSI versions

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and fingerprint.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the protocol that was selected to establish the secure connection. One of the following values will be returned:

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol was selected.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection. One of the following values will be returned:

Value	Description
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.
SECURITY_CIPHER_DES	The DES (Data Encryption Standard) block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.

SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher (also known as the Rijndael cipher) is a fixed block size cipher which use a key size of 128, 192 or 256 bits. This cipher is supported on Windows XP SP3 and later versions of the operating system.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected. One of the following values will be returned:

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected. One of the following values will be returned:

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography. This key exchange algorithm is only supported on Windows XP SP3 and later versions of the operating system.

dwCertStatus

This member is not used with SSH connections and will have a value of zero.

stCertIssued

This member is not used with SSH connections and will have a value of zero.

stCertExpires

This member is not used with SSH connections and will have a value of zero.

lpszCertIssuer

This member is not used with SSH connections and will have a value of zero.

lpszCertSubject

This member is not used with SSH connections and will have a value of zero.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and cannot be used when establishing a connection with the server. Although SSH protocol version 1.0 is defined in the header file, it is important to note that it is considered insecure and is no longer supported.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A value which specifies which security protocols are supported:

Value	Description
SECURITY_PROTOCOL_SSH2	Version 2.0 of the protocol will be used when establishing the connection. Currently, this is the only supported protocol option for SSH connections. In older versions of SocketTools, you had the option of selecting either version 1.0 or 2.0; however, version 1.0 is no longer considered secure and is not supported.

dwOptions

This structure member is reserved for use with TLS connections and should always be initialized to zero.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating a server certificate. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if a private key file has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. This member should always be initialized as a NULL pointer for connections using the SSH protocol.

lpszKeyFile

A null-terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used with the SSH protocol. If the member is NULL, then no private key is used. The private key file must be in the standard PEM format defined in RFC 1422. Both the standard RSA private key format and the proprietary OpenSSH format are supported.

Remarks

This is a common structure used by several SocketTools APIs when establishing a secure connection. You should always initialize all unused members to zero or NULL and the ***dwSize*** member must be initialized to the size of the structure in bytes. In C/C++ this is done using the **sizeof** operator and other languages typically offer similar methods to determine the size of a user-defined structure.

You only need to create this structure when authenticating the client session using a private key file instead of an account password. If the private key was protected with a password, the ***lpszPassword*** member must be assigned to that value or the connection request will fail with an authentication error.

The ***lpszKeyFile*** path can use environment variables enclosed in percent symbols, and the path to the private key file will be normalized. It is recommended you always use an absolute path to the private key file. If you do not include a path, it will use the current working directory for the process. This can produce inconsistent results with multithreaded applications because the current working directory for a process is a global value and it can be changed by any thread at any time.

Example

```
HCLIENT hClient;
SECURITYCREDENTIALS myCredentials;

// Initialize the SECURITYCREDENTIALS structure and specify the
// path to the private key file for the current user
ZeroMemory(&myCredentials, sizeof(myCredentials));
myCredentials.dwSize = sizeof(myCredentials);
myCredentials.lpszKeyFile = _T("%USERPROFILE%\\.ssh\\id_rsa.pem");

// Establish a connection with the SSH server on port 22
hClient = SshConnect(lpszHostName,
                     SSH_PORT_DEFAULT,
                     lpszUserName,
                     NULL, // No password, using a private key file
                     SSH_TIMEOUT,
                     SSH_OPTION_COMMAND,
                     NULL,
                     &myCredentials);
```

```
if (hClient == INVALID_CLIENT)
{
    DWORD dwError;
    TCHAR szError[128];

    dwError = SshGetLastError();
    if (dwError > 0)
    {
        SshGetErrorString(dwError, szError, 128);
        MessageBox(NULL, szError, _T("Error"), MB_ICONEXCLAMATION);
    }

    return;
}
```

In this example, the path to the private key file will be expanded to an absolute path because the USERPROFILE environment variable defines the home directory for the current user. The path must resolve to a normal file which that can be read by the current process. If the file does not exist, or it does not specify a PEM formatted file which contains an RSA or OpenSSH private key, the connection will fail and the last error code will be set to `ST_ERROR_INVALID_PRIVATE_KEY`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SSHOPTIONDATA

The **SSHOPTIONDATA** structure specifies additional option information for the client session.

```
typedef struct _SSHOPTIONDATA
{
    DWORD dwSize;
    DWORD dwReserved;
    UINT  nProxyType;
    UINT  nProxyPort;
    TCHAR szProxyHost[128];
    TCHAR szProxyUser[128];
    TCHAR szProxyPassword[128];
    UINT  nTermCols;
    UINT  nTermRows;
    TCHAR szTermName[32];
    TCHAR szCommandLine[512];
} SSHOPTIONDATA, *LPSSHOPTIONDATA;
```

Members

dwSize

An unsigned integer value which specifies the size of the SSHOPTIONDATA structure. This member must be initialized prior to passing the structure to the **SshAsyncConnect** or **SshConnect** functions.

dwReserved

An unsigned integer value that is reserved for internal use, and should always be initialized to a value of zero.

nProxyType

An unsigned integer value that specifies the type of proxy that the client should connect through. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified. Possible values are:

Value	Description
SSH_PROXY_NONE	No proxy server should be used when establishing the connection.
SSH_PROXY_HTTP	The connection should be established on port 80 using HTTP. An alternate port number can be specified by setting the ***nProxyPort*** structure member to the desired value.
SSH_PROXY_TELNET	The connection should be established on port 23 using TELNET. An alternate port number can be specified by setting the ***nProxyPort*** structure member to the desired value.

nProxyPort

An unsigned integer value that specifies the port number which should be used to establish the proxy connection. A value of zero specifies that the default port number appropriate for the selected protocol should be used. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyHost

A null-terminated string which specifies the host name or IP address of the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyUser

A null-terminated string which specifies the user name which is used to authenticate the connection through the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

szProxyPassword

A null-terminated string which specifies the password which is used to authenticate the connection through the proxy server. This structure member is only used if the option SSH_OPTION_PROXYSERVER has been specified.

nTermCols

An unsigned integer value which specifies the number of columns for the virtual terminal allocated for the client session. The default number of columns is 80. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

nTermRows

An unsigned integer value which specifies the number of rows for the virtual terminal allocated for the client session. The default number of rows is 25. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

szTermName

A null-terminated string which specifies the name of the terminal emulation type. On UNIX based systems, this name typically corresponds to an entry in the terminal capability database (either termcap or terminfo). If the name is not specified, then the default name terminal name of "unknown" will be used. This structure member is only used if the option SSH_OPTION_TERMINAL has been specified.

szCommandLine

A null-terminated string which specifies the command that should be executed on the server. The output from the command is returned to the client, and the session is terminated. This structure member is only used if the option SSH_OPTION_COMMAND has been specified.

Simple Mail Transfer Protocol Library

Submit email messages for delivery to one or more recipients.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSMTPV12.DLL
Version	12.0.3024.1286
LibID	7EFD241B-CEB0-4667-8944-4231A1B46064
Import Library	CSMTPV12.LIB
Dependencies	None
Standards	RFC 821, RFC 1425, RFC 1869, RFC 2821

Overview

The Simple Mail Transfer Protocol (SMTP) enables applications to deliver email messages to one or more recipients. The library provides an API for addressing and delivering messages, and extended features such as user authentication and delivery status notification. Unlike Microsoft's Messaging API (MAPI) or Collaboration Data Objects (CDO), there is no requirement to have certain third-party email applications installed or specific types of servers installed on the local system. The library can be used to deliver mail through a wide variety of systems, from standard UNIX based mail servers to Windows systems running Microsoft Exchange.

Using this library, messages can be delivered directly to the recipient, or they can be routed through a relay server, such as an Internet service provider's mail system. The Mail Message library can be combined with this library to provide a flexible interface for composing and delivering messages.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on

ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Simple Mail Transfer Protocol Functions

Function	Description
SmtpAddRecipient	Add an address to the recipient list
SmtpAppendMessage	Append contents of specified file to the current message
SmtpAsyncConnect	Establish an asynchronous connection with a server
SmtpAsyncSendMessage	Send message to the specified recipient
SmtpAsyncSubmitMessage	Compose and submit a message for delivery to the specified mail server
SmtpAttachThread	Attach the specified client handle to another thread
SmtpAuthenticate	Authenticate the client session with a user name and password
SmtpCancel	Cancel the current blocking operation
SmtpCloseMessage	Close the message being composed and submit for delivery
SmtpCommand	Send a command to the server
SmtpConnect	Establish a connection with a server
SmtpCreateMessage	Create a new message
SmtpCreateSecurityCredentials	Allocate a structure to establish client security credentials
SmtpDeleteSecurityCredentials	Delete the specified client security credentials
SmtpDisableEvents	Disable all event notification, including event callbacks
SmtpDisableTrace	Disable logging of network function calls
SmtpDisconnect	Disconnect from the current server
SmtpEnableEvents	Enable event handling by the library
SmtpEnableTrace	Enable logging of network function calls to a file
SmtpEnumTasks	Return a list of asynchronous tasks
SmtpEventProc	Process events generated by the client
SmtpExpandAddress	Expand the specified address
SmtpFreezeEvents	Suspend and resume event handling by the client
SmtpGetCurrentDate	Return the current date and time
SmtpGetDeliveryOptions	Return the delivery options for the current session
SmtpGetErrorString	Return a description for the specified error code
SmtpGetExtendedOptions	Return the extended options supported by the server
SmtpGetLastError	Return the last error code
SmtpGetResultCode	Return the result code from the previous command
SmtpGetResultString	Return the result string from the previous command
SmtpGetSecurityInformation	Return security information about the current client connection

SmtpGetStatus	Return the current status of the client
SmtpGetTaskError	Return the last error code for the specified asynchronous task
SmtpGetTaskId	Return the unique task identifier associated with the specified client session
SmtpGetTimeout	Return the number of seconds until an operation times out
SmtpGetTransferStatus	Return data transfer statistics
SmtpInitialize	Initialize the library and validates the specified license key at runtime
SmtpIsBlocking	Determine if the client is blocked, waiting for information
SmtpIsConnected	Determine if the client is connected to the server
SmtpIsReadable	Determine if data can be read from the server
SmtpIsWritable	Determine if data can be written to the server
SmtpRegisterEvent	Register an event handler for the specified event
SmtpReset	Reset the client and return to a command state
SmtpSendMessage	Send message to the specified recipient
SmtpSetDeliveryOptions	Set the delivery options for the current session
SmtpSetLastError	Set the last error code
SmtpSetTimeout	Set the number of seconds until an operation times out
SmtpSubmitMessage	Compose and submit a message for delivery to the specified mail server
SmtpSubmitMessageEx	Compose and submit a message for delivery with additional options
SmtpTaskAbort	Abort the specified asynchronous task
SmtpTaskDone	Determine if an asynchronous task has completed
SmtpTaskResume	Resume execution of an asynchronous task
SmtpTaskSuspend	Suspend execution of an asynchronous task
SmtpTaskWait	Wait for an asynchronous task to complete
SmtpUninitialize	Terminate use of the library by the application
SmtpVerifyAddress	Verify that the specified address is valid
SmtpWrite	Write data to the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpAddRecipient Function

```
INT WINAPI SmtpAddRecipient(
   HCLIENT hClient,
   LPCTSTR lpszAddress
);
```

The **SmtpAddRecipient** function adds the specified address to the recipient list for the current message. This function should be called once for each recipient.

Parameters

hClient

Handle to the client session.

lpszAddress

Points to a string which specifies the address to be added to the recipient list.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SmtpCloseMessage, SmtpCreateMessage, SmtpExpandAddress, SmtpVerifyAddress

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpAppendMessage Function

```
INT WINAPI SmtpAppendMessage(
   HCLIENT hClient,
   LPVOID lpvMessage,
   DWORD dwMessageSize,
   DWORD dwOptions
);
```

The **SmtpAppendMessage** function writes the contents of a specified file or buffer to the data stream, appending it to the current message contents.

Parameters

hClient

Handle to the client session.

lpvMessage

Pointer to a buffer which contains the message data to be appended, or a pointer to the name of the file which contains the data to be written to the data stream. The use of this parameter depends on the value of the ***dwOptions*** parameter.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

dwOptions

Specifies the source of the message data that will be written to the data stream; it may be one of the following values:

Value	Description
SMTP_MESSAGE_MEMORY	The ***lpvMessage*** parameter specifies a pointer to an array of characters. If the value of ***dwMessageSize*** is zero, then it is assumed to be a pointer to a string. If the Unicode version of this function is called and the ***dwMessageSize*** parameter is zero, the ***lpvMessage*** parameter must point to a wide string terminated with a null character. The string will be automatically converted to UTF-8 when the contents are appended to the message. In all other cases, the ***lpvMessage*** parameter is treated as a pointer to a byte array which contains the message contents and the ***dwMessageSize*** parameter specifies the number of bytes in the array.
SMTP_MESSAGE_HGLOBAL	The ***lpvMessage*** parameter specifies an HGLOBAL which contains the data to be written to the data stream. If the value of the ***dwMessageSize*** parameter is zero, then the data is assumed to be null-terminated. If the Unicode version of this function is called, the HGLOBAL handle should point to a buffer which contains a UTF-8 encoded byte array.
SMTP_MESSAGE_FILE	The ***lpvMessage*** parameter specifies a pointer to a string which contains the name of a file. The file is opened and the contents of the file are written to the data stream. The

	value of the *dwMessageSize* parameter is ignored when this option is specified.
SMTP_MESSAGE_CLIPBOARD	The *lpvMessage* and *dwMessageSize* parameters are ignored. The current contents of the clipboard are written to the data stream.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpAppendMessage** function is used to append the contents of a memory buffer, file or the system clipboard to the current message that is being composed for delivery. To send a complete RFC 822 formatted message, refer to the **SmtpSendMessage** function.

This function will cause the current thread to block until the complete message has been written, a timeout occurs or the operation is canceled. During the transfer, the SMTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **SmtpEnableEvents**, or by registering a callback function using the **SmtpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **SmtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SmtpCloseMessage, SmtpCreateMessage, SmtpSendMessage

SmtpAsyncConnect Function

```
HCLIENT WINAPI SmtpAsyncConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPCTSTR lpszLocalName,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **SmtpAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **SmtpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For secure connections, the default port number is 465. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used and the client will not attempt to use extended (ESMTP) features of the protocol. Note that if the mail server requires authentication, the SMTP_OPTION_EXTENDED option must be specified.
SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as

	authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if the connection is established on port 587 because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option is the same as specifying SMTP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server using the STARTTLS command. Note that the server must support secure connections using the TLS protocol.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
SMTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
SMTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has

	been specified.
SMTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpszLocalName

A null-terminated string which specifies the domain name of the local host. This parameter can be NULL or point to an empty string, in which case the local domain name is determined automatically from the system configuration. This parameter should be used if the mail server only accepts messages from a client that identifies itself using a specific domain name.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which is used to establish the client credentials for a secure connection to the server. The function **SmtpCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur. If this parameter is NULL, a blocking connection is established with the server.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **SmtpGetLastError**.

Remarks

The ***lpszLocalName*** argument should only specify a domain name if it is absolutely necessary. In most cases, it is preferable to pass this parameter as NULL or an empty string and allow the library to automatically determine the correct domain name to use. Providing an invalid domain name may cause the mail server to reject the connection.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
SMTP_EVENT_CONNECT	The connection to the server has completed. The high word of the lParam parameter should be checked, since this notification message will be posted if an error has occurred.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the client. No additional messages will be

	posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
SMTP_EVENT_CANCEL	The client has canceled the current operation.
SMTP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the lParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
SMTP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

To cancel asynchronous notification and return the client to a blocking mode, use the **SmtpDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **SmtpAttachThread** function.

Specifying the SMTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpAsyncSendMessage Function

```
UINT WINAPI SmtpAsyncSendMessage(
   HCLIENT hClient,
   LPCTSTR lpszFrom,
   LPCTSTR lpszRecipient,
   LPVOID lpvMessage,
   DWORD dwMessageSize,
   DWORD dwOptions,
   SMTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Send the contents of a file or memory buffer to the specified recipients.

Parameters

hClient

Handle to the client session.

lpszFrom

Pointer to a string which specifies the email address of the sender.

lpszRecipient

Pointer to a string which specifies the recipient of the message. Multiple recipients may be specified by separating each address with a comma.

lpvMessage

Pointer to a buffer which contains the message to be delivered, or a pointer to the name of the file which contains the data to be written to the data stream. The use of this parameter depends on the value of the ***dwOptions*** parameter.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

dwOptions

Specifies the source of the message data that will be written to the data stream; it may be one of the following values:

Value	Description
SMTP_MESSAGE_MEMORY	The ***lpvMessage*** parameter specifies a pointer to an array of characters. If the value of ***dwMessageSize*** is zero, then it is assumed to be a pointer to a string.
SMTP_MESSAGE_HGLOBAL	The ***lpvMessage*** parameter specifies an HGLOBAL which contains the data to be written to the data stream. If the value of the ***dwMessageSize*** parameter is zero, then the data is assumed to be null-terminated.
SMTP_MESSAGE_FILE	The ***lpvMessage*** parameter specifies a pointer to a string which contains the name of a file. The file is opened and the contents of the file are written to the data stream. The value of the ***dwMessageSize*** parameter is ignored when this option is specified.
SMTP_MESSAGE_CLIPBOARD	The ***lpvMessage*** and ***dwMessageSize*** parameters are

	ignored. The current contents of the clipboard are written to the data stream.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SmtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpAsyncSendMessage** function is used to send the contents of a memory buffer, file or the system clipboard to the specified recipients. This function is similar to the **SmtpSendMessage** function, however it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the message is being submitted to mail server for delivery.

Because this function works asynchronously, it is important that the memory allocated for the message is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, ensure that your code does not return from the function while the message is being submitted. This can be achieved by calling the **SmtpTaskWait** function or periodically calling the **SmtpTaskDone** function to determine if the background task has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpvMessage* parameter on the heap and free that memory after the task has completed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the SMTP_EVENT_CONNECT event after the connection has been established, and the SMTP_EVENT_DISCONNECT event after the message has been submitted. This enables your application to know when the message is being submitted to the mail server, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SmtpAsyncSubmitMessage, SmtpSendMessage, SmtpSubmitMessage, SmtpTaskWait

SmtpAsyncSubmitMessage Function

```
UINT WINAPI SmtpAsyncSubmitMessage(
   LPSMTPSERVER lpServer,
   LPSMTPMESSAGE lpMessage,
   SMTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **SmtpSubmitMessage** function composes and submits a message for delivery to the specified mail server.

Parameters

lpServer

A pointer to an **SMTPSERVER** structure that contains information about the mail server that the message will be submitted to for delivery. This parameter cannot be NULL and the structure members must be properly initialized prior to calling this function.

lpMessage

A pointer to an **SMTPMESSAGE** structure that contains information about the message, including the sender, recipients and the body of the message. This parameter cannot be NULL and the structure members must be property initialized prior to calling this function.

lpEventProc

The procedure-instance address of an application defined callback function. For more information about event handling and the callback function, see the description of the **SmtpEventProc** callback function. If this parameter is NULL, event notification is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the *lpEventProc* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpAsyncSubmitMessage** function provides a high-level interface that enables an application to send an email message with a single function call. This function is similar to the **SmtpSubmitMessage** function; however, it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the message is being submitted to the mail server.

The **SMTPSERVER** and **SMTPMESSAGE** structures are used to provide the function with information about the mail server that will accept the message and the contents of the message itself. Note that this function does not require a client session handle, and therefore it is not required that you call the **SmtpConnect** function prior to calling this function.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the SMTP_EVENT_CONNECT event after the connection has been established, and the SMTP_EVENT_DISCONNECT event after the message has been submitted. This enables your application to know when the message is being submitted to the mail server, and immediately before

the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

Example

```
SMTPSERVER mailServer;
ZeroMemory(&mailServer, sizeof(mailServer));
mailServer.lpszHostName = _T("smtp.gmail.com");
mailServer.nHostPort = SMTP_PORT_SUBMIT;
mailServer.lpszUserName = m_strSender;
mailServer.lpszPassword = m_strPassword;
mailServer.dwOptions = SMTP_OPTION_SECURE;

SMTPMESSAGE mailMessage;
ZeroMemory(&mailMessage, sizeof(mailMessage));
mailMessage.lpszFrom = m_strSender;
mailMessage.lpszTo = m_strRecipients;
mailMessage.lpszSubject = m_strSubject;
mailMessage.lpszText = m_strMessage;

UINT nTaskId = SmtpAsyncSubmitMessage(&mailServer, &mailMessage, NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the message to be submitted
    SmtpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);

    if (dwError == NO_ERROR)
        _tprintf(_T("SmtpAsyncSubmitMessage was successful\n"));
}
else
{
    DWORD dwError = SmtpGetLastError();
    _tprintf(_T("SmtpSubmitMessage failed with error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

SmtpAttachThread Function

```
DWORD WINAPI SmtpAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **SmtpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **SmtpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **SmtpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **SmtpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **SmtpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

SmtpAuthenticate Function

```
INT WINAPI SmtpAuthenticate(
   HCLIENT hClient,
   UINT nAuthType,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

The **SmtpAuthenticate** function provides client authentication information to the server.

Parameters

hClient

The handle to the client session.

nAuthType

An integer value which specifies which method the library should use to authenticate the client session. This parameter should be set to one of the following values:

Value	Description
SMTP_AUTH_LOGIN	The client will authenticate using the AUTH LOGIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. This is the default method accepted by most mail servers and is the preferred authentication type for most clients.
SMTP_AUTH_PLAIN	The client will authenticate using the AUTH PLAIN command. This encodes the username and password, however the credentials are not encrypted and it is recommended you use a secure connection. The server must support the PLAIN Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4616.
SMTP_AUTH_XOAUTH2	The client will authenticate using the AUTH XOAUTH2 command. This authentication method does not require the user password, instead the ***lpszPassword*** parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.
SMTP_AUTH_BEARER	The client will authenticate using the AUTH OAUTHBEARER command as defined in RFC 7628. This authentication method does not require the user password, instead the ***lpszPassword*** parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.

lpszUserName

A null-terminated string which specifies the account name for the user authorized to send mail through the server.

lpszPassword

A null-terminated string which specifies the password to be used when authenticating the current client session. If you are using the SMTP_AUTH_XOAUTH2 or SMTP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the OAuth 2.0 access token provided by the mail service.

Return Value

If the function succeeds, the return value is the command result code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

To submit a mail message for delivery, virtually all public mail servers require clients to authenticate and will only accept messages from authorized users. In some cases, they may also require the sender email address match the account being used to authenticate the session. It is also typical for most public mail servers to reject authentication attempts over a standard (non-secure) connection. You should always use a secure connection whenever possible.

All authentication methods require the mail server to support the standard service extensions for authentication as specified in the RFC 4954. The server must support the ESMTP protocol extensions and the AUTH command. A user name and password are required for authentication. If you wish to authenticate without a user password, you must use one of the OAuth 2.0 authentication methods.

The default authentication method is SMTP_AUTH_LOGIN and this is accepted by most mail servers. It is common for mail servers to allow the SMTP_AUTH_PLAIN method as well, however it is recommended you explicitly check whether the server supports the desired authentication method by calling the **SmtpGetExtendedOptions** function. If you attempt to use an authentication method which is not supported by the server, this function will fail and the last error code will be set to ST_ERROR_INVALID_AUTHENTICATION_TYPE.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The SMTP_AUTH_XOAUTH2 and SMTP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Example

```
BOOL bExtended = FALSE;
DWORD dwOptions = 0;

// Determine which extended options and authentication methods
// are supported by this server
```

```
bExtended = SmtpGetExtendedOptions(hClient, &dwOptions);

if (bUseBearerToken)
{
    if (bExtended && (dwOptions & SMTP_EXTOPT_XOAUTH2))
    {
        INT nResult = SmtpAuthenticate(hClient, SMTP_AUTH_XOAUTH2, lpszUserName,
lpszBearerToken);

        if (nResult == SMTP_ERROR)
        {
            // An error occurred during authentication; when using an
            // OAuth 2.0 bearer token, this typically means that the token
            // has expired and must be refreshed
            return;
        }
    }
    else
    {
        // The server does not support XOAUTH2
        return;
    }
}
else
{
    if (bExtended && (dwOptions & SMTP_EXTOPT_AUTHLOGIN))
    {
        INT nResult = SmtpAuthenticate(hClient, SMTP_AUTH_LOGIN, lpszUserName,
lpszPassword);

        if (nResult == SMTP_ERROR)
        {
             // An error occurred during authentication
            return;
        }
    }
    else
    {
         // The server does not support AUTH LOGIN
        return;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SmtpCancel Function

```
INT WINAPI SmtpCancel(
   HCLIENT hClient
);
```

The **SmtpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

When the **SmtpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpIsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpCloseMessage Function

```
INT WINAPI SmtpCloseMessage(
    HCLIENT hClient
);
```

The **SmtpCloseMessage** function ends the composition of the current message. The server then queues the message for delivery to each recipient specified by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpCloseMessage** function should be called after all of the message data has been written to the data stream.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

SmtpCommand Function

```
INT WINAPI SmtpCommand(
   HCLIENT hClient,
   LPCTSTR lpszCommand,
   LPCTSTR lpszParameter
);
```

The **SmtpCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the command was successful, the function returns the result code. If the command failed, the function returns SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. Many servers will list supported commands when the HELP command is used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpConnect Function

```
HCLIENT WINAPI SmtpConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPCTSTR lpszLocalName,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **SmtpConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For implicit TLS connections, the default port number is 465.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used and the client will not attempt to use extended (ESMTP) features of the protocol. Note that if the mail server requires authentication, the SMTP_OPTION_EXTENDED option must be specified.
SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not specified, the library will not attempt to use any extended features. This option is automatically enabled if the connection is established on port 587 because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior

	of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. The client will initiate the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
SMTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
SMTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
SMTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpszLocalName

A null-terminated string which specifies the domain name of the local host. This parameter can be NULL or point to an empty string, in which case the local domain name is determined automatically from the system configuration. This parameter should be used if the mail server only accepts messages from a client that identifies itself using a specific domain name.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which is used to establish the client credentials for a secure connection to the server. The function **SmtpCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client

credentials are not required by the server, this parameter can be NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **SmtpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **SmtpConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *lpszLocalName* argument should only point to a specific domain name if it is absolutely necessary. In most cases, it is preferable to pass this parameter as NULL or an empty string and allow the library to automatically determine the correct domain name to use. Providing an invalid domain name may cause the mail server to reject the connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **SmtpAttachThread** function.

Specifying the SMTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpCreateMessage Function

```
INT WINAPI SmtpCreateMessage(
   HCLIENT hClient
   LPCTSTR lpszSender,
   DWORD dwMessageSize,
   DWORD dwReserved
);
```

The **SmtpCreateMessage** function creates a new message for delivery.

Parameters

hClient

Handle to the client session.

lpszSender

A null-terminated string which specifies the email address of the user sending the message. This typically corresponds to the address in the From header of the message, but it is not required that they be the same.

dwMessageSize

An unsigned integer which specifies the size of the message in bytes. If the size of the message is unknown, this value should be zero. This parameter is ignored if the server does not support extended features. If the message size is larger than what the server will accept, this function will fail. Most Internet Service Providers impose a limit on the size of an email message, typically between 5 and 10 megabytes.

dwReserved

A reserved parameter. This value should be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpCreateMessage** function begins the composition of a new message to be submitted to the mail server for delivery. There are several steps that must be followed when dynamically composing a message for delivery:

1. Call the **SmtpCreateMessage** function to begin the message composition. The sender email address should generally be the same address as the one used in the "From" header field in the message.

2. Call the **SmtpAddRecipient** function for each recipient of the message. These addresses are typically specified in the "To" and "Cc" header fields in the message. Additional addresses may also be be provided which are not specified in the email message itself. This is how one or more blind carbon copies of a message is delivered. Most servers have a limit on the total number of recipients that may be specified for a single message. This limit is usually around 100 addresses.

3. Call the **SmtpWrite** function to write the contents of the message to the data stream. The application may also choose to use the **SmtpAppendMessage** function to write out a large amount of message data, or write the contents of a file to the data stream.

4. Call the **SmtpCloseMessage** function to close the message and submit it to the mail server for delivery.

For applications that do not need to dynamically compose the message and already have the message contents stored in a file or memory buffer, the **SmtpSendMessage** function is the preferred method of submitting a message for delivery.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpCreateSecurityCredentials Function

```
BOOL WINAPI SmtpCreateSecurityCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **SmtpCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **SmtpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **SmtpConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
SmtpCreateSecurityCredentials(SECURITY_PROTOCOL_DEFAULT,
                              0,
                              NULL,
                              NULL,
                              lpszCertStore,
                              lpszCertName,
                              NULL,
                              &lpSecCred);

hClient = SmtpConnect(lpszHostName,
                      SMTP_PORT_SECURE,
                      SMTP_TIMEOUT,
                      SMTP_OPTION_EXTENDED | SMTP_OPTION_SECURE,
                      lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpDeleteSecurityCredentials Function

```
VOID WINAPI SmtpDeleteSecurityCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **SmtpDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)
    SmtpDeleteSecurityCredentials(&lpSecCred);

SmtpUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpDisableEvents Function

```
INT WINAPI SmtpDisableEvents(
    HCLIENT hClient
);
```

The **SmtpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpDisableEvents** function is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this function has been called.

This function is automatically called if the client has event notification enabled, and the **SmtpDisconnect** function is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

SmtpDisableTrace Function

```
BOOL WINAPI SmtpDisableTrace();
```

The **SmtpDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SmtpGetLastError**.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpDisconnect Function

```
INT WINAPI SmtpDisconnect(
   HCLIENT hClient
);
```

The **SmtpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

SmtpConnect, SmtpUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpEnableEvents Function

```
INT WINAPI SmtpEnableEvents(
   HCLIENT hClient,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **SmtpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **SmtpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. To avoid conflict with standard Windows messages, this value must be greater than WM_USER (1024) or an error will be returned. If the ***hEventWnd*** parameter is NULL, this value should be WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpEnableEvents** function is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer. The client must create a window message handler, which processes the various events. The ***wParam*** argument will contain the client handle, the low word of the ***lParam*** argument will contain the event identifier, and the high word will contain any error code. If no error has occurred, the high word will have a value of zero. The following events may be generated:

Value	Description
SMTP_EVENT_CONNECT	The connection to the server has completed. The high word of the lParam parameter should be checked, since this notification message will be posted if an error has occurred.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the client. No additional messages will be

	posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
SMTP_EVENT_CANCEL	The client has canceled the current operation.
SMTP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the lParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
SMTP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

It is not required that the client be placed in asynchronous (non-blocking) mode in order to receive event notifications, except for the connect, disconnect, read and write events. To disable event notification, call the **SmtpDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpDisableEvents, SmtpRegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpEnableTrace Function

```
BOOL WINAPI SmtpEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **SmtpEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpEnumTasks Function

```
INT WINAPI SmtpEnumTasks(
   UINT *lpTasks,
   INT nMaxTasks,
   DWORD dwOptions
);
```

Return a list of active, suspended or finished asynchronous tasks.

Parameters

lpTasks

A pointer to an array of unsigned integer values that will contain unique task identifiers when the function returns. If this parameter is NULL, the function will return the number of tasks.

nMaxTasks

An integer value that specifies the maximum number of task identifiers that may be copied into the ***lpTasks*** array. If the ***lpTasks*** parameter is NULL, this value must be zero.

dwOptions

An unsigned integer that specifies the type of asynchronous tasks that may be returned by this function. It may be a combination of the following values:

Value	Description
SMTP_TASK_DEFAULT	The list of asynchronous task IDs should include both active and suspended tasks. This option is the same as specifying both the SMTP_TASK_ACTIVE and SMTP_TASK_SUSPENDED options.
SMTP_TASK_ACTIVE	The list of asynchronous task IDs should include those tasks which are currently active. An active task represents a background connection to a server that is in the process of performing the requested action, such as uploading or downloading a file.
SMTP_TASK_SUSPENDED	The list of asynchronous task IDs should include those tasks which have been suspended. A suspended task represents a background connection that has been established, but the worker thread is not scheduled for execution.
SMTP_TASK_FINISHED	The list of asynchronous task IDs should include those tasks which have completed recently.

Return Value

If the function is successful, the return value is the number of task identifiers copied into the provided array. If there are no tasks which match the requested criteria, the return value is zero. A return value of SMTP_ERROR indicates an error has occurred. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpEnumTasks** function can be used to obtain a list of numeric identifiers that represent the asynchronous tasks that have been started or those that have completed. These task IDs are used by other functions to reference the background worker thread that has been created and obtain status

information for the task. For example, the **SmtpTaskDone** function can be used to determine if a particular task has completed, and the **SmtpTaskWait** function can be used to wait for a task to complete and return an error status code if the background operation failed.

There is an internal limit of 128 asynchronous tasks per process that may be active at any one time. When a task completes, the status information about that task is maintained for period of time after the task has completed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

SmtpEventProc Function

```
VOID CALLBACK SmtpEventProc(
   HCLIENT hClient,
   UINT nEvent,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **SmtpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **SmtpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **SmtpRegisterEvent** function. This callback function is also used by asynchronous tasks to notify the application when the task has started and completed. The **SmtpEventProc** function is a placeholder for the application-defined function name.

If the callback function is invoked by an asynchronous task, it will execute in the context of the worker thread that is managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function for an asynchronous task. Controls should only be modified by the same UI thread that created their window. One common approach to resolve this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpDisableEvents, SmtpEnableEvents, SmtpFreezeEvents, SmtpRegisterEvent

SmtpExpandAddress Function

```
INT WINAPI SmtpExpandAddress(
   HCLIENT hClient,
   LPCTSTR lpszMailingList,
   LPTSTR lpszAddresses,
   INT nMaxLength
);
```

The **SmtpExpandAddress** function expands the specified mailing list, returning the membership of that list.

Parameters

hClient

Handle to the client session.

lpszMailingList

Points to a string which specifies the mailing list that the server should expand into full addresses.

lpszAddresses

Points to a buffer that the expanded addresses will be copied into.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpExpandAddress** function requests that the server expand the specified email address. Typically this is used to expand aliases which refer to a mailing list, returning all of the members of that list. A server may not support this command, or may restrict its usage. An application should not depend on the ability to expand addresses.

This function cannot be called while a mail message is being composed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SmtpFreezeEvents Function

```
INT WINAPI SmtpFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **SmtpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four events of the same type occur, once event handling is resumed only one of those events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpGetCurrentDate Function

```
INT WINAPI SmtpGetCurrentDate(
   LPTSTR lpszDateString,
   INT nMaxLength
);
```

The **SmtpGetCurrentDate** function copies the current date and time to the specified buffer in a format that is commonly used in mail messages. This date format should be used in all date-related fields in the message header.

Parameters

lpszDateString

Pointer to a string buffer that will contain the current date and time when the function returns.

nMaxLength

The maximum number of characters that can be copied into the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null-terminator. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The date value that is returned is adjusted for the local timezone.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpGetDeliveryOptions Function

```
BOOL WINAPI SmtpGetDeliveryOptions(
    HCLIENT hClient,
    LPDWORD lpdwOptions
);
```

The **SmtpGetDeliveryOptions** function returns the delivery status notification options for the current session.

Parameters

hClient

Handle to the client session.

lpdwOptions

Address of a variable that will be set to the current delivery options. This bitmask is created by combining one or more of the following values with a bitwise Or operator:

Value	Description
SMTP_NOTIFY_NEVER	Never return information about the success or failure of the message delivery process.
SMTP_NOTIFY_SUCCESS	Return a message to the sender if the message has been successfully delivered to the recipient's mail server.
SMTP_NOTIFY_FAILURE	Return a message to the sender if the message could not be delivered to the recipient's mail server.
SMTP_NOTIFY_DELAY	Return a message to the sender if delivery of the message was delayed.
SMTP_RETURN_HEADERS	Return only the message headers to the sender.
SMTP_RETURN_MESSAGE	Return the complete message headers and body to the sender.

Return Value

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetDeliveryOptions** function returns the current delivery options for the client session. Note that delivery options are only available on those mail servers which support delivery status notification (DSN) using the extended SMTP protocol. The client must connect specifying SMTP_OPTION_EXTENDED in order to use extended server options.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpGetErrorString Function

```
INT WINAPI SmtpGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **SmtpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **SmtpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description should be returned. If this value is zero, then the description of the last error will be returned. If the last error code is zero, indicating no error, then this function will return zero.

lpszDescription

The buffer that will contain a description of the specified error code. It is recommended that this buffer be at least 128 characters in length. If a NULL pointer is specified, then no message will be returned but the function will return the length of the error string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SmtpGetExtendedOptions Function

```
BOOL WINAPI SmtpGetExtendedOptions(
    HCLIENT hClient,
    LPDWORD lpdwOptions
);
```

The **SmtpGetExtendedOptions** function returns the extended server options for the current session.

Parameters

hClient

Handle to the client session.

lpdwOptions

Address of a variable that will be set to the current server options. This bitmask is created by combining one or more of the following values with a bitwise Or operator:

Value	Description
SMTP_EXTOPT_EXPN	The server supports address expansion using the EXPN command. The **SmtpExpandAddress** function can be used to expand addresses, which typically returns the email addresses associated with a mailing list. Most public mail servers restrict or disable this functionality because it can present a security risk. If a server does permit the use of the command, it is often limited to specific authorized users.
SMTP_EXTOPT_VRFY	The server supports verification of addresses using the VRFY command. The **SmtpVerifyAddress** function can be used to verify addresses. Most public mail servers restrict the ability for clients to verify email addresses to prevent potential abuse. If a server does permit the use of the command, it is often limited to specific authorized users.
SMTP_EXTOPT_DSN	The server supports delivery status notification (DSN) which allows the sender to be notified when a message has been delivered, or when an error occurs during the delivery process. The **SmtpSetDeliveryOptions** function can be used to specify the delivery options to be used in the current session.
SMTP_EXTOPT_SIZE	The server supports the use of the SIZE parameter, which enables the client to determine the maximum message size that may be delivered through the server. Most public mail servers impose a limit of on the total size of a message, including any encoded attachments.
SMTP_EXTOPT_ETRN	The server supports the use of the ETRN command, instructing the server to start processing its message queues for a specific host. Most public mail servers do not support this capability and its use has been deprecated.
SMTP_EXTOPT_8BITMIME	The server supports the delivery of messages that contain characters with the high bit set. Most servers support this option, however it is recommended that you encode any

	message text which contains non-ASCII characters to ensure the broadest compatibility with other servers and clients.
SMTP_EXTOPT_STARTTLS	The server supports explicit TLS sessions. This extended option is used internally to determine how secure connections should be established, and if a secure connection can be made using the standard submission port.
SMTP_EXTOPT_UTF8	The server supports UTF-8 encoding in email addresses and the message envelope. Not all mail servers will have this extended capability enabled, and applications should not depend on being able to provide internationalized user and domain names unless this option bit flag has been set.

In addition, there are extended options which specify the authentication methods supported by the server. A server will typically support multiple authentication methods and may be one or more of the following values:

Value	Description
SMTP_EXTOPT_AUTHLOGIN	The server supports client authentication using the AUTH LOGIN command. This is the default authentication method and is supported by most mail servers. The user name and password are encoded in a specific format, but are not encrypted. The client should use a secure connection whenever possible.
SMTP_EXTOPT_AUTHPLAIN	The server supports client authentication using the AUTH PLAIN command. The use name and password are encoded in a specific format, but are not encrypted. If a server supports this authentication method, it is very likely it also supports AUTH LOGIN. It is recommended you use only use AUTH PLAIN authentication if the server does not support AUTH LOGIN.
SMTP_EXTOPT_XOAUTH2	The server supports client authentication using AUTH XOAUTH2 command. Instead of a password, an OAuth 2.0 bearer token is used to authenticate the user which previously authorized access to the mail server using their account information. The connection must be secure to use this authentication method.
SMTP_EXTOPT_BEARER	The server supports client authentication using AUTH OAUTHBEARER command as specified in RFC 7628. Instead of a password, an OAuth 2.0 bearer token is used to authenticate the user which previously authorized access to the mail server using their account information. The connection must be secure to use this authentication method.

Return Value

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetExtendedOptions** function returns the extended options supported by the server. The use of extended options requires that the server support the ESMTP protocol, and that the client connect using the SMTP_OPTION_EXTENDED option.

You should check these options prior to calling **SmtpAuthenticate** to determine which authentication methods are acceptable to the server. If you wish to use an OAuth 2.0 bearer token, always check to make sure either the SMTP_EXTOPT_XOAUTH2 or SMTP_EXTOPT_BEARER bit flags are set in the options value returned by this function.

Example

```
BOOL bExtended = FALSE;
DWORD dwOptions = 0;

// Determine which extended options and authentication methods
// are supported by this server

bExtended = SmtpGetExtendedOptions(hClient, &dwOptions);

if (bExtended && (dwOptions & SMTP_EXTOPT_XOAUTH2))
{
    INT nResult = SmtpAuthenticate(hClient, SMTP_AUTH_XOAUTH2, lpszUserName,
lpszBearerToken);

    if (nResult == SMTP_ERROR)
    {
        // An error occurred during authentication; when using an
        // OAuth 2.0 bearer token, this typically means that the token
        // has expired and must be refreshed
        return;
    }
}
else
{
    // The server does not support XOAUTH2
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpAuthenticate, SmtpConnect, SmtpGetDeliveryOptions, SmtpSetDeliveryOptions

SmtpGetLastError Function

```
DWORD WINAPI SmtpGetLastError();
```

Parameters

None.

Return Value

The return value is the calling thread's last error code value. Functions set this value by calling the **SmtpSetLastError** function. The return value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

You should call the **SmtpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **SmtpSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_CLIENT or SMTP_ERROR. Those functions which call **SmtpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpGetErrorString, SmtpSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpGetResultCode Function

```
INT WINAPI SmtpGetResultCode(
    HCLIENT hClient
);
```

The **SmtpGetResultCode** function reads the result code returned by the server in response to a command. The result code is an integer value, and indicates if the operation succeeded or failed.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, it returns SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The following result codes may be returned by the SMTP server:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpCommand, SmtpGetResultString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpGetResultString Function

```
INT WINAPI SmtpGetResultString(
    HCLIENT hClient,
    LPTSTR lpszResult,
    INT nMaxLength
);
```

The **SmtpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

The buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **SmtpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpGetSecurityInformation Function

```
BOOL WINAPI SmtpGetSecurityInformation(
   HCLIENT hClient,
   LPSECURITYINFO lpSecurityInfo
);
```

The **SmtpGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SmtpGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Notifies the user if the connection is secure or not
SECURITYINFO securityInfo;

securityInfo.dwSize = sizeof(SECURITYINFO);
if (SmtpGetSecurityInformation(hClient, &securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpGetStatus Function

```
INT WINAPI SmtpGetStatus(
   HCLIENT hClient
);
```

The **SmtpGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
SMTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
SMTP_STATUS_CONNECT	The client is establishing a connection with the server.
SMTP_STATUS_READ	The client is reading data from the server.
SMTP_STATUS_WRITE	The client is writing data to the server.
SMTP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpGetTaskError Function

```
DWORD WINAPI SmtpGetTaskError(
    UINT nTaskId
);
```

Return the last error code for the specified asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed successfully, this function returns a value of zero. A non-zero return value indicates an error has occurred.

Remarks

The **SmtpGetTaskError** function returns the last error code associated with the specified asynchronous task. If the task completed successfully, the return value will be zero. If the task is still active, the function will return the error ST_ERROR_TASK_ACTIVE. If the task has been suspended, the function will return ST_ERROR_TASK_SUSPENDED. Any other value indicates that the task completed, but the operation has failed and the error code will specify the cause of the failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpTaskAbort, SmtpTaskResume, SmtpTaskSuspend, SmtpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpGetTaskId Function

```
UINT WINAPI SmtpGetTaskId(
   HCLIENT hClient
);
```

Return the asynchronous task identifier associated with the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the client handle is not associated with an asynchronous task, the function will return a value of zero.

Remarks

The **SmtpGetTaskId** function will return the task ID that is associated with a client session. This is a unique unsigned integer value that references the worker thread that was created to manage the asynchronous client session. This function should only be called within an event handler that is invoked by a background task that has been started using a function such as **SmtpAsyncGetFile**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

SmtpGetTimeout Function

```
INT WINAPI SmtpGetTimeout(
   HCLIENT hClient
);
```

The **SmtpGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpSetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpGetTransferStatus Function

```
INT WINAPI SmtpGetTransferStatus(
   HCLIENT hClient,
   LPSMTPTRANSFERSTATUS lpStatus
);
```

The **SmtpGetTransferStatus** function returns information about the message being submitted to the mail server.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an SMTPTRANSFERSTATUS structure which contains information about the status of the message being submitted for delivery.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpGetTransferStatus** function returns information about the current message being submitted, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no message currently being submitted, this function will return the status of the last successful submission made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain the status of a submission for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpInitialize Function

```
BOOL WINAPI SmtpInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **SmtpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SmtpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **SmtpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **SmtpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **SmtpInitialize** or **SmtpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpIsBlocking Function

```
BOOL WINAPI SmtpIsBlocking(
   HCLIENT hClient
);
```

The **SmtpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **SmtpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action such as warning the user that they must wait for the operation to complete.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpCancel, SmtpIsConnected, SmtpIsReadable, SmtpIsWritable

SmtpIsConnected Function

```
BOOL WINAPI SmtpIsConnected(
    HCLIENT hClient
);
```

The **SmtpIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpIsBlocking, SmtpIsReadable, SmtpIsWritable

SmtpIsReadable Function

```
BOOL WINAPI SmtpIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **SmtpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpGetStatus, SmtpIsBlocking, SmtpIsConnected, SmtpIsWritable, SmtpWrite

SmtpIsWritable Function

```
BOOL WINAPI SmtpIsWritable(
   HCLIENT hClient,
   INT nTimeout
);
```

The **SmtpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

SmtpRegisterEvent Function

```
INT WINAPI SmtpRegisterEvent(
   HCLIENT hClient,
   UINT nEvent,
   SMTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **SmtpRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
SMTP_EVENT_CONNECT	The connection to the server has completed.
SMTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
SMTP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
SMTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
SMTP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
SMTP_EVENT_CANCEL	The client has canceled the current operation.
SMTP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command.
SMTP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **SmtpEventProc** callback

function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpRegisterEvent** function associates a callback function with a specific event. The event handler is an **SmtpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a message is being submitted to the server for delivery. The SMTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one SMTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpReset Function

```
INT WINAPI SmtpReset(
   HCLIENT hClient
);
```

The **SmtpReset** function resets the client state and resynchronizes with the server. This function is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The client cannot be reset while in a blocked state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpCancel, SmtpCloseMessage, SmtpCreateMessage, SmtpIsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpSendMessage Function

```
INT WINAPI SmtpSendMessage(
   HCLIENT hClient,
   LPCTSTR lpszFrom,
   LPCTSTR lpszRecipient,
   LPVOID lpvMessage,
   DWORD dwMessageSize,
   DWORD dwOptions
);
```

The **SmtpSendMessage** function sends the contents of a file or memory buffer to the specified recipients.

Parameters

hClient

Handle to the client session.

lpszFrom

Pointer to a string which specifies the email address of the sender.

lpszRecipient

Pointer to a string which specifies the recipient of the message. Multiple recipients may be specified by separating each address with a comma.

lpvMessage

Pointer to a buffer which contains the message to be delivered, or a pointer to the name of the file which contains the data to be written to the data stream. The use of this parameter depends on the value of the ***dwOptions*** parameter.

dwMessageSize

An unsigned integer which specifies the length of the message in bytes.

dwOptions

Specifies the source of the message data that will be written to the data stream; it may be one of the following values:

Value	Description
SMTP_MESSAGE_MEMORY	The ***lpvMessage*** parameter specifies a pointer to an array of characters. If the value of ***dwMessageSize*** is zero, then it is assumed to be a pointer to a string. If the Unicode version of this function is called and the ***dwMessageSize*** parameter is zero, the ***lpvMessage*** parameter must point to a wide string terminated with a null character. The string will be automatically converted to UTF-8 when the message is sent. In all other cases, the ***lpvMessage*** parameter is treated as a pointer to a byte array which contains the message contents and the ***dwMessageSize*** parameter specifies the number of bytes in the array.
SMTP_MESSAGE_HGLOBAL	The ***lpvMessage*** parameter specifies an HGLOBAL which contains the data to be written to the data stream. If the value of the ***dwMessageSize*** parameter is zero, then the

	data is assumed to be null-terminated. If the Unicode version of this function is called, the HGLOBAL handle should point to a buffer which contains a UTF-8 encoded byte array.
SMTP_MESSAGE_FILE	The *lpvMessage* parameter specifies a pointer to a string which contains the name of a file. The file is opened and the contents of the file are written to the data stream. The value of the *dwMessageSize* parameter is ignored when this option is specified.
SMTP_MESSAGE_CLIPBOARD	The *lpvMessage* and *dwMessageSize* parameters are ignored. The current contents of the clipboard are written to the data stream.

Return Value

If the function succeeds, the return value is the result code from the server. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpSendMessage** function is used to send the contents of a memory buffer, file or the system clipboard to the specified recipients. The message must be in the standard format as described in RFC 822 or a MIME multipart message. The MIME API can be used to compose and export a message in the correct format.

This protocol is only concerned with the delivery of a message and not its contents. Header fields in the message are not parsed to determine the recipients. This recipient parameter should be a concatenation of all recipients, including carbon copies and blind carbon copies, with each address separated with a comma.

This function will cause the current thread to block until the complete message has been delivered, a timeout occurs or the operation is canceled. During the transfer, the SMTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **SmtpEnableEvents**, or by registering a callback function using the **SmtpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **SmtpGetTransferStatus** function.

An alternative approach to creating a message without using the MIME API is the **SmtpSubmitMessage** function. It accepts two structure parameters which define the message contents and the connection information for the mail server. This enables the application to compose the message and submit it for delivery in a single function call.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpSetDeliveryOptions Function

```
BOOL WINAPI SmtpSetDeliveryOptions(
    HCLIENT hClient,
    DWORD dwOptions
);
```

The **SmtpSetDeliveryOptions** function sets the delivery status notification options for the current session.

Parameters

hClient

Handle to the client session.

dwOptions

A bitmask that defines the current delivery options. This value is created by combining one or more of the following constants with a bitwise Or operator:

Value	Description
SMTP_NOTIFY_NEVER	Never return information about the success or failure of the message delivery process.
SMTP_NOTIFY_SUCCESS	Return a message to the sender if the message has been successfully delivered to the recipient's mail server.
SMTP_NOTIFY_FAILURE	Return a message to the sender if the message could not be delivered to the recipient's mail server.
SMTP_NOTIFY_DELAY	Return a message to the sender if delivery of the message was delayed.
SMTP_RETURN_HEADERS	Return only the message headers to the sender.
SMTP_RETURN_MESSAGE	Return the complete message headers and body to the sender.

Return Value

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpSetDeliveryOptions** function sets the current delivery options for the client session. Note that delivery options are only available on those mail servers which support delivery status notification (DSN) using the extended SMTP protocol. The client must connect specifying SMTP_OPTION_EXTENDED in order to use extended server options.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpGetDeliveryOptions, SmtpGetExtendedOptions

SmtpSetLastError Function

```
VOID WINAPI SmtpSetLastError(
   DWORD dwErrorCode
);
```

The **SmtpSetLastError** function sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the caller. A value of zero clears the last error code.

Return Value

None.

Remarks

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_CLIENT or SMTP_ERROR. Those functions which call **SmtpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **SmtpGetLastError** function. The use of **SmtpGetLastError** is optional. An application can call it to find out the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpSetTimeout Function

```
INT WINAPI SmtpSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **SmtpSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpGetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpSubmitMessage Function

```
INT WINAPI SmtpSubmitMessage(
   LPSMTPSERVER lpServer,
   LPSMTPMESSAGE lpMessage,
   SMTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **SmtpSubmitMessage** function composes and submits a message for delivery to the specified mail server.

Parameters

lpServer

A pointer to an **SMTPSERVER** structure that contains information about the mail server that the message will be submitted to for delivery. This parameter cannot be NULL and the structure members must be properly initialized prior to calling this function.

lpMessage

A pointer to an **SMTPMESSAGE** structure that contains information about the message, including the sender, recipients and the body of the message. This parameter cannot be NULL and the structure members must be property initialized prior to calling this function.

lpEventProc

The procedure-instance address of an application defined callback function. For more information about event handling and the callback function, see the description of the **SmtpEventProc** callback function. If this parameter is NULL, event notification is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the *lpEventProc* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpSubmitMessage** function provides a high-level interface that enables an application to send an email message with a single function call. The **SMTPSERVER** and **SMTPMESSAGE** structures are used to provide the function with information about the mail server that will accept the message and the contents of the message itself. Note that this function does not require a client session handle, and therefore it is not required that you call the **SmtpConnect** function prior to calling this function.

If you need to specify additional custom headers in the message that is submitted for delivery, you should use the **SmtpSubmitMessageEx** function. That version of the function uses an extended version of the message structure which will allow you to define custom headers to be included in the message.

This function will cause the calling thread to block until the message has been submitted for delivery, an error occurs or the connection to the mail server times out. If an event handler is specified, then the callback function will be periodically invoked as the message is being sent. For large messages, the SMTP_EVENT_PROGRESS event can be used to monitor the submission process and update the user interface. The **SmtpGetTransferStatus** function can be used within the callback function to obtain

information about the current status of the submission.

Example

```
SMTPSERVER mailServer;
ZeroMemory(&mailServer, sizeof(mailServer));
mailServer.lpszHostName = _T("smtp.gmail.com");
mailServer.nHostPort = SMTP_PORT_SUBMIT;
mailServer.lpszUserName = m_strSender;
mailServer.lpszPassword = m_strPassword;
mailServer.dwOptions = SMTP_OPTION_SECURE;

SMTPMESSAGE mailMessage;
ZeroMemory(&mailMessage, sizeof(mailMessage));
mailMessage.lpszFrom = m_strSender;
mailMessage.lpszTo = m_strRecipients;
mailMessage.lpszSubject = m_strSubject;
mailMessage.lpszText = m_strMessage;

INT nResult = SmtpSubmitMessage(&mailServer, &mailMessage, NULL, 0);

if (nResult != SMTP_ERROR)
    _tprintf(_T("SmtpSubmitMessage was successful\n"));
else
{
    DWORD dwError = SmtpGetLastError();
    _tprintf(_T("SmtpSubmitMessage failed with error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SmtpEventProc, SmtpSendMessage, SmtpSubmitMessageEx, SMTPMESSAGE, SMTPSERVER

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpSubmitMessageEx Function

```
INT WINAPI SmtpSubmitMessageEx(
   LPSMTPSERVER lpServer,
   LPSMTPMESSAGEEX lpMessageEx,
   DWORD dwReserved,
   SMTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **SmtpSubmitMessageEx** function composes and submits a message for delivery to the specified mail server.

Parameters

lpServer

A pointer to an **SMTPSERVER** structure that contains information about the mail server that the message will be submitted to for delivery. This parameter cannot be NULL and the structure members must be properly initialized prior to calling this function.

lpMessageEx

A pointer to an **SMTPMESSAGEEX** structure that contains information about the message, including the sender, recipients and the body of the message. This parameter cannot be NULL and the structure members must be property initialized prior to calling this function.

dwReserved

An integer value that is reserved for future use. This value must be zero or the function will fail.

lpEventProc

The procedure-instance address of an application defined callback function. For more information about event handling and the callback function, see the description of the **SmtpEventProc** callback function. If this parameter is NULL, event notification is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the *lpEventProc* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpSubmitMessageEx** function provides a high-level interface that enables an application to send an email message with a single function call. The **SMTPSERVER** and **SMTPMESSAGEEX** structures are used to provide the function with information about the mail server that will accept the message and the contents of the message itself. Note that this function does not require a client session handle, and therefore it is not required that you call the **SmtpConnect** function prior to calling this function.

This function will cause the calling thread to block until the message has been submitted for delivery, an error occurs or the connection to the mail server times out. If an event handler is specified, then the callback function will be periodically invoked as the message is being sent. For large messages, the SMTP_EVENT_PROGRESS event can be used to monitor the submission process and update the user interface. The **SmtpGetTransferStatus** function can be used within the callback function to obtain

information about the current status of the submission.

Example

```
SMTPSERVER mailServer;
ZeroMemory(&mailServer, sizeof(mailServer));
mailServer.lpszHostName = _T("smtp.gmail.com");
mailServer.nHostPort = SMTP_PORT_SUBMIT;
mailServer.lpszUserName = m_strSender;
mailServer.lpszPassword = m_strPassword;
mailServer.dwOptions = SMTP_OPTION_SECURE;

SMTPMESSAGEEX mailMessageEx;
ZeroMemory(&mailMessageEx, sizeof(mailMessageEx));
mailMessageEx.dwSize = sizeof(mailMessageEx);
mailMessageEx.lpszFrom = m_strSender;
mailMessageEx.lpszTo = m_strRecipients;
mailMessageEx.lpszSubject = m_strSubject;
mailMessageEx.lpszText = m_strMessage;

INT nResult = SmtpSubmitMessageEx(&mailServer, &mailMessageEx, 0, NULL, 0);

if (nResult != SMTP_ERROR)
    _tprintf(_T("SmtpSubmitMessageEx was successful\n"));
else
{
    DWORD dwError = SmtpGetLastError();
    _tprintf(_T("SmtpSubmitMessageEx failed with error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpTaskAbort Function

```
BOOL WINAPI SmtpTaskAbort(
   UINT nTaskId,
   DWORD dwMilliseconds
);
```

Abort the specified asynchronous task.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to abort.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpTaskAbort** function signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the *dwMilliseconds* parameter has a value of zero, the function returns immediately after the background thread has been signaled. If the *dwMilliseconds* parameter is non-zero, the function will wait that amount of time for the background thread to terminate.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock. To abort a file transfer within an event handler, use the **SmtpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpTaskDone, SmtpTaskResume, SmtpTaskSuspend, SmtpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpTaskDone Function

```
BOOL WINAPI SmtpTaskDone(
    UINT nTaskId
);
```

Determine if an asynchronous task has completed.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed, this function returns a non-zero value. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpTaskDone** function is used to determine if the specified asynchronous task has completed. If you use this function to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this function rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **SmtpGetTaskError** function will return the last error code associated with the task. A return value of zero indicates success, while a non-zero return value specifies an error code that indicates the cause of the failure. The last error code for the task can also be retrieved using the **SmtpTaskWait** function, which causes the application to wait for the asynchronous task to complete.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpGetTaskError, SmtpTaskAbort, SmtpTaskResume, SmtpTaskSuspend, SmtpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpTaskResume Function

```
BOOL WINAPI SmtpTaskResume(
    UINT nTaskId
);
```

Resume execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpTaskResume** function resumes execution of the background worker thread that was previously suspended using the **SmtpTaskSuspend** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

SmtpTaskSuspend Function

```
BOOL WINAPI SmtpTaskSuspend(
    UINT nTaskId
);
```

Suspend execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpTaskSuspend** function will suspend execution of the background worker thread associated with the task. Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **SmtpTaskResume** function. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpTaskAbort, SmtpTaskDone, SmtpTaskResume, SmtpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmtpTaskWait Function

```
BOOL WINAPI SmtpTaskWait(
   UINT nTaskId,
   DWORD dwMilliseconds,
   DWORD dwReserved,
   LPDWORD lpdwElapsed,
   LPDWORD lpdwError
);
```

Wait for an asynchronous task to complete.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to complete.

dwReserved

An unsigned integer reserved for future use. This value should always be zero.

lpdwElapsed

A pointer to an unsigned integer that will contain elapsed time in milliseconds when the function returns. If this information is not required, this parameter may be NULL.

lpdwError

A pointer to an unsigned integer that will contain the error code associated with the completed task. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **SmtpGetLastError** function.

Remarks

The **SmtpTaskWait** function waits for the specified task to complete. If the task is active and the *dwMilliseconds* parameter is non-zero, this function will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the *dwMilliseconds* parameter is zero, then this function will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this function is called, the function will return immediately without causing the current thread to block. If the *lpdwElapsed* parameter is not NULL, it will contain the number of milliseconds that it took for the task to complete. If the *lpdwError* parameter is not NULL, it will contain the last error code value that was set by the worker thread before it terminated. If this value is zero, that means that the background operation was successful and no error occurred. A non-zero value will indicate that the background operation has failed.

You should not call this function from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this function is blocked waiting for the background task to complete, and this can cause your application to appear non-

responsive to the end-user. If you have a GUI application and you need to periodically check to see if a task has completed, create a timer to periodically call the **SmtpTaskDone** function. When it returns a non-zero value (indicating that the task has completed), you can safely call **SmtpTaskWait** to obtain the elapsed time and last error code without blocking the current thread.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

SmtpUninitialize Function

```
VOID WINAPI SmtpUninitialize();
```

The **SmtpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **SmtpInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **SmtpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **SmtpUninitialize** for every successful call to **SmtpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib

See Also

SmtpConnect, SmtpDisconnect, SmtpInitialize

SmtpVerifyAddress Function

```
INT WINAPI SmtpVerifyAddress(
   HCLIENT hClient,
   LPCTSTR lpszAddress,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **SmtpVerifyAddress** function verifies the specified address is valid.

Parameters

hClient

Handle to the client session.

lpszAddress

Points to a string which specifies the address that the server should verify.

lpszBuffer

Points to a buffer that the verified address will be copied into.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The **SmtpVerifyAddress** function requests that the server verify the specified email address. Typically this is used to verify that a recipient address is valid, and return a fully qualified email address for that recipient. A server may not support this command, or may restrict its usage. An application should not depend on the ability to verify addresses.

This function cannot be called while a mail message is being composed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmtpWrite Function

```
INT WINAPI SmtpWrite(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **SmtpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is SMTP_ERROR. To get extended error information, call **SmtpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the SMTP_EVENT_WRITE asynchronous notification message before it resumes sending data.

If the **SmtpWrite** function is used to send the message contents to the server, the application must first call the **SmtpCreateMessage** function to specify the sender and the length of the message, followed by one or more calls to the **SmtpAddRecipient** function to specify each recipient of the message. When all of the message text has been submitted to the server, the application must call the **SmtpCloseMessage** function.

The message text is filtered by the **SmtpWrite** function, and it will automatically normalize end-of-line character sequences to ensure the message meets the protocol requirements. The message itself must be in a standard RFC 822 or multi-part MIME message format, or the server may reject the message. Binary data, such as file attachments, should always be encoded. The MIME API can be used to compose and export a message in the correct format, which can then be submitted to the server.

It is recommended that most applications use the **SmtpSendMessage** function to submit the message for delivery.

An alternative approach to creating a message without using the MIME API is the **SmtpSubmitMessage** function. It accepts two structure parameters which define the message contents and the connection information for the mail server. This enables the application to compose the message and submit it for delivery in a single function call.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SMTPMESSAGE

This structure provides information about the contents of a message and is used by the SmtpSubmitMessage function.

```
typedef struct _SMTPMESSAGE
{
    LPCTSTR  lpszFrom;
    LPCTSTR  lpszTo;
    LPCTSTR  lpszCc;
    LPCTSTR  lpszBcc;
    LPCTSTR  lpszSubject;
    LPCTSTR  lpszText;
    LPCTSTR  lpszHTML;
    LPCTSTR  lpszAttach;
    UINT     nCharSet;
    UINT     nEncType;
    DWORD    dwReserved;
} SMTPMESSAGE, *LPSMTPMESSAGE;
```

Members

lpszFrom

A null-terminated string that specifies the email address of the person sending the message. This structure member must point to a valid address and cannot be NULL.

lpszTo

A null-terminated string that specifies the email addresses of one or more recipients. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member must point to at least one valid address and cannot be NULL.

lpszCc

A null-terminated string that specifies the email addresses of one or more recipients that will receive copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string.

lpszBcc

A null-terminated string that specifies the email addresses of one or more recipients that will receive blind copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string. Unlike the recipients specified by the ***lpszTo*** and ***lpszCc*** members, any addresses specified by this member will not be included in the header of the email message.

lpszSubject

A null-terminated string that specifies the subject of the message. This structure member may be NULL, in which case no subject will be included in the message.

lpszText

A null-terminated string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this structure member is NULL or points to an empty string, then the ***lpszHTML*** member must specify the body of the message.

lpszHTML

A null-terminated string which contains the message using HTML formatting. If the ***lpszText*** member is not NULL, then a multipart message will be created with both plain text and HTML text

as the alternative. This allows mail clients to select which message body they wish to display. If the ***lpszText*** member is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

lpszAttach

A null-terminated string which specifies one or more file attachments for the message. If multiple files are to be attached to the message, each file name must be separated by a semi-colon. It is recommended that you provide the complete path to the file. If this structure member is NULL or points to an empty string, the message will be created without attachments.

nCharSet

An integer value which specifies the character set to use when composing the message. A value of zero specifies that the default USASCII character set should be used. The following values may also be used:

Value	Description
MIME_CHARSET_USASCII	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_CHARSET_ISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1.
MIME_CHARSET_ISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2.
MIME_CHARSET_ISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian.
MIME_CHARSET_ISO8859_6	An 8-bit character set for Arabic languages. Note that the application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	An 8-bit character set for the Greek language.
MIME_CHARSET_ISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English.
MIME_CHARSET_ISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5.

nEncType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be

used:

Value	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Remarks

This structure is used to define the contents of a message that will be submitted for delivery using the **SmtpSubmitMessage** function. It is required that you specify a sender, at least one recipient and a message body. All other structure members may be NULL or have a value of zero to indicate that either the value is not required, or that a default should be used. It is recommended that you initialize all of the structure members to a value of zero using the **ZeroMemory** function prior to populating the structure.

email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpszFrom* member cannot specify multiple addresses, however it is permitted with the *lpszTo*, *lpszCc* and *lpszBcc* structure members. Each message must have at least one valid recipient, or the message cannot be submitted for delivery.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SMTPMESSAGEEX

This structure provides information about the contents of a message and is used by the SmtpSubmitMessageEx function.

```
typedef struct _SMTPMESSAGEEX
{
    DWORD    dwSize
    LPCTSTR  lpszFrom;
    LPCTSTR  lpszTo;
    LPCTSTR  lpszCc;
    LPCTSTR  lpszBcc;
    LPCTSTR  lpszDate;
    LPCTSTR  lpszSubject;
    LPCTSTR  lpszHeaders;
    LPCTSTR  lpszText;
    LPCTSTR  lpszHTML;
    LPCTSTR  lpszAttach;
    UINT     nCharSet;
    UINT     nEncType;
    DWORD    dwReserved;
} SMTPMESSAGEEX, *LPSMTPMESSAGEEX;
```

Members

dwSize

An integer value that specifies the size of the **SMTPMESSAGEEX** data structure. This must always be explicitly defined, and if the value is incorrect, an error will be returned. This structure member is used to ensure that the correct version of the structure is being passed to the function.

lpszFrom

A null-terminated string that specifies the email address of the person sending the message. This structure member must point to a valid address and cannot be NULL.

lpszTo

A null-terminated string that specifies the email addresses of one or more recipients. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member must point to at least one valid address and cannot be NULL.

lpszCc

A null-terminated string that specifies the email addresses of one or more recipients that will receive copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string.

lpszBcc

A null-terminated string that specifies the email addresses of one or more recipients that will receive blind copies of the message. If multiple addresses are provided, they must be separated by commas or semi-colons. This structure member may be NULL or point to an empty string. Unlike the recipients specified by the *lpszTo* and *lpszCc* members, any addresses specified by this member will not be included in the header of the email message.

lpszDate

A null-terminated string that specifies the date and time for the message. This structure member may be NULL or point to an empty string. If the date is not specified, then the current date and time will be used by default. If a date is specified, it should be in the standard format as defined by RFC822.

lpszSubject

A null-terminated string that specifies the subject of the message. This structure member may be NULL, in which case no subject will be included in the message.

lpszHeaders

A null-terminated string that specifies additional headers that should be included in the message. Header names should be separated from values by a colon, and multiple headers may be defined by separating them with a newline character. This structure member may be NULL, in which case no additional headers will be included in the message.

lpszText

A null-terminated string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this structure member is NULL or points to an empty string, then the ***lpszHTML*** member must specify the body of the message.

lpszHTML

A null-terminated string which contains the message using HTML formatting. If the ***lpszText*** member is not NULL, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the ***lpszText*** member is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

lpszAttach

A null-terminated string which specifies one or more file attachments for the message. If multiple files are to be attached to the message, each file name must be separated by a semi-colon. It is recommended that you provide the complete path to the file. If this structure member is NULL or points to an empty string, the message will be created without attachments.

nCharSet

An integer value which specifies the character set to use when composing the message. A value of zero specifies that the default USASCII character set should be used. The following values may also be used:

Value	Description
MIME_CHARSET_USASCII	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the first bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_CHARSET_ISO8859_1	An 8-bit character set for most western European languages such as English, French, Spanish and German. This character set is also commonly referred to as Latin1.
MIME_CHARSET_ISO8859_2	An 8-bit character set for most central and eastern European languages such as Czech, Hungarian, Polish and Romanian. This character set is also commonly referred to as Latin2.
MIME_CHARSET_ISO8859_5	An 8-bit character set for Cyrillic languages such as Russian, Bulgarian and Serbian.
MIME_CHARSET_ISO8859_6	An 8-bit character set for Arabic languages. Note that the

	application is responsible for displaying text that uses this character set. In particular, any display engine needs to be able to handle the reverse writing direction and analyze the context of the message to correctly combine the glyphs.
MIME_CHARSET_ISO8859_7	An 8-bit character set for the Greek language.
MIME_CHARSET_ISO8859_8	An 8-bit character set for the Hebrew language. Note that similar to Arabic, Hebrew uses a reverse writing direction. An application which displays this character should be capable of processing bi-directional text where a single message may include both right-to-left and left-to-right languages, such as Hebrew and English.
MIME_CHARSET_ISO8859_9	An 8-bit character set for the Turkish language. This character set is also commonly referred to as Latin5.

nEncType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Value	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Remarks

This structure is used to define the contents of a message that will be submitted for delivery using the **SmtpSubmitMessageEx** function. It is required that you specify a sender, at least one recipient and a message body. Other structure members may be NULL or have a value of zero to indicate that either the value is not required, or that a default should be used. It is recommended that you initialize all of the structure members to a value of zero using the **ZeroMemory** function prior to populating the

structure.

Note that you must explicitly define the size of the structure by setting the value of the **dwSize** member variable. This ensures that the correct version of the structure is being passed to the function. This structure is not compatible with the **SmtpSubmitMessage** function and must only be used with **SmtpSubmitMessageEx**.

Email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpszFrom* member cannot specify multiple addresses, however it is permitted with the *lpszTo*, *lpszCc* and *lpszBcc* structure members. Each message must have at least one valid recipient, or the message cannot be submitted for delivery.

If you specify a message date by assigning a value to the *lpszDate* member, and it does not include any timezone information, Coordinated Universal Time (UTC) will be used by default. This is an important consideration if you provide input from a user, because in most cases they will not include the timezone and will assume the date and time they enter is for their current timezone.

If you wish to include additional headers in the message, you can specify them in a string. Each header consists of a name and value, separated by a colon (":") character. If you wish to define multiple headers, then you can separate them with a newline (e.g.: a linefeed character or combination of a carriage-return and linefeed). Extraneous leading and trailing whitespace are trimmed from header names and values. Invalid names or values will be ignored and will not generate an error.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SMTPSERVER

This structure provides connection information for a mail server and is used by the SmtpSubmitMessage function.

```
typedef struct _SMTPSERVER
{
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    UINT     nHostPort;
    UINT     nTimeout;
    DWORD    dwOptions;
    DWORD    dwReserved;
} SMTPSERVER, *LPSMTPSERVER;
```

Members

lpszHostName

A null-terminated string that specifies the host name or IP address of the mail server. This structure member cannot be NULL.

lpszUserName

A null-terminated string that specifies the username that will be used to authenticate the client session. If the mail server does not require authentication, this structure member can be NULL or point to an empty string.

lpszPassword

A null-terminated string that specifies the password that will be used to authenticate the client session. If the mail server does not require authentication, this structure member can be NULL or point to an empty string.

nHostPort

An integer value that specifies the port number used to establish the connection. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 25. An alternative port is 587, which is commonly used by authenticated clients to submit messages for delivery. For implicit TLS connections, the default port number is 465.

nTimeout

An integer value that specifies the number of seconds that the client will wait for a response from the server before failing the operation. A value of zero specifies the default timeout period of 20 seconds.

dwOptions

An unsigned integer that specifies one or more options. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SMTP_OPTION_NONE	No additional options are specified when establishing a connection with the server. A standard, non-secure connection will be used.
SMTP_OPTION_EXTENDED	Extended SMTP commands should be used if possible. This option enables features such as authentication and delivery status notification. If this option is not

	specified, the library will not attempt to use any extended features. This option is automatically enabled if a username and password are specified, or if the connection is established on port 587, because submitting messages for delivery using this port typically requires client authentication.
SMTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
SMTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
SMTP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. The client will initiate the secure session using the STARTTLS command.
SMTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.

dwReserved

An unsigned integer value reserved for future use. This structure member should always have a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

SMTPTRANSFERSTATUS

This structure is used by the SmtpGetTransferStatus function to return information about a message being submitted for delivery.

```
typedef struct _SMTPTRANSFERSTATUS
{
    DWORD  dwBytesTotal;
    DWORD  dwBytesCopied;
    DWORD  dwBytesPerSecond;
    DWORD  dwTimeElapsed;
    DWORD  dwTimeEstimated;
} SMTPTRANSFERSTATUS, *LPSMTPTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the size of the message cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Telnet Protocol Library

Establish an interactive terminal session with a server.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSTNTV12.DLL
Version	12.0.3024.1286
LibID	552A583F-46C0-4A66-8BC5-B75B468763EE
Import Library	CSTNTV12.LIB
Dependencies	None
Standards	RFC 854

Overview

The Telnet protocol is used to establish a connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The class provides an interface for establishing the connection, negotiating certain options (such as whether characters will be echoed back to the client) and handling the standard I/O functions needed by the program.

The API also includes functions that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. This library can be combined with the Terminal Emulation API to provide terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this library supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the Secure Shell API.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1

(SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Telnet Protocol Functions

Function	Description
TelnetAbort	Abort the current session and close the connection with the server
TelnetAsyncConnect	Connect asynchronously to the specified server
TelnetAttachThread	Attach the specified client handle to another thread
TelnetBreak	Send a break signal to the server
TelnetCancel	Cancel the current blocking operation
TelnetConnect	Connect to the specified server
TelnetCreateSecurityCredentials	Create a new security credentials structure
TelnetDeleteSecurityCredentials	Delete a previously created security credentials structure
TelnetDisableEvents	Disable asynchronous event notification
TelnetDisableTrace	Disable logging of network function calls
TelnetDisconnect	Disconnect from the current server
TelnetEnableEvents	Enable asynchronous event notification
TelnetEnableTrace	Enable logging of network function calls to a file
TelnetEventProc	Callback function that processes events generated by the client
TelnetFreezeEvents	Suspend asynchronous event processing
TelnetGetErrorString	Return a description for the specified error code
TelnetGetLastError	Return the last error code
TelnetGetMode	Return the current client mode
TelnetGetSecurityInformation	Return security information about the current client connection
TelnetGetStatus	Return the current client status
TelnetGetTerminalType	Return the current terminal type
TelnetGetTimeout	Return the number of seconds until an operation times out
TelnetInitialize	Initialize the library and validates the specified license key at runtime
TelnetIsBlocking	Determine if the client is blocked, waiting for information
TelnetIsConnected	Determine if the client is connected to the server
TelnetIsReadable	Determine if data can be read from the server
TelnetIsThere	Determine if the server is available
TelnetIsWritable	Determine if data can be written to the server
TelnetLogin	Login to the server using the specified username and password
TelnetRead	Read data returned by the server
TelnetReadLine	Read a line of text from the server and return it in a string buffer

TelnetRegisterEvent	Register an event callback function
TelnetSearch	Search for a specific character sequence in the data stream
TelnetSetLastError	Set the last error code
TelnetSetMode	Set the current client mode
TelnetSetTerminalType	Set the current terminal type
TelnetSetTimeout	Set the number of seconds until an operation times out
TelnetUninitialize	Terminate use of the library by the application
TelnetWrite	Write data to the server
TelnetWriteLine	Write a line of text to the server

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetAbort Function

```
INT WINAPI TelnetAbort(
   HCLIENT hClient
);
```

The **TelnetAbort** function aborts the current session and terminates the connection.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

When the **TelnetAbort** function is called, the Telnet abort sequence is sent to the server and the connection to the server is terminated. Once this function returns, the client handle is no longer valid. If a program is currently executing on the server at the time this function is called, that program may be terminated as a result of the session being aborted. Applications should normally call **TelnetDisconnect** to gracefully disconnect from the server and should only use this function when the connection must be aborted immediately.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

TelnetAsyncConnect Function

```
HCLIENT WINAPI TelnetAsyncConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **TelnetAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **TelnetConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TELNET_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
TELNET_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
TELNET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection

	will always be permitted. This option only affects connections using the TLS protocol.
TELNET_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
TELNET_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server using the START_TLS option. The client initiates a standard connection with the server, then requests a secure connection during the option negotiation process.
TELNET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
TELNET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
TELNET_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This parameter is only used if the TELNET_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **TelnetGetLastError**.

Remarks

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this library supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the Secure Shell API.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
TELNET_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **TelnetDisableEvents** function.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The ***dwOptions*** argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle.

The ownership of the handle may be transferred from one thread to another using the **TelnetAttachThread** function.

Specifying the TELNET_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetAttachThread Function

```
DWORD WINAPI TelnetAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **TelnetAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **TelnetAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **TelnetAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **TelnetCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **TelnetUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetConnect, TelnetDisconnect, TelnetUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetBreak Function

```
INT WINAPI TelnetBreak(
   HCLIENT hClient
);
```

The **TelnetBreak** function sends a signal to the server which may terminate an application that is currently running. The actual response to the break signal depends on the application.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetAbort, TelnetCancel, TelnetRead, TelnetWrite

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetCancel Function

```
INT WINAPI TelnetCancel(
   HCLIENT hClient
);
```

The **TelnetCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

When the **TelnetCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

TelnetConnect Function

```
HCLIENT WINAPI TelnetConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **TelnetConnect** function is used to establish a connection with the server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TELNET_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
TELNET_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
TELNET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
TELNET_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
TELNET_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server using the START_TLS option. The client initiates a

	standard connection with the server, then requests a secure connection during the option negotiation process.
TELNET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
TELNET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
TELNET_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This parameter is only used if the TELNET_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **TelnetGetLastError**.

Remarks

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this library supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the Secure Shell API.

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **TelnetConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The ***dwOptions*** argument can be used to specify the threading model that is used by the library when

a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **TelnetAttachThread** function.

Specifying the TELNET_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

TelnetCreateSecurityCredentials, TelnetDeleteSecurityCredentials, TelnetDisconnect, TelnetInitialize, TelnetUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetCreateSecurityCredentials Function

```
BOOL WINAPI TelnetCreateSecurityCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **TelnetCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **TelnetDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **TelnetGetLastError** function.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **TelnetConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
TelnetCreateSecurityCredentials(SECURITY_PROTOCOL_DEFAULT,
                                0,
                                NULL,
                                NULL,
                                lpszCertStore,
                                lpszCertName,
                                NULL,
                                &lpSecCred);

hClient = TelnetConnect(lpszHostName,
                        TELNET_PORT_SECURE,
                        TELNET_TIMEOUT,
                        TELNET_OPTION_SECURE,
                        lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

TelnetDeleteSecurityCredentials Function

```
VOID WINAPI TelnetDeleteSecurityCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **TelnetDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)
    TelnetDeleteSecurityCredentials(&lpSecCred);

TelnetUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

TelnetCreateSecurityCredentials, TelnetUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetDisableEvents Function

```
INT WINAPI TelnetDisableEvents(
    HCLIENT hClient
);
```

The **TelnetDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetDisableTrace Function

```
BOOL WINAPI TelnetDisableTrace();
```

The **TelnetDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetDisconnect Function

```
INT WINAPI TelnetDisconnect(
    HCLIENT hClient
);
```

The **TelnetDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetConnect, TelnetUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetEnableEvents Function

```
INT WINAPI TelnetEnableEvents(
    HCLIENT hClient,
    HWND hEventWnd,
    UINT uEventMsg
);
```

The **TelnetEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **TelnetRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the ***hEventWnd*** parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
TELNET_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.

TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetEnableTrace Function

```
BOOL WINAPI TelnetEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **TelnetEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

TelnetEventProc Function

```
VOID CALLBACK TelnetEventProc(
    HCLIENT hClient,
    UINT nEvent,
    DWORD dwError,
    DWORD_PTR dwParam
);
```

The **TelnetEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **TelnetRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **TelnetRegisterEvent** function. The **TelnetEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetDisableEvents, TelnetEnableEvents, TelnetFreezeEvents, TelnetRegisterEvent

TelnetFreezeEvents Function

```
INT WINAPI TelnetFreezeEvents(
    HCLIENT hClient,
    BOOL bFreeze
);
```

The **TelnetFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetGetErrorString Function

```
INT WINAPI TelnetGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **TelnetGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **TelnetGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

TelnetGetLastError, TelnetSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetGetLastError Function

```
DWORD WINAPI TelnetGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **TelnetSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **TelnetGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **TelnetSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TELNET_ERROR. Those functions which call **TelnetSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetGetMode Function

```
UINT WINAPI TelnetGetMode(
   HCLIENT hClient
);
```

The **TelnetGetMode** function returns the current client mode.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the current client mode. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The client mode is a combination of one or more flags which determines how the client handles local character echo and character processing. The following values are recognized:

Value	Description
TELNET_MODE_LOCALECHO	The local client is responsible for echoing data entered by the user. By default, this mode is not set which means that the server is responsible for echoing back each character written to it.
TELNET_MODE_BINARY	Data exchanged between the client and server should not be converted or line buffered. If this option is not specified, the high-bit will be cleared on all characters and single linefeeds will be automatically converted to carriage-return/linefeed sequences.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

TelnetGetSecurityInformation Function

```
BOOL WINAPI TelnetGetSecurityInformation(
   HCLIENT hClient,
   LPSECURITYINFO lpSecurityInfo
);
```

The **TelnetGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Notifies the user if the connection is secure or not
SECURITYINFO securityInfo;

securityInfo.dwSize = sizeof(SECURITYINFO);
if (TelnetGetSecurityInformation(hClient, &securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

TelnetGetStatus Function

```
INT WINAPI TelnetGetStatus(
   HCLIENT hClient
);
```

The **TelnetGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
TELNET_STATUS_IDLE	The client is current idle and not sending or receiving data.
TELNET_STATUS_CONNECT	The client is establishing a connection with the server.
TELNET_STATUS_READ	The client is reading data from the server.
TELNET_STATUS_WRITE	The client is writing data to the server.
TELNET_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

TelnetGetTerminalType Function

```
INT WINAPI TelnetGetTerminalType(
   HCLIENT hClient,
   LPCTSTR lpszTermType,
   INT nMaxLength
);
```

The **TelnetGetTerminalType** function returns the terminal type for the current client session.

Parameters

hClient

Handle to the client session.

lpszTermType

Points to a buffer which the current terminal type is copied into. This buffer should be at least 32 characters in length, including the terminating null character.

nMaxLength

Maximum number of characters that may be copied to the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the terminal type name. A value of zero indicates that no terminal type has been specified. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

TelnetGetTimeout Function

```
INT WINAPI TelnetGetTimeout(
    HCLIENT hClient
);
```

The **TelnetGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetSetTimeout

TelnetInitialize Function

```
BOOL WINAPI TelnetInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **TelnetInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **TelnetInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **TelnetUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **TelnetInitialize** or **TelnetUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetIsBlocking Function

```
BOOL WINAPI TelnetIsBlocking(
    HCLIENT hClient
);
```

The **TelnetIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **TelnetIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action such as warning the user that they must wait for the operation to complete.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetCancel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetIsConnected Function

```
BOOL WINAPI TelnetIsConnected(
    HCLIENT hClient
);
```

The **TelnetIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetIsBlocking, TelnetIsReadable, TelnetIsThere, TelnetIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetIsReadable Function

```
BOOL WINAPI TelnetIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **TelnetIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetGetStatus, TelnetIsBlocking, TelnetIsConnected, TelnetIsThere, TelnetIsWritable, TelnetRead

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetIsThere Function

```
BOOL WINAPI TelnetIsThere(
   HCLIENT hClient
);
```

The **TelnetIsThere** function reports the response of the client to a "Are you there" command to the telnet server.

Parameters

hClient

Handle to the client session.

Return Value

The function returns a non-zero value if the server acknowledges a specific control sequence used to determine if a Telnet server is responsive. If the server does not respond, the function will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetGetStatus, TelnetIsBlocking, TelnetIsConnected, TelnetIsReadable, TelnetIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetIsWritable Function

```
BOOL WINAPI TelnetIsWritable(
    HCLIENT hClient,
    INT nTimeout
);
```

The **TelnetIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

TelnetLogin Function

```
BOOL WINAPI TelnetLogin(
   HCLIENT hClient,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

The **TelnetLogin** function attempts to authenticate the user and log them in to the current session.

Parameters

hClient

Handle to the client session.

lpszUserName

A null-terminated string which specifies the name of the user to authenticate.

lpszPassword

A null-terminated string which specifies the password to be used when authenticating the user. If the user does not require a password, this parameter may be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this library supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the Secure Shell API.

This function is used to authenticate a user, logging them into the server. This function is specifically designed to work with most UNIX based servers, and may work with other servers that use a similar login process. The function works by scanning the data stream for a username prompt and then replying with the specified username. If that is successful, it will then scan for a password prompt and provide the specified password. If no recognized prompt is found, or if the server responds with an error indicating that the username or password is invalid, the function will fail.

If the **TelnetLogin** function succeeds, the next call to **TelnetRead** by the client will return any welcome message to the user. This is typically followed by a command prompt where the user can enter commands to be executed on the server. The data sent by the server during the login process is discarded and not available when the function returns. If the client requires this information, use the **TelnetSearch** function to automate the login process instead.

Because the **TelnetLogin** function is designed for UNIX based systems, it may not work with servers running on other operating system platforms such as Windows or VMS. In this case, applications should use the **TelnetSearch** function to search for the appropriate login prompts in the data stream.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

TelnetConnect, TelnetIsConnected, TelnetIsReadable, TelnetRead, TelnetSearch

TelnetRead Function

```
INT WINAPI TelnetRead(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **TelnetRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

When **TelnetRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

TelnetReadLine Function

```
BOOL WINAPI TelnetReadLine(
   HCLIENT hClient,
   LPTSTR lpszBuffer,
   LPINT lpnLength
);
```

The **TelnetReadLine** function reads up to a line of data and returns it in a string buffer.

Parameters

hClient

Handle to the client session.

lpszBuffer

Pointer to the string buffer that will contain the data when the function returns. The string will be terminated with a null byte, and will not contain the end-of-line characters.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the function returns, its value will updated with the actual length of the string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetReadLine** function reads data sent by the server and copies it into a specified string buffer. Unlike the **TelnetRead** function which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **TelnetReadLine**. The function should only be used to read text, never binary data. In particular, the function will discard nulls, linefeed and carriage return control characters. The Unicode version of this function will return a Unicode string, however this function does not support reading raw Unicode data from the server. The data is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This function will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the connection. If this function is called with asynchronous events enabled, it will automatically switch the client into a blocking mode, read the data and then restore the client to asynchronous operation. If another client operation is attempted while **TelnetReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this function only be used with blocking (synchronous) client connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **TelnetRead** and **TelnetReadLine** function calls can be intermixed, however be aware that **TelnetRead** will consume any data that has already been buffered by the **TelnetReadLine** function and this may have unexpected results.

Unlike the **TelnetRead** function, it is possible for data to be returned in the buffer even if the return value is zero. Applications should also check the value of the *lpnLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the function is waiting for more data to arrive, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Example

```
TCHAR szBuffer[MAXBUFLEN];
INT nLength;
BOOL bResult;

do
{
    nLength = sizeof(szBuffer);
    bResult = TelnetReadLine(hSocket, szBuffer, &nLength);

    if (nLength > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = TelnetGetLastError();
if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The server has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

TelnetRegisterEvent Function

```
INT WINAPI TelnetRegisterEvent(
   HCLIENT hClient,
   UINT nEvent,
   TELNETEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **TelnetRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
TELNET_EVENT_CONNECT	The connection to the server has completed.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **TelnetEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86

(32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetRegisterEvent** function associates a callback function with a specific event. The event handler is an **TelnetEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

TelnetSearch Function

```
BOOL WINAPI TelnetSearch(
   HCLIENT hClient,
   LPCTSTR lpszString,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwReserved
);
```

The **TelnetSearch** function searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

hClient

Handle to the client session.

lpszString

A null-terminated string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpvBuffer

A buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the function returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the ***lpvBuffer*** parameter is NULL, this parameter should also be NULL.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds and the character sequences was found in the data stream, the return value is non-zero. If the function fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetSearch** function searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as logging in a user and executing a command. The function collects the output from the server and stores it in the buffer specified by the ***lpvBuffer*** parameter. When the function returns, the buffer will contain everything sent by the server up to and including the search string.

The ***lpvBuffer*** parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the *lpvBuffer* parameter point to a global memory handle which will contain the output when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Example

```
LPCTSTR lpszUserName = "abc123\r\n";
LPCTSTR lpszPassword = "secret\r\n";
LPCTSTR lpszCommand = "/bin/ls -l\r\n";
HGLOBAL hgblOutput = NULL;
DWORD cbOutput = 0;
BOOL bResult;

// Search for the login prompt issued by the server

bResult = TelnetSearch(hClient,
                       _T("ogin: "),
                       NULL,
                       NULL,
                       0);

// If the Login: prompt was found, then write out the
// username and search for the Password: prompt; note
// that the username, password and command strings are
// terminated with a carriage-return/linefeed sequence
// which the server will see as the user pressing the
// Enter or Return key on the keyboard

if (bResult)
{
    TelnetWrite(hClient,
                (LPBYTE)lpszUserName,
                lstrlen(lpszUserName));

    bResult = TelnetSearch(hClient,
                           _T("word: "),
                           NULL,
                           NULL,
                           0);
}

// If the Password: prompt was found, write out the
// password and then search for the shell prompt;
// the prompt may be different, depending on what
// operating system and shell is being used

if (bResult)
{
    TelnetWrite(hClient,
                (LPBYTE)lpszPassword,
                lstrlen(lpszPassword));

    bResult = TelnetSearch(hClient,
                           _T("$ "),
                           NULL,
```

```
                            NULL,
                            0);
}

// If the shell prompt was found, issue the command
// and capture the output into the hgblBuffer global
// memory buffer; the cbBuffer variable will contain
// the actual number of bytes in the buffer when the
// function returns

if (bResult)
{
    TelnetWrite(hClient,
                (LPBYTE)lpszCommand,
                lstrlen(lpszCommand));

    bResult = TelnetSearch(hClient,
                           _T("$ "),
                           &hgblOutput,
                           &cbOutput,
                           0);
}

// Write the contents of the output buffer to the
// standard output stream

if (bResult)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    if (lpBuffer)
        fwrite(lpBuffer, 1, cbBuffer, stdout);

    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

TelnetSetLastError Function

```
VOID WINAPI TelnetSetLastError(
    DWORD dwErrorCode
);
```

The **TelnetSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TELNET_ERROR. Those functions which call **TelnetSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **TelnetGetLastError** function. The use of **TelnetGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

TelnetSetMode Function

```
UINT WINAPI TelnetSetMode(
   HCLIENT hClient,
   UINT nMode,
   BOOL bEnable
);
```

The **TelnetSetMode** function sets one or more client modes for the specified session.

Parameters

hClient

Handle to the client session.

nMode

The client mode. This value is a combination of one or more flags which determines how the client handles local character echo and character processing. The following values are recognized:

Value	Description
TELNET_MODE_LOCALECHO	The local client is responsible for echoing data entered by the user. By default, this mode is not set which means that the server is responsible for echoing back each character written to it.
TELNET_MODE_BINARY	Data exchanged between the client and server should not be converted or line buffered. If this option is not specified, the high-bit will be cleared on all characters, and single linefeed characters will be converted to carriage-return/linefeed sequences.

bEnable

This boolean flag specifies if the specified mode is to be enabled or disabled.

Return Value

If the function succeeds, the return value is the previous mode. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

TelnetSetTerminalType Function

```
INT WINAPI TelnetSetTerminalType(
   HCLIENT hClient,
   LPCTSTR lpszTermType
);
```

The **TelnetSetTerminalType** function sets the terminal type for the current client session.

Parameters

hClient

Handle to the client session.

lpszTermType

Points to a string which specifies the terminal type.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

TelnetSetTimeout Function

```
INT WINAPI TelnetSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **TelnetSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetGetTimeout

TelnetUninitialize Function

```
VOID WINAPI TelnetUninitialize();
```

The **TelnetUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **TelnetInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **TelnetUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **TelnetUninitialize** for every successful call to **TelnetInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

TelnetWrite Function

```
INT WINAPI TelnetWrite(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **TelnetWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is TELNET_ERROR. To get extended error information, call **TelnetGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the TELNET_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

TelnetWriteLine Function

```
BOOL WINAPI TelnetWriteLine(
   HCLIENT hClient,
   LPCTSTR lpszBuffer,
   LPINT lpnLength
);
```

The **TelnetWriteLine** function sends a line of text to the server, terminated by a carriage-return and linefeed.

Parameters

hClient

Handle to the client session.

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the server. All characters up to, but not including, the terminating null character will be written to the server. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the server.

lpnLength

A pointer to an integer value which will contain the number of characters written to the server, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **TelnetGetLastError**.

Remarks

The **TelnetWriteLine** function writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **TelnetWrite** function which writes arbitrary bytes of data to the server, this function is specifically designed to write a single line of text data from a string.

If the ***lpszBuffer*** string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the ***lpnLength*** parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **TelnetWriteLine**. The function should only be used to send text, never binary data. In particular, the function will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this function will accept a Unicode string, however this function does not support sending raw Unicode data to the server. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written as a stream of bytes.

This function will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this function is called with asynchronous events enabled, it will automatically switch the client into a blocking mode, send the data and then

restore the client to asynchronous operation. If another network operation is attempted while **TelnetWriteLine** is blocked sending data to the server, an error will occur. It is recommended that this function only be used with blocking (synchronous) connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **TelnetWrite** and **TelnetWriteLine** function calls can be safely intermixed.

Unlike the **TelnetWrite** function, it is possible for data to have been written to the server if the return value is zero. For example, if a timeout occurs while the function is waiting to send more data to the server, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the ***lpnLength*** argument will specify the number of characters actually written up to that point.

Requirements

Telnet Protocol Data Structures

- SECURITYCREDENTIALS
- SECURITYINFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Terminal Emulation Library

Emulate an ANSI or DEC VT-220 character mode display terminal.

Reference

- Functions
- Data Structures
- Control Sequences
- Error Codes

Library Information

File Name	CSNVTV12.DLL
Version	12.0.3024.1286
LibID	9A302CB9-6BEE-4D11-9785-76E7624BD130
Import Library	CSNVTV12.LIB
Dependencies	None

Overview

The Terminal Emulation library provides a comprehensive API for emulating an ANSI or DEC-VT220 terminal, with full support for all standard escape and control sequences, color mapping and other advanced features. The library functions provide both a high level interface for parsing escape sequences and updating a display, as well as lower level primitives for directly managing the virtual display, such as controlling the individual display cells, moving the cursor position and specifying display attributes.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or

later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Terminal Emulation Functions

Function	Description
NvtClearDisplay	Clear the specified display
NvtConvertDisplayPos	Convert between pixel and screen coordinates
NvtCopySelectedText	Copy the selected text to the clipboard
NvtCreateDisplay	Create a new virtual terminal emulation display
NvtDeleteChar	Delete the specified number of characters
NvtDeleteLine	Delete the current line, shifting remaining lines up
NvtDestroyDisplay	Destroy the specified virtual display
NvtEraseChar	Erase the specified number of characters
NvtEraseLine	Erase the current line
NvtGetCursorPos	Return the current cursor position
NvtGetDisplayAttributes	Return the current display attributes
NvtGetDisplayCell	Return information about the specified cell in the virtual display
NvtGetDisplayCellSize	Return the size of the display character cells
NvtGetDisplayColor	Get the current virtual display colors
NvtGetDisplayColorMap	Return the virtual display color table
NvtGetDisplayDC	Get the current virtual display device context
NvtGetDisplayEmulation	Get the current terminal emulation type
NvtGetDisplayFont	Get the current virtual display font
NvtGetDisplayInfo	Return information about the virtual display
NvtGetDisplayLine	Return a line of text from the virtual display
NvtGetDisplayMode	Get the current virtual display mode
NvtGetDisplayRect	Return the rectangle for the display window client area
NvtGetDisplayScrollPos	Get the display scroll box position
NvtGetDisplaySize	Return the current size of the virtual display
NvtGetDisplayText	Get the specified block of text from the virtual display
NvtGetDisplayWindow	Get the current virtual display window
NvtGetMappedKey	Return the escape sequence for the mapped key
NvtGetScrollRegion	Return the current scrolling region
NvtGetSelectedText	Return the currently selected text
NvtGetTextColor	Return the current text foreground or background color
NvtInitialize	Initialize the library for use by the client

NvtInsertChar	Insert the specified number of characters
NvtInsertLine	Insert a line, shifting the remaining lines down
NvtRefreshDisplay	Refresh the specified display
NvtResetDisplay	Reset the virtual display
NvtResetMappedKeys	Reset the mapped key table to default values
NvtResizeDisplay	Resize the virtual display
NvtRestoreCursor	Restore the saved cursor position and text attributes
NvtSaveCursor	Save the current cursor position and text attributes
NvtScrollDisplay	Scroll the virtual display
NvtSelectDisplayText	Select a region of the virtual display
NvtSetCursorPos	Set the current cursor position
NvtSetDisplayAttributes	Set the current display attributes
NvtSetDisplayBackColor	Set the background color for the virtual display
NvtSetDisplayBoldColor	Set the bold color for the virtual display
NvtSetDisplayCell	Set the value of a character cell in the virtual display
NvtSetDisplayColor	Set the virtual display colors
NvtSetDisplayColorMap	Set the virtual display color table
NvtSetDisplayDC	Set the current virtual display device context
NvtSetDisplayEmulation	Set the current terminal emulation type
NvtSetDisplayFocus	Set the focus on the virtual display
NvtSetDisplayFont	Set the current virtual display font
NvtSetDisplayFontName	Set the current virtual display font by name
NvtSetDisplayForeColor	Set the foreground color for the virtual display
NvtSetDisplayMode	Set the current virtual display mode
NvtSetDisplayScrollPos	Set the display scroll box position
NvtSetDisplaySize	Set the size of the virtual display
NvtSetDisplayWindow	Set the current virtual display window
NvtSetMappedKey	Set the escape sequence for the specified key
NvtSetScrollRegion	Set the current scrolling region
NvtSetTextColor	Set the current text foreground or background color
NvtTranslateMappedKey	Translate the keypress to a mapped key escape sequence
NvtUninitialize	Terminate use of the library by the application
NvtUpdateCaret	Update the display window caret
NvtUpdateDisplay	Update the window attached to the virtual display
NvtWriteDisplay	Write the specified buffer to the virtual display

NvtClearDisplay Function

```
BOOL WINAPI NvtClearDisplay(
   HDISPLAY hDisplay,
   UINT nMode
);
```

The **NvtClearDisplay** function clears the specified display, erasing the text and clearing any attributes.

Parameters

hDisplay

Handle to the virtual display.

nMode

Mode which specifies how the display will be cleared. The following values may be used:

Value	Description
NVT_CLEAR_EOS	The display is cleared from the current cursor position to the end of the display. The cursor position is not changed.
NVT_CLEAR_TOS	The display is cleared from the beginning of the display to the current cursor position. The cursor position is not changed.
NVT_CLEAR_ALL	The entire display is cleared and the cursor is repositioned to the upper left corner of the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtConvertDisplayPos Function

```
BOOL WINAPI NvtConvertDisplayPos(
    HDISPLAY hDisplay,
    INT nMethod,
    INT xPos,
    INT yPos,
    LPPOINT lppt
);
```

The **NvtConvertDisplayPos** function converts the specified X,Y position and stores the result in the POINT structure provided by the caller.

Parameters

hDisplay

Handle to the virtual display.

nMethod

An integer value which specifies the conversion method to use. This may be one of the following values:

Value	Description
NVT_CURSOR_TO_PIXELS	Convert cursor X,Y coordinates to the current window X,Y pixel coordinates. An error is returned if the coordinates are out of bounds for the current display.
NVT_PIXELS_TO_CURSOR	Convert window X,Y pixel coordinates to cursor X,Y coordinates. If the point is outside of the bounds of the display, it is normalized to account for mouse capture.

xPos

An integer value which specifies the X position in the virtual display. This may either be the cursor position or a pixel position, based on the value of the ***nMethod*** parameter.

yPos

An integer value which specifies the Y position in the virtual display. This may either be the cursor position or a pixel position, based on the value of the ***nMethod*** parameter.

lppt

A pointer to a POINT structure which will contain the converted coordinates.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetCursorPos, NvtSetDisplayScrollPos

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NvtCopySelectedText Function

```
BOOL WINAPI NvtCopySelectedText(
    HDISPLAY hDisplay
);
```

The **NvtCopySelectedText** function copies any selected text to the system clipboard.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtCreateDisplay Function

```
HDISPLAY WINAPI NvtCreateDisplay(
    HWND hWnd,
    HFONT hFont,
    UINT nEmulation,
    UINT nColumns,
    UINT nRows
);
```

The **NvtCreateDisplay** function creates a new virtual terminal emulation display using the specified window and font.

Parameters

hWnd

Handle to the window that will be used to display the virtual terminal.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case a default fixed-width font will be used. If a font is specified, it must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

nEmulation

Identifies the virtual terminal emulation type. The following emulation types are currently supported.

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process escape sequences.
NVT_EMULATION_ANSI	The virtual display processes ANSI escape sequences for screen management and cursor positioning. This emulation also supports escape sequences to control the foreground and background color. The default keymap for ANSI function key escape sequences will be selected.
NVT_EMULATION_VT100	The virtual display processes DEC VT-100 escape sequences for screen management and cursor positioning. The default keymap for a DEC VT-100 terminal will be selected.
NVT_EMULATION_VT220	The virtual display processes DEC VT-220 escape sequences for screen management and cursor positioning. This emulation also supports DEC VT-320 escape sequences to control the foreground and background color. The default keymap for a DEC VT-220 terminal will be selected.

nColumns

The maximum number of columns used by the virtual display. This value must be at least 5, and no greater than 255.

nRows

The maximum number of rows used by the virtual display. This value must be at least 5, and no greater than 127.

Return Value

If the function succeeds, the return value is a handle to the virtual display. If the function fails, the return value is INVALID_DISPLAY.

Remarks

The default colors for the display is a black background and white foreground. If ANSI terminal emulation is selected, bold characters will be displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtDeleteChar Function

```
BOOL WINAPI NvtDeleteChar(
   HDISPLAY hDisplay,
   INT nChars
);
```

The **NvtDeleteChar** function deletes the specified number of characters from the display, shifting the characters that follow to the left. The characters are deleted from the current cursor position.

Parameters

hDisplay

Handle to the virtual display.

nChars

Number of characters to delete from the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. To erase characters from the display without affecting the characters that follow, use the **NvtEraseChar** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtDeleteLine Function

```
BOOL WINAPI NvtDeleteLine(
   HDISPLAY hDisplay
);
```

The **NvtDeleteLine** function deletes the current line, shifting up the lines that follow.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. To erase a line from the display without affecting the lines that follow, use the **NvtEraseLine** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtDestroyDisplay Function

```
VOID WINAPI NvtDestroyDisplay(
   HDISPLAY hDisplay
);
```

The **NvtDestroyDisplay** function releases the memory allocated for the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

None.

Remarks

If the display font was specified when the display was created, then it is the responsibility of the application to delete the font object using the **DeleteObject** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtEraseChar Function

```
BOOL WINAPI NvtEraseChar(
   HDISPLAY hDisplay,
   INT nChars
);
```

The **NvtEraseChar** function erases the specified number of characters from the display, without affecting the position of the characters that follow. The characters are erased from the current cursor position.

Parameters

hDisplay

Handle to the virtual display.

nChars

Number of characters to erase from the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. To delete characters from the display and shift the remaining characters to the left, use the **NvtDeleteChar** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtEraseLine Function

```
BOOL WINAPI NvtEraseLine(
   HDISPLAY hDisplay,
   UINT nMode
);
```

The **NvtEraseLine** function erases the current line without affecting the lines that follow.

Parameters

hDisplay

Handle to the virtual display.

nMode

Mode which specifies how the line will be erased. The following values may be used:

Value	Description
The line is erased from the current cursor position to the end of the line.	
The line is cleared from the beginning of the line to the current cursor position.	
The entire line is cleared.	

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. To delete a line from the display and shift the remaining lines up, use the **NvtDeleteLine** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtGetCursorPos Function

```
BOOL WINAPI NvtGetCursorPos(
   HDISPLAY hDisplay,
   LPINT lpnCursorX,
   LPINT lpnCursorY
);
```

The **NvtGetCursorPos** function returns the current cursor column and row position on the virtual display.

Parameters

hDisplay

Handle to the virtual display.

lpnCursorX

Address of the variable that will be set to the column of the current cursor position. If this argument is a NULL pointer, the argument is ignored.

lpnCursorY

Address of the variable that will be set to the row of the current cursor position. If this argument is a NULL pointer, the argument is ignored.

Return Value

If the function succeeds, the return value is a non-zero value. If the handle to the virtual display is invalid, the function will return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NvtGetDisplayAttributes Function

```
UINT WINAPI NvtGetDisplayAttributes(
    HDISPLAY hDisplay
);
```

The **NvtGetDisplayAttributes** function returns the current display attributes which have been set, either explicitly by the client or as the result of an escape sequence parsed by the emulator.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value the current display attributes. If the function fails, the return value is NVT_ERROR.

The following table lists the valid attributes:

Value	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtGetDisplayCell, NvtSetDisplayAttributes

NvtGetDisplayCell Function

```
DWORD WINAPI NvtGetDisplayCell(
    HDISPLAY hDisplay,
    INT xPos,
    INT yPos
);
```

The **NvtGetDisplayCell** function returns information about the specified character cell in the display.

Parameters

hDisplay

Handle to the virtual display.

xPos

An integer value which specifies the X cursor position in the display.

yPos

An integer value which specifies the Y cursor position in the display.

Return Value

If the function succeeds, the return value is the cell character and attributes. If the function fails, it returns NVT_ERROR.

Remarks

The value returned by the **NvtGetDisplayCell** function is an unsigned 32-bit integer value, where the low order word specifies the ANSI character stored at that position and the high order word specifies the display attributes for that cell.

The character cell attributes may be one or more of the following values:

Value	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayCellSize Function

```
BOOL WINAPI NvtGetDisplayCellSize(
    HDISPLAY hDisplay,
    LPSIZE lpCellSize
);
```

The **NvtGetDisplayCellSize** function returns the size of a character cell in pixels.

Parameters

hDisplay

Handle to the virtual display.

lpCellSize

A pointer to a SIZE structure which will contain the size of a character cell in pixels.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

The **NvtGetDisplayCellSize** function is used to determine the size of a character cell in the display. This can be useful when the application needs to determine where a display cell is physically located within the virtual display window.

To convert between display and window coordinates, use the **NvtConvertDisplayPos** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayColor Function

```
COLORREF WINAPI NvtGetDisplayColor(
    HDISPLAY hDisplay,
    UINT nColorIndex,
    BOOL bForeground
);
```

The **NvtGetDisplayColor** function returns the color used by the virtual display to display text with a specific attribute.

Parameters

hDisplay

Handle to the virtual display.

nColorIndex

The index into the virtual display color table. It may be one of the following values.

Value	Description
NVT_COLOR_NORMAL	The colors displayed for normal text. These are the default colors used with the display.
NVT_COLOR_REVERSE	The colors displayed for text with the reverse attribute set. This is only used when emulation is enabled.
NVT_COLOR_BOLD	The colors displayed for text with the bold attribute set. This is only used when emulation is enabled.
NVT_COLOR_REVERSEBOLD	The colors displayed for text with the reverse and bold attributes set. This is only used when emulation is enabled.

bForeground

A boolean flag which specifies if the color is a foreground color, used when displaying text, or a background color.

Return Value

If the function succeeds, the return value is the RGB value of the specified color. If the function fails, it returns zero.

Remarks

The default colors for the display is a black background and white foreground. Bold characters are displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayColorMap Function

```
BOOL WINAPI NvtGetDisplayColorMap(
    HDISPLAY hDisplay,
    COLORREF* lpColor,
    INT nMaxColors
);
```

The **NvtGetDisplayColorMap** function returns the virtual display color table which determines what RGB values are used to display foreground and background text color attributes.

Parameters

hDisplay

Handle to the virtual display.

lpColor

A pointer to an array of COLORREF values which will contain the color values currently being used in the virtual display.

nMaxColors

The maximum number of colors which may be stored in the color array. The minimum value for this parameter is 1, and the maximum value is 16.

Return Value

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. Failure indicates that the handle to the virtual display is invalid, the pointer to the color table is NULL or the maximum number of color values is invalid.

Remarks

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **NvtGetDisplayColorMap** function is useful for determining what values are being used when a color attribute is set. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals:

Index	Color	Default (Hex)	Default (Integer)	Default (RGB)
Black	RGB(0,0,0)			
Red	000000A0h	RGB(160,0,0)		
Green	0000A000h	RGB(0,160,0)		
Yellow	0000A0A0h	RGB(160,160,0)		
Blue	00A00000h	RGB(0,0,160)		
Magenta	00A000A0h	RGB(160,0,160)		
Cyan	00A0A000h	RGB(0,160,160)		
White	00E0E0E0h	RGB(224,224,224)		
Gray	00C0C0C0h	RGB(192,192,192)		
Light Red	008080FFh	RGB(255,128,128)		

Light Green	0090EE90h	RGB(144,238,144)
Light Yellow	00C0FFFFh	RGB(255,255,192)
Light Blue	00E6D8ADh	RGB(173,216,230)
Light Magenta	00FFC0FFh	RGB(255,192,255)
Light Cyan	00FFFFE0h	RGB(224,255,255)
High White	00FFFFFFh	RGB(255,255,255)

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

```
ESC [ 37;44 m
```

Note that if you wanted to set the foreground color to a bold version of standard yellow, you would first set the bold attribute, and then use the index value of 3, such as:

```
ESC [ 1;33m
```

NvtGetDisplayColorMap is typically used in conjunction with the **NvtSetDisplayColorMap** function to load the current color values and then make selective changes to the actual RGB color value that is used when a color attribute is set. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters.

Example

The following example will load the current color table for the virtual display and change the standard white color attribute to use the same value as the high-intensity white:

```
COLORREF rgbColor[16];

if ( NvtGetDisplayColorMap(hDisplay, rgbColor, 16) )
{
     rgbColor[7] = rgbColor[15];
     NvtSetDisplayColorMap(hDisplay, rgbColor, 16);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayDC Function

```
HDC WINAPI NvtGetDisplayDC(
   HDISPLAY hDisplay
);
```

The **NvtGetDisplayDC** returns the device context that has been specified for the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is a handle to the device context. If the function fails, or no device context has been specified, the return value is NULL.

Remarks

Normally there is no device context explicitly set for the display. Instead, the device context is dynamically created and released when the virtual display is updated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayEmulation Function

```
UINT WINAPI NvtGetDisplayEmulation(
    HDISPLAY hDisplay
);
```

The **NvtGetDisplayEmulation** function returns the current virtual terminal emulation type.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is the terminal emulation type and may contain one of the following values:

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
NVT_EMULATION_ANSI	The virtual display will process ANSI escape sequences. The default keymap for an ANSI console is loaded.
NVT_EMULATION_VT100	The virtual display will process DEC VT100 escape sequences. The default keymap for a VT100 terminal is loaded.
NVT_EMULATION_VT220	The virtual display will process DEC VT220 escape sequences. The default keymap for a VT220 terminal is loaded.

If the function fails, because an invalid display handle was specified, the return value will be NVT_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayFont Function

```
HFONT WINAPI NvtGetDisplayFont(
    HDISPLAY hDisplay
);
```

The **NvtGetDisplayFont** function returns the current font handle being used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is a handle to the font. If the function fails, it returns NULL.

Remarks

The handle returned by this function should not be released, and the font object should never be directly modified by the application. Functions that return information about the font, such as **GetTextMetrics**, may be safely called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayInfo Function

```
BOOL WINAPI NvtGetDisplayInfo(
   HDISPLAY hDisplay,
   LPNVTDISPLAYINFO lpvdi
);
```

The **NvtGetDisplayInfo** function returns information about the specified virtual display.

Parameters

hDisplay

Handle to the virtual display.

lpvdi

Pointer to a NVTDISPLAYINFO structure which contains information about the virtual display, including the display window, font, cursor and scrolling position.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayLine Function

```
INT WINAPI NvtGetDisplayLine(
   HDISPLAY hDisplay,
   INT nRow,
   LPTSTR lpszText,
   INT nMaxLength
);
```

The **NvtGetDisplayLine** function copies a block of text from the specified virtual display into a string buffer.

Parameters

hDisplay

Handle to the virtual display.

nRow

The row in the virtual display to return the line of text from. The first row in the display is zero. If the value -1 is specified, the row where the cursor is currently located will be used.

lpszText

Pointer to the buffer that the display text will be copied to, terminated with a null character character.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the function fails, it returns zero.

Remarks

The **NvtGetDisplayLine** function allows the application to copy the contents of the display at a specific row. Note that the buffer must be large enough to accommodate the text and the null character terminator. Unlike the **NvtGetDisplayText** function, any trailing whitespace in the specified row is not copied to the buffer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

NvtGetDisplayMode Function

```
UINT WINAPI NvtGetDisplayMode(
    HDISPLAY hDisplay
);
```

The **NvtGetDisplayMode** function returns the current virtual display modes.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is the display mode for the virtual display. If the function fails, it returns zero.

Remarks

The display mode is a combination of one or more flags which determines how the emulator handles automatic line wrapping, caret display, and other functions. The following values are recognized.

Value	Description
NVT_MODE_AUTOWRAP	The emulator will automatically wrap to the next line when a character is written to the last column on the virtual display.
NVT_MODE_SHOWCARET	The emulator will display a caret when the display receives the focus.
NVT_MODE_BLOCKCARET	The emulator will display a block carat that is the height of the selected font characters. If this mode is not set, the caret is displayed as an underline.
NVT_MODE_BELL	The emulator will beep when a BEL character is processed.
NVT_MODE_CRLF	The cursor will automatically be positioned at the first column when a linefeed character is processed.
NVT_MODE_CRNL	The cursor will automatically advance to the next row when a carriage return character is processed.
NVT_MODE_APPCURSOR	The emulator cursor keys are placed in application mode. This mode changes the default key mappings used when the cursor (arrow) keys are translated. This corresponds to the application mode supported by DEC VT terminals.
NVT_MODE_APPKEYPAD	The emulator keypad keys are placed in application mode. This mode changes the default key mappings used when the keypad keys are translated. This corresponds to the application keypad mode supported by DEC VT terminals.
NVT_MODE_ORIGIN	The emulator is in origin mode. If enabled, the cursor cannot be positioned outside of the current scrolling region. Otherwise, the cursor can be positioned at any valid location on the virtual display.
NVT_MODE_COLOR	The emulator supports the use of escape sequences to change the foreground and background colors. This option is enabled by default if emulating an ANSI console or DEC VT220 terminal.

NVT_MODE_TABOVER	The emulator will clear the character cells between the current cursor position and the next tab stop when the HT (horizontal tab) control sequence is processed. By default this mode is disabled, and the cursor is simply positioned at the next tab stop.
NVT_MODE_HSCROLL	The emulator will display a horizontal scroll bar if the number of visible columns are less then that total number of columns in the virtual display. Disabling this mode prevents a horizontal scrollbar from being displayed, regardless of the number of visible columns. By default, this mode is enabled.
NVT_MODE_VSCROLL	The emulator will display a vertical scroll bar if the number of visible rows are less then that total number of rows in the virtual display. Disabling this mode prevents a vertical scrollbar from being displayed, regardless of the number of visible rows. By default, this mode is enabled.
NVT_MODE_NOREFRESH	The emulator will not automatically refresh the window after any change has been made to the virtual display, including changes in the cursor position or display mode. This allows the caller to make a sequence of changes, and then update the display all at one time to prevent a flicker effect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayRect Function

```
BOOL WINAPI NvtGetDisplayRect(
   HDISPLAY hDisplay,
   LPRECT lpRect
);
```

The **NvtGetDisplayRect** returns the client rectangle for the virtual display window.

Parameters

hDisplay

Handle to the virtual display.

lpRect

Pointer to a RECT structure which will contain the client rectangle values when the function returns.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetDisplayScrollPos Function

```
INT WINAPI NvtGetDisplayScrollPos(
    HDISPLAY hDisplay,
    INT nScrollBar
);
```

The **NvtGetDisplayScrollPos** function gets the position of the scroll box for the specified scroll bar.

Parameters

hDisplay

Handle to the virtual display.

nScrollBar

Specifies the scroll bar to return the position for. This parameter can be one of the following values:

Value	Description
SB_HORZ	Gets the position of the scroll box in the display's standard horizontal scroll bar.
SB_VERT	Gets the position of the scroll box in the display's standard vertical scroll bar.

Return Value

If the function succeeds, the return value is the position of the scroll box. If the function fails, it returns -1.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtGetDisplaySize Function

```
BOOL WINAPI NvtGetDisplaySize(
   HDISPLAY hDisplay,
   LPSIZE lpSize
);
```

The **NvtGetDisplaySize** returns the size of the virtual display in columns and rows.

Parameters

hDisplay

Handle to the virtual display.

lpSize

Pointer to a SIZE structure which will contain the size of the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

The **NvtGetDisplaySize** function returns the number of columns and rows in the virtual display. To convert this to pixels, use the **NvtGetDisplayCellSize** function to determine the size of a character cell and multiply that by the number of columns and/or rows.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtGetDisplayText Function

```
INT WINAPI NvtGetDisplayText(
   HDISPLAY hDisplay,
   INT nOffset,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **NvtGetDisplayText** function copies a block of text from the specified virtual display into a string buffer.

Parameters

hDisplay

Handle to the virtual display.

nOffset

Offset into the virtual display buffer. A value of -1 specifies that the current cursor position should be used as the offset.

lpszBuffer

Pointer to the buffer that the display text will be copied to, terminated with a null character character.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the function fails, it returns zero.

Remarks

The **NvtGetDisplayText** function allows the application to copy the contents of the display at a specific location. Note that the buffer must be large enough to accommodate the text and the null character terminator. To copy an entire row of text in the display, use the **NvtGetDisplayLine** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

NvtGetDisplayWindow Function

```
HWND WINAPI NvtGetDisplayWindow(
    HDISPLAY hDisplay
);
```

The **NvtGetDisplayWindow** returns the handle to the window being used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is a handle to the virtual display window. If the function fails, it returns NULL.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetMappedKey Function

```
BOOL WINAPI NvtGetMappedKey(
   HDISPLAY hDisplay,
   UINT nMappedKey,
   LPTSTR lpszKeyBuffer,
   UINT cchKeyBuffer
);
```

The **NvtGetMappedKey** function returns the escape sequence mapped to the specified key.

Parameters

hDisplay

Handle to the virtual display.

nMappedKey

The key which is an index into the display key mapping table. This defines the values returned by special (function) keys for the current emulation.

lpszKeyBuffer

Address of the buffer which will receive the escape sequence mapped to the specified key.

cchKeyBuffer

The maximum number of characters that may be copied into the key buffer string, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero and the escape sequence for the mapped key is copied into the specified buffer. If the key has not been mapped, and there is no default escape sequence defined, then the function will return zero.

Remarks

The **NvtGetMappedKey** function returns the escape sequence that has been mapped to a special key. This function can be used to determine what sequence of characters should be sent in response to a keypress (for example, what sequence should be sent to a server when the user presses the F1 function key). If a sequence has not been explicitly mapped through a call to **NvtSetMappedKey**, the default sequence for the current emulation will be returned.

Note that the current display mode, such as whether or not the emulator is in application mode or not, should be considered when determining which mapped key to use. For example, if the emulator is not in application mode and the user presses the up-arrow key, the sequence mapped to the NVT_UP key should be sent to the server. However, if the emulator is in application mode, the sequence mapped to the NVT_APPUP key should be sent instead. This is automatically handled by the **NvtTranslateMappedKey** function, so it is recommended that it be used when mapping a virtual keypress to the appropriate escape sequence.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

NvtGetScrollRegion Function

```
BOOL WINAPI NvtGetScrollRegion(
    HDISPLAY hDisplay,
    LPINT lpnTop,
    LPINT lpnBottom
);
```

The **NvtGetScrollRegion** function returns the top and bottom rows of the current scrolling region.

Parameters

hDisplay

Handle to the virtual display.

lpnTop

Address of the variable that will be set to the top row of the current scrolling region. If no scrolling region has been defined, the value will be 0, the first row in the virtual display. If a NULL pointer is passed as the value, this argument will be ignored.

lpnBottom

Address of the variable that will be set to the bottom row of the current scrolling region. If no scrolling region has been defined, the value will be one less than the maximum number of rows in the virtual display. If a NULL pointer is passed as the value, this argument will be ignored.

Return Value

If the function succeeds, it will return zero. If the handle to the display is invalid, the function will return zero.

Remarks

The **NvtGetScrollRegion** function allows an application to determine the top and bottom rows of the current scrolling region. By default, the scrolling region is the entire virtual display, however this may be changed through a call to **NvtSetScrollRegion** or an ANSI escape sequence. If the display is in origin mode, note that the cursor cannot be positioned outside of the current scrolling region.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtGetSelectedText Function

```
INT WINAPI NvtGetSelectedText(
   HDISPLAY hDisplay,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **NvtGetSelectedText** function copies the currently selected text into the specified buffer.

Parameters

hDisplay

Handle to the virtual display.

lpszBuffer

Pointer to the buffer that the selected text will be copied to, terminated with a null character character.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

NvtGetTextColor Function

```
BOOL WINAPI NvtGetTextColor(
   HDISPLAY hDisplay,
   COLORREF * lprgbColor,
   BOOL bForeground
);
```

The **NvtGetTextColor** function returns the current foreground or background text color.

Parameters

hDisplay

Handle to the virtual display.

lprgbColor

A pointer to a COLORREF variable which will contain the current foreground or background text color.

bForeground

A boolean value which determines if the foreground or background color is returned. A value of TRUE indicates that the foreground color should be returned, otherwise the background color is returned.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. Failure indicates that the handle to the display is invalid, the display does not support text color attributes, or the pointer to the color value is NULL.

Remarks

This function is used to return the current foreground or background color, as determined by the text attribute. The RGB color value for a color attribute is determined by the virtual display's color table.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtInitialize Function

```
BOOL WINAPI NvtInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **NvtInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **NvtGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **NvtInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **NvtUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **NvtInitialize** or **NvtUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

NvtInsertChar Function

```
BOOL WINAPI NvtInsertChar(
   HDISPLAY hDisplay,
   INT nChars
);
```

The **NvtInsertChar** function inserts one or more space characters at the current cursor position.

Parameters

hDisplay

Handle to the virtual display.

nChars

Number of space characters to insert at the current cursor position.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the cursor position. Inserting space characters may cause the virtual display to scroll.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtDeleteChar, NvtEraseChar, NvtInsertLine

NvtInsertLine Function

```
BOOL WINAPI NvtInsertLine(
   HDISPLAY hDisplay
);
```

The **NvtInsertLine** function inserts an empty line at the current row, shifting the remaining lines down.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the cursor position. Inserting a line may cause the virtual display to scroll.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtRefreshDisplay Function

```
BOOL WINAPI NvtRefreshDisplay(
   HDISPLAY hDisplay,
   BOOL bUpdate
);
```

The **NvtRefreshDisplay** function refreshes the specified virtual display, updating the current scroll position and caret.

Parameters

hDisplay

Handle to the virtual display.

bUpdate

Boolean flags which specifies if the display window is to be updated. If set, the window client area is invalidated and the virtual display is redrawn.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtResetDisplay Function

```
BOOL WINAPI NvtResetDisplay(
   HDISPLAY hDisplay,
   HWND hWnd,
   HFONT hFont,
   UINT nColumns,
   UINT nRows
);
```

The **NvtResetDisplay** resets the virtual terminal display, using the new window, font, columns and rows. This function should be used when the virtual display must be attached to a different window, or the number of rows or columns must be changed.

Parameters

hDisplay

Handle to the virtual display.

hWnd

Handle to the window that will be used to display the virtual terminal. This parameter may be NULL, in which case the current window will be used.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case the current font will be used. If a font is specified, it must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

nColumns

The maximum number of columns used by the virtual display. A value of zero specifies that the same number of columns should be used. If a non-zero value is specified, it must be at least 5, and no greater than 255.

nRows

The maximum number of rows used by the virtual display. A value of zero specifies that the same number of columns should be used. If a non-zero value is specified, it must be at least 5, and no greater than 127.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will clear the display and reset the current text attributes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtResetMappedKeys Function

```
BOOL WINAPI NvtResetMappedKeys(
    HDISPLAY hDisplay
);
```

The **NvtResetMappedKeys** function resets all mapped function keys to their default values, based on the current emulation.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the handle to the display is invalid, the function will return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtResizeDisplay Function

```
BOOL WINAPI NvtResizeDisplay(
   HDISPLAY hDisplay,
   INT cxClient,
   INT cyClient
);
```

The **NvtResizeDisplay** function resizes the virtual display to the specified width and height.

Parameters

hDisplay

Handle to the virtual display.

cxClient

New width of the display window in pixels. If this value is zero, the width of the virtual display remains unchanged.

cyClient

New height of the display window in pixels. If this value is zero, the height of the virtual display remains unchanged.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function resizes the virtual display and updates the scrolling information. Typically this function is called when the display window receives a WM_SIZE message, causing the virtual display to match the size of the window's client area.

This function will not change the size of the display window. To change the size of the display window, use the **SetWindowPos** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtRestoreCursor Function

```
BOOL WINAPI NvtRestoreCursor(
   HDISPLAY hDisplay
);
```

The **NvtRestoreCursor** function restores the cursor position and text attributes to their previous values.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

Use the **NvtSaveCursor** function to save the current cursor position and text attributes. This function may only be called once for each time that the cursor position is saved.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSaveCursor Function

```
BOOL WINAPI NvtSaveCursor(
   HDISPLAY hDisplay
);
```

The **NvtSaveCursor** function saves the current cursor position and text attributes.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

Use the **NvtRestoreCursor** function to restore the cursor position and text attributes to their previous values.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtScrollDisplay Function

```
BOOL WINAPI NvtScrollDisplay(
   HDISPLAY hDisplay,
   BOOL bScrollUp
);
```

The **NvtScrollDisplay** function scrolls the virtual display up or down and updates the scroll box position if necessary.

Parameters

hDisplay

Handle to the virtual display.

bScrollUp

Boolean flag which specifies if the virtual display is scrolled up or down.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function does not change the current cursor position. The **NvtRefreshDisplay** function should be called to update the window attached to the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtSelectDisplayText Function

```
BOOL WINAPI NvtSelectDisplayText(
    HDISPLAY hDisplay,
    LPRECT lpRect,
    DWORD dwOptions
);
```

The **NvtSelectDisplayText** function selects or unselects a region of the virtual display.

Parameters

hDisplay

Handle to the virtual display.

lpRect

A pointer to a region of the display to select. The coordinates must be in display cursor coordinates, not pixels. If this parameter is NULL, any selected text in the display is unselected.

dwOptions

One or more options which specifies how the region will be selected. These options may be combined using a bitwise Or operator. The following values may be used:

Value	Description
NVT_SELECT_DEFAULT	The default selection option. If there is a region of the display already selected, it will be cleared and the new region is selected.
NVT_SELECT_CLIPBOARD	Copy the selected text to the clipboard. If this option is not specified, the selected text is buffered and may be copied at a later point.
NVT_SELECT_NOREFRESH	The display is not refreshed when the region is selected. This is useful if the application is going to be selecting multiple regions of the display, or combining more than one region, in order to minimize output to the window.
NVT_SELECT_NOBUFFER	Do not buffer the text in the selected region of the display. The display will show any text as being selected, but it will not be available to be copied by the application. This can be useful if the application is going to select multiple regions and combine them.
NVT_SELECT_COMBINE	If there is already a region of the display that has been selected, the new region is combined with the previous region, selecting all of the text.
NVT_SELECT_UNSELECT	Unselect the specified region of the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetCursorPos Function

```
BOOL WINAPI NvtSetCursorPos(
   HDISPLAY hDisplay,
   INT nCursorX,
   INT nCursorY
);
```

The **NvtSetCursorPos** function sets the current cursor column and row position on the virtual display.

Parameters

hDisplay

Handle to the virtual display.

nCursorX

New cursor column position. If this value is greater than the maximum number of columns, the current position is set to the last column on the display. The first column on the display is zero.

nCursorY

New cursor row position. If this value is greater than the maximum number of rows, the current position is set to the last row on the display. The first row on the display is zero.

Return Value

If the function succeeds, the return value is non-zero. If the handle to the virtual display is invalid, the function will return zero.

Remarks

The **NvtSetCursorPos** function sets the current cursor position on the virtual display. If the display is in origin mode (a scrolling region has been set), then the cursor row position is bound by the current region.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetDisplayAttributes Function

```
UINT WINAPI NvtSetDisplayAttributes(
    HDISPLAY hDisplay,
    UINT nAttributes
);
```

The **NvtSetDisplayAttributes** function sets the current display attributes.

Parameters

hDisplay

Handle to the virtual display.

nAttributes

An unsigned integer value which specifies the new display attributes. This may be one or more of the following values:

Value	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

Return Value

If the function succeeds, the return value is the previous display attributes. If the function fails, the return value is NVT_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetDisplayBackColor Function

```
BOOL WINAPI NvtSetDisplayBackColor(
   HDISPLAY hDisplay,
   COLORREF rgbBackground
);
```

The **NvtSetDisplayBackColor** sets the background color used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

rgbBackground

The background color specified as a 32-bit RGB value.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function sets the background color for normal, reverse, bold and reverse-bold text attributes. To set the background color for a specific attribute, use the **NvtSetDisplayColor** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtSetDisplayBoldColor Function

```
BOOL WINAPI NvtSetDisplayBoldColor(
    HDISPLAY hDisplay,
    COLORREF rgbBold
);
```

The **NvtSetDisplayBoldColor** sets the color used by the virtual display to display text with the bold attribute enabled.

Parameters

hDisplay

Handle to the virtual display.

rgbBold

The bold attribute color specified as a 32-bit RGB value.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function sets the foreground color for the bold and reverse-bold text attributes. To set the color for a specific attribute, use the **NvtSetDisplayColor** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtSetDisplayCell Function

```
DWORD WINAPI NvtSetDisplayCell(
    HDISPLAY hDisplay,
    INT xPos,
    INT yPos,
    DWORD dwCell
);
```

The **NvtSetDisplayCell** function sets the value of the specified cell in the virtual display.

Parameters

hDisplay

Handle to the virtual display.

xPos

An integer value which specifies the cell column in the virtual display. A value of -1 specifies that the current cursor position should be used.

yPos

An integer value which specifies the cell row in the virtual display. A value of -1 specifies that the current cursor position should be used.

dwCell

An unsigned integer which specifies the new value for the cell in the virtual display. The low order word of this value should contain the character to be displayed at that location. The high order word should specify the attributes for that cell.

Return Value

If the function succeeds, the return value is the previous cell value. If the function fails, it returns 0xFFFFFFFF. The previous cell value is the same value returned by the **NvtGetDisplayCell** function.

Remarks

The **NvtSetDisplayCell** function is used to modify a specific character cell in the virtual display, changing both the character and the attributes for that cell. Unlike the higher level functions such as **NvtWriteDisplay** which process character strings and escape sequences, the **NvtGetDisplayCell** and **NvtSetDisplayCell** functions allow direct, low-level access to the virtual display in memory. After one or more cells are modified using this function, you should call the **NvtRefreshDisplay** function to redraw the virtual display.

The character cell attributes may be one or more of the following values:

Value	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.

NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtSetDisplayColor Function

```
BOOL WINAPI NvtSetDisplayColor(
    HDISPLAY hDisplay,
    UINT nColorIndex,
    COLORREF dwColor,
    BOOL bForeground
);
```

The **NvtSetDisplayColor** function sets the colors used by the virtual display. Each display has a color table which specifies the foreground and background colors used when displaying text with a specific attribute.

Parameters

hDisplay

Handle to the virtual display.

nColorIndex

The index into the virtual display color table. It may be one of the following values.

Value	Description
NVT_COLOR_NORMAL	The colors displayed for normal text. These are the default colors used with the display.
NVT_COLOR_REVERSE	The colors displayed for text with the reverse attribute set. This is only used when emulation is enabled.
NVT_COLOR_BOLD	The colors displayed for text with the bold attribute set. This is only used when emulation is enabled.
NVT_COLOR_REVERSEBOLD	The colors displayed for text with the reverse and bold attributes set. This is only used when emulation is enabled.

dwColor

The RGB color value that will be used.

bForeground

A boolean flag which specifies if the color is a foreground color, used when displaying text, or a background color.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

The default colors for the display is a black background and white foreground. Bold characters are displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtSetDisplayColorMap Function

```
BOOL WINAPI NvtSetDisplayColorMap(
    HDISPLAY hDisplay,
    COLORREF *lpColor,
    INT nColors
);
```

The **NvtSetDisplayColorMap** function modifies the virtual display color table which determines what RGB values are used to display foreground and background text color attributes.

Parameters

hDisplay

Handle to the virtual display.

lpColor

A pointer to an array of COLORREF values which specifies the values to be used by the emulator when setting a color attribute. If this value is NULL, the default color table will be loaded.

nColors

The number of colors which are stored in the array. The minimum value for this parameter is 1, and the maximum value is 16.

Return Value

If the function succeeds, the return value is a non-zero value. If the function fails, the return value is zero. Failure indicates that the handle to the virtual display is invalid or the number of color values is invalid.

Remarks

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **NvtSetDisplayColorMap** function is useful for changing what values are being used when a color attribute it set. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals:

Index	Color	Default (Hex)	Default (Integer)	Default (RGB)
Black	RGB(0,0,0)			
Red	000000A0h	RGB(160,0,0)		
Green	0000A000h	RGB(0,160,0)		
Yellow	0000A0A0h	RGB(160,160,0)		
Blue	00A00000h	RGB(0,0,160)		
Magenta	00A000A0h	RGB(160,0,160)		
Cyan	00A0A000h	RGB(0,160,160)		
White	00E0E0E0h	RGB(224,224,224)		
Gray	00C0C0C0h	RGB(192,192,192)		
Light Red	008080FFh	RGB(255,128,128)		

Light Green	0090EE90h	RGB(144,238,144)
Light Yellow	00C0FFFFh	RGB(255,255,192)
Light Blue	00E6D8ADh	RGB(173,216,230)
Light Magenta	00FFC0FFh	RGB(255,192,255)
Light Cyan	00FFFFE0h	RGB(224,255,255)
High White	00FFFFFFh	RGB(255,255,255)

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

```
ESC [ 37;44 m
```

Note that if you wanted to set the foreground color to a bold version of standard yellow, you would first set the bold attribute, and then use the index value of 3, such as:

```
ESC [ 1;33m
```

The **NvtSetDisplayColorMap** function is used to modify the actual color displayed by the emulator. For example, if the emulator processes an escape sequence which sets the current foreground color to white, the actual color displayed could be changed to light green. Passing a NULL pointer as the second parameter restores the original color map back to the default values. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters.

Example

The following example will load the current color table for the virtual display and change the standard white color attribute to use the same value as the high-intensity white:

```
COLORREF rgbColor[16];

if ( NvtGetDisplayColorMap(hDisplay, rgbColor, 16) )
{
     rgbColor[7] = rgbColor[15];
     NvtSetDisplayColorMap(hDisplay, rgbColor, 16);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetDisplayDC Function

```
BOOL WINAPI NvtSetDisplayDC(
   HDISPLAY hDisplay,
   HDC hDC
);
```

The **NvtSetDisplayDC** function sets the device context to be used by the virtual display when updating the window.

Parameters

hDisplay

Handle to the virtual display.

hDC

Handle to the device context. This parameter may be NULL, any device context that is currently associated with the virtual display will be removed. Note that the application still has the responsibility for deleting the device context, otherwise a handle leak will occur.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

It is not required that the device context be explicitly set by the application. By default, the library will use a device context created using the window attached to the virtual display. If a device context is specified by the application, it must be released when it is no longer needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetDisplayEmulation Function

```
BOOL WINAPI NvtSetDisplayEmulation(
    HDISPLAY hDisplay,
    UINT nEmulation
);
```

The **NvtSetDisplayEmulation** function specifies the type of terminal emulation to be performed by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

nEmulation

Identifies the virtual terminal emulation type. The following emulation types are currently supported.

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
NVT_EMULATION_ANSI	The virtual display will process ANSI escape sequences. The default keymap for an ANSI console is loaded.
NVT_EMULATION_VT100	The virtual display will process DEC VT100 escape sequences. The default keymap for a VT100 terminal is loaded.
NVT_EMULATION_VT220	The virtual display will process DEC VT220 escape sequences. The default keymap for a VT220 terminal is loaded.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

Changing the emulation type will not affect the current display.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetDisplayFocus Function

```
BOOL WINAPI NvtSetDisplayFocus(
    HDISPLAY hDisplay,
    BOOL bFocus
);
```

The **NvtSetDisplayFocus** function sets or removes the focus from the virtual display. This function should be called when the display window receives or loses focus.

Parameters

hDisplay

Handle to the virtual display.

bFocus

A boolean flag which specifies that the display should receive or lose focus.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

When the virtual display receives focus, it updates the current cursor position and displays the caret. When the display loses focus, the caret is hidden. This function should be called in response to the display window receiving the WM_SETFOCUS and WM_KILLFOCUS messages.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetDisplayFont Function

```
BOOL WINAPI NvtSetDisplayFont(
   HDISPLAY hDisplay,
   HFONT hFont
);
```

The **NvtSetDisplayFont** sets the font that will be used when updating the display. The specified font must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

Parameters

hDisplay

Handle to the virtual display.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case a default fixed-width font will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

If the previous font was a default font created by the library as the result of a NULL font handle being passed to a function, it will be released. However, if the previous font was created by the application, the **DeleteObject** function must be called to release it.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtSetDisplayFontName Function

```
BOOL WINAPI NvtSetDisplayFontName(
    HDISPLAY hDisplay,
    LPTSTR lpszFontName,
    INT nFontSize
);
```

The **NvtSetDisplayFontName** function sets the font that is to be used when updating the display. This function always attempts to load a font which is fixed-width and uses the OEM character set.

Parameters

hDisplay

Handle to the virtual display.

lpszFontName

A null-terminated string which specifies the name of the font that will be loaded. If a NULL pointer or an empty string is passed as the value, the default **Terminal** font will be used.

nFontSize

The point size of the font that will be loaded. If this value is zero, a default point size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

The **NvtGetDisplayFont** function will return the handle to the font created by this function. However, this handle should not be released using the **DeleteObject** function. Font handles created by calling this function or passing a NULL handle to the **NvtSetDisplayFont** function will be automatically released by the library when the font is changed or the virtual display is destroyed.

If the previous display font was created using the **CreateFont** or **CreateFontIndirect** functions and then set using **NvtSetDisplayFont**, the font handle must be released by calling the **DeleteObject** function after this function has been called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

NvtSetDisplayForeColor Function

```
BOOL WINAPI NvtSetDisplayForeColor(
   HDISPLAY hDisplay,
   COLORREF rgbForeground
);
```

The **NvtSetDisplayForeColor** sets the foreground color used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

rgbForeground

The foreground color specified as a 32-bit RGB value.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function sets the foreground color for the normal and reverse text attributes. To set the foreground color for a specific attribute, use the **NvtSetDisplayColor** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetDisplayMode Function

```
BOOL WINAPI NvtSetDisplayMode(
   HDISPLAY hDisplay,
   UINT nMode,
   BOOL bEnable
);
```

The **NvtSetDisplayMode** function sets one or more display modes for the specified virtual display.

Parameters

hDisplay

Handle to the virtual display.

nMode

The virtual display mode bitmask. This value is a combination of one or more flags which determines how the emulator handles automatic line wrapping, caret display, and other functions. The following values may be specified.

Value	Description
NVT_MODE_AUTOWRAP	The emulator will automatically wrap to the next line when a character is written to the last column on the virtual display.
NVT_MODE_SHOWCARET	The emulator will display a caret when the display receives the focus.
NVT_MODE_BLOCKCARET	The emulator will display a block carat that is the height of the selected font characters. If this mode is not set, the caret is displayed as an underline.
NVT_MODE_BELL	The emulator will beep when a BEL character is processed.
NVT_MODE_CRLF	The cursor will automatically be positioned at the first column when a linefeed character is processed.
NVT_MODE_CRNL	The cursor will automatically advance to the next row when a carriage return character is processed.
NVT_MODE_APPCURSOR	The emulator cursor keys are placed in application mode. This mode changes the default key mappings used when the cursor (arrow) keys are translated. This corresponds to the application mode supported by DEC VT terminals.
NVT_MODE_APPKEYPAD	The emulator keypad keys are placed in application mode. This mode changes the default key mappings used when the keypad keys are translated. This corresponds to the application keypad mode supported by DEC VT terminals.
NVT_MODE_ORIGIN	The emulator is in origin mode. If enabled, the cursor cannot be positioned outside of the current scrolling region. Otherwise, the cursor can be positioned at any valid location on the virtual display.
NVT_MODE_COLOR	The emulator supports the use of escape sequences to change the foreground and background colors. This option is

	enabled by default if emulating an ANSI console or DEC VT220 terminal.
NVT_MODE_TABOVER	The emulator will clear the character cells between the current cursor position and the next tab stop when the HT (horizontal tab) control sequence is processed. By default this mode is disabled, and the cursor is simply positioned at the next tab stop.
NVT_MODE_HSCROLL	The emulator will display a horizontal scroll bar if the number of visible columns are less then the total number of columns in the virtual display. Disabling this mode prevents a horizontal scroll bar from being displayed, regardless of the number of visible columns. By default, this mode is enabled.
NVT_MODE_VSCROLL	The emulator will display a vertical scroll bar if the number of visible rows are less then the total number of rows in the virtual display. Disabling this mode prevents a vertical scroll bar from being displayed, regardless of the number of visible rows. By default, this mode is enabled.
NVT_MODE_NOREFRESH	The emulator will not automatically refresh the window after any change has been made to the virtual display, including changes in the cursor position or display mode. This allows the caller to make a sequence of changes, and then update the display all at one time to prevent a flicker effect.

bEnable

This boolean flag specifies if the specified mode is to be enabled or disabled.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetDisplayScrollPos Function

```
BOOL WINAPI NvtSetDisplayScrollPos(
    HDISPLAY hDisplay,
    INT nScrollBar,
    INT nScrollPos
);
```

The **NvtSetDisplayScrollPos** function sets the position of the scroll box for the specified scroll bar and redraws the scroll bar to reflect the new position of the scroll box.

Parameters

hDisplay

Handle to the virtual display.

nScrollBar

Specifies the scroll bar to be set. This parameter can be one of the following values:

Value	Description
SB_HORZ	Sets the position of the scroll box in the display's standard horizontal scroll bar.
SB_VERT	Sets the position of the scroll box in the display's standard vertical scroll bar.

nScrollPos

Specifies the new row or column of the scroll box. The position must be within the scrolling range.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function should always be used to change the scroll box position. The **NvtSetDisplayScrollPos** function will result in unpredictable behavior if used on the virtual display window.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtSetDisplaySize Function

```
BOOL WINAPI NvtSetDisplaySize(
   HDISPLAY hDisplay,
   LPSIZE lpSize
);
```

The **NvtSetDisplaySize** sets the size of the virtual display.

Parameters

hDisplay

Handle to the virtual display.

lpSize

Pointer to a SIZE structure which specifies the new size of the virtual display. The width should be specified in columns and the height should be specified in rows.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetDisplayWindow Function

```
BOOL WINAPI NvtSetDisplayWindow(
    HDISPLAY hDisplay,
    HWND hWnd
);
```

The **NvtSetDisplayWindow** function sets the window used by the virtual display.

Parameters

hDisplay

Handle to the virtual display.

hWnd

Handle to the window that will be used by the virtual display. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function will clear the display and reset the current text attributes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetMappedKey Function

```
BOOL WINAPI NvtSetMappedKey(
   HDISPLAY hDisplay,
   UINT nMappedKey,
   LPCTSTR lpszKeyBuffer
);
```

The **NvtSetMappedKey** function maps an escape sequence to the specified key.

Parameters

hDisplay

Handle to the virtual display.

nMappedKey

The key which is an index into the display key mapping table. This defines the values returned by special (function) keys for the current emulation.

lpszKeyBuffer

Pointer to a string which defines the sequence of characters that are to be mapped to the specified key. Passing an empty string or NULL pointer will delete the current sequence mapped to the key and restore the default value, if one has been defined.

Return Value

If the function succeeds, the return value is non-zero and the escape sequence is mapped to the specified key. If the key value is invalid or could not be mapped, then the function will return zero.

Remarks

The **NvtSetMappedKey** function maps an escape sequence to a special key. This function can be used to specify what sequence of characters should be sent in response to a keypress (for example, what sequence should be sent to a server when the user presses the F1 function key). There are a number of default sequences that are mapped to the function and cursor keys, based on the current emulation. Calling this function will override the default sequence for a key, if one has been defined.

The following special keys are defined:

Value	Description
NVT_F1	F1 function key
NVT_F2	F2 function key
NVT_F3	F3 function key
NVT_F4	F4 function key
NVT_F5	F5 function key
NVT_F6	F6 function key
NVT_F7	F7 function key
NVT_F8	F8 function key
NVT_F9	F9 function key
NVT_F10	F10 function key

NVT_F11	F11 function key
NVT_F12	F12 function key
NVT_SF1	Shift F1 function key
NVT_SF2	Shift F2 function key
NVT_SF3	Shift F3 function key
NVT_SF4	Shift F4 function key
NVT_SF5	Shift F5 function key
NVT_SF6	Shift F6 function key
NVT_SF7	Shift F7 function key
NVT_SF8	Shift F8 function key
NVT_SF9	Shift F9 function key
NVT_SF10	Shift F10 function key
NVT_SF11	Shift F11 function key
NVT_SF12	Shift F12 function key
NVT_ENTER	Enter key
NVT_ERASE	Backspace key
NVT_UP	Cursor up key
NVT_DOWN	Cursor down key
NVT_LEFT	Cursor left key
NVT_RIGHT	Cursor right key
NVT_INSERT	Insert key
NVT_DELETE	Delete key
NVT_HOME	Home key
NVT_END	End key
NVT_PGUP	Page up key
NVT_PGDN	Page down key
NVT_APPUP	Up arrow key
NVT_APPDOWN	Down arrow key
NVT_APPLEFT	Left arrow key
NVT_APPRIGHT	Right arrow key
NVT_APPENTER	Keypad enter key
NVT_KEYPAD0	Numeric keypad 0
NVT_KEYPAD1	Numeric keypad 1
NVT_KEYPAD2	Numeric keypad 2
NVT_KEYPAD3	Numeric keypad 3

NVT_KEYPAD4	Numeric keypad 4
NVT_KEYPAD5	Numeric keypad 5
NVT_KEYPAD6	Numeric keypad 6
NVT_KEYPAD7	Numeric keypad 7
NVT_KEYPAD8	Numeric keypad 8
NVT_KEYPAD9	Numeric keypad 9

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

NvtSetScrollRegion Function

```
BOOL WINAPI NvtSetScrollRegion(
    HDISPLAY hDisplay,
    INT nTop,
    INT nBottom
);
```

The **NvtSetScrollRegion** function sets the top and bottom rows of the current scrolling region.

Parameters

hDisplay

Handle to the virtual display.

nTop

The top row of the current scrolling region. If this value is greater than the bottom scrolling region row or the total number of rows in the display, it will be silently adjusted.

nBottom

The bottom row of the current scrolling region. If this value is less than zero or the top scrolling region row, it will be silently adjusted.

Return Value

If the function succeeds, it will return zero. If the handle to the display is invalid, the function will return zero.

Remarks

The **NvtSetScrollRegion** function allows an application to set the current scrolling region for the virtual display. This specifies the region (between the top and bottom rows) in which text will normally scroll. If the display is in origin mode, the cursor cannot be positioned outside of the scrolling region.

The minimum scrolling region that may be defined is two rows. If a scrolling region is specified that is less than two rows, the function will fail and the current scrolling region will remain unchanged. Specifying values of -1 for both arguments will reset the scrolling region to the default values (the full display).

The DEC STBM escape sequence is used to set or clear the scrolling region of the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtSetTextColor Function

```
BOOL WINAPI NvtSetTextColor(
   HDISPLAY hDisplay,
   COLORREF rgbColor,
   BOOL bForeground
);
```

The **NvtSetTextColor** function changes the current foreground or background text color.

Parameters

hDisplay

Handle to the virtual display.

rgbColor

A color value which specifies the current foreground or background text color. The RGB macro can be used to specify the red, green and blue values for the color.

bForeground

A boolean value which determines if the foreground or background color is changed. A value of TRUE indicates that the foreground color should be changed, otherwise the background color is changed.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. Failure indicates that the handle to the display is invalid or that the current display does not support color text attributes.

Remarks

This function is used to change the current foreground or background color, as determined by the text attribute. Note that changing the current foreground or background text color does not affect the virtual display color table. To change how color attributes are mapped to an RGB color value, use the **NvtSetDisplayColorMap** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtTranslateMappedKey Function

```
BOOL WINAPI NvtTranslateMappedKey(
   HDISPLAY hDisplay,
   UINT nKey,
   UINT nFlags,
   UINT *lpnMappedKey,
   LPTSTR lpszKeyBuffer,
   UINT cchBuffer
);
```

The **NvtTranslateMappedKey** function translates a virtual key press to an escape sequence based on the current terminal emulation that has been selected.

Parameters

hDisplay

Handle to the virtual display.

nKey

The virtual key code for the specified key.

nFlags

The scan code, key-transition code, previous key state, and context code for the specified key.

lpnMappedKey

A pointer to an unsigned integer which will contain the index into the keymap table when the function returns. This is the same value used with the **NvtGetMappedKey** and **NvtSetMappedKey** function. If the index into the keymap is not required, this parameter can be NULL.

lpszKeyBuffer

Address of the buffer to receive the escape sequence mapped to the specified key. If the mapped key string is not required, this parameter can be NULL.

cchBuffer

The maximum number of characters that can be copied into the key buffer, including the terminating null character. If the ***lpszKeyBuffer*** parameter is NULL, this value must be zero.

Return Value

If the virtual key can be mapped to an escape sequence, the function will return a non-zero value. If the key is not mapped, or one of the arguments is invalid, the function will return zero.

Remarks

The **NvtTranslateMappedKey** function allows an application to map a virtual key code to an escape sequence that is appropriate for the type of terminal that is being emulated. For example, it will return the escape sequence for the F1 function key when passed the VK_F1 key value. This function should be called when the WM_KEYDOWN message is processed by an application so that it may send the correct sequence to the server.

This function should only be called in response to a keyboard message such as WM_KEYDOWN. To determine if a specific key has been mapped to an escape sequence, use the **NvtGetMappedKey** function.

Example

```
case WM_KEYDOWN:
    /*
     * If the Num Lock key is pressed, then set the terminal into application
     * keypad mode. This will change how the NvtTranslateMappedKey function will
     * translate the keypad keys.
     *
     * Note that the terminal may also be placed into application keypad mode
     * if emulating a DEC VT terminal and the DECNKM escape sequence is sent
     * by the host.
     */
    if (wParam == VK_NUMLOCK)
        NvtSetDisplayMode(hDisplay, NVT_MODE_APPKEYPAD, !(GetKeyState(VK_NUMLOCK) &
1));
    else
    {
        BOOL bMapped;
        UINT nMappedKey;
        TCHAR szKey[128];

        bMapped = NvtTranslateMappedKey(hDisplay, wParam, HIWORD(lParam),
                                        &nMappedKey, szKey, 128);

        if (bMapped)
            TelnetWrite(hClient, szKey, lstrlen(szKey));
    }
    break;
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

NvtUninitialize Function

```
VOID WINAPI NvtUninitialize();
```

The **NvtUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **NvtInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **NvtUninitialize** to allow the library to free any resources allocated on behalf of the process.

There should be a call to **NvtUninitialize** for every successful call to **NvtInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtDestroyDisplay, NvtUninitialize

NvtUpdateCaret Function

```
BOOL WINAPI NvtUpdateCaret(
   HDISPLAY hDisplay
);
```

The **NvtUpdateCaret** function updates the position of the caret in the display window to the current cursor position.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

NvtSetCursorPos, NvtSetDisplayMode, NvtUpdateDisplay

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NvtUpdateDisplay Function

```
BOOL WINAPI NvtUpdateDisplay(
   HDISPLAY hDisplay
);
```

The **NvtUpdateDisplay** function updates the window attached to the virtual display.

Parameters

hDisplay

Handle to the virtual display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function should be called when the display window receives a WM_PAINT message. If the **NvtSetDisplayDC** function has not been called to explicitly set the display device context, this function will acquire one for the display window. In this case, the application should not create a device context for the window or call the **BeginPaint** and **EndPaint** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

NvtWriteDisplay Function

```
BOOL WINAPI NvtWriteDisplay(
   HDISPLAY hDisplay,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **NvtWriteDisplay** function writes the contents of the specified buffer to the virtual display.

Parameters

hDisplay

Handle to the virtual display.

lpBuffer

Pointer to the buffer which contains the data to be written to the virtual display.

cbBuffer

Number of bytes to write to the display.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero.

Remarks

This function writes the data at the current cursor location. Control characters are recognized by this function and processed accordingly. If ANSI emulation is enabled, embedded escape sequences will also be parsed and processed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

Terminal Emulation Data Structures

- NVTDISPLAYINFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NVTDISPLAYINFO

The **NVTDISPLAYINFO** structure contains information about the virtual terminal display.

```
typedef struct _NVTDISPLAYINFO {
   HWND    hWnd;
   HFONT   hFont;
   INT     xPos;
   INT     yPos;
   INT     cxClient;
   INT     cyClient;
   INT     cxChar;
   INT     cyChar;
   INT     nScrollCol;
   INT     nScrollRow;
   INT     nMaxScrollCol;
   INT     nMaxScrollRow;
} NVTDISPLAYINFO, *LPNVTDISPLAYINFO;
```

Members

hWnd

The handle to the terminal emulation display window.

hFont

The handle to the current font.

xPos

The current display x coordinate.

yPos

The current display y coordinate.

cxClient

The width of the client window in pixels.

cyClient

The height of the client window in pixels.

cxChar

The width of the current font in pixels.

cyChar

The height of the current font in pixels.

nScrollCol

The current horizontal scrolling column.

nScrollRow

The current vertical scrolling row.

nMaxScrollCol

The maximum horizontal scrolling column.

nMaxScrollRow

The maximum vertical scrolling row.

Remarks

This structure is populated by the **NvtGetDisplayInfo** function to provide information about the current state of the virtual terminal. Member of this structure should be modified directly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

<ESC>(0	Assign graphics character set to font bank G0
<ESC>)A	Assign ISO Latin 1 character set to font bank G1
<ESC>)B	Assign United States ASCII character set to font bank G1
<ESC>)0	Assign graphics character set to font bank G1

Erase Sequences

<ESC>[*n*@ Insert ***n*** blank spaces

Erase all or part of the display

<ESC>[*n*J

n Value	Description
0	From current position to end of display
1	From beginning of display to current position
2	Erase the entire display

Erase all or part of a line

<ESC>[*n*K

n Value	Description
0	From current position to end of line
1	From beginning of line to current position
2	Erase the entire line

<ESC>[*n*L Insert ***n*** new blank lines

<ESC>[*n*M	Delete *n* lines from current cursor position
<ESC>[*n*P	Delete *n* characters from current cursor position

Scrolling Sequences

<ESC>[*n*S	Scroll display up *n* lines
<ESC>[*n*T	Scroll display down *n* lines
<ESC>[*n*X	Erase *n* characters from the current position
<ESC>[*y1*;*y2*r	Set scrolling region from lines *y1* to *y2*

Keypad Sequences

<ESC>=	Place keypad into applications mode
<ESC>>	Place keypad into numeric mode

Emulation Option Sequences

<ESC>[?*n*h

Set emulation option

n Value	Description
1	Enable cursor key application mode
2	Enable ANSI escape sequences
5	Reverse foreground and background colors
6	Enable origin mode
7	Enable auto-wrap mode
20	Enable linefeed/newline mode
25	Display caret
66	Place keypad in applications mode

<ESC>[?*n*1

Set emulation option

n Value	Description
1	Disable cursor key application mode
2	Enable VT52 escape sequences
5	Restore foreground and background colors
6	Disable origin mode
7	Disable auto-wrap mode
20	Disable linefeed/newline mode
25	Hide caret
66	Place keypad in numeric mode

Console Escape Sequences

<ESC>[=*n*A	Set the overscan color (ignored)
<ESC>[=*n1*;*n2*B	Set bell sound (parameters ignored)
<ESC>[=*n1*;*n2*C	Set the caret size

<ESC>[=*n*D

Set background color intensity

n Value	Description
0	Decrease background color intensity

	1	Increase background color intensity
<ESC>[=*n*E	Set blink vs. bold attribute (ignored)	
<ESC>[=*n*F	Set normal foreground color	
<ESC>[=*n*G	Set normal background color	
<ESC>[=*n*H	Set reverse foreground color	
<ESC>[=*n*I	Set reverse background color	
<ESC>[=*n*J	Set graphics foreground color	
<ESC>[=*n*K	Set graphics background color	

n Value	Description
0	Black
1	Blue
2	Green
3	Cyan
4	Red
5	Magenta
6	Brown
7	White
8	Gray
9	Light blue
10	Light green
11	Light cyan
12	Light red
13	Light magenta
14	Yellow
15	High White

Control Character Sequences

<CTL>G	Ring audible bell, if enabled
<CTL>H	Move cursor one character backwards
<CTL>I	Move cursor forward to next tabstop
<CTL>J	Move cursor down to next line
<CTL>M	Move cursor to beginning of line
<CTL>N	Select G1 character set
<CTL>O	Select G0 character set
<CTL>Z	Abort current escape sequence
<DEL>	Erase and move cursor one character backwards

Text Message Library

Send text messages to a mobile communications device using a gateway service.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSTXTV12.DLL
Version	12.0.3024.1286
LibID	3F750221-287C-4D42-AFD5-570CE6A41217
Import Library	CSTXTV12.LIB
Dependencies	None

Overview

Short Message Service (SMS) is a text messaging service used by mobile communication devices to exchange brief text messages. Most service providers also provide gateway servers that can be used to send messages to a wireless device on their network using standard email protocols. The Text Message API provides functions that can be used to determine the provider associated with a specific telephone number and send a text message to the device using the provider's mail gateway.

This library has been designed to assist developers in sending text message notifications as part of their application. For example, it can be used to enable your software to automatically send notifications when a specific event occurs, such as an error condition. This library is not designed to be used with software that will send out a large number of text messages to many users, and there are limitations on the number of messages that may be sent to different phone numbers over a short period of time. Because many recipients must pay a fee for each text message they receive, text messages should only be sent to those who explicitly request them.

Applications should use an alternate method for sending text messages. Most mobile carriers have shut down their email-to-SMS gateways, making this method of sending text messages unreliable or unavailable. It is recommended that you transition to dedicated SMS service providers, which deliver messages over HTTPS-based APIs instead of email.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1

(SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Text Message Functions

Function	Description
SmsDisableTrace	Disable logging of network function calls
SmsEnableTrace	Enable logging of network function calls to a text file
SmsEnumProviders	Enumerate the available wireless service providers
SmsGetErrorString	Return a description for the specified error code
SmsGetFirstProvider	Return information about the first supported wireless service provider
SmsGetGateway	Return information about the gateway server for the specified phone number
SmsGetNextProvider	Return information about the next supported wireless service provider
SmsGetProvider	Return information about the wireless service provider for the specified phone number
SmsGetLastError	Return the last error code
SmsInitialize	Initialize the library and validates the specified license key at runtime
SmsSendMessage	Send a text message to the specified mobile device
SmsSetLastError	Set the last error code
SmsUninitialize	Terminate use of the library by the application

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmsDisableTrace Function

```
BOOL WINAPI SmsDisableTrace();
```

The **SmsDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

SmsEnableTrace Function

```
BOOL WINAPI SmsEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **SmsEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmsEnumProviders Function

```
INT WINAPI SmsEnumProviders(
   LPSMSPROVIDER lpProviders,
   INT nMaxProviders,
   DWORD dwReserved
);
```

The **SmsEnumProviders** function enumerates the supported wireless service providers and populates an array of **SMSPROVIDER** structures.

Parameters

lpProviders

A pointer to an array of SMSPROVIDER structures that will be populated with information about each service provider. If this parameter is NULL, the function will return the number of service providers that are known.

nMaxProviders

An integer value which specifies the maximum number of service providers that may be enumerated by this function. If this parameter is zero, the function will return the number of service providers that are known. If the ***lpProviders*** parameter is NULL, this value should be zero.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the number of known service providers. If the function fails, the return value is SMS_ERROR. To get extended error information, call **SmsGetLastError**. If the ***lpProviders*** parameter is not NULL and the ***nMaxProviders*** parameter indicates the array is not large enough to store all of the provider information, this function will fail with an error indicating that the buffer is too small.

Remarks

The **SmsEnumProviders** function is used to enumerate all of the supported service providers, populating an array of **SMSPROVIDER** structures that contains information about each provider, such as their name, domain, region of the country they service and the maximum message size they will accept. Typically this would be used to update a user interface control such as a listbox or drop-down combobox, enabling a user to select a preferred service provider.

Because some programming languages may not support arrays of structures in the same way that C/C++ does, the **SmsGetFirstProvider** and **SmsGetNextProvider** functions offer an alternative way to easily enumerate the available service providers.

To obtain information about a single service provider, use the **SmsGetProvider** function.

Example

```
SMSPROVIDER smsProviders[MAXPROVIDERS];
INT nProviders;

nProviders = SmsEnumProviders(smsProviders, MAXPROVIDERS, 0);
if (nProviders == SMS_ERROR)
{
    DWORD dwError = SmsGetLastError();
```

```
    _tprintf(_T("An error has occurred, error code %d\n"), (INT)LOWORD(dwError));
}
else
{
    for (INT nIndex = 0; nIndex < nProviders; nIndex++)
        _tprintf(_T("%s\n"), smsProviders[nIndex].szName);

    _tprintf(_T("%d providers returned\n"), nProviders);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmsGetErrorString Function

```
INT WINAPI SmsGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **SmsGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **SmsGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SmsGetFirstProvider Function

```
BOOL WINAPI SmsGetFirstProvider(
   LPSMSPROVIDER lpProvider,
   LPDWORD lpdwToken,
);
```

The **SmsGetFirstProvider** function returns information about the first supported wireless service provider.

Parameters

lpProvider

A pointer to an SMSPROVIDER structure that will contain information about the service provider. This parameter cannot be NULL.

lpdwToken

A pointer to an unsigned integer value that is used when enumerating the service providers. The value will be initialized by this function and the modified by subsequent calls to the **SmsGetNextProvider** function. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsGetFirstProvider** function is used in conjunction with **SmsGetNextProvider** to enumerate all of the supported wireless providers available to the client. These two functions can be used as an alternative to the **SmsEnumProviders** function, which may not be easily used with some programming languages because it populates an array of data structures rather than a single structure. The data that is returned is identical, the only difference is the method by which the service providers are enumerated.

The *lpdwToken* parameter is used to maintain context between multiple calls to the **SmsGetNextProvider** function. It should be treated as an opaque value and never modified directly by the application.

Example

```
SMSPROVIDER smsProvider;
DWORD dwToken;
BOOL bResult;

bResult = SmsGetFirstProvider(&smsProvider, &dwToken);
while (bResult)
{
    pListBox->AddString(smsProvider.szName);
    bResult = SmsGetNextProvider(&smsProvider, &dwToken);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmsGetGateway Function

```
INT WINAPI SmsGetGateway(
   LPCTSTR lpszPhoneNumber,
   LPCTSTR lpszProvider,
   LPSMSGATEWAY lpGateway
);
```

The **SmsGetGateway** function returns text message service information for a phone number.

Parameters

lpszPhoneNumber

A null-terminated string which specifies the telephone number that you wish to obtain information about. Any whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpszProvider

A null-terminated string which specifies the preferred service provider for this telephone number. If the preferred service provider is unknown, this parameter can be NULL and the default provider will be selected.

lpGateway

A pointer to an SMSGATEWAY structure that will contain information about the text message gateway when the function returns. This includes information such as the name of the provider, the server that will accept text messages for this phone number, and the recipient address that should be used. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMS_ERROR. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsGetGateway** function returns information about the service provider and mail gateway for a specific phone number, and can be used to determine if a given phone number is assigned to a mobile device capable of receiving text messages. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices. If the phone number is valid, information will be returned about the provider that is responsible for that number along with information about its text message gateway service.

If the ***lpszProvider*** parameter is not NULL, this will identify a preferred provider for the phone number specified. In the United States and Canada, most wireless common carriers are required to provide wireless number portability (WNP) which allows a customer to continue to use their current phone number even if they switch to another service provider. This can result in a situation where a specific phone number is shown as allocated to one provider, but in actuality that user has switched to a different provider. For example, a user may have originally purchased a phone and service with AT&T and then later switched to Verizon, but decided to keep their phone number. In this case, if Verizon was not specified as the preferred provider, the library would attempt to send the message to the AT&T gateway, since that was the original provider who allocated the phone number.

For most applications, the correct way to handle the situation in which a user may have switched to a different service provider is to allow them to select an alternate service provider in your user interface.

For example, you could display a drop-down list of available service providers, populated using the **SmsEnumProviders** function. If they select a preferred provider, then you would pass that value to this function. If they do not, then specify a NULL pointer and the default provider will be selected.

This function sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the function will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this function is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this function multiple times using the same phone number will not increase the request count.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmsGetLastError Function

```
DWORD WINAPI SmsGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SmsSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **SmsGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **SmsSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CHANNEL or SMS_ERROR. Those functions which call **SmsSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

SmsGetNextProvider Function

```
BOOL WINAPI SmsGetNextProvider(
   LPSMSPROVIDER lpProvider,
   LPDWORD lpdwToken,
);
```

The **SmsGetNextProvider** function returns information about the next supported wireless service provider.

Parameters

lpProvider

A pointer to an SMSPROVIDER structure that will contain information about the service provider. This parameter cannot be NULL.

lpdwToken

A pointer to an unsigned integer value that is used when enumerating the service providers. The value will be initialized by the **SmsGetFirstProvider** function and the modified by subsequent calls to this function. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the last service provider has been enumerated or the function fails, the return value is zero. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsGetNextProvider** function is used in conjunction with **SmsGetFirstProvider** to enumerate all of the supported wireless providers available to the client. These two functions can be used as an alternative to the **SmsEnumProviders** function, which may not be easily used with some programming languages because it populates an array of data structures rather than a single structure. The data that is returned is identical, the only difference is the method by which the service providers are enumerated.

The *lpdwToken* parameter is used to maintain context between multiple calls to this function. It should be treated as an opaque value and never modified directly by the application.

Example

```
SMSPROVIDER smsProvider;
DWORD dwToken;
BOOL bResult;

bResult = SmsGetFirstProvider(&smsProvider, &dwToken);
while (bResult)
{
    pListBox->AddString(smsProvider.szName);
    bResult = SmsGetNextProvider(&smsProvider, &dwToken);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

SmsEnumProviders, SmsGetGateway, SmsGetNextProvider, SMSPROVIDER

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmsGetProvider Function

```
INT WINAPI SmsGetProvider(
   LPCTSTR lpszPhoneNumber,
   LPSMSPROVIDER lpProvider
);
```

The **SmsGetProvider** function returns information about the service provider for the specified phone number.

Parameters

lpszPhoneNumber

A null-terminated string which specifies the telephone number that you wish to obtain information about. Any whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpProvider

A pointer to an SMSPROVIDER structure that will contain information about the service provider for the specified phone number.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMS_ERROR. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsGetProvider** function returns information about the service provider associated with a phone number. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices. If the phone number is valid, information will be returned about the provider that is responsible for that number.

Because most wireless carriers in the United States and Canada must provide for wireless number portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify an alternate preferred provider to use when sending the text message. For more information, refer to the **SmsGetGateway** function.

This function sends an HTTP query to the server **api.sockettools.com** to obtain information about the wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the function will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this function is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this function multiple times using the same phone number will not increase the request count.

For a list of all supported wireless service providers, use the **SmsEnumProviders** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

SmsInitialize Function

```
BOOL WINAPI SmsInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **SmsInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **SmsGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **SmsInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **SmsUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **SmsInitialize** or **SmsUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmsSendMessage Function

```
INT WINAPI SmsSendMessage(
   LPSMSSERVICE lpService,
   LPSMSMESSAGE lpMessage,
   DWORD dwReserved,
);
```

The **SmsSendMessage** function sends a text message to the specified mobile device.

Parameters

lpService

A pointer to an SMSSERVICE structure that identifies the messaging service that will be used to send the text message. The default service sends the message through the mail server gateway for the wireless service provider associated with the recipient's phone number. This parameter cannot be NULL.

lpMessage

A pointer to an SMSMESSAGE structure that contains information about the message to be sent, including the sender, the recipient and the text message itself. This parameter cannot be NULL.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is SMS_ERROR. To get extended error information, call **SmsGetLastError**.

Remarks

The **SmsSendMessage** function is used to send a text message to a mobile device. This API is designed to support multiple methods of sending text messages, with the default method sending the message through a server gateway established by the wireless service provider.

SMS_SERVICE_SMTP

This message service sends the message through the wireless service provider's mail gateway using the SMTP protocol. However, it is important to note that many of these gateways will not accept messages from a client that is connected to them using a residential Internet service provider. If the application is being run on a system that uses a residential provider, that service provider may also block outbound connections to all mail servers other than their own. These anti-spam measures typically require that most end-user applications specify a relay mail server rather than submitting the message directly to the wireless provider's gateway.

Because most wireless carriers in the United States and Canada must provide for wireless number portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify an alternate preferred provider to use when sending the text message. For more information, refer to the **SmsGetGateway** function.

This service also sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the function will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per

minute. If this function is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this function multiple times using the same phone number will not increase the request count.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

SmsSetLastError Function

```
VOID WINAPI SmsSetLastError(
   DWORD dwErrorCode
);
```

The **SmsSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMS_ERROR. Those functions which call **SmsSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **SmsGetLastError** function. The use of **SmsGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

See Also

SmsGetErrorString, SmsGetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SmsUninitialize Function

```
VOID WINAPI SmsUninitialize();
```

The **SmsUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **SmsInitialize** call before it can call any of the other the library functions. When it has finished using the library, the application must call **SmsUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **SmsUninitialize** for every successful call to **SmsInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

SMSGATEWAY

This structure contains information about a text message gateway server and the recipient.

```
typedef struct _SMSGATEWAY
{
    INT     nGatewayId;
    INT     nCountryCode;
    INT     nAreaCode;
    INT     nExchange;
    INT     nMessageLength;
    DWORD   dwReserved;
    TCHAR   szProvider[SMS_MAXPROVIDERNAMELEN];
    TCHAR   szDomain[SMS_MAXDOMAINNAMELEN];
    TCHAR   szServer[SMS_MAXMAILSERVERLEN];
    TCHAR   szAddress[SMS_MAXMAILADDRESSLEN];
}  SMSCHANNEL, *LPSMSCHANNEL;
```

Members

nGatewayId

An integer value which identifies the gateway record. This value is used internally and an application should not depend on the value not changing over time for a specific telephone number. As new area codes are introduced, the provider database will be updated to reflect these changes and that can result in a change to the gateway ID associated with a specific telephone number.

nCountryCode

An integer value which specifies the ITU country calling code associated with the service provider. Currently this value will always be 1, which is the country code used by North American service providers. If the service provider database is expanded to include additional countries in the future, this value will identify the country of origin.

nAreaCode

An integer value which specifies the Numbering Plan Area (NPA) code, commonly known as the area code. For the United States and Canada, area codes are assigned by the North American Numbering Plan Administration (NANPA). In North America, the area code is digits 1-3 for a 10-digit telephone number. This value, along with the exchange, is used to determine which company provides wireless service for a specific telephone number.

nExchange

An integer value which specifies the exchange area. In North America, the exchange is digits 4-6 for a 10-digit telephone number. This value, along with the area code, is used to determine which company provides wireless service for a specific telephone number.

nMessageLength

An integer value which specifies the maximum number of characters that the service provider will accept for a single text message. If the message exceeds this number of characters, the service provider may reject the message, or it may split the message into multiple messages.

dwReserved

A value reserved for internal use.

szProvider

A null-terminated string which identifies the name of the service provider that is associated with the specified telephone number. Note that this value may not represent the actual company that is providing the wireless service.

szDomain

A null-terminated string which identifies the gateway domain name used by the service provider to accept text messages for their customer. This domain name is used to determine the actual name of the gateway mail server that is responsible for accepting messages.

szServer

A null-terminated string which identifies the host name or IP address of the mail server used to accept text messages for the specified service provider. In some cases, a provider may have multiple gateway servers and this value will represent the preferred mail server for the domain.

szAddress

A null-terminated string which contains the complete email address that should be used when sending the text message through the gateway mail server. Different service providers can have slightly different rules about how the address is formatted, but it typically is a combination of the telephone number and the gateway domain name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SMSMESSAGE

This structure provides information about a text message.

```
typedef struct _SMSMESSAGE
{
    DWORD dwFormat;
    DWORD dwLength;
    DWORD dwFlags;
    DWORD dwReserved;
    LPCTSTR lpszProvider;
    LPCTSTR lpszPhoneNumber;
    LPCTSTR lpszSender;
    LPCTSTR lpszMessage;
}  SMSMESSAGE, *LPSMSMESSAGE;
```

Members

dwFormat

An integer value which specifies the format of the message message. This member is included for future use where a service provider supports multiple message formats based on different versions of the protocol. The default value for this member is SMS_FORMAT_TEXT.

dwLength

An integer value which specifies the length of the message. If this member is zero, the length will be automatically calculated based on the length of the ***lpszMessage*** text that is terminated by a null character. If this value is larger than the actual length of the message text, it will be ignored.

dwFlags

An integer value which specifies one or more message options.

Value	Description
SMS_MESSAGE_DEFAULT	The default value used with standard text messages.
SMS_MESSAGE_URGENT	The text message should be flagged as urgent. For messages that are sent through a mail gateway, this will set the header to indicate that it is a high priority message. Note that service providers handle urgent messages differently and some may ignore the message priority.

dwReserved

Reserved for future use. This value should always be zero.

lpszProvider

A null-terminated string which specifies the name of the preferred wireless service provider responsible for handling the message. If this member is NULL or an empty string, the default provider assigned to the recipient's phone number will be used. This structure member is only used with SMS_SERVICE_SMTP messages and is ignored for other message services.

lpszPhoneNumber

A null-terminated string which specifies the recipient's phone number. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored. This structure member cannot be NULL.

lpszSender

A null-terminated string which identifies the sender of the message. For SMS_SERVICE_SMTP messages, this string should be a valid email address. For other services, this string may specify a phone number or shortcode. This structure member cannot be NULL.

lpszMessage

A null-terminated string that contains the message to be sent to the recipient. In most cases, a message should not exceed 160 characters in length, although some service providers may accept longer messages. If a message exceeds the maximum number of characters accepted by a service provider, the message may be ignored or it may be split into multiple messages.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SMSPROVIDER

This structure contains information about a wireless service provider.

```
typedef struct _SMSPROVIDER
{
    INT     nProviderId;
    INT     nCountryCode;
    INT     nRegionCode;
    INT     nMessageLength;
    DWORD   dwFlags;
    DWORD   dwReserved;
    TCHAR   szGuid[SMS_MAXPROVIDERGUIDLEN];
    TCHAR   szName[SMS_MAXPROVIDERNAMELEN];
    TCHAR   szCompany[SMS_MAXCOMPANYNAMELEN];
    TCHAR   szDomain[SMS_MAXDOMAINNAMELEN];
}  SMSPROVIDER, *LPSMSPROVIDER;
```

Members

nProviderId

An integer value which identifies the provider record. This value is used internally and an application should not depend on the value not changing over time for a specific service provider. To uniquely identify a provider, use the ***szGuid*** member of the structure, which is guaranteed not to change as providers are added and removed from the database.

nCountryCode

An integer value which specifies the ITU country calling code associated with the service provider. Currently this value will always be 1, which is the country code used by North American service providers. If the service provider database is expanded to include additional countries in the future, this value will identify the country of origin.

nRegionCode

An integer value which identifies the region that the service provider covers. In North America, each region consists of multiple states and/or provinces. If a provider services multiple regions, this will identify the primary region where they provide coverage.

Value	Description
SMS_REGION_NATIONAL 0	All regions. This region code is used for service providers that have national coverage and do not exclusively provide service within one or more specific geographical regions.
SMS_REGION_NORTH_EAST_ATLANTIC 1	Northeastern Atlantic region which includes Connecticut, Maine, Massachusetts, New Hampshire, New Brunswick, Newfoundland, Nova Scotia, Rhode Island and Vermont.
SMS_REGION_MIDDLE_ATLANTIC 2	Middle Atlantic region which includes New Jersey, New York, Delaware, District of Columbia, Maryland, Pennsylvania, Quebec, Virginia and West Virginia.
SMS_REGION_EAST_NORTH_CENTRAL 3	Northeastern central region which includes Illinois, Indiana, Michigan, Ohio and Wisconsin.

SMS_REGION_SOUTH_ATLANTIC 4	Southern Atlantic region which includes Florida, Georgia, North Carolina and South Carolina.
SMS_REGION_EAST_SOUTH_CENTRAL 5	Southeastern central region which includes Alabama, Kentucky, Mississippi and Tennessee.
SMS_REGION_WEST_NORTH_CENTRAL 6	Northwestern central region which includes Iowa, Kansas, Manitoba, Minnesota, Missouri, Nebraska, North Dakota, Ontario and South Dakota.
SMS_REGION_WEST_SOUTH_CENTRAL 7	Southwestern central region which includes Arkansas, Louisiana, Oklahoma and Texas.
SMS_REGION_MOUNTAIN 8	Mountain region which includes Alberta, Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Northwest Territories, Saskatchewan, Utah and Wyoming.
SMS_REGION_PACIFIC 9	Pacific region which includes Alaska, British Columbia, California, Hawaii, Oregon, Washington and Yukon.

nMessageLength

An integer value which specifies the maximum number of characters that the service provider will accept for a single text message. If the message exceeds this number of characters, the service provider may reject the message, or it may split the message into multiple messages.

dwFlags

An unsigned integer value which specifies one or more flags that provides additional information about the service provider. This value is constructed by using a bitwise operator with any of the following constants:

Value	Description
SMS_PROVIDER_DEFAULT 0	A standard service provider. Typically this means that customers have a service contract for their mobile device and pay monthly access and service charges.
SMS_PROVIDER_PREPAID 1	A service provider that offers pre-paid calling cards or fixed month-to-month payments that do not require long-term service contracts.

dwReserved

A value reserved for internal use.

szGuid

A null-terminated string which uniquely identifies the service provider. The string is in a standard format used for globally unique identifiers (GUIDs) and is guaranteed to not change for the service provider it has been assigned to.

szName

A null-terminated string which specifies the name of service provider. Note that this value may not represent the actual company that is providing the wireless service.

szCompany

A null-terminated string which specifies the name of the company associated with the service provider. This may be the same as name of the service provider itself or it may be the name of a parent company that owns the service provider.

szDomain

A null-terminated string which identifies the gateway domain name used by the service provider to accept text messages for their customer. This domain name is used to determine the actual name of the gateway mail server that is responsible for accepting messages.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SMSSERVICE

This structure provides information about the service used to send a text message.

```
typedef struct _SMSSERVICE
{
    DWORD dwServiceType;
    DWORD dwAuthType;
    DWORD dwVersion;
    DWORD dwTimeout;
    DWORD dwOptions;
    DWORD dwReserved;
    LPCTSTR lpszResource;
    LPCTSTR lpszAccount;
    LPCTSTR lpszUserName;
    LPCTSTR lpszPassword;
}  SMSSERVICE, *LPSMSSERVICE;
```

Members

dwServiceType

An integer value which identifies the type of service that will be used to send the message. This member can be one of the following values:

Value	Description
SMS_SERVICE_SMTP	The text message will be sent through the mail gateway for the specified service provider. This service uses SMTP to submit the message for delivery, either directly to the server provider's mail gateway server or through a relay server. This is the default service type.

dwAuthType

An integer value which identifies the type of authentication used with the service. This member can be one of the following values:

Value	Description
SMS_AUTH_DEFAULT	The default authentication method for this service type should be used. Most applications should use this value unless a service type provides multiple authentication methods.
SMS_AUTH_USERNAME	The service requires authentication using a username and password. This value can be used with an SMTP service that requires user authentication and is typically needed when using a mail server relay. For the SMS_SERVICE_SMTP service, this is the default authentication method.

dwVersion

An integer value which identifies the interface version for the service being used. This member is included for future use where a service may support multiple versions of their interface and should normally be set to the value SMS_VERSION_DEFAULT.

dwTimeout

An integer value which specifies the amount of time in seconds that a function will wait for a response from the service. If this value is zero, a default timeout period of 20 seconds will be used.

If the service does not respond within this time period, the function will fail.

dwOptions

An integer value which specifies one or more options.

Value	Description
SMS_OPTION_NONE	No additional options for the service.
SMS_OPTION_SECURE	This option specifies that TLS will be used to establish a secure, encrypted connection with the service. For some services, it may be required to connect to them securely and this option will be enabled automatically.

dwReserved

Reserved for future use. This value should always be zero.

lpszResource

A null-terminated string that specifies a resource for the service. Typically this will be either a fully qualified domain name or a URL. For gateways using SMTP, this string should identify the mail server. An alternate port number can also be specified by appending it to the hostname, separated by a colon. For example, **smtp.company.com:587** would connect to the server on port 587. If you are specifying an IPv6 address with an alternate port number, the address must be enclosed in brackets. For services where a domain name or resource URL is not required, this member will be ignored and can be NULL.

lpszAccount

A null-terminated string that specifies an account name or identifier. Some service providers may require a unique account name or a token (application ID) in conjunction with other credentials. This member is not used with mail gateways and ignored if the service type is SMS_SERVICE_SMTP. If no account name is required for session authentication, this member can be NULL.

lpszUserName

A null-terminated string that specifies a user name to authenticate the session. If the authentication type is SMS_AUTH_USERNAME this member must specify a valid user name. If no authentication is required, this member may be NULL. Note that some service providers may use terminology other than "username" with their documentation; this member will always specify the first of a pair of authentication tokens.

lpszPassword

A null-terminated string that specifies the password used to authenticate the session. If the authentication type is SMS_AUTH_USERNAME this member must specify a valid password. If no authentication is required, this member may be NULL. Note that some service providers may use terminology other than "password" with their documentation; this member will always specify the second of a pair of authentication tokens.

Web Services Library

The Web Services library provides data storage and location services for applications.

Reference

- Functions
- Constants
- Data Structures
- Error Codes

Library Information

File Name	CSWEBV12.DLL
Version	12.0.3024.1286
LibID	ECC96063-0D95-4378-A747-E0040B8618F1
Import Library	CSWEBV12.LIB
Dependencies	None

Overview

The Web Services library enables an application to store and manage data remotely, and return information about the current physical location of the client. These functions use secure services provided by SocketTools API servers and do not require third-party party APIs or accounts with other cloud service providers.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most

commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Web Services Functions

Function	Description
WebCancelTransfer	Cancel a storage operation that is currently in progress
WebCloseStorage	Close a storage container and release resources allocated for the client session
WebCompareFile	Compare the contents of a stored object with a local file
WebCompareObject	Compare the contents of a stored object with a memory buffer
WebCompareText	Compare the contents of a stored object with a string
WebCopyObject	Copy a storage object to a new location and optionally rename the object label
WebDeleteObject	Delete an existing storage object
WebDownloadFile	Download the contents of a stored object to a local file
WebDownloadFileEx	Download the contents of a stored object with progress notifications
WebDisableTrace	Disable logging of function calls
WebEnableTrace	Enable logging of function calls to a file
WebEnumApplications	Enumerate all registered storage applications
WebEnumObjects	Enumerate all storage objects that match the specified label or content type
WebGetAccountId	Return the current web services account identifier
WebGetErrorString	Return a description for the specified error code
WebGetFile	Download the contents of a storage object and copy to a local file
WebGetFileEx	Download the contents of a storage object and return information about the object
WebGetFirstApplication	Return information about the first registered storage application
WebGetFirstObject	Return information about the first object that matches search criteria
WebGetLastError	Return the last error code
WebGetLocation	Return the current physical location of the local computer system
WebGetNextApplication	Return information about the next registered storage application
WebGetNextObject	Return information about the next object that matches search criteria
WebGetObject	Download the contents of a storage object to a buffer
WebGetObjectEx	Download the contents of a storage object to buffer and return information about the object
WebGetObjectInformation	Retrieve the metadata for the specified storage object
WebGetObjectSize	Return the size of the specified storage object
WebGetObjectTime	Return the creation and last modification time for the specified storage object
WebGetPosixTime32	Return a POSIX timestamp value as a 32-bit integer
WebGetPosixTime64	Return a POSIX timestamp value as a 64-bit integer
WebGetStorageId	Return the returns the storage container ID
WebGetStorageQuota	Return quota limits assigned to your storage account
WebGetStorageTimeout	Get the number of seconds until a storage operation times out
WebGetSystemTime	Return the current date and time in a SYSTEMTIME structure
WebGetTextObject	Download the contents of a text object into a string buffer

WebGetTransferStatus	Return status information about the progress of a data transfer
WebInitialize	Initialize the library and validates the specified license key at runtime
WebMoveObject	Move a storage object to a new location and optionally rename the object label
WebOpenStorage	Open a storage container and return a handle for the client session
WebPutFile	Upload the contents of a local file to a new storage object
WebPutFileEx	Upload the contents of a local file and return information about the new object
WebPutObject	Upload the contents of a memory buffer to a new storage object
WebPutObjectEx	Upload the contents of a memory buffer and return information about the new object
WebPutTextObject	Create or replace a text object with the contents of a string buffer
WebRegisterAppId	Register a new application identifier used to store and retrieve data
WebRegisterEvent	Register an event handler to receive notifications for the session
WebRenameObject	Change the label associated with a storage object
WebResetStorage	Resets the application storage container and deletes all stored objects
WebResetStorageEx	Resets the specified storage container for an application and deletes all stored objects
WebSetLastError	Set the last error code
WebSetStorageTimeout	Set the number of seconds until a storage operation times out
WebUninitialize	Terminates the use of the library
WebUnregisterAppId	Unregister the application identifier and delete all associated storage objects
WebUploadFile	Upload the contents of a local file, creating or overwriting a stored object
WebUploadFileEx	Upload the contents of a local file with progress notifications
WebValidateAppId	Validate the specified application identifier
WebValidateLabel	Check the specified string to ensure it is a valid object label

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebCancelTransfer Function

```
BOOL WINAPI WebCancelTransfer(
   HSTORAGE hStorage
);
```

The **WebCancelTransfer** function cancels the current data transfer in progress.

Parameters

hStorage

A handle to the storage container.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCancelTransfer** function will cancel the current data transfer and abort the connection to the storage server. This function will fail if an active data transfer (either an upload or download) is not in progress.

This would typically be used within an event handler to cancel an operation as the contents of an object are being read or written. There is no mechanism to resume a canceled data transfer and this function should only be used when absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)
Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

WebGetTransferStatus, WebRegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebCloseStorage Function

```
BOOL WINAPI WebCloseStorage(
   HSTORAGE hStorage
);
```

The **WebCloseStorage** function closes the storage container.

Parameters

hStorage

A handle to the storage container.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCloseStorage** function must be called after all operations using the storage container have completed. The access token granted to the application will be released and the memory allocated for the session cache will be freed. Failure to call this function can result in a memory leak.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)
Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)

WebCompareFile Function

```
BOOL WINAPI WebCompareFile(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszLocalFile
);
```

The **WebCompareFile** function compares the contents of a stored object with a local file.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string which specifies the label of the object to be compared.

lpszLocalFile

A null-terminated string that specifies the name of the local file. If a path is not specified, the file will be created in the current working directory.

Return Value

If the function succeeds, the return value is a non-zero and the contents of the file matches the stored object. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCompareFile** function performs a binary comparison of the contents of a local file with a stored object on the server. The contents of the file must be identical to the contents of the stored object or the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebCompareObject, WebCompareText, WebGetObjectInformation

WebCompareObject Function

```
BOOL WINAPI WebCompareObject(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   LPCVOID lpvBuffer,
   DWORD dwLength
);
```

The **WebCompareObject** function compares the contents of a stored object with the data provided by the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string which specifies the label of the object to be compared.

lpvBuffer

A buffer that contains the data to be compared against the storage object.

dwLength

An unsigned integer which specifies the length of the data buffer to be compared.

Return Value

If the function succeeds, the return value is a non-zero and the data matches the contents of the stored object. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCompareObject** function performs a binary comparison of the data in the specified buffer with the contents of the storage object on the server. The ***dwLength*** parameter must match the size of the stored object exactly, or this function will fail. Partial comparisons are not supported by this function.

If you wish to compare the contents of a text object, it is recommended that you use **WebCompareText**. This function ensures that Unicode text is compared correctly.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebCompareFile, WebCompareText, WebGetObjectInformation

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebCompareText Function

```
BOOL WINAPI WebCompareText(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszObjectText,
   INT cchObjectText
);
```

The **WebCompareText** function compares the contents of a stored object with the string provided by the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string which specifies the label of the object to be compared.

lpszObjectText

A null-terminated string which contains the text to be compared with the stored object.

cchObjectText

The number of characters in the ***lpszObjectText*** string to be compared. This value may be -1, in which case the string length will be determined by counting the number of characters up to the terminating null.

Return Value

If the function succeeds, the return value is a non-zero and the data matches the contents of the stored object. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCompareText** function performs a text comparison of the characters in the string with the contents of the storage object on the server. The string length must match the amount of text in the stored object exactly, or this function will fail. Partial comparisons are not supported by this function.

The Unicode version of this function will automatically convert the UTF-16 string to UTF-8 encoding in the same way the **WebPutTextObject** function does.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebCopyObject Function

```
BOOL WINAPI WebCopyObject(
  HSTORAGE hStorage,
  LPCTSTR lpszOldLabel,
  LPCTSTR lpszNewLabel,
  DWORD dwStorageType,
  LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebCopyObject** function creates a copy of an existing storage object using a new label.

Parameters

hStorage

A handle to the storage container.

lpszOldLabel

A null-terminated string which specifies the label of the existing storage object to be copied. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A null-terminated string which specifies the name of the new storage object that will be created. This parameter may be NULL or point to an empty string, in which case the label name is not changed. In this case, the ***dwStorageType*** parameter cannot be WEB_STORAGE_DEFAULT.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Value	Description
WEB_STORAGE_DEFAULT	The default storage type. If this value is specified, the new object will be created using the same storage type as the original storage object.
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously

	stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain information about the new storage object. If this information is not required, this parameter may be a NULL pointer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebCopyObject** function is used to create a copy of an existing storage object. It may be used to duplicate an object with a different label, or it may be used to copy the object to a new storage container type. For example, it can copy an object originally created using WEB_STORAGE_USER to a new object stored using WEB_STORAGE_MACHINE.

Copied objects are assigned their own unique ID and are not linked to one another. Any subsequent changes made to the original object will not affect the copied object. Attempting to copy an object to itself or another existing object will result in an error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebDeleteObject, WebMoveObject, WebRenameObject

WebDeleteObject Function

```
BOOL WINAPI WebDeleteObject(
  HSTORAGE hStorage,
  LPCTSTR lpszObjectLabel
);
```

The **WebDeleteObject** function deletes an object from the storage container.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string which specifies the label of the object to be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebDeleteObject** function permanently deletes the storage object and its associated data from the server. Deleted objects cannot be recovered by the application. To remove all objects stored in the container, use the **WebResetStorage** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebDisableTrace Function

```
BOOL WINAPI WebDisableTrace();
```

The **WebDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, a value of zero is returned.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebDownloadFile Function

```
BOOL WINAPI WebDownloadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebDownloadFile** function downloads the contents of a storage object and copies it to a local file.

Parameters

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server. This parameter cannot be NULL or an empty string. Refer to the **WebValidateLabel** function for more information about object labels.

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebDownloadFile** function downloads the contents of the storage object and stores it in a local file. The object must have been previously created in the storage container WEB_STORAGE_GLOBAL using the application ID `SocketTools.Storage.Default`. This is the same default container used by the **WebUploadFile** function.

Unlike the **WebGetFile** and **WebGetFileEx** functions, it is not required that you open a storage container using the **WebOpenStorage** function prior to calling **WebDownloadFile**.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

The **WebDownloadFileEx** function provides similar functionality with a more complex interface that supports custom application IDs, additional options and the ability to provide a callback function that is invoked during the download process.

Example

```
WEB_STORAGE_OBJECT webObject;

// Download the object from global storage to a local file
if (WebDownloadFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
```

```
    // The object was downloaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be downloaded, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to download \"%s\" (%s)\n"), lpszObjectLabel, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebDownloadFileEx, WebGetFile, WebUploadFile, WebValidateLabel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebDownloadFileEx Function

```
BOOL WINAPI WebDownloadFileEx(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszAppId,
   DWORD dwStorageType,
   DWORD dwReserved,
   DWORD dwTimeout,
   LPWEB_STORAGE_OBJECT lpObject,
   WEBEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **WebDownloadFileEx** function downloads the contents of a storage object and copies it to a local file.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

lpszAppId

A null-terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is NULL or an empty string, the default identifier `SocketTools.Storage.Default` will be used.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.

WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

dwTimeout

An unsigned integer value that specifies a timeout period in seconds. If this value is zero, a default timeout period will be used.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WebEventProc** callback function. If this parameter is NULL, no callback function will be invoked during the data transfer.

dwParam

A user-defined integer value that is passed to the callback function specified by ***lpEventProc***. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebDownloadFileEx** function downloads the contents of the storage object and stores it in a local file. The **WebDownloadFile** function provides a simpler interface that defaults to downloading an object from the global storage container.

Unlike the **WebGetFile** and **WebGetFileEx** functions, it is not required that you open a storage container using the **WebOpenStorage** function prior to calling **WebDownloadFileEx**.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are downloading a large object and want your application to receive progress updates during the data transfer, provide a pointer to a callback function as the ***lpEventProc*** parameter. That function will receive event notifications as the data is being downloaded.

Example

```
WEB_STORAGE_OBJECT webObject;

// Download the object from global storage to a local file
if (WebDownloadFileEx(lpszLocalFile,
                      lpszObjectLabel,
                      lpszAppId,
                      WEB_STORAGE_GLOBAL,
                      0,
                      &webObject,
                      NULL, 0))
{
    // The object was downloaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be retrieved, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to retrieve \"%s\" (%s)\n"), lpszObjectLabel, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebEnableTrace Function

```
BOOL WINAPI WebEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **WebEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebEnumApplications Function

```
BOOL WINAPI WebEnumApplications(
   LPWEB_STORAGE_APPLICATION lpApplications,
   LPDWORD lpdwRegistered
);
```

The **WebEnumApplications** function enumerates all registered applications associated with the storage account.

Parameters

lpApplications

A pointer to an array of WEB_STORAGE_APPLICATION structures that will contain information about the enumerated application IDs. If this parameter is NULL, then no information is returned.

lpdwRegistered

A pointer to an unsigned integer that will contain the number of registered applications enumerated by this function. If the ***lpApplications*** parameter points to an array of WEB_STORAGE_APPLICATION structures, this parameter must be initialized to the maximum size of the array being passed to the function. If the ***lpApplications*** parameter is NULL, this value must be initialized to zero and when the function returns it will contain the number of registered applications.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebEnumApplications** function can be used to enumerate the application IDs registered with the storage account using the **WebRegisterAppId** function.

This function can be used in two ways. If the ***lpApplications*** parameter is NULL and the value passed by reference in the ***lpdwRegistered*** parameter is initialized to zero, the function will return the number of registered applications in ***lpdwRegistered***. This can be used to dynamically determine the size of the ***lpApplications*** array instead of declaring a fixed-size array in your application.

If the ***lpApplications*** parameter is not NULL, then the value referenced by ***lpdwRegistered*** must be initialized to the maximum size of the array that ***lpApplications*** points to. It is important to note that if either parameter is not initialized correctly, it can result in memory corruption and/or an unhandled exception.

The **WebGetFirstApplication** and **WebGetNextApplication** functions can be used to iterate through all registered application IDs without requiring you to preallocate memory for an array. This can be more efficient if a large number of application IDs have been registered.

Example

```
DWORD dwAppCount = 0;

if (WebEnumApplications(NULL, &dwAppCount ))
{
    LPWEB_STORAGE_APPLICATION lpAppArray = NULL;
    DWORD dwIndex;
```

```
    // Return if there are no registered applications
    if (dwAppCount == 0)
        return;

    // Allocate memory for an array of WEB_STORAGE_APPLICATION structures
    lpAppArray = (LPWEB_STORAGE_APPLICATION)LocalAlloc(LPTR,
sizeof(WEB_STORAGE_APPLICATION) * dwAppCount);

    if (lpAppArray == NULL)
        return; // Exhausted virtual memory?

    // Enumerate the registered application IDs
    if (!WebEnumApplications(lpAppArray, &dwAppCount))
        return;

    // Print information about each application
    for (dwIndex = 0; dwIndex < dwAppCount ; dwIndex++)
    {
        _tprintf(_T("AppId: %s\n"), lpAppArray[dwIndex].szAppId);
        _tprintf(_T("Key: %s\n"), lpAppArray[dwIndex].szApiKey);
        _tprintf(_T("LUID: %s\n"), lpAppArray[dwIndex].szLuid);
        _tprintf(_T("Tokens: %lu\n"), lpAppArray[dwIndex].dwTokens);

        if (dwAppCount > 1 && dwIndex < dwAppCount - 1)
            _tprintf(_T("\n"));
    }

    LocalFree((HLOCAL)lpAppArray);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebEnumObjects Function

```
BOOL WINAPI WebEnumObjects(
   HSTORAGE hStorage,
   LPCTSTR lpszMatchLabel,
   LPCTSTR lpszContentType,
   DWORD dwReserved,
   LPWEB_STORAGE_OBJECT lpObjects,
   LPDWORD lpdwObjects
);
```

The **WebEnumObjects** function enumerates all storage objects that match the specified label or content type.

Parameters

hStorage

A handle to the storage container.

lpszMatchLabel

A null-terminated string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this value is a NULL pointer or an empty string, all objects in the container will be matched.

lpszContentType

A null-terminated string which specifies the content type of the objects to be enumerated. If this value is a NULL pointer or an empty string, the content type is ignored and all matching objects are returned.

dwReserved

An unsigned integer value that is reserved for future use. This value must be zero.

lpObjects

A pointer to an array of WEB_STORAGE_OBJECT structures that will contain information about the enumerated objects. If this parameter is NULL, then no object information is returned.

lpdwObjects

A pointer to an unsigned integer that will contain the number of objects enumerated by this function. If the ***lpObjects*** parameter points to an array of WEB_STORAGE_OBJECT structures, this parameter must be initialized to the maximum size of the array being passed to the function. If the ***lpObjects*** parameter is NULL, this value must be initialized to zero, and when the function returns it will contain the number of matching objects.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebEnumObjects** function can be used to enumerate the number of objects that match a given label, content type or both. If a content type is specified, it must be a valid MIME media content type designated using the type/subtype nomenclature. For example, "text/plain" or "image/jpeg". An invalid MIME type will cause the function to fail.

This function can be used in two ways. If the ***lpObjects*** parameter is NULL and the value passed by reference in the ***lpdwObjects*** parameter is initialized to zero, the function will return the number of matching objects in ***lpdwObjects***. This can be used to dynamically determine the size of the lpObjects array instead of declaring a fixed-size array in your application.

If the ***lpObjects*** parameter is not NULL, then the value referenced by ***lpdwObjects*** must be initialized to the maximum size of the array that ***lpObjects*** points to. It is important to note that if either parameter is not initialized correctly, it can result in memory corruption and/or an unhandled exception.

The **WebGetFirstObject** and **WebGetNextObject** functions can be used to iterate through all matching storage objects without requiring you to preallocate memory for an array. Using **WebGetFirstObject** and **WebGetNextObject** is more efficient when the container contains a large number of objects that match the specified label and/or content type.

Example

```
DWORD dwObjects = 0;

if (WebEnumObjects(hStorage, _T("*.pdf"), NULL, 0, NULL, &dwObjects))
{
    LPWEB_STORAGE_OBJECT lpObjects = NULL;
    DWORD dwIndex;

    // Return if there are no matching objects in the container
    if (dwObjects == 0)
        return;

    // Allocate memory for an array of WEB_STORAGE_OBJECT structures
    lpObjects = (LPWEB_STORAGE_OBJECT)LocalAlloc(LPTR, sizeof(WEB_STORAGE_OBJECT) *
dwObjects);

    if (lpObjects == NULL)
        return; // Exhausted virtual memory?

    // Enumerate the matching objects
    if (!WebEnumObjects(hStorage, NULL, NULL, 0, lpObjects, &dwObjects))
        return;

    // Print information about each object
    for (dwIndex = 0; dwIndex < dwObjects; dwIndex++)
    {
        _tprintf(_T("Object: %s\n"), lpObjects[dwIndex].szObjectId);
        _tprintf(_T("Label: %s\n"), lpObjects[dwIndex].szLabel);
        _tprintf(_T("Size: %lu\n"), lpObjects[dwIndex].dwObjectSize);
        _tprintf(_T("Digest: %s\n"), lpObjects[dwIndex].szDigest);
        _tprintf(_T("Content: %s\n"), lpObjects[dwIndex].szContent);

        if (dwObjects > 1 && dwIndex < dwObjects - 1)
            _tprintf(_T("\n"));
    }

    LocalFree((HLOCAL)lpObjects);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebEventProc Function

```
VOID CALLBACK WebEventProc(
   HSTORAGE hStorage,
   UINT nEventId,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **WebEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hStorage

A handle to the storage container.

nEventId

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **WebRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **WebRegisterEvent** function. The **WebEventProc** function is a placeholder for the application-defined function name.

To obtain information about the current status of the read or write operation, call the **WebGetTransferStatus** function. An event handler can cancel the current operation by calling the **WebCancelTransfer** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetAccountId Function

```
BOOL WINAPI WebGetAccountId(
   LPCTSTR lpszAccountId,
   INT nMaxLength
);
```

The **WebGetAccountId** function returns the web services account ID associated with the current session.

Parameters

lpszAccountId

A null-terminated string that will contain the account ID when the function returns. This parameter cannot be NULL and must be at least 35 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the *lpszAccountId* string parameter, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The account ID is a string that uniquely identifies the web services account that is associated with the session. The account ID corresponds with your product serial number and runtime license key, but it is not identical to either of those values.

If you are using an evaluation license, the account ID is temporary and only valid during the evaluation period. After the evaluation period has expired, the account ID is revoked and objects stored using this ID will be deleted. It is not recommended that you store critical application data using an evaluation license.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetErrorString Function

```
INT WINAPI WebGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **WebGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **WebGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebGetFile Function

```
BOOL WINAPI WebGetFile(
   HSTORAGE hStorage,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel
);
```

The **WebGetFile** function downloads the contents of a storage object and copies it to a local file.

Parameters

hStorage

A handle to the storage container.

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetFile** function downloads the contents of the storage object and stores it in a local file. For information about the stored object that has been downloaded, use the **WebGetFileEx** function.

If you are downloading a large object and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebDownloadFile, WebGetFileEx, WebGetObject, WebPutFile, WebPutObject, WebRegisterEvent, WebUploadFile

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebGetFileEx Function

```
BOOL WINAPI WebGetFileEx(
   HSTORAGE hStorage,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   DWORD dwReserved,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebGetFileEx** function downloads the contents of a storage object and copies it to a local file.

Parameters

hStorage

A handle to the storage container.

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetFileEx** function downloads the contents of the storage object and stores it in a local file. Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are downloading a large object and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

The **WebDownloadFile** and **WebDownloadFileEx** functions provide similar functionality, but do not require a handle to an open storage container.

Example

```
WEB_STORAGE_OBJECT webObject;

// Download the object and store the contents in a local file
if (WebGetFileEx(hStorage, lpszLocalFile, lpszObjectLabel, 0, &webObject))
```

```
{
    // The object was downloaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %I64u\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be retrieved, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to retrieve \"%s\" (%s)\n"), lpszObjectLabel, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetLastError Function

```
DWORD WINAPI WebGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **WebSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **WebGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **WebSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WEB_ERROR. Those functions which call **WebSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

WebGetFirstApplication Function

```
BOOL WINAPI WebGetFirstApplication(
   LPWEB_STORAGE_APPLICATION lpAppInfo,
   LPDWORD lpdwContext,
);
```

The **WebGetFirstApplication** function returns information about the first registered application for the current storage account.

Parameters

lpAppInfo

A pointer to a WEB_STORAGE_APPLICATION structure that will contain information about the registered application when the function returns. This parameter cannot be NULL.

lpdwContext

A pointer to an unsigned integer that is used with subsequent calls to the **WebGetNextApplication** function. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetFirstApplication** function returns information about the first registered application. It is used in conjunction with the **WebGetNextApplication** function to enumerate all of the registered application IDs associated with your storage account.

This function provides an alternative to the **WebEnumApplications** function, which populates an array of WEB_STORAGE_APPLICATION structures. In some cases, iterating through each AppID in a loop may be preferred to preallocating memory for an array to store every registered application. Using **WebGetFirstApplication** and **WebGetNextApplication** is more efficient when you have registered a large number of application IDs.

You cannot intermix calls between **WebGetFirstApplication** and **WebEnumApplications**. The **WebEnumApplications** function will reset the internal application ID cache for the client session and subsequent calls to **WebGetNextApplication** will fail. The cached application ID information used by this function is shared by the entire process. Attempting to enumerate all registered application IDs in multiple threads at the same time can yield unexpected results. It is recommended that multithreaded clients use a critical section to ensure that only a single thread is enumerating the AppIDs at any one time.

Example

```
WEB_STORAGE_APPLICATION webApp;
DWORD dwContext = 0;

if (WebGetFirstApplication(&webApp, &dwContext))
{
    do
    {
        // Print information for each registered application
        _tprintf(_T("AppId: %s\n"), webApp.szAppId);
        _tprintf(_T("Key: %s\n"), webApp.szApiKey);
```

```
        _tprintf(_T("LUID: %s\n"), webApp.szLuid);
        _tprintf(_T("Tokens: %lu\n"), webApp.dwTokens);
        _tprintf(_T("\n"));
    }
    while (WebGetNextApplication(&webApp, &dwContext));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetFirstObject Function

```
BOOL WINAPI WebGetFirstObject(
   HSTORAGE hStorage,
   LPCTSTR lpszMatchLabel,
   LPCTSTR lpszContentType,
   DWORD dwReserved,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebGetFirstObject** function returns information about the first storage object that matches the specified label or content type.

Parameters

hStorage

A handle to the storage container.

lpszMatchLabel

A null-terminated string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this value is a NULL pointer or an empty string, all objects in the container will be matched.

lpszContentType

A null-terminated string which specifies the content type of the objects to be enumerated. If this value is a NULL pointer or an empty string, the content type is ignored and all matching objects are returned. If a content type is specified, it must be a valid MIME media content type designated using the **type/subtype** nomenclature.

dwReserved

An unsigned integer value that is reserved for future use. This value must be zero.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain information about the storage object when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetFirstObject** function returns information about the first object that matches a given label, content type or both. It is used in conjunction with the **WebGetNextObject** function to enumerate all of the matching objects in the storage container.

This function provides an alternative to the **WebEnumObjects** function, which populates an array of WEB_STORAGE_OBJECT structures. In some cases, iterating over each object in a loop may be preferred to preallocating memory for an array to store every matching object. Using **WebGetFirstObject** and **WebGetNextObject** is more efficient when the container contains a large number of objects that match the specified label and/or content type.

You cannot intermix calls between **WebGetFirstObject** and **WebEnumObjects**. The

WebEnumObjects function will reset the internal object cache for the client session and subsequent calls to **WebGetNextObject** will fail.

Example

```
WEB_STORAGE_OBJECT webObject;

if (WebGetFirstObject(hStorage, _T("*.pdf"), NULL, 0, &webObject))
{
    do
    {
        // Print information about each object
        _tprintf(_T("Object: %s\n"), webObject.szObjectId);
        _tprintf(_T("Label: %s\n"), webObject.szLabel);
        _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
        _tprintf(_T("Digest: %s\n"), webObject.szDigest);
        _tprintf(_T("Content: %s\n"), webObject.szContent);
        _tprintf(_T("\n"));
    }
    while (WebGetNextObject(hStorage, &webObject));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebEnumObjects, WebGetNextObject

WebGetLocation Function

```
BOOL WINAPI WebGetLocation(
   LPWEB_LOCATION lpLocation
);
```

The **WebGetLocation** function returns the current physical location of the local computer system.

Parameters

lpLocation

A pointer to a WEB_LOCATION structure that will contain information about the location when the function returns. The structure members will be automatically initialized to zero and zero-length strings when the function is called. This parameter cannot be a NULL pointer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetLocation** function is used to obtain physical location information associated with the with the external IP address of the local system. The accuracy of this information can vary depending on the location, with the most detailed information being available for North America. The country and time zone information for all locations is generally accurate. However, as the location information becomes more precise, details such as city names, postal codes and specific geographic locations (e.g.: longitude and latitude) may have reduced accuracy.

This location information should not be used by programs that require extremely accurate map coordinates, such as navigation applications. The location information in North America should be generally accurate within a 25 mile (40km) radius. However, given the nature of how IP address location works, there is no guarantee that location information for any specific IP address or network will be accurate.

Software that is designed to protect the privacy of users, such as those which route all Internet traffic through proxy servers or VPNs, can significantly impact the accuracy of this information. In this case, the data returned in this structure may reflect the location of the network or proxy server, and not the location of the person using your application. It is recommended that you always request permission from the user before acquiring their location, have them confirm that the location is correct and provide a mechanism for them to update that information.

Example

```
WEB_LOCATION webLocation;

// Return information about the location of the local system
if (WebGetLocation(&webLocation))
{
    _tprintf(_T("Location ID: %s\n"), webLocation.szLocationId);
    _tprintf(_T("IP address: %s\n"), webLocation.szIPAddress);
    _tprintf(_T("ASN: %u\n"), webLocation.nAutonomousSystemNumber);
    _tprintf(_T("Organization: %s\n"), webLocation.szOrganization);
    _tprintf(_T("Region Name: %s\n"), webLocation.szRegionName);
    _tprintf(_T("Region Code: %03u\n"), webLocation.nRegionCode);
    _tprintf(_T("Country Name: %s\n"), webLocation.szCountryName);
    _tprintf(_T("Country Code: %03u\n"), webLocation.nCountryCode);
```

```
    _tprintf(_T("Subdivision: %s\n"), webLocation.szSubdivision);
    _tprintf(_T("City Name: %s\n"), webLocation.szCityName);
    _tprintf(_T("Postal Code: %s\n"), webLocation.szPostalCode);
    _tprintf(_T("Timezone: %s (%ld)\n"), webLocation.szTimezone,
webLocation.nTimezoneOffset);
    _tprintf(_T("Local Time: %04d-%02d-%02d %02d:%02d:%02d %s\n"),
             webLocation.stLocalTime.wYear,
             webLocation.stLocalTime.wMonth,
             webLocation.stLocalTime.wDay,
             webLocation.stLocalTime.wHour,
             webLocation.stLocalTime.wMinute,
             webLocation.stLocalTime.wSecond,
             webLocation.szTzShortName);
    _tprintf(_T("Coordinates: %s\n"), webLocation.szCoordinates);
    _tprintf(_T("Latitude: %.4f\n"), webLocation.dLatitude);
    _tprintf(_T("Longitude: %.4f\n"), webLocation.dLongitude);
}
else
{
    _tprintf(_T("Unable to determine the current location\n"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetNextApplication Function

```
BOOL WINAPI WebGetNextApplication(
   LPWEB_STORAGE_APPLICATION lpAppInfo,
   LPDWORD lpdwContext,
);
```

The **WebGetNextApplication** function returns information about the next registered application for the current storage account.

Parameters

lpAppInfo

A pointer to a WEB_STORAGE_APPLICATION structure that will contain information about the registered application when the function returns. This parameter cannot be NULL.

lpdwContext

A pointer to an unsigned integer that is used with subsequent calls to the **WebGetNextApplication** function. The value of this parameter is initialized by calling the **WebGetFirstApplication** function. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetNextApplication** function returns information about the next registered application after initially calling the **WebGetFirstApplication** function. It is used to enumerate all of the registered application IDs associated with your storage account.

This function provides an alternative to the **WebEnumApplications** function, which populates an array of WEB_STORAGE_APPLICATION structures. In some cases, iterating through each AppID in a loop may be preferred to preallocating memory for an array to store every registered application. Using **WebGetFirstApplication** and **WebGetNextApplication** is more efficient when you have registered a large number of application IDs.

You cannot intermix calls between **WebGetNextApplication** and **WebEnumApplications**. The **WebEnumApplications** function will reset the internal application ID cache for the client session and subsequent calls to **WebGetNextApplication** will fail. The cached application ID information used by this function is shared by the entire process. Attempting to enumerate all registered application IDs in multiple threads at the same time can yield unexpected results. It is recommended that multithreaded clients use a critical section to ensure that only a single thread is enumerating the AppIDs at any one time.

Example

```
WEB_STORAGE_APPLICATION webApp;
DWORD dwContext = 0;

if (WebGetFirstApplication(&webApp, &dwContext))
{
    do
    {
        // Print information for each registered application
        _tprintf(_T("AppId: %s\n"), webApp.szAppId);
```

```
        _tprintf(_T("Key: %s\n"), webApp.szApiKey);
        _tprintf(_T("LUID: %s\n"), webApp.szLuid);
        _tprintf(_T("Tokens: %lu\n"), webApp.dwTokens);
        _tprintf(_T("\n"));
    }
    while (WebGetNextApplication(&webApp, &dwContext));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetNextObject Function

```
BOOL WINAPI WebGetNextObject(
   HSTORAGE hStorage,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebGetNextObject** function returns information about the next storage object that matches the specified label or content type.

Parameters

hStorage

A handle to the storage container.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain information about the storage object when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetNextObject** function returns information about the next object that matches the label and/or content type that was specified by the **WebGetFirstObject** function call. This function may only be called after **WebGetFirstObject** has been called, otherwise it will fail.

When all matching objects have been returned to the caller, this function will return zero (FALSE) and the **WebGetLastError** function will return NO_ERROR. Any other error code indicates an underlying problem with the request, such as an invalid parameter passed to the function.

You cannot intermix calls between **WebGetNextObject** and **WebEnumObjects**. The **WebEnumObjects** function will reset the internal object cache for the client session and subsequent calls to **WebGetNextObject** will fail.

Example

```
WEB_STORAGE_OBJECT webObject;

if (WebGetFirstObject(hStorage, _T("*.pdf"), NULL, 0, &webObject))
{
    do
    {
        // Print information about each object
        _tprintf(_T("Object: %s\n"), webObject.szObjectId);
        _tprintf(_T("Label: %s\n"), webObject.szLabel);
        _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
        _tprintf(_T("Digest: %s\n"), webObject.szDigest);
        _tprintf(_T("Content: %s\n"), webObject.szContent);
        _tprintf(_T("\n"));
    }
    while (WebGetNextObject(hStorage, &webObject));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetObject Function

```
BOOL WINAPI WebGetObject(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   LPVOID lpvBuffer,
   DWORD lpdwLength
);
```

The **WebGetObject** function retrieves the contents of a storage object and copies it to the memory buffer that is provided.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetObject** function is used to retrieve a stored object from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the object. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated and the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvBuffer*** parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
DWORD dwLength = 0;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
```

```
// returned in the hgblBuffer parameter
if (WebGetObject(hStorage, lpszObjectLabel, &hgblBuffer, &dwLength))
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetObjectEx Function

```
BOOL WINAPI WebGetObjectEx(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   DWORD dwReserved,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   LPWEB_STORAGE_OBJECT lpObject,
);
```

The **WebGetObjectEx** function retrieves the contents of a storage object and copies it to the memory buffer that is provided. Additional information about the object is returned to the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

dwReserved

An unsigned integer that is reserved for future use. This value should always be zero.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetObjectEx** function is used to retrieve a stored object from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the object. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated and the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvBuffer*** parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory

handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

If you wish to retrieve the contents of a text object and store it in a null-terminated string buffer, use the **WebGetTextObject** function. If you wish to download the contents of a stored file, use the **WebGetFileEx** function.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
DWORD dwLength = 0;
WEB_STORAGE_OBJECT webObject;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
if (WebGetObjectEx(hStorage, lpszObjectLabel, 0, &hgblBuffer, &dwLength,
&webObject))
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetObjectInformation Function

```
BOOL WINAPI WebGetObjectInformation(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   DWORD dwReserved,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebGetObjectInformation** function retrieves the metadata for a storage object.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string that specifies the label of the storage object.

dwReserved

An unsigned integer that is reserved for future use. This value should always be zero.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter cannot be a NULL pointer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetObjectInformation** function is used to retrieve the metadata for a stored object on the server, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents. This function can also be used as a simple method to determine if the specified object exists without the overhead of requesting the server attempt to retrieve the contents of an object.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

If you are only interested in obtaining the size of a stored object, you can use the **WebGetObjectSize** function.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **WebGetStorageQuota** function.

Example

```
WEB_STORAGE_OBJECT webObject;

// Get information about the object
if (WebGetObjectInformation(hStorage, lpszObjectLabel, 0, &webObject))
{
    // The object exists, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
```

```
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object does not exist, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to get information on \"%s\" (%s)\n"), lpszObjectLabel,
szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetObjectSize Function

```
BOOL WINAPI WebGetObjectSize(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   LPDWORD lpdwObjectSize
);
```

The **WebGetObjectSize** function returns the size of the stored object.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string that specifies the label of the storage object. This parameter cannot be a NULL pointer.

lpdwObjectSize

A pointer to an unsigned integer value that will contain the size of the object. If this parameter is NULL, the parameter is ignored and the function only checks for the existence of an object that matches the specified label.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetObjectSize** function is used to retrieve the size of a stored object on the server. This function can also be used as a simple method to determine if the specified object exists. An object size of zero means the object exists, but currently has no data associated with it.

If the *lpObjectSize* parameter is not NULL, its value is initialized to zero when the function is called, and updated with the object size when the function returns.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting the size of an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

The **WebGetObjectInformation** function can be used to obtain the metadata associated with the storage object, including the size, content type, creation date and a SHA-256 digest of the data.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **WebGetStorageQuota** function.

Example

```
// Check if the object exists
DWORD dwObjectSize;

if (WebGetObjectSize(hStorage, lpszObjectLabel, &dwObjectSize))
{
    // The object exists, display the size in bytes
    _tprintf(_T("The size of \"%s\" is %lu bytes\n"), lpszObjectLabel,
dwObjectSize);
}
```

```
else
{
    // The object size could not be determined, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to get the size of \"%s\" (%s)\n"), lpszObjectLabel,
szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebGetObject, WebGetObjectInformation, WebGetObjectTime, WebGetStorageQuota, WebPutObject

WebGetObjectTime Function

```
BOOL WINAPI WebGetObjectTime(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   LPFILETIME lpTimeCreated,
   LPFILETIME lpTimeModified
);
```

The **WebGetObjectTime** function returns the creation and last modification time of the stored object.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string that specifies the label of the storage object. This parameter cannot be a NULL pointer.

lpTimeCreated

A pointer to a FILETIME structure which will contain the time the storage object was created when the function returns. If this information is not required, the parameter may be NULL.

lpTimeModified

A pointer to a FILETIME structure which will contain the time the storage object was last modified when the function returns. If this information is not required, the parameter may be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetObjectTime** function is used to retrieve the creation and modification times for a stored object on the server. This function can also be used as a simple method to determine if the specified object exists. Each of the LPFILETIME parameters are optional and may be NULL if either the creation or modification times are not needed. If a pointer to a FILETIME structure is provided, its members will be initialized to zero and then updated with the creation and/or modification time if the function succeeds.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting the size of an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

If you wish to obtain all of the metadata associated with a specific object with a single function call, including the size, content type, creation and modification times, use the **WebGetObjectInformation** function.

Example

```
// Check if the object exists
FILETIME ftCreated;
FILETIME ftModified;

if (WebGetObjectTime(hStorage, lpszObjectLabel, &ftCreated, &ftModified))
```

```
{
    // The object exists, display the last modification time
    TCHAR szLocalDate[128];
    TCHAR szLocalTime[128];
    FILETIME ftLocalTime;
    SYSTEMTIME stLocalTime;

    FileTimeToLocalFileTime(&ftModified, &ftLocalTime);
    FileTimeToSystemTime(&ftLocalTime, &stLocalTime);

    GetDateFormat(LOCALE_USER_DEFAULT,
                  DATE_SHORTDATE,
                  &stLocalTime,
                  NULL,
                  szLocalDate, 128);

    GetTimeFormat(LOCALE_USER_DEFAULT,
                  TIME_FORCE24HOURFORMAT,
                  &stLocalTime,
                  NULL,
                  szLocalTime, 128);

    _tprintf(_T("The object \"%s\" was lasted modified on %s %s\n"),
lpszObjectLabel, szLocalDate, szLocalTime);
}
else
{
    // The object times could not be determined, display an error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to get the size of \"%s\" (%s)\n"), lpszObjectLabel,
szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetPosixTime32 Function

```
BOOL WINAPI WebGetPosixTime32(
    LONG *lpTime32
);
```

The **WebGetPosixTime32** function returns a 32-bit POSIX timestamp value.

Parameters

lpTime32

A pointer to a signed 32-bit integer which will contain a POSIX timestamp value when the function returns. This value will be initialized to zero when the function is called and then updated when it returns successfully. This parameter cannot be NULL or the function will fail.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetPosixTime32** function returns the current date and time as a 32-bit POSIX timestamp, expressed as the number of whole seconds that have elapsed since 00:00:00 UTC on January 1, 1970. The value returned by this function is based on Coordinated Universal Time (UTC) and is not affected by the local time zone or daylight saving time settings.

The timestamp returned by this function is obtained from the SocketTools API server and may be cached locally using the same internal time synchronization mechanisms used by other functions in this library. This helps ensure that the value reflects an accurate UTC time while avoiding unnecessary network time queries when synchronization is performed periodically.

This function is provided for compatibility with legacy applications or development environments that cannot work with 64-bit integer values. Whenever possible, applications should use **WebGetPosixTime64** instead. A 64-bit POSIX timestamp avoids the limitations of 32-bit values and should be preferred for all new development.

A 32-bit POSIX timestamp can only represent dates up to January 19, 2038. This limitation is commonly referred to as the Year 2038 problem. Unlike some implementations which allow the value to overflow and wrap around, this function will fail if the timestamp exceeds the maximum value that can be represented by a signed 32-bit integer. This means that after that date, this function will no longer return a valid timestamp.

This function returns the timestamp as a signed 32-bit integer for compatibility with common C and C++ data types. Under normal conditions the value returned by this function will always be a positive number representing a date after the POSIX epoch. The timestamp is returned with one-second precision; fractional seconds are not included.

If the function cannot obtain the current universal time or the time value cannot be converted to a valid POSIX timestamp, the function will fail and the value pointed to by *lpTime32* will remain zero.

Example

```
LONG posixTime32;

if (WebGetPosixTime32(&posixTime32))
{
```

```
    // Display the current POSIX timestamp value
    _tprintf(_T("The current POSIX timestamp value is %ld\n"), posixTime32);
}
else
{
  DWORD dwError = WebGetLastError();
  _tprintf(_T("Unable to obtain a POSIX timestamp value, error 0x%08lx\n"),
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

WebGetPosixTime64 Function

```
BOOL WINAPI WebGetPosixTime64(
    LONGLONG *lpTime64
);
```

The **WebGetPosixTime64** function returns a 64-bit POSIX timestamp value.

Parameters

lpTime64

A pointer to a signed 64-bit integer which will contain a POSIX timestamp value when the function returns. This value will be initialized to zero when the function is called and then updated when it returns successfully. This parameter cannot be NULL or the function will fail.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetPosixTime64** function returns the current date and time as a 64-bit POSIX timestamp, expressed as the number of whole seconds that have elapsed since 00:00:00 UTC on January 1, 1970. The value returned by this function is based on Coordinated Universal Time (UTC) and is not affected by the local time zone or daylight saving time settings.

The timestamp returned by this function is obtained from the SocketTools API server and may be cached locally using the same internal time synchronization mechanisms used by other functions in this library. This helps ensure that the value reflects an accurate UTC time while avoiding unnecessary network time queries when synchronization is performed periodically.

Whenever possible, applications should use this function instead of **WebGetPosixTime32**. A 32-bit POSIX timestamp can only represent dates up to January 19, 2038, after which it overflows and can no longer represent later dates correctly. This limitation is commonly referred to as the Year 2038 problem. Because this function returns a 64-bit value, it avoids that limitation and should be preferred for all new development.

This function returns the timestamp as a signed 64-bit integer for compatibility with common C and C++ data types. Under normal conditions the value returned by this function will always be a positive number representing a date after the POSIX epoch. The timestamp is returned with one-second precision; fractional seconds are not included.

If the function cannot obtain the current universal time or the time value cannot be converted to a valid POSIX timestamp, the function will fail and the value pointed to by *lpTime64* will remain zero.

Example

```
LONGLONG posixTime64;

if (WebGetPosixTime64(&posixTime64))
{
    // Display the current POSIX timestamp value
    _tprintf(_T("The current POSIX timestamp value is %I64d\n"), posixTime64);
}
else
{
```

```
  DWORD dwError = WebGetLastError();
  _tprintf(_T("Unable to obtain a POSIX timestamp value, error 0x%08lx\n"),
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebGetStorageId Function

```
BOOL WINAPI WebGetStorageId(
   HSTORAGE hStorage,
   LPCTSTR lpszStorageId,
   INT nMaxLength
);
```

The **WebGetStorageId** function returns the storage container ID.

Parameters

hStorage

A handle to the storage container.

lpszStorageId

A null-terminated string that will contain the storage ID when the function returns. This parameter cannot be NULL and must be at least 35 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the ***lpszStorageId*** string parameter, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The storage ID is a string that identifies the storage container that was opened with the **WebOpenStorage** function. The storage ID is associated with your development license and is guaranteed to be a unique value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetStorageQuota Function

```
BOOL WINAPI WebGetStorageQuota(
   LPWEB_STORAGE_QUOTA lpQuota
);
```

The **WebGetStorageQuota** function returns quota limits assigned to your storage account.

Parameters

lpQuota

A pointer to a WEB_STORAGE_QUOTA structure that will contain information the quota limits for your account when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetStorageQuota** function can be used to determine how much storage space is available to your application. The *ulBytesFree* structure member will tell you how many bytes of storage you have available, and the *dwObjectSize* member will tell you the maximum size of any individual storage object. In addition to the bytes allocated for storage, there is also a limit on the total number of objects that your application may create which is specified by the *dwObjectLimit* member.

Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

Example

```
WEB_STORAGE_QUOTA appQuota;

// Initialize the library
if (WebInitialize(CSTOOLS12_LICENSE_KEY, NULL) == FALSE)
{
    _tprintf(_T("Unable to initialize the SocketTools library\n"));
    return;
}

// Display storage account usage and limits
if (WebGetStorageQuota(&appQuota))
{
     _tprintf(_T("Objects Used:  %lu\n"), appQuota.dwObjects);
     _tprintf(_T("Object Limit:  %lu\n"), appQuota.dwObjectLimit);
     _tprintf(_T("Object Size:   %lu\n"), appQuota.dwObjectSize);
     _tprintf(_T("Bytes Used:    %I64u\n"), appQuota.ulBytesUsed);
     _tprintf(_T("Bytes Free:    %I64u\n"), appQuota.ulBytesFree);
     _tprintf(_T("Storage Limit: %I64u\n"), appQuota.ulStorageLimit);
}
else
{
    // Unable to get the quota information for this account
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
```

```
    _tprintf(_T("Unable to get the account quota (%s)\n"), szError);
}
```

Requirements

WebGetStorageTimeout Function

```
DWORD WINAPI WebGetStorageTimeout(
    HSTORAGE hStorage
);
```

The **WebGetStorageTimeout** function returns the number of seconds the client will wait for a response from the storage server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hStorage

A handle to the storage container.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The default timeout period is 10 seconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebGetSystemTime Function

```
BOOL WINAPI WebGetSystemTime(
   DWORD dwOptions,
   LPSYSTEMTIME lpDateTime
);
```

The **WebGetSystemTime** function returns the current date and time in a SYSTEMTIME structure.

Parameters

dwOptions

An integer parameter which specifies one or more options.

Value	Description
WEB_TIME_DEFAULT	The default options should be used when retrieving the date and time. This is the same as specifying WEB_TIME_UNIVERSAL.
WEB_TIME_UNIVERSAL	The date and time values returned in the SYSTEMTIME structure will use Univeral Coordinated Time (UTC) and will not be adjusted for the current timezone. This is similar to the value returned by the **GetSystemTime** function in the Win32 API.
WEB_TIME_LOCAL	The date and time values returned in the SYSTEMTIME structure will adjusted for the current timezone. This is similar to the value returned by the **GetLocalTime** function in the Win32 API. The local timezone is determined by system settings for the current user.

lpDateTime

A pointer to a SYSTEMTIME structure which contains the current date and time. The structure members will be initialized to zero when the function is called and then updated when it returns successfully. This parameter cannot be NULL or the function will fail.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetSystemTime** function returns the current date and time into a SYSTEMTIME structure. Unlike the **GetSystemTime** function, this function does not use the local system clock. Instead, it obtains the current time from the SocketTools API server, which is synchronized with official time servers using the Network Time Protocol (NTP). This helps ensure that the returned value is accurate and has not been altered by the user or affected by incorrect system clock settings.

This function can be useful in scenarios where an application must rely on a trusted and consistent time source. For example, it may be used for validating software licenses, enforcing time-based restrictions, generating timestamps for logging or auditing, or coordinating events across multiple systems where the local system time cannot be assumed to be accurate.

Because the time value is retrieved from a remote server, this function requires an active network connection and may be subject to network latency or temporary connectivity issues. To reduce network overhead, the function internally caches the most recently retrieved time value for a short

period (typically up to 60 seconds). When the function is called again within this interval, it does not immediately query the server. Instead, it calculates the elapsed time since the last successful request using a high-resolution system tick count and adjusts the cached time value accordingly.

This approach allows the returned time to continue advancing between server synchronizations, providing a smooth and consistent progression of time values without requiring a network request for each call. However, because this adjustment is based on the local system timer, it should be considered an approximation of the actual server time. The time value will be re-synchronized with the server periodically to maintain overall accuracy.

In most cases, it is recommended that applications use the **WEB_TIME_UNIVERSAL** option when storing or comparing date/time values. Universal (UTC) time provides a consistent, timezone-independent reference that avoids issues related to daylight saving time changes or differences in local system settings. This is particularly important when timestamps are shared between systems or persisted for later comparison.

The **WEB_TIME_LOCAL** option can be used when the application requires a date/time value adjusted for the user's current timezone, such as when displaying timestamps in a user interface. However, because the timezone adjustment is based on the local system configuration, it may still be affected by incorrect timezone or daylight saving settings on the client system.

Developers should consider using the local system time (for example, via **GetSystemTime** or **GetLocalTime**) when absolute accuracy is not critical or when network access is unavailable. Retrieving the time locally avoids the overhead of a network request and is typically sufficient for general-purpose tasks such as UI updates, file timestamps, or short-lived timing operations.

This function is not intended to replace standard system time APIs for high-frequency or real-time operations. Applications that require precise time measurements or guaranteed monotonic behavior should use dedicated high-resolution timing APIs instead of relying on this function.

Example

```
SYSTEMTIME stDateTime;

if (WebGetSystemTime(WEB_TIME_UNIVERSAL, &stDateTime))
{
    // Display the current date and time in ISO 8601 format
    _tprintf(_T("The current date and time is %04hu-%02hu-
%02huT%02hu:%02hu:%02huZ\n"),
             stDateTime.wYear,
             stDateTime.wMonth,
             stDateTime.wDay,
             stDateTime.wHour,
             stDateTime.wMinute,
             stDateTime.wSecond);
}
else
{
  DWORD dwError = WebGetLastError();
  _tprintf(_T("Unable to determine the current date and time, error 0x%08lx\n"),
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cswebv12.lib

WebGetTextObject Function

```
BOOL WINAPI WebGetTextObject(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   LPTSTR lpszBuffer,
   INT nMaxLength,
   LPWEB_STORAGE_OBJECT lpObject,
);
```

The **WebGetTextObject** function retrieves the contents of a text storage object and copies it to the string buffer that is provided. Additional information about the object is returned to the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string that specifies the label of the text object that should be retrieved from the server.

lpszBuffer

A null-terminated string buffer which will contain the text stored in the object. The string must be large enough to store the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. This value must be large enough to store the complete text and the terminating null character.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetTextObject** function is used to retrieve the text from a stored object and copy it into a string buffer. The string buffer must be pre-allocated and large enough to contain the entire text and a terminating null character.

If you use the **WebGetObjectSize** function to determine the size of the object so your application can dynamically allocate memory for the string buffer, be sure to allocate a string buffer that is larger than the reported size. The size of the stored text object may differ slightly from what is returned in the string, depending on how the text has been encoded.

Text objects that are created or updated using the Unicode version of **WebPutTextObject** function will always be converted and stored as UTF-8 encoded text. If your application uses the ANSI version of this function to retrieve that text, it will be UTF-8 encoded and your application will need to convert it back to UTF-16 encoded text, if needed. The Unicode version of this function will perform the conversion automatically.

This function should never be used to retrieve data from an object that does not contain text. If the **WebPutObject** function was previously used to store UTF-16 encoded text, you must use **WebGetObject** to retrieve that data. This function only recognizes UTF-8 encoded text and considers UTF-16 encoded text to be binary data.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

Example

```
LPTSTR lpszBuffer = (LPTSTR)NULL;
INT nMaxLength = 8192;
WEB_STORAGE_OBJECT webObject;

lpszBuffer = (LPTSTR)LocalAlloc(LPTR, nMaxLength);
if (lpszBuffer == NULL)
{
    // Unable to allocate memory for the string
    _ftprintf(stderr, _T("Unable to allocate %d bytes of memory\n"), nMaxLength);
    return;
}

if (WebGetTextObject(hStorage, lpszObjectLabel, lpszBuffer, nMaxLength,
&webObject))
{
    // Output the text contained in the object
    _fputts(lpszBuffer, stdout);
}
else
{
    DWORD dwError = WebGetLastError();
    TCHAR szError[128];

    WebGetErrorString(dwError, szError, 128);
    _ftprintf(stderr, _T("Unable to get \"%s\": %s\n"), lpszObjectLabel, szError);
}

// Free memory allocated for the text when no longer needed
LocalFree((HLOCAL)lpszBuffer);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebGetTransferStatus Function

```
BOOL WINAPI WebGetTransferStatus(
   HSTORAGE hStorage,
   LPWEB_STORAGE_TRANSFER lpStatus
);
```

The **WebGetTransferStatus** function returns information about the current data transfer in progress.

Parameters

hStorage

Handle to the storage container.

lpStatus

A pointer to a WEB_STORAGE_TRANSFER structure which contains information about the status of the current data transfer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebGetTransferStatus** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this function will return the status of the last successful data transfer.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified storage session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebInitialize Function

```
BOOL WINAPI WebInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **WebInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **WebInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **WebUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **WebInitialize** or **WebUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebMoveObject Function

```
BOOL WINAPI WebMoveObject(
  HSTORAGE hStorage,
  LPCTSTR lpszOldLabel,
  LPCTSTR lpszNewLabel,
  DWORD dwStorageType,
  LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebMoveObject** function moves an existing object to a different storage container.

Parameters

hStorage

A handle to the storage container.

lpszOldLabel

A null-terminated string which specifies the name of the existing storage object to be moved. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A null-terminated string which specifies a new label for the storage object being moved. This parameter may be NULL or point to an empty string, in which case the label name is not changed.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local

	machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain information about the new storage object. If this information is not required, this parameter may be a NULL pointer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebMoveObject** function is used to move an existing storage object to a new container. For example, it can move an object originally created using WEB_STORAGE_USER to the WEB_STORAGE_MACHINE container. The ***dwStorageType*** parameter must specify a valid storage container type and cannot be WEB_STORAGE_DEFAULT.

If the ***dwStorageType*** parameter specifies the same container that the object is currently in, and the ***lpszNewLabel*** parameter specifies a new label name, this function will simply rename the existing object and is effectively the same as calling the **WebRenameObject** function.

To duplicate an existing storage object, use the **WebCopyObject** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebOpenStorage Function

```
HSTORAGE WINAPI WebOpenStorage(
    LPCTSTR lpszAppId,
    DWORD dwStorageType
```

The **WebOpenStorage** function establishes a connection with the server and opens the storage container associated with the specified storage type.

Parameters

lpszAppId

A null-terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is NULL or an empty string, the default identifier `SocketTools.Storage.Default` will be used.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

Return Value

If the function succeeds, the return value is a handle to the storage container. If the function fails, the

return value is INVALID_HANDLE. To get extended error information, call **WebGetLastError**.

Remarks

The **WebOpenStorage** function opens the specified storage container and requests an access token for the application. This is the first function that must be called prior to accessing any stored objects.

The application ID is a string that uniquely identifies the application requesting the access and must have been previously registered with the server by calling the **WebRegisterAppId** function. If the *lpszAppId* parameter is NULL or an empty string, the function will use a default internal ID that is allocated for each storage account. You can use this default ID if you wish to share data between all of the applications you create.

The storage type specifies the type of container that objects will be stored in. In most cases, we recommend using WEB_STORAGE_GLOBAL which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if WEB_STORAGE_MACHINE is specified, the objects that are stored there can only be accessed from that computer system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application can no longer be accessed.

It is advisable is to store critical application data and configuration information using WEB_STORAGE_GLOBAL and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

Example

```
 HSTORAGE hStorage = INVALID_HANDLE;
LPCTSTR lpszAppId = _T("MyCompany.WebTest.1");
LPCTSTR lpszLocalFile = _T("TestDocument.pdf");
LPCTSTR lpszObjectLabel = _T("TestDocument.pdf");
WEB_STORAGE_OBJECT webObject = { 0, };
BOOL bSuccess = FALSE;

// Register the application ID which identifies the application
if (!WebRegisterAppId(lpszAppId))
{
    tprintf(_T("Unable to register the application ID"));
    _exit(0);
}

// Open the application storage container
hStorage = WebOpenStorage(lpszAppId, WEB_STORAGE_GLOBAL);

if (hStorage == INVALID_HANDLE)
{
    tprintf(_T("Unable to open global storage for this application"));
    _exit(0);
}

// Upload a local file to the storage server and return information
// about the stored object when it completes
bSuccess = WebPutFileEx(hStorage,
                        lpszLocalFile,
                        lpszObjectLabel,
                        NULL,
```

```
                        WEB_OBJECT_DEFAULT,
                        0,
                        &webObject);

if (bSuccess)
{
    // Print information about the object that was created
    _tprintf(_T("Object: %s\n"), webObject.szObjectId);
    _tprintf(_T("Label: %s\n"), webObject.szLabel);
    _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest: %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The upload failed, display error information
    DWORD dwError = WebGetLastError();
    TCHAR szError[128];

    WebGetErrorString(dwError, szError, 128);
    _tprintf(_T("WebPutFileEx failed, error 0x%08lX (%s)\n"), dwError, szError);
}

// Release the handle allocated for this storage session
WebCloseStorage(hStorage);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebPutFile Function

```
BOOL WINAPI WebPutFile(
   HSTORAGE hStorage,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel
);
```

The **WebPutFile** function uploads the contents of a local file to a storage container.

Parameters

hStorage

A handle to the storage container.

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be uploaded. If a path is not specified, the file will be read from the current working directory. The current user must have read access to the file, and an error will be returned if the function cannot obtain an exclusive lock on the file during the upload process.

lpszObjectLabel

A null-terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The function will fail if the label contains any illegal characters.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutFile** function uploads the contents of a local file to the storage container specified by the *hStorage* handle. If an object with this name already exists, its data will be replaced with the contents of the file. The object will be created using the default attributes that permit read and write access, and will automatically determine the content type based on the type of file being uploaded.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this function will fail. To replace a read-only object, the application must first move, rename or delete the existing object.

If you want to specify the object content type, its attributes, or obtain additional information about the storage object that was created, use the **WebPutFileEx** function.

The **WebValidateLabel** function can be used to ensure a label is valid prior to calling this function. Refer to that function for more information about the difference between Windows file names and object labels.

If you are uploading a large file and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

Example

```
// Upload a local file to the storage container
if (WebPutFile(hStorage, lpszLocalFile, lpszObjectLabel)
{
```

```
    // The file was uploaded successfully
    _tprintf(_T("The file was stored as \"%s\"\n"), lpszObjectLabel);
}
else
{
    // The file could not be uploaded, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to store \"%s\" (%s)\n"), lpszLocalFile, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebDownloadFile, WebGetFile, WebPutFileEx, WebRegisterEvent, WebUploadFile, WebValidateLabel

WebPutFileEx Function

```
BOOL WINAPI WebPutFileEx(
  HSTORAGE hStorage,
  LPCTSTR lpszLocalFile,
  LPCTSTR lpszObjectLabel,
  LPCTSTR lpszContentType,
  DWORD dwAttributes,
  DWORD dwReserved,
  LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebPutFileEx** function uploads the contents of a local file to a storage container and returns information about the new object.

Parameters

hStorage

A handle to the storage container.

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be uploaded. If a path is not specified, the file will be read from the current working directory. The current user must have read access to the file, and an error will be returned if the function cannot obtain an exclusive lock on the file during the upload process.

lpszObjectLabel

A null-terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The function will fail if the label contains any illegal characters.

lpszContentType

A null-terminated string that identifies the contents of the file being uploaded. If this parameter is a NULL pointer, or specifies a zero-length string, the function will attempt to automatically determine the content type based on the file name extension and the contents of the file.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. This value can be a combination of one or more of the following bit flags using a bitwise OR operation:

Value	Description
WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the **WebEnumObjects** function. The

	object can only be accessed directly when specifying its label.

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutFileEx** function uploads the contents of a local file to the storage container specified by the *hStorage* handle. The caller is responsible for specifying the object's content type and the attributes for the object being created.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text files have a content type of **text/plain** while an XML-formatted text file would have a content type of **text/xml**. Files that contain unstructured binary data are typically identified as **application/octet-stream**.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this function will fail. To replace a read-only object, the application must first move, rename or delete the existing object.

The **WebValidateLabel** function can be used to ensure a label is valid prior to calling this function. Refer to that function for more information about the difference between Windows file names and object labels

If you are uploading a large file and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

The **WebUploadFile** and **WebUploadFileEx** functions provide similar functionality, but do not require a handle to an open storage container.

Example

```
WEB_STORAGE_OBJECT webObject;

// Upload a local file to the storage container, automatically
// determining the content type with normal read/write access
if (WebPutFileEx(hStorage, lpszLocalFile, lpszObjectLabel, NULL, WEB_OBJECT_NORMAL,
0, &webObject))
{
    // The file was uploaded, display the object metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The file could not be uploaded, display the error
```

```
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to store \"%s\" (%s)\n"), lpszLocalFile, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebPutObject Function

```
BOOL WINAPI WebPutObject(
  HSTORAGE hStorage,
  LPCTSTR lpszObjectLabel,
  LPCVOID lpvBuffer,
  DWORD dwLength
);
```

The **WebPutObject** function creates a new storage object or overwrites an existing object with the contents of the buffer provided.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The function will fail if the label contains any illegal characters.

lpvBuffer

A buffer that contains the data to be stored. If this parameter is NULL, the ***dwLength*** parameter must have a value of zero and a storage object will be created which has no data associated with it.

dwLength

An unsigned integer value that specifies the number of bytes that will be copied from the ***lpvBuffer*** parameter and stored in the object. If the ***lpvBuffer*** parameter is NULL, this value must be zero or the function will fail.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutObject** function stores the contents of a buffer to the storage container specified by the ***hStorage*** handle. If an object with this name already exists, its data will be replaced with the contents of the file. The object will be created using the default attributes that permit read and write access, and it will automatically determine the content type based on the data being stored.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this function. The object label cannot contain wildcard characters.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this function will fail. To replace a read-only object, the application must first move, rename or delete the existing object.

If you want to specify the object content type, its attributes, or obtain additional information about the storage object that was created, use the **WebPutObjectEx** function.

If you want to upload the contents of a file, the **WebPutFile** function simplifies this process. The example code below demonstrates how the Windows API can be used to read from a local file and store the contents using **WebPutObject**.

If you are storing a large amount of data and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

Example

```
HANDLE hFile = INVALID_HANDLE_VALUE;
LPBYTE lpContents = NULL;
DWORD dwLength = 0;
BOOL bFileRead = FALSE;

// Open a file on the local system and read the contents
// into a buffer that will be stored on the server
hFile = CreateFile(lpszLocalFile,
                   GENERIC_READ,
                   0,
                   NULL,
                   OPEN_EXISTING,
                   FILE_ATTRIBUTE_NORMAL,
                   NULL);

if (hFile == INVALID_HANDLE_VALUE)
{
    // Unable to open the file
    return;
}

// Get the size of the file and allocate a buffer large
// enough to store the contents of the file
dwLength = GetFileSize(hFile, NULL);
lpContents = (LPBYTE)LocalAlloc(LPTR, dwLength + 1);

if (lpContents == NULL)
{
    // Memory allocation failed
    return;
}

bFileRead = ReadFile(hFile, lpContents, dwLength, &dwLength, NULL);
CloseHandle(hFile);

if (!bFileRead)
{
    // Unable to read the contents of the file
    return;
}

// Store the contents of the buffer
if (WebPutObject(hStorage, lpszObjectLabel, lpContents, dwLength))
{
    _tprintf(_T("WebPutObject stored %lu bytes\n"), dwLength);
}
else
{
    // The object could not be created
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to create \"%s\" (%s)\n"), lpszObjectLabel, szError);
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebPutObjectEx Function

```
BOOL WINAPI WebPutObjectEx(
  HSTORAGE hStorage,
  LPCTSTR lpszObjectLabel,
  LPCTSTR lpszContentType,
  DWORD dwAttributes,
  DWORD dwReserved,
  LPCVOID lpvBuffer,
  DWORD dwLength,
  LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebPutObjectEx** function stores the contents of buffer to a container and returns information about the new object.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The function will fail if the label contains any illegal characters.

lpszContentType

A null-terminated string that identifies the contents of the buffer being stored. If this parameter is a NULL pointer, or specifies a zero-length string, the function will attempt to automatically determine the content type based on the object label and the contents of the buffer.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. This value can be a combination of one or more of the following bit flags using a bitwise OR operation:

Value	Description
WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the **WebEnumObjects** function. The object can only be accessed directly when specifying its label.

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

lpvBuffer

A buffer that contains the data to be stored. If this parameter is NULL, the ***dwLength*** parameter must have a value of zero and a storage object will be created which has no data associated with it.

dwLength

An unsigned integer value that specifies the number of bytes that will be copied from the ***lpvBuffer*** parameter and stored in the object. If the ***lpvBuffer*** parameter is NULL, this value must be zero or the function will fail.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object that was created or replaced. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutObjectEx** function uploads the contents of a buffer to the storage container specified by the ***hStorage*** handle. The caller is responsible for specifying the object's content type and the attributes for the object being created.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created using this function. The object label cannot contain wildcard characters.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, typical text data has a content type of **text/plain** while XML-formatted text would have a content type of **text/xml**. Data which contains unstructured binary data is typically identified as **application/octet-stream**.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this function will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If you wish to store the contents of a null-terminated string, you can use the **WebPutTextObject** function. If you want to upload the contents of a file, the **WebPutFileEx** function simplifies this process. The example code below demonstrates how the Windows API can be used to read from a local file and store the contents using **WebPutObjectEx**.

If you are storing a large amount of data and want your application to receive progress updates during the data transfer, use the **WebRegisterEvent** function and provide a pointer to a callback function that will receive event notifications.

Example

```
HANDLE hFile = INVALID_HANDLE_VALUE;
LPBYTE lpContents = NULL;
DWORD dwLength = 0;
BOOL bFileRead = FALSE;
WEB_STORAGE_OBJECT webObject;

// Open a file on the local system and read the contents
// into a buffer that will be stored on the server
hFile = CreateFile(lpszLocalFile,
                   GENERIC_READ,
```

```
                    0,
                    NULL,
                    OPEN_EXISTING,
                    FILE_ATTRIBUTE_NORMAL,
                    NULL);

if (hFile == INVALID_HANDLE_VALUE)
{
    // Unable to open the file
    return;
}

// Get the size of the file and allocate a buffer large
// enough to store the contents of the file
dwLength = GetFileSize(hFile, NULL);
lpContents = (LPBYTE)LocalAlloc(LPTR, dwLength + 1);

if (lpContents == NULL)
{
    // Memory allocation failed
    return;
}

bFileRead = ReadFile(hFile, lpContents, dwLength, &dwLength, NULL);
CloseHandle(hFile);

if (!bFileRead)
{
    // Unable to read the contents of the file
    return;
}

// Store the contents of the buffer, identifying it as an unstructured
// stream of bytes, and the object is created with read/write access
if (WebPutObjectEx(hStorage,
                    lpszObjectLabel,
                    _T("application/octet-stream"),
                    WEB_OBJECT_NORMAL,
                    0,
                    lpContents,
                    dwLength,
                    &webObject))
{
    // The object was created or replaced, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be created
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to create \"%s\" (%s)\n"), lpszObjectLabel, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

WebPutTextObject Function

```
BOOL WINAPI WebPutTextObject(
   HSTORAGE hStorage,
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszObjectText,
   INT cchObjectText,
   LPWEB_STORAGE_OBJECT lpObject,
);
```

The **WebPutTextObject** function creates or replaces a text object with the contents of a string buffer. Additional information about the object is returned to the caller.

Parameters

hStorage

A handle to the storage container.

lpszObjectLabel

A null-terminated string that specifies the label of the text object that should be created or updated.

lpszObjectText

A null-terminated string which contains the text that should be uploaded to the storage server. This parameter may be NULL, in which case the object is created but no data is stored.

cchObjectText

The number of characters that are stored in the ***lpszObjectText*** string. If this value is -1, the size of the string will be determined automatically by counting the number of characters up to the terminating null character. If the ***lpszObjectText*** parameter is NULL, this value must be zero.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebPutTextObject** function is used to store the contents of a string as a text object. The string should be terminated with a null character and cannot contain embedded nulls. If the Unicode version of this function is called, the contents of the string will be normalized prior to being converted to UTF-8 using canonical composition, where decomposed characters are combined to create their canonical precomposed equivalent.

The size of the text object that is created can be different from the length of the string buffer passed to this function, depending on how the text has been encoded and stored. This will almost always be the case when the Unicode version of this function is called because the UTF-16 string will be converted and stored as UTF-8 encoded text. This encoding will typically increase the size of the stored object unless the string only contains ASCII characters.

This function should only be used to store textual data in a null terminated string, and should never be used to store binary data. If you wish to create or update an object which contains binary data, use the **WebPutObjectEx** function instead. If you want to upload the contents of a file, the **WebPutFileEx**

function simplifies this process.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

Example

```
LPCTSTR lpszObjectLabel = _T("LoremIpsum");
LPCTSTR lpszObjectText = _T("Lorem ipsum dolor sit amet, consectetur adipiscing
elit.");
WEB_STORAGE_OBJECT webObject;

if (WebPutTextObject(hStorage, lpszObjectLabel, lpszObjectText, -1, &webObject))
{
    // The object was created or replaced, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    DWORD dwError = WebGetLastError();
    TCHAR szError[128];

    WebGetErrorString(dwError, szError, 128);
    _ftprintf(stderr, _T("Unable to store \"%s\": %s\n"), lpszObjectLabel,
szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebRegisterAppId Function

```
BOOL WINAPI WebRegisterAppId(
   LPCTSTR lpszAppId
);
```

The **WebRegisterAppId** function registers a unique application identifier with the server.

Parameters

lpszAppId

A null-terminated string which identifies the application requesting access. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the function will fail. See the remarks below on the recommended method for identifying your application.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebRegisterAppId** function registers an application ID with the server which uniquely identifies the application that is requesting access to the storage container. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 64 characters, including the terminating null character.

It is recommended that you use a standard format for the application ID that consists of your company name, application name and optionally a version number. For example:

- MyCompany.MyApplication
- MyCompany.MyApplication.1

It is important to note that with these two example IDs, although they are similar, they reference two different applications. Objects stored using the first ID will not be accessible using the second ID. If you want to store objects that should be shared between all versions of the application, it is recommended that you use the first form, without the version number. If you want to store objects that should only be accessible to a specific version of your application, then it is recommended that you use the second form that includes the version number.

It is safe to call this function with an application ID that was previously registered. If the provided application ID has already been registered, this function will succeed. You can choose to call this function every time your application starts to ensure the application has been registered correctly.

If you no longer wish to use an application ID you have previously registered, you can call the **WebUnregisterAppId** function. Exercise caution when unregistering an application. This will cause all objects stored using that ID to be deleted by the storage server. Once an application ID has been unregistered, the operation is permanent. Calling **WebUnregisterAppId** and then **WebRegisterAppId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

The application ID is intended to be an application defined human-readable string that uniquely

identifies your application. If you want to obtain the internal storage ID associated with your application, use the **WebGetStorageId** function. The storage ID is a fixed-length string of letters and numbers guaranteed to be unique across all applications that you register.

It is not required for your application to create a unique application ID. Each storage account has a default internal application ID named **SocketTools.Storage.Default**. This default ID is used if a NULL pointer or an empty string is specified to functions like **WebOpenStorage**. It is intended to identify storage available to all applications that you create.

To enumerate the application IDs that you have created, use the **WebGetFirstApplication** and **WebGetNextApplication** functions.

Example

```
 HSTORAGE hStorage = INVALID_HANDLE;
LPCTSTR lpszAppId = _T("MyCompany.WebTest.1");
LPCTSTR lpszLocalFile = _T("TestDocument.pdf");
LPCTSTR lpszObjectLabel = _T("TestDocument.pdf");
WEB_STORAGE_OBJECT webObject = { 0, };
BOOL bSuccess = FALSE;

// Register the application ID which identifies the application
if (!WebRegisterAppId(lpszAppId))
{
    tprintf(_T("Unable to register the application ID"));
    _exit(0);
}

// Open the application storage container
hStorage = WebOpenStorage(lpszAppId, WEB_STORAGE_GLOBAL);

if (hStorage == INVALID_HANDLE)
{
    tprintf(_T("Unable to open global storage for this application"));
    _exit(0);
}

// Upload a local file to the storage server and return information
// about the stored object when it completes
bSuccess = WebPutFileEx(hStorage,
                        lpszLocalFile,
                        lpszObjectLabel,
                        NULL,
                        WEB_OBJECT_DEFAULT,
                        0,
                        &webObject);

if (bSuccess)
{
    // Print information about the object that was created
    _tprintf(_T("Object: %s\n"), webObject.szObjectId);
    _tprintf(_T("Label: %s\n"), webObject.szLabel);
    _tprintf(_T("Size: %I64u\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest: %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The upload failed, display error information
```

```
    DWORD dwError = WebGetLastError();
    TCHAR szError[128];

    WebGetErrorString(dwError, szError, 128);
    _tprintf(_T("WebPutFileEx failed, error 0x%08lX (%s)\n"), dwError, szError);
}

// Release the handle allocated for this storage session
WebCloseStorage(hStorage);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebRegisterEvent Function

```
INT WINAPI WebRegisterEvent(
  HSTORAGE hStorage,
  UINT nEventId,
  WEBEVENTPROC lpEventProc,
  DWORD_PTR dwParam
);
```

The **WebRegisterEvent** function registers an event handler for the specified event.

Parameters

hStorage

A handle to the storage container.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. This parameter cannot be zero.

Value	Description
WEB_EVENT_CONNECT	The connection to the storage server has been established and the session has been authenticated. This is the first event that occurs when initiating an operation to create or retrieve a storage object.
WEB_EVENT_DISCONNECT	The connection to the storage server has been closed and the session is terminating. This is the last event that occurs after completing an operation to create or retrieve a storage object.
WEB_EVENT_READ	The contents of an object is being read from the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of retrieving the object contents from the container.
WEB_EVENT_WRITE	The contents of an object is being written to the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of submitting the object contents to the container.
WEB_EVENT_TIMEOUT	The operation has exceeded the specified timeout period. The application may attempt to retry the operation or report an error to the user. This event typically indicates a connectivity problem with the storage server.
WEB_EVENT_CANCEL	The operation has been canceled. This event occurs after the application calls **WebCancelTransfer** while an object is being stored or retrieved.
WEB_EVENT_PROGRESS	A storage operation is in progress. This event

	periodically occurs as the contents of a storage object is being read or written from the container. To retrieve information about the status of the operation, the application should register a handler for this event and call the **WebGetTransferStatus** function from within that handler.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WebEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function specified by ***lpEventProc***. If the application targets x86 (32-bit) platforms, this parameter must be a 32-bit unsigned integer. If the application targets x64 (64-bit) platforms, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebRegisterEvent** function associates a callback function with a specific event. The event handler is a **WebEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the storage handle, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

Events are only generated as the result of a call to the **WebGetFile**, **WebGetFileEx**, **WebPutFile** and **WebPutFileEx** functions. Other storage functions will not generate event notifications.

This function is typically used to register an event handler that is invoked while the contents of a storage object is being transferred. The WEB_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one WEB_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

WebRenameObject Function

```
BOOL WINAPI WebRenameObject(
   HSTORAGE hStorage,
   LPCTSTR lpszOldLabel,
   LPCTSTR lpszNewLabel
);
```

The **WebRenameObject** function changes the label associated with the storage object.

Parameters

hStorage

A handle to the storage container.

lpszOldLabel

A null-terminated string which specifies the name of the existing storage object to be renamed. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A null-terminated string which specifies a new label for the storage object being moved. This parameter may not be NULL or point to an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebRenameObject** function is used to change the label for an existing storage object. Although storage object labels are similar to Windows file names, they are case-sensitive. When renaming an object, your application must specify the original label name exactly as it was created. The object label cannot contain wildcard characters.

To duplicate an existing storage object, use the **WebCopyObject** function. If you need to move the object to a different storage container, use the **WebMoveObject** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebResetStorage Function

```
BOOL WINAPI WebResetStorage(
   HSTORAGE hStorage
);
```

The **WebResetStorage** function resets the application storage container and deletes all stored objects.

Parameters

hStorage

A handle to the storage container.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The storage container contains information for each of the objects that have been stored using the handle returned by the **WebOpenStorage** function. Each of these objects are associated with both the application ID and the storage type that was specified by the caller. This function instructs the server to reset the container back to its initial state, deleting all of the objects that were stored in it.

Exercise caution when using this function. The reset operation is immediate and the objects that are stored in the container are permanently deleted. They cannot be recovered by your application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

WebResetStorageEx Function

```
BOOL WINAPI WebResetStorageEx(
   HSTORAGE hStorage,
   DWORD dwStorageType,
   LPVOID lpvReserved,
   LPDWORD lpdwObjects
);
```

The **WebResetStorageEx** function resets the specified storage container and deletes all stored objects.

Parameters

hStorage

A handle to the storage container.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

lpvReserved

A reserved parameter that should always be NULL. If your project targets the x64 platform, this

must be a 64-bit pointer with a value of zero. If this parameter is not a NULL pointer, the function will fail.

lpdwObjects

A pointer to an unsigned integer value which will contain the number of objects that were deleted when the contents of the container were expunged.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The storage container contains information for each of the objects that have been stored using the handle returned by the **WebOpenStorage** function. Each of these objects are associated with both the application ID and the storage type that was specified by the caller. This function instructs the server to reset the container back to its initial state, deleting all of the objects that were stored in it.

Exercise caution when using this function. The reset operation is immediate and the objects that are stored in the container are permanently deleted. They cannot be recovered by your application.

Unlike the **WebResetStorage** function which deletes all of the objects in the container opened using **WebOpenStorage**, this function enables you reset the contents of a different container without explicitly opening it. For example, if you used **WebOpenStorage** to open the WEB_STORAGE_GLOBAL container, you could call this version of the function using that handle, but specifying the WEB_STORAGE_USER container to remove all of the objects created by the current user without affecting the stored objects in the global container.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

WebSetLastError Function

```
VOID WINAPI WebSetLastError(
   DWORD dwErrorCode
);
```

The **WebSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WEB_ERROR. Those functions which call **WebSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **WebGetLastError** function. The use of **WebGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

WebGetErrorString, WebGetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebSetStorageTimeout Function

```
INT WINAPI WebSetStorageTimeout(
    HSTORAGE hStorage,
    INT nSeconds
);
```

The **WebSetStorageTimeout** function sets the number of seconds the client will wait for a response from the storage server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hStorage

A handle to the storage container.

nSeconds

The number of seconds to wait for a storage operation to complete.

Return Value

If the function succeeds, the return value is the previous timeout period set for this storage handle. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The default timeout period is 10 seconds. The minimum timeout period is 5 seconds, and the maximum timeout period is 60 seconds. Values outside of this range will be normalized internally and will not cause the function to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

WebGetStorageTimeout, WebOpenStorage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebUninitialize Function

```
VOID WINAPI WebUninitialize();
```

The **WebUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **WebInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **WebUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **WebUninitialize** for every successful call to **WebInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

WebCloseStorage, WebInitialize, WebOpenStorage, WebRegisterAppId

WebUnregisterAppId Function

```
BOOL WINAPI WebUnregisterAppId(
    LPCTSTR lpszAppId
);
```

The **WebUnregisterAppId** function unregisters the application identifier and deletes all associated storage objects.

Parameters

lpszAppId

A null-terminated string which specifies the application ID to be deleted. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the function will fail.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebUnregisterAppId** function deletes the internal storage identifier associated with the application ID and revokes all access tokens that were granted for the application. This operation is immediate and permanent.

Exercise caution when using this function. This will permanently delete all objects that were stored for the specified application. Calling **WebUnregisterAppId** and then **WebRegisterAppId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

This function cannot be used to unregister the default storage application identifier `SocketTools.Storage.Default`. If this ID is specified, the function will fail with an error indicating that the ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebUploadFile Function

```
BOOL WINAPI WebUploadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **WebUploadFile** function uploads the contents of a local file and creates or overwrites a storage object.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server. This parameter cannot be NULL or an empty string. Refer to the **WebValidateLabel** function for more information about object labels.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebUploadFile** function uploads the contents of a local file and either creates a new storage object, or replaces an object if one already exists with the same label. The object will be created in the storage container WEB_STORAGE_GLOBAL using the application ID `SocketTools.Storage.Default`. This is the same default container used by the **WebDownloadFile** function.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this function will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

Unlike the **WebPutFile** and **WebPutFileEx** functions, it is not required that you open a storage container using the **WebOpenStorage** function prior to calling **WebUploadFile**.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

The **WebUploadFileEx** function provides similar functionality with a more complex interface that supports custom application IDs, additional options and the ability to provide a callback function that is invoked during the upload process.

Example

```
WEB_STORAGE_OBJECT webObject;

// Upload a local file to the global storage container
if (WebUploadFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // The object was uploaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be uploaded, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to upload \"%s\" (%s)\n"), lpszLocalFile, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebDownloadFile, WebGetFile, WebPutFile, WebUploadFileEx, WebValidateLabel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebUploadFileEx Function

```
BOOL WINAPI WebUploadFileEx(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszAppId,
   DWORD dwStorageType,
   DWORD dwAttributes,
   DWORD dwReserved,
   DWORD dwTimeout,
   LPWEB_STORAGE_OBJECT lpObject,
   WEBEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **WebUploadFileEx** function uploads the contents of a local file and creates or overwrites a storage object.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

lpszAppId

A null-terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is NULL or an empty string, the default identifier `SocketTools.Storage.Default` will be used.

dwStorageType

An integer value that identifies the storage container type. One of the following values should be specified:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.

WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. This value can be a combination of one or more of the following bit flags using a bitwise OR operation:

Value	Description
WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the **WebEnumObjects** function. The object can only be accessed directly when specifying its label.

dwReserved

An unsigned integer value that is reserved for future use. This value should always be zero.

dwTimeout

An unsigned integer value that specifies a timeout period in seconds. If this value is zero, a default timeout period will be used.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WebEventProc** callback function. If this parameter is NULL, no callback function will be invoked during the data transfer.

dwParam

A user-defined integer value that is passed to the callback function specified by ***lpEventProc***. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If

the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebUploadFileEx** function uploads the contents of a local file and either creates a new storage object, or replaces an object if one already exists with the same label. The **WebUploadFile** function provides a simpler interface that defaults to uploading an object to the global storage container.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this function will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

Unlike the **WebPutFile** and **WebPutFileEx** functions, it is not required that you open a storage container using the **WebOpenStorage** function prior to calling **WebUploadFileEx**.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are uploading a large file and want your application to receive progress updates during the data transfer, provide a pointer to a callback function as the *lpEventProc* parameter. That function will receive event notifications as the data is being uploaded.

Example

```
WEB_STORAGE_OBJECT webObject;

// Upload a local file to the global storage container
if (WebUploadFileEx(lpszLocalFile,
                    lpszObjectLabel,
                    lpszAppId,
                    WEB_STORAGE_GLOBAL,
                    WEB_OBJECT_DEFAULT,
                    0,
                    &webObject,
                    NULL, 0))
{
    // The object was uploaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be uploaded, display the error
    TCHAR szError[128];

    WebGetErrorString(WebGetLastError(), szError, 128);
    _tprintf(_T("Unable to upload \"%s\" (%s)\n"), lpszLocalFile, szError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebValidateAppId Function

```
BOOL WINAPI WebValidateAppId(
   LPCTSTR lpszAppId
);
```

The **WebValidateAppId** function validates the specified application identifier.

Parameters

lpszAppId

A null-terminated string which specifies the application ID to be validated. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the function will fail.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **WebValidateAppId** function is used to determine if the specified application identifier is valid and has been previously registered using the **WebRegisterAppId** function. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 64 characters, including the terminating null character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WebRegisterAppId, WebUnregisterAppId

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebValidateLabel Function

```
BOOL WINAPI WebValidateLabel(
   LPCTSTR lpszObjectLabel
);
```

The **WebValidateLabel** function validates the specified object label.

Parameters

lpszObjectLabel

A null-terminated string which specifies the object label to be validated. This parameter cannot be NULL or point to a zero-length string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

Object labels are similar to Windows file names, except they are case-sensitive. The maximum length of a label string is 512 characters, including the terminating null character. Leading and trailing whitespace (spaces, tabs, linebreaks, etc.) are ignored in label names.

Illegal characters include ASCII and Unicode control characters 1 through 31, single quotes (39), double quotes (34), less than symbol (60), greater than symbol (62), pipe (124), asterisk (42) and question mark (63). A null character (0) specifies the end of the label and any subsequent characters are ignored. It is not possible to embed null characters in the label name.

Label names may contain forward slash (47) characters and backslash (92) characters, however it is important to note that objects are not stored in a hierarchical structure. An application can create its own folder-like structure to the labels it creates, but this structure is not imposed or enforced by the library.

If the application is built to use Unicode, labels can contain Unicode characters which are internally encoded as UTF-8. This is important to consider if you have an project built using a multi-byte (ANSI) character set and it needs to access an object that was created using Unicode characters. In that case, the ANSI application must be prepared to handle UTF-8 encoded names and display them appropriately.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

Web Services Data Structures

- SYSTEMTIME
- WEB_LOCATION
- WEB_STORAGE_APPLICATION
- WEB_STORAGE_QUOTA
- WEB_STORAGE_OBJECT
- WEB_STORAGE_TRANSFER

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: windows.h.

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WEB_LOCATION

The **WEB_LOCATION** structure contains information about the current location of the local computer system.

```
typedef struct _WEB_LOCATION
{
    TCHAR   szLocationId[40];
    TCHAR   szIPAddress[46];
    UINT    nAutonomousSytemNumber;
    TCHAR   szOrganization[64];
    TCHAR   szRegionName[64];
    UINT    nRegionCode;
    TCHAR   szCountryName[64];
    TCHAR   szCountryAlpha2[4];
    TCHAR   szCountryAlpha3[4];
    UINT    nCountryCode;
    TCHAR   szSubdivision[64];
    TCHAR   szSubdivisionCode[4];
    TCHAR   szCityName[64];
    TCHAR   szPostalCode[32];
    TCHAR   szCoordinates[32];
    TCHAR   szTimezone[64];
    TCHAR   szTzShortName[16];
    LONG    nTimezoneOffset;
    DOUBLE  dLatitude;
    DOUBLE  dLongitude;
    SYSTEMTIME stLocalTime;
} WEB_LOCATION, *LPWEB_LOCATION;
```

Members

szLocationId

A null-terminated string which contains contains a string of hexadecimal characters which uniquely identifies the location for this computer system. This value is used internally by the location service, and may also be used by the application for its own purposes. If this value changes in subsequent queries, it indicates the external IP address for the local system has changed.

lpszIPAddress

A null-terminated string which contains the external IP address for the local system. If the system has been assigned multiple IP addresses, it reflects the address of the interface that was used to establish a connection with the SocketTools server. If the connection is made through a Virtual Private Network (VPN) it will use that assigned IP address. If a connection is made through a proxy server, the IP address may the address of the proxy rather than the local host, depending on how the connection is made.

nAutonomousSystemNumber

An unsigned integer value which is used to uniquely identify a global network (autonomous system) that is connected to the Internet. This number is assigned by regional registries and used by large networks, such as Internet Service Providers, for exchanging routing information with one another. This value can be used to determine the ownership of a particular network.

szOrganization

A null-terminated string which identifies the organization associated with the local system's external IP address. For residential end-users this is typically the name of their Internet Service provider, however it may also identify a private company such as Microsoft, Google or Amazon. Because of

the nature of how this information is updated, the organization names can change over time due to acquisitions or changes of ownership. If the owner of the network cannot be determined, this member may contain an empty string.

szRegionName

A null-terminated string which identifies the region in which the external IP address is located. This refers to a broad geographical area, such as "North America" or "Southeast Asia" and uses the conventions for supranational regions as defined by UN M49 codes. These names will always be in English, regardless of the current system locale.

nRegionCode

An unsigned integer value which identifies the geographical region in which the external IP address is located. This value corresponds to the name returned in the ***szRegionName*** structure member. The numeric values use the UN M49 standard established by the United Nations Statistics Division.

szCountryName

A null-terminated string which contains the full name of the country in which the external IP address is located. These names will always be in English, regardless of the current system locale.

szCountryAlpha2

A null-terminated string which contains the ISO 3166-1 alpha-2 code for the country the external IP address is located in. This is a two-letter country code established by the International Organization for Standardization (ISO). For example, the code for the United States is "US".

szCountryAlpha3

A null-terminated string which contains the ISO 3166-1 alpha-3 code for the country the external IP address is located in. This is a three-letter country code established by the International Organization for Standardization (ISO). For example, the code for the United States is "USA".

nCountryCode

An unsigned integer value which identifies the country where the external IP address is located. These codes can be up to three digits (usually displayed with leading zeros as necessary) and correspond to the country codes assigned by the United Nations. For example, the code for the United States is 840. It is important to note that these are not international dialing codes and should not be used with telephony applications.

szSubdivision

A null-terminated string which identifies the geopolitical subdivision within a country where the external IP address is located. In the United States, this will contain the full name of the state or commonwealth. In Canada, this will contain the name of the province or territory. These names will always be in English, regardless of the current system locale.

szSubdivisionCode

A null-terminated string which is either a two- or three-letter code which identifies a geopolitical subdivision within the country where the external IP address is located. These codes are defined by the ISO 3166-2 standard. For example, the code for the state of California in the United States is "CA". For specificity, these subdivision codes are often combined with the ISO 3166-1 alpha-2 or alpha-3 code for the country the subdivision is located within. Using the previous example of California, ISO alpha-2 code and subdivision code would be combined as "US-CA".

szCityName

A null-terminated string which identifies the city in which the external IP address is located. These names will always be in English, regardless of the current system locale. If the city name cannot be determined, this member may contain an empty string.

szPostalCode

A null-terminated string which contains the postal code associated with the area where the IP address is located. In the United States, this is a 5-digit numeric code. In Canada, this will contain the forward sortation area (the first three characters of the six character postal code). Local delivery portions of a postal code (such as the ZIP+4 code in the United States, or the local delivery unit in Canada) are not included. This information will be most accurate within the geographic region of North America. Postal codes are locale specific, and this structure member may contain an empty string if the postal code for the location cannot be determined.

szCooordinates

A null-terminated string which specifies the location expressed using the Universal Transverse Mercator (UTM) coordinate system with the WGS-84 ellipsoid. UTM coordinates are commonly used with the Global Positioning System (GPS) and are comprised of three parts: the zone, the easting (the eastward-measured distance or ***x***-coordinate) and the northing (the northward-measured distance or ***y***-coordinate). An example of a string value returned in this structure member would be "14S 702089E 3646476N".

szTimezone

A null-terminated string which specifies the full time zone name in which the external IP address is located. These names are defined by the Internet Assigned Numbers Authority (IANA) and have values like "America/Los_Angeles" and "Europe/London". These time zones may also be defined as "Etc/GMT+10" if there is not a regional name associated with the time zone.

szTzShortName

A null-terminated string which specifies the abbreviated time zone code in which the external IP address is located. If daylight savings time is used within the time zone, then this value can change based on whether or not daylight savings is in effect. For example, if the IP address is located within the Pacific time zone in the United States, this will return "PDT" when daylight savings is in effect and "PST" when it is not. If a short time zone code cannot be determined, a value such as "UTC+9" may be returned, indicating the number of hours ahead or behind UTC.

nTimezoneOffset

A signed integer which specifies the number of seconds east or west of the prime meridian (UTC). A positive value indicates a time zone that is east of the prime meridian and a negative value indicates a time zone that is west of the prime meridian. For example, the Pacific time zone in the western United States during daylight savings time would have a value of -25200 (7 hours).

dLatitude

A floating point value which specifies the latitude of the location in decimal format. A positive value indicates a location that is north of the equator, while a negative value is a location that is south of the equator.

dLongitude

A floating point value which specifies the longitude of the location in decimal format. A positive value indicates a location that is east of the prime meridian, while a negative value is a location that is west of the prime meridian.

stLocalTime

A SYSTEMTIME structure that contains information about the current date and time at the location, adjusted for its time zone and whether or not it's in daylight savings time.

Remarks

Use the **WebGetLocation** function to populate this structure with information about the physical

location of the local computer system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

WEB_STORAGE_APPLICATION

The **WEB_STORAGE_APPLICATION** structure contains information about a registered application.

```
typedef struct _WEB_STORAGE_APPLICATION
{
    TCHAR      szAppId[64];
    TCHAR      szApiKey[64];
    TCHAR      szLuid[64];
    DWORD      dwTokens;
    DWORD      dwReserved;
    SYSTEMTIME stCreated;
    SYSTEMTIME stUpdated;
} WEB_STORAGE_APPLICATION, *LPWEB_STORAGE_APPLICATION;
```

Members

szAppId

A null-terminated string which contains the application ID that was registered using the **WebRegisterAppId** function.

szApiKey

A null-terminated string which contains the API key value that is used internally by the storage services. The AppID is effectively the human readable alias for this key value used to identify the stored objects for the application. This value is guaranteed to be unique across all applications registered with the storage service.

szLuid

A null-terminated string which specifies a locally unique value associated with the registered application. This value is used internally by the storage service and guaranteed to be unique to the storage account that has registered the application. Note that there are no functions that currently accept the application LUID as parameter, but you may choose to use this value in your own application for other purposes.

dwTokens

An unsigned integer value which specifies the number of access tokens associated with the registered application. Typically there is only one access token associated with a given AppID at any one time, although it is possible that the API may allocate additional access tokens under some circumstances.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

stCreated

A SYSTEMTIME structure that specifies the date and time the AppID was registered. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone.

stUpdated

A SYSTEMTIME structure that specifies the date and time the AppID object was last updated. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone. When a storage object is first created, this value will be the same as the object creation time.

Remarks

This structure is used in conjunction with the **WebEnumApplications** function which is used to enumerate all of the registered applications for the storage account. It is also used with the

WebGetFirstApplication and **WebGetNextApplication** functions which provide an alternative method for enumerating registered applications.

To adjust the creation and update times to account for the local time zone, use the **SystemTimeToTzSpecificLocalTime** function. If you prefer to use FILETIME values, use the **SystemTimeToFileTime** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WEB_STORAGE_OBJECT

The **WEB_STORAGE_OBJECT** structure contains information about an individual storage object.

```
typedef struct _WEB_STORAGE_OBJECT
{
    TCHAR      szObjectId[64];
    TCHAR      szLabel[512];
    TCHAR      szDigest[128];
    TCHAR      szContent[128];
    DWORD      dwAttributes;
    DWORD      dwObjectSize;
    SYSTEMTIME stCreated;
    SYSTEMTIME stModified;
} WEB_STORAGE_OBJECT, *LPWEB_STORAGE_OBJECT;
```

Members

szObjectId

A null-terminated string which contains the unique identifier associated with this object. Object IDs are guaranteed to be unique for each storage object that is created by the application. The maximum length of an object ID is 64 characters, including the terminating null character.

szLabel

A null-terminated string which contains the label assigned to the object by the application. Object labels are case-sensitive and must be unique for each object. An application uses labels to reference an object with a human-recognizable name, rather than referencing them by their object ID. The maximum length of an object label is 512 characters, including the terminating null character.

szDigest

A null-terminated string which specifies the digest of the object contents, computed using an SHA-256 hash. The maximum length of the ***szDigest*** string is 128 characters, including the terminating null character. However, the digest value is always represented as a string of hexadecimal numbers that is exactly 64 characters long. It is important to note that even a zero-length object will have a digest, which is the standard SHA-256 NULL hash value.

szContent

A null-terminated string which specifies the MIME content type for the storage object. The content type is determined by the object label and evaluating the contents of the object. It is also possible for the application to explicitly specify the content type of the object when it is created.

dwAttributes

An unsigned integer value that specifies the attributes for the storage object. The object attributes are comprised of one or more bit flags:

Value	Description
WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
WEB_OBJECT_READONLY	A read-only object that can only be read by the application.

	Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the **WebEnumObjects** function. The object can only be accessed directly when specifying its label.

dwObjectSize

An unsigned integer value that specifies the size of the storage object in bytes. The maximum size of an individual object is determined by the storage quota limits established for the account.

stCreated

A SYSTEMTIME structure that specifies the date and time the storage object was created. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone.

stModified

A SYSTEMTIME structure that specifies the date and time the storage object was last modified. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone. When a storage object is first created, this value will be the same as the object creation time.

Remarks

The object content type will always be in the format **type/subtype** where the type specifies a common media type (e.g.: text, audio, video, etc.) and subtype specifies the specific content. The most common content type for text files is **text/plain**. If the content type is unknown, the default content type is **application/octet-stream**.

Text objects may also optionally include the character encoding as part of the content type. For example, if an object contains UTF-8 encoded text, the content type may be returned as **text/plain; charset=utf-8**. If your application is parsing the content types, you must check if a character encoding was also included in the value. Text objects that do not specify an encoding either contain ASCII or text which uses the system code page. Unicode text will always be stored using UTF-8 encoding.

To adjust the object creation and modification times to account for the local time zone, use the **SystemTimeToTzSpecificLocalTime** function. If you prefer to use FILETIME values, use the **SystemTimeToFileTime** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WEB_STORAGE_QUOTA

The **WEB_STORAGE_QUOTA** structure contains information about the current storage account data usage and limits.

```
typedef struct _WEB_STORAGE_QUOTA
{
    DWORD     dwObjects;
    DWORD     dwObjectLimit;
    DWORD     dwObjectSize;
    ULONGLONG ulBytesUsed;
    ULONGLONG ulBytesFree;
    ULONGLONG ulStorageLimit;
} WEB_STORAGE_QUOTA, *LPWEB_STORAGE_QUOTA;
```

Members

dwObjects

An unsigned integer value which specifies the number of storage objects allocated for the account. This value may not exceed the total number of objects specified by the ***dwObjectLimit*** member.

dwObjectLimit

An unsigned integer value which specifies the maximum number of storage objects that may be created. In addition to the limit on the total amount of storage that may be used, there is a limit on the total number of objects that may be created by all applications.

dwObjectSize

An unsigned integer value which specifies the maximum size of an individual storage object. In addition to a limit on the total amount of storage used and the number of objects created, each object stored by the application cannot exceed this size.

ulBytesUsed

An unsigned 64-bit integer value which specifies the total number of bytes of data allocated for all storage objects. This value may not exceed the total number of bytes of storage available, which is specified by the ***ulStorageLimit*** member.

ulBytesFree

An unsigned 64-bit integer value which specifies the number of bytes available for the storage of new objects. This value reflects the total amount of available storage across all applications registered with the development account. If this value is zero, your storage account has reached its storage limit.

ulStorageLimit

An unsigned 64-bit integer value which specifies the maximum number of bytes of data storage available. This limit applies to all applications registered with the development account.

Remarks

Storage quota limits are assigned for each SocketTools development account. The **WebGetStorageQuota** function will populate this structure with information about the limits on your account. Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

These values do not represent limits on storage usage by a specific application. Quotas limits apply to all applications that are registered with the development account, which is identified with the runtime

license key passed to the **WebInitialize** function.

If your storage quota has been exceeded, either because the total number of objects or the total bytes of storage has reached their limit, your applications will be unable to create new objects. Your application can continue to access existing objects, regardless of your current quota limits.

To free storage space, use the **WebDeleteObject** function to delete individual storage objects that are no longer needed by your application, or use the **WebResetStorage** function to delete all objects in a container.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

WEB_STORAGE_TRANSFER

This structure is used by the **WebGetTransferStatus** function to return information about a data transfer in progress.

```
typedef struct _WEB_STORAGE_TRANSFER
{
   TCHAR     szObjectLabel[512];
   DWORD     dwStorageType;
   DWORD     dwBytesTotal;
   DWORD     dwBytesCopied;
   DWORD     dwBytesPerSecond;
   DWORD     dwTimeElapsed;
   DWORD     dwTimeEstimated;
} WEB_STORAGE_TRANSFER, *LPWEB_STORAGE_TRANSFER
```

Members

szObjectLabel

A null-terminated string that specifies the label for the object that is being retrieved, created or replaced.

dwStorageType

An integer value that identifies the storage container type. This will be one of the following values:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwBytesTotal

An unsigned integer which specifies the total number of bytes that will be transferred. If the object is being downloaded to the local host, this is the size of the stored object. If the data is being uploaded from the local host to be stored on the server, it is the size of the buffer or local file.

dwBytesCopied

An unsigned integer which specifies the total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

WebView Browser Library

The SocketTools WebView library provides an embedded Chromium-based web browser that can be integrated into desktop applications. The library is implemented using the Microsoft Edge WebView2 runtime and provides a much simpler API which can be used with most languages, without requiring direct use of the COM-based interfaces in the WebView2 SDK.

- Error Codes

Library Information

File Name	CSHTMV12.DLL
Version	12.0.3024.1286
LibID	175ACE49-FE5D-46C8-A0EF-5188C97B993D
Import Library	CSHTMV12.LIB
Dependencies	None

Overview

The SocketTools WebView library makes it possible to embed modern web content into Windows applications using a simple procedural interface. Developers can work entirely with standard data types and function calls, avoiding the complexity of COM programming or .NET interop layers. The API is designed to be language-agnostic and can be called from C or C++, as well as other environments that support invoking functions from a dynamic link library such as Object Pascal and Visual Basic. Applications can use a traditional Windows GUI or be console-based, and functions are thread-safe where appropriate.

Because the library encapsulates the creation of the WebView2 environment and its associated controller, applications require only minimal setup. Developers can host a browser window, execute scripts, or capture output with just a few lines of code. Advanced features such as asynchronous execution, response header enumeration, and event callbacks are supported, but optional, making it easy to start simple and grow into more complex scenarios.

Applications are not limited to navigating to external websites. You can dynamically generate HTML content within your program and load it directly into the browser, making it possible to render reports, status pages, or other application data without creating temporary files. The browser also supports displaying local content using `file://` URLs, including HTML, images, PDF documents, and other formats that WebView2 can natively render. This makes it easy to blend remote and local resources within the same user interface.

When connecting to web servers, the control uses the underlying WebView2 runtime and supports modern versions of HTTP, including HTTP/1.1, HTTP/2, and HTTP/3 where available. Connections are secured with Transport Layer Security (TLS), with support for TLS 1.2 and TLS 1.3 by default, and certificate validation is performed automatically by the runtime. This ensures that applications embedding the browser benefit from the same security standards as Microsoft Edge, including

enforcement of current best practices for encryption and certificate handling.

Unlike most SocketTools libraries which return pseudo-handles to reference client sessions, the WebView library uses window handles (HWND) for nearly all of its functions. The only exceptions are the functions used to create or attach to a WebView instance. This design provides a direct connection between the library and the underlying windowing system, and ensures consistent behavior with standard Windows APIs. Even in console applications, the library creates a host window which provides the handle used with the other functions. Using window handles also makes integration with GUI frameworks such as MFC, WinForms, or WPF more natural, since those frameworks are already designed around standard Windows window management.

Requirements

It is not necessary to download the Microsoft.Web.WebView2 SDK NuGet package and include it in your project to use this library. However, the end-user system must have the current version of the Edge WebView2 Runtime installed. On Windows 11 and Windows 10 version 2004 (build 19041) and later, the runtime is considered part of the operating system and is updated automatically. On earlier platforms such as Windows 7, Windows 8, and Windows 10 builds prior to 19041, you may need to redistribute or install the WebView2 runtime separately. The library includes functions which can tell you if the runtime is installed and what version is available.

For Windows 7 and Windows 8, the last version of the WebView2 runtime available is 109.0.1518.140. This version is supported by SocketTools, however it is important to note that Microsoft is no longer updating the control on those platforms. This means it will no longer receive security updates or other improvements; some features may work differently on older platforms, and newer features will not be available.

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

In addition to the SocketTools library, the WebView2 Runtime must be present on the target system. On current versions of Windows 10 and Windows 11 the runtime is treated as part of the operating system and is updated automatically. On earlier platforms, you may need to redistribute or install the runtime using Microsoft's evergreen installer. We recommend always using the evergreen runtime rather than the fixed version, as it ensures security updates and feature improvements are delivered through Windows Update without requiring changes to your application.

The WebView2 Runtime is available as a separate download from Microsoft. For current links and redistribution guidelines, please refer to the SocketTools knowledge base or Microsoft's official documentation.

WebView Functions

Function	Description
WebViewAsyncExecute	Execute JavaScript asynchronously in the current document.
WebViewAttachWindow	Attach the browser to an existing host window.
WebViewAttachWindowEx	Attach the browser to an existing host window with additional options.
WebViewCancelDownload	Cancel the specified file download.
WebViewCancelNavigation	Cancel the current navigation and stop loading.
WebViewClearCache	Clear the cache of viewed pages for the current user profile.
WebViewClearCookies	Delete cookies for the current user profile or session.
WebViewClearHeaders	Clear the request and/or response headers for the current session.
WebViewClearHistory	Clear the navigation history for the current session.
WebViewCreateWindow	Create an instance of the browser in a new window.
WebViewCreateWindowEx	Create an instance of the browser in a new window with additional options.
WebViewDestroyWindow	Destroy a host window and release resources allocated for the browser session.
WebViewDetachWindow	Detach the browser from its host window without destroying the host window.
WebViewDisableEvents	Disable event handling for the specified browser.
WebViewEnableEvents	Enable event handling for the specified browser.
WebViewEnumDownloads	Enumerate the file identifiers for all downloads during the current session.
WebViewEventProc	An application-defined callback function that processes events generated by the browser
WebViewExecute	Execute JavaScript and return the result synchronously.
WebViewFindWindow	Locate the associated host or child window handle for an instance.
WebViewFreezeEvents	Suspend or re-enable event notifications for the specified browser.
WebViewGetAllOptions	Return the current option flags for the browser instance.
WebViewGetBackgroundColor	Get the background color used behind the page content.
WebViewGetBrowserVersion	Get the installed browser runtime version information.
WebViewGetChildWindow	Get the handle of the internal browser child window.
WebViewGetContentType	Return the Content-Type from the last response, if available.
WebViewGetCurrentUrl	Get the URL of the current document.
WebViewGetDocumentText	Return the content for the current document.
WebViewGetDocumentTitle	Return the document title.
WebViewGetDownloadInfo	Return information about the status of the specified download.
WebViewGetDownloadPath	Return the full path for the downloaded file.
WebViewGetErrorString	Return a description for the specified error code.
WebViewGetFilteredText	Return the current document text without HTML formatting.
WebViewGetFirstHeader	Begin enumerating response headers and return the first name/value pair.
WebViewGetFocus	Return whether the browser control currently has input focus.
WebViewGetHeader	Get the value of a specific response header by name.

WebViewGetHeaderCount	Return the number of response headers from the last navigation.
WebViewGetHttpStatus	Return the HTTP status code from the last completed navigation.
WebViewGetInterface	Returns a raw COM interface pointer to the WebView2 browser control.
WebViewGetLastError	Return the last error code.
WebViewGetMessage	Retrieve the next pending message sent from the current document.
WebViewGetNavigationStatus	Return the current navigation state.
WebViewGetNavigationTime	Return the elapsed time for the last navigation.
WebViewGetNextHeader	Continue header enumeration and return the next name/value pair.
WebViewGetOption	Checks whether a specific option flag is enabled.
WebViewGetResult	Return the result from the most recent completed script execution.
WebViewGetSecurityInfo	Return certificate and host security details for the last navigation.
WebViewGetSecurityLevel	Return the evaluated security level for the last navigation.
WebViewGetTimeout	Get the number of seconds to wait for a navigation to complete.
WebViewGetUserAgent	Return the current User-Agent value for this instance.
WebViewGetUserDataFolder	Return the full path to the current user data folder.
WebViewGetZoomLevel	Return the current zoom level as a percentage.
WebViewGoBack	Navigate backwards through the browser history.
WebViewGoForward	Navigate forwards through the browser history.
WebViewInEvent	Determine if the current thread is executing code within an event handler.
WebViewInitialize	Initialize the library and validate a license key at runtime.
WebViewIsVisible	Determine if the browser window is currently visible.
WebViewKeyEventHandled	Set an accelerator key event as handled to suppress default processing.
WebViewNavigateUrl	Navigate to the specified URL or local file path.
WebViewNormalizeUrl	Normalize a URL or path for safe, consistent navigation.
WebViewPostMessage	Post a string or JSON message to the current page.
WebViewPrintDocument	Display the browser print dialog for the current document.
WebViewRedrawWindow	Force the host window and browser control to redraw themselves.
WebViewReloadDocument	Reload the current document and optionally clear the cache.
WebViewResetBrowser	Reset the embedded runtime control.
WebViewRuntimeAvailable	Return whether the required runtime is installed and available.
WebViewSaveDocument	Save the current document to a local file.
WebViewSetBackgroundColor	Set the background color used behind the page content.
WebViewSetBounds	Set the position and size of the browser child window.
WebViewSetDocumentText	Replace the current document with the specified HTML or plain text.
WebViewSetDownloadPath	Change the local file path for the specified download.
WebViewSetFocus	Give keyboard focus to the browser control.
WebViewSetHeader	Set or override a request header for subsequent navigations.
WebViewSetIcon	Set custom large and small icons for the host window.

WebViewSetLastError	Set the last error code.
WebViewSetOption	Enable or disable a specific option.
WebViewSetTimeout	Set the number of seconds to wait for a navigation to complete.
WebViewSetUserAgent	Set the default User-Agent string for this instance.
WebViewSetZoomLevel	Set the zoom level for the current view.
WebViewShowWindow	Show or hide the browser window.
WebViewUninitialize	Terminate use of the library and release global resources.
WebViewWaitForEvent	Wait until a specific event occurs or the timeout period expires.
WebViewWaitUntilClosed	Wait until the host window is closed or destroyed.

WebViewAsyncExecute Function

```
BOOL WINAPI WebViewAsyncExecute(
   HWND hWndHost,
   LPCTSTR lpszJavaScript,
   DWORD_PTR dwParam
);
```

The **WebViewAsyncExecute** function executes a script on the current page, returning the results asynchronously.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszJavaScript

A null-terminated string which specifies the JavaScript that should be executed in the context of the current page being viewed. This parameter is required and cannot be NULL.

dwParam

An optional parameter which can be used to provide context to the script being executed asynchronously. This user-defined value is passed back to the event handler which is invoked when the result from the script is returned back to the application. If this information is not required, this parameter can be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewAsyncExecute** function evaluates a JavaScript expression within the context of the currently loaded page and returns the result asynchronously. Unlike **WebViewExecute**, this function does not block while waiting for the script to complete. Instead, the result is delivered through the `WEBVIEW_EVENT_SCRIPT_COMPLETED` event. The application can use the dwParam value to correlate the completion event with the original request.

The script must be valid JavaScript and should not assume synchronous execution. Results are returned by calling **WebViewGetResult** which will provide you with the response in JSON-encoded form; for example, string values will be quoted. Because script execution is dispatched to the underlying WebView2 control, this function will fail if navigation is still in progress. Applications should always wait for the `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event before invoking script execution.

Example

```
// A simple event handler implementation
VOID CALLBACK WebViewEventProc(HWND hWnd, UINT uEvent, WPARAM wParam, LPARAM
lParam, DWORD_PTR dwParam)
{
    if (uEvent == WEBVIEW_EVENT_SCRIPT_COMPLETED)
    {
        BOOL bSuccess = (BOOL)wParam;

        if (bSuccess)
        {
```

```
            TCHAR szResult[512];
            if (WebViewGetResult(hWnd, szResult, _countof(szResult)))
            {
                // Get the response from the script
                // szResult will be a null-terminated string which may contain
                // a JSON object or JSON string (quoted and escaped if needed)
            }
        }
        else
        {
            // The script could not be executed
        }
    }
}

void RunExample(HWND hWebView)
{
    // Execute a simple script asynchronously
    if (!WebViewAsyncExecute(hWebView, _T("document.title"), 0))
    {
        DWORD dwError = WebViewGetLastError();
        // Handle the error condition
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewAttachWindow Function

```
BOOL WINAPI WebViewAttachWindow(
   HWND hWndHost,
   LPCTSTR lpszUrl,
   WEBVIEWEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **WebViewAttachWindow** function attaches a new instance of the browser control to a host window.

Parameters

hWndHost

A handle to the window that will serve as a container for the browser control. This may either be a top-level application window or a child window. If the handle does not specify a valid window, the function will fail. This parameter is required and cannot be NULL.

lpszUrl

A null-terminated string which specifies the initial URL the browser should navigate to after the control has been attached to the window. If this parameter is NULL or an empty string, the browser instance will be created with a blank page. The only schemes permitted are `https://`, `http://` and `file://`. If a domain name is specified without a scheme, it will default to using `https://`.

lpEventProc

A callback function which will be invoked whenever browser events occur. If the application does not need to process events, this parameter can be NULL. The callback function will be invoked in the current thread and the executes in the same context as the browser control. For more information, refer to the WebViewEventProc and WebView Events documentation.

dwParam

An optional parameter which can be used to provide additional context to the event handler. This user-defined value is passed back to the callback function when an event occurs. If this information is not required, this parameter can be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewAttachWindow** function binds a new WebView instance to an existing top-level or child window you have already created. The host window must be created on the current UI thread and remain valid for the lifetime of the WebView. Do not call this function from a worker thread or for a window that was created by another thread; if a background thread needs a browser, create a dedicated window on that thread or use **WebViewCreateWindow** instead. Only one WebView instance can be attached to a given host window at a time. If you need to recreate the browser, call **WebViewDetachWindow** before attaching again.

The calling thread must be in a single-threaded apartment (STA). During initialization the library calls **CoInitializeEx** as needed and if your process has already initialized COM as MTA (`COINIT_MULTITHREADED`), the attach will fail. This requirement comes directly from the Edge WebView2 control which cannot be created in an MTA COM application.

By default, the instance is created with `WEBVIEW_OPTION_ENABLE_DEFAULT`, enabling common browser features (accelerator keys, context menu, basic status UI, zoom, audio, script execution, and script dialogs). If you need a more restrictive experience (such as no context menu enabled), you can use **WebViewAttachWindowEx** to specify an explicit option mask up front.

Your `WEBVIEWEVENTPROC` event callback function is invoked on the same thread that owns the WebView. Because events are raised on the UI thread, long-running work in an event handler can block the user interface and stall navigation. Where possible, defer heavy operations to background threads. You should avoid displaying modal dialogs or message boxes from within event handlers. Also note that some events may fire multiple times during a single navigation. For example, the security state can transition through several levels (unknown, neutral, secure, or warning) before settling on a final value. Applications should be written to handle these changes incrementally.

To present correctly inside a resizable child window, resize the browser view when the host window size changes. The library tracks the host window position but relies on your WM_SIZE handling to drive layout.

Example

```
#include "cstools12.h"

// Windows message handler
static LRESULT CALLBACK WndProc(HWND, UINT, WPARAM, LPARAM);

// WebView event handler for navigation and security events
static VOID CALLBACK WebViewEvents(HWND hWnd, UINT uEvent, WPARAM wParam, LPARAM
lParam, DWORD_PTR dwParam)
{
    switch (uEvent)
    {
    case WEBVIEW_EVENT_NAVIGATION_STARTING:
        OutputDebugString(_T("[WebView] Navigation starting\n"));
        break;

    case WEBVIEW_EVENT_NAVIGATION_COMPLETED:
        if (wParam)
            OutputDebugString(_T("[WebView] Navigation completed\n"));
        else
            OutputDebugString(_T("[WebView] Navigation failed\n"));
        break;

    case WEBVIEW_EVENT_SECURITY_CHANGED:
        OutputDebugString(_T("[WebView] Security changed\n"));
        break;
    }
}

INT WINAPI _tWinMain(HINSTANCE hInstance, HINSTANCE hPrevInstance, LPTSTR
lpCmdLine, INT nCmdShow)
{
    if (!WebViewInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        MessageBox(NULL, _T("Unable to initialize the WebView API"), _T("Error"),
MB_ICONEXCLAMATION);
        return 0;
    }

    LPCTSTR kClass = _T("MyWebViewWndClass");
```

```
    WNDCLASS wc{};
    wc.style = CS_HREDRAW | CS_VREDRAW;
    wc.lpfnWndProc = WndProc;
    wc.hInstance = hInstance;
    wc.hCursor = LoadCursor(nullptr, IDC_ARROW);
    wc.hbrBackground = (HBRUSH)(COLOR_WINDOW + 1);
    wc.lpszClassName = kClass;
    RegisterClass(&wc);

    HWND hWnd = CreateWindowEx(0, kClass, _T("WebView"),
                               WS_OVERLAPPEDWINDOW,
                               CW_USEDEFAULT, CW_USEDEFAULT, 1024, 720,
                               NULL, NULL, hInstance, NULL);

    ShowWindow(hWnd, nCmdShow);
    UpdateWindow(hWnd);

    // A standard Windows message loop
    MSG uMsg;

    while (GetMessage(&uMsg, nullptr, 0, 0))
    {
        TranslateMessage(&uMsg);
        DispatchMessage(&uMsg);
    }

    WebViewUninitialize();
    return (int)uMsg.wParam;
}

static LRESULT CALLBACK WndProc(HWND hWnd, UINT uMsg, WPARAM wParam, LPARAM lParam)
{
    switch (uMsg)
    {
    case WM_CREATE:
        // Create a WebView2 browser instance and attach to this window
        if (!WebViewAttachWindow(hWnd, _T("https://example.com"), WebViewEvents,
0))
        {
            MessageBox(NULL, _T("Unable to attach the WebView2 control"),
_T("Error"), MB_ICONEXCLAMATION);
        }
        return 0;

    case WM_SIZE:
        // Make sure the browser window resizes with the window
        {
            RECT rc;
            GetClientRect(hWnd, &rc);
            WebViewSetBounds(hWnd, rc.left, rc.top, rc.right - rc.left, rc.bottom -
rc.top);
        }
        return 0;

    case WM_DESTROY:
        // Detach the WebView2 browser instance from the window
        WebViewDetachWindow(hWnd);
        PostQuitMessage(0);
        return 0;
```

```
    }

    return DefWindowProc(hWnd, uMsg, wParam, lParam);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewAttachWindowEx Function

```
BOOL WINAPI WebViewAttachWindowEx(
   HWND hWndHost,
   DWORD dwOptions,
   LPCTSTR lpszUrl,
   LPCTSTR lpszLanguage,
   LPCTSTR lpszDataFolder,
   WEBVIEWEVENTPROC lpEventProc,
   DWORD dwParam
);
```

The **WebViewAttachWindowEx** function attaches a new instance of the browser control to a host window. This extended version of the function allows the developer to provide additional options, an alternate display language and specify an optional folder where the browser will store session data.

Parameters

hWndHost

A handle to the window that will serve as a container for the browser control. This may either be a top-level application window or a child window. If the handle does not specify a valid window, the function will fail. This parameter is required and cannot be NULL.

dwOptions

One or more option bitflags. For more information, refer to the WebView Options documentation. Most applications should not use a value of zero for this parameter. If no options are specified, the browser instance will be created with a very restrictive set of permissions that can prevent many websites from functioning correctly.

lpszUrl

A null-terminated string which specifies the initial URL the browser should navigate to after the control has been attached to the window. If this parameter is NULL or an empty string, the browser instance will be created with a blank page. The only schemes permitted are `https://`, `http://` and `file://`. If a domain name is specified without a scheme, it will default to using `https://`.

lpszLanguage

A null-terminated string which specifies an alternate language to use when the browser displays a context menu or dialogs. This value can be a standard language tag in BCP-47 format (such as "en-US") or it can be a string which specifies a hexadecimal Windows locale identifier (such as "0x0409"). It is recommended you use the language tag whenever possible, as Microsoft is deprecating the use of locale identifiers (LCIDs) and their associated APIs. If this parameter is a NULL pointer or an empty string, the browser will use the current default language for the local user.

lpszDataFolder

A folder name where the user profile data will be stored. This is the location where the browser will cache viewed pages, store cookies and form data, and where scripts may store session data. This value may be just a name (such as the name of the application) or an absolute path. If the folder name contains environment variables surrounded in percent (%) symbols, they will be replaced with their value in the current user's environment. If folder name does specify an absolute path, the profile will be stored in the current user's LocalAppData folder. If this parameter is NULL or an empty string, a temporary profile will be created for the session and then automatically deleted when the session ends.

lpEventProc

A callback function which will be invoked whenever browser events occur. If the application does not need to process events, this parameter can be NULL. The callback function will be invoked in the current thread and the executes in the same context as the browser control. For more information, refer to the WebViewEventProc and WebView Events documentation.

dwParam

An optional parameter which can be used to provide additional context to the event handler. This user-defined value is passed back to the callback function when an event occurs. If this information is not required, this parameter can be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewAttachWindowEx** function binds a new WebView instance to an existing top-level or child window you have already created. The host window must be created on the current UI thread and remain valid for the lifetime of the WebView. Do not call this function from a worker thread or for a window that was created by another thread; if a background thread needs a browser, create a dedicated window on that thread or use **WebViewCreateWindowEx** instead. Only one WebView instance can be attached to a given host window at a time. If you need to recreate the browser, call **WebViewDetachWindow** before attaching again.

The calling thread must be in a single-threaded apartment (STA). During initialization the library calls **CoInitializeEx** as needed and if your process has already initialized COM as MTA (`COINIT_MULTITHREADED`), the attach will fail. This requirement comes directly from the Edge WebView2 control which cannot be created in an MTA COM application.

The dwOptions parameter enables you to specify what features are enabled in the browser. It is recommended that most applications use `WEBVIEW_OPTION_ENABLE_DEFAULT` which enables functionality which is most commonly found in web browsers. If you want your host application to exchange messages with scripts executing in the browser, you should also specify the `WEBVIEW_OPTION_ENABLE_MESSAGES` options. This option must be enabled to use **WebViewPostMessage** and **WebViewGetMessage** functions.

When clicking on a link would normally open that page in a new tab or browser window, it will be redirected to the primary browser window by default. This ensures that the browser control retains focus and all events are within the context of that window. If you wish to permit the creation of popup windows and/or support the creation of new browser windows (for example, if a link target is "_blank") then specify the `WEBVIEW_OPTION_ENABLE_NEW_WINDOWS` option. Note that if you permit the creation of new popup windows, it can shift focus away from your main browser window. There is no mechanism in the API to enumerate the child popup windows and they are independent of the window attached to the browser.

By default, the browser will use the language associated with the current user's locale. If you specify an alternate language, this also affects what languages the browser includes with the **Accept-Language** request header. This will provide hints to the website as to what language is preferred when it returns content to the browser. However, it does not guarantee that a website will return content in that language and will not automatically cause a page to be translated from one language to another.

If you pass NULL or an empty string for the ***lpszDataFolder*** parameter, the library creates a temporary, per-session user-data folder under the current user's `LocalAppData` folder. That folder is flagged as temporary and is automatically deleted when you detach the WebView from the window via **WebViewDetachWindow**. If you pass a relative path (such as "MyApp"), the library creates or

uses that folder beneath `%LocalAppData%\WebView`, creating a folder path like `%LocalAppData%\WebView\MyApp`.

If you pass a fully qualified path as the *lpszDataFolder* parameter, it will use that path. However, it will not accept paths to unsafe locations and will return an error if your application does not have permission to create a folder in that location. If there are environment variables surrounded by percent (%) symbols, those variables will be expanded when the folder path is resolved. If you enable privacy mode with `WEBVIEW_OPTION_ENABLE_PRIVACY`, the library will ensure the profile is unique to the session by appending a GUID to the base folder and treating it as temporary. The **WebViewGetUserDataFolder** function can be used to obtain the full path to the data folder being used.

When multiple WebView instances point at the same user-data folder, they share a single WebView2 profile created with that folder path. In this configuration the browser cache, cookies, history, and site storage are persisted under that folder and are reused across windows and processes, which speeds up subsequent navigations and preserves sign-in/session state. The library passes your folder directly to WebView2 when creating the environment, so any instance using that same path participates in the same profile, and you can clear portions of that profile at runtime via the provided helpers for cache, history, and cookies.

Your `WEBVIEWEVENTPROC` event callback function is invoked on the same thread that owns the WebView window. Because events are raised on the UI thread, long-running work in an event handler can block the user interface and stall navigation. Where possible, defer heavy operations to background threads. You should avoid displaying modal dialogs or message boxes from within event handlers. Also note that some events may fire multiple times during a single navigation. For example, the security state can transition through several levels (unknown, neutral, secure, or warning) before settling on a final value. Applications should be written to handle these changes incrementally.

To present correctly inside a resizable child window, resize the browser view when the host window size changes. The library tracks the host window position but relies on your WM_SIZE handling to drive layout.

Example

```
#include "cstools12.h"

// Windows message handler
static LRESULT CALLBACK WndProc(HWND, UINT, WPARAM, LPARAM);

// WebView event handler for navigation and security events
static VOID CALLBACK WebViewEvents(HWND hWnd, UINT uEvent, WPARAM wParam, LPARAM
lParam, DWORD_PTR dwParam)
{
    switch (uEvent)
    {
    case WEBVIEW_EVENT_NAVIGATION_STARTING:
        OutputDebugString(_T("[WebView] Navigation starting\n"));
        break;

    case WEBVIEW_EVENT_NAVIGATION_COMPLETED:
        if (wParam)
            OutputDebugString(_T("[WebView] Navigation completed\n"));
        else
            OutputDebugString(_T("[WebView] Navigation failed\n"));
        break;

    case WEBVIEW_EVENT_SECURITY_CHANGED:
```

```
        OutputDebugString(_T("[WebView] Security changed\n"));
        break;
    }
}

INT WINAPI _tWinMain(HINSTANCE hInstance, HINSTANCE hPrevInstance, LPTSTR
lpCmdLine, INT nCmdShow)
{
    if (!WebViewInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        MessageBox(NULL, _T("Unable to initialize the WebView API"), _T("Error"),
MB_ICONEXCLAMATION);
        return 0;
    }

    LPCTSTR kClass = _T("MyWebViewWndClass");
    WNDCLASS wc{};
    wc.style = CS_HREDRAW | CS_VREDRAW;
    wc.lpfnWndProc = WndProc;
    wc.hInstance = hInstance;
    wc.hCursor = LoadCursor(nullptr, IDC_ARROW);
    wc.hbrBackground = (HBRUSH)(COLOR_WINDOW + 1);
    wc.lpszClassName = kClass;
    RegisterClass(&wc);

    HWND hWnd = CreateWindowEx(0, kClass, _T("WebView"),
                               WS_OVERLAPPEDWINDOW,
                               CW_USEDEFAULT, CW_USEDEFAULT, 1024, 720,
                               NULL, NULL, hInstance, NULL);

    ShowWindow(hWnd, nCmdShow);
    UpdateWindow(hWnd);

    // A standard Windows message loop
    MSG uMsg;

    while (GetMessage(&uMsg, nullptr, 0, 0))
    {
        TranslateMessage(&uMsg);
        DispatchMessage(&uMsg);
    }

    WebViewUninitialize();
    return (int)uMsg.wParam;
}

static LRESULT CALLBACK WndProc(HWND hWnd, UINT uMsg, WPARAM wParam, LPARAM lParam)
{
    switch (uMsg)
    {
    case WM_CREATE:
        // Create a WebView2 browser instance and attach to this window
        {
            DWORD dwOptions = WEBVIEW_OPTION_ENABLE_DEFAULT;
            LPCTSTR pszInitialUrl = _T("https://example.com");
            LPCTSTR pszDataFolder = _T("MyTestApp");

            if (!WebViewAttachWindowEx(hWnd, dwOptions, pszInitialUrl, NULL,
pszDataFolder, WebViewEvents, 0))
```

```
            {
                MessageBox(NULL, _T("Unable to attach the WebView2 control"),
_T("Error"), MB_ICONEXCLAMATION);
            }
        }
        return 0;

    case WM_SIZE:
        // Make sure the browser window resizes with the window
        {
            RECT rc;
            GetClientRect(hWnd, &rc);
            WebViewSetBounds(hWnd, rc.left, rc.top, rc.right - rc.left, rc.bottom -
rc.top);
        }
        return 0;

    case WM_DESTROY:
        // Detach the WebView2 browser instance from the window
        WebViewDetachWindow(hWnd);
        PostQuitMessage(0);
        return 0;
    }

    return DefWindowProc(hWnd, uMsg, wParam, lParam);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebViewCancelDownload Function

```
BOOL WINAPI WebViewCancelDownload(
    HWND hWndHost,
    DWORD dwFileId
);
```

The **WebViewCancelDownload** function cancels the specified download in progress.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwFileId

An integer which specifies a unique file identifier. This value cannot be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewCancelDownload** function causes the specified file download to be canceled. If the transfer has completed or has already been canceled, this function has no effect. This function does not wait for the download to be canceled before it returns; it returns immediately after asynchronously requesting the download be canceled. The `WEBVIEW_EVENT_DOWNLOAD_COMPLETED` event will fire once the download has stopped.

The *dwFileId* value is obtained when the `WEBVIEW_EVENT_DOWNLOAD_STARTING` event is fired and the *lParam* event argument will contain the unique file identifier for the download. You should treat the identifier as an opaque integer and not depend on the value being sequential. It is only guaranteed that the value will be unique for all downloads during the session and is only valid for the browser that initiated the download. Note there can be multiple downloads in progress simultaneously.

The **WebViewGetDownloadInfo** function can be used to get the status of the download and determine if it completed successfully, failed or was canceled.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewCancelNavigation Function

```
BOOL WINAPI WebViewCancelNavigation(
     HWND hWndHost
);
```

The **WebViewCancelNavigation** function cancels any current or pending navigations.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function can be safely called at any time, but only has an effect if the browser is currently in the process of navigating to a new location. A canceled navigation will fire the `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event and the event handler's *wParam* value will be FALSE. The navigation status will also include the `WEBVIEW_STATUS_NAVIGATION_CANCELED` bitflag which can be used to distinguish between a navigation that was canceled and one that failed for another reason.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

WebViewGetNavigationStatus, WebViewNavigateUrl

WebViewClearCache Function

```
BOOL WINAPI WebViewClearCache(
    HWND hWndHost
);
```

The **WebViewClearCache** function removes visited pages from the cache.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function will clear the browser cache for the current session. This can be useful if you wish to force the browser to reload content. If you have created the browser instance using a temporary data folder, or you have specified the `WEBVIEW_OPTION_ENABLE_PRIVACY` option, the browser session will always start with a new user profile and will not contain any cached content.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewClearCookies Function

```
BOOL WINAPI WebViewClearCookies(
    HWND hWndHost,
    BOOL bAllCookies
);
```

The **WebViewClearCookies** function deletes cookies for the current profile or session.

Parameters

hWndHost

Handle to the window attached to the browser session.

bAllCookies

A boolean value which specifies if all cookies for the current user profile should be deleted, or only those cookies created during the current session. If this parameter is a non-zero value then all cookies stored in the current user's profile will be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function deletes cookies that have been created by the current WebView profile. If the *bAllCookies* parameter is set to TRUE, all stored cookies for every site are removed; if set to FALSE, only the cookies associated with the current session are cleared. The effect is comparable to clearing cookies in a regular browser: login sessions, preferences, and other state information stored in cookies will no longer be available. This only affects the WebView's private user data folder and does not modify cookies stored by the user's standalone Edge browser.

If you have used the WebView browser to authenticate with one or more websites, calling this function will typically log you out of those sites and require you to re-authenticate. If you have created the browser instance using a temporary data folder, or you have specified the `WEBVIEW_OPTION_ENABLE_PRIVACY` option, no cookies will be preserved after the session ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewClearHeaders Function

```
BOOL WINAPI WebViewClearHeaders(
    HWND hWndHost
    DWORD dwHeaderType
);
```

The **WebViewClearHeaders** function clears the current request and/or response headers for the current session.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwHeaderType

An unsigned integer value which may be one of the following values.

Value	Description
WEBVIEW_HEADERS_REQUEST	The custom request headers for the current session should be deleted. These are the HTTP headers which can be set or changed prior to the browser navigating to a new page. The standard request headers included with every request will continue to be sent.
WEBVIEW_HEADERS_RESPONSE	The response headers for the current session should be deleted. These are the headers which are returned by the server after navigation has completed. These headers are automatically deleted with each new navigation, making this option unnecessary in most cases.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function can be used to delete the custom request headers set with **WebViewSetHeader** or clear the response headers returned by the previous navigation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewClearHistory Function

```
BOOL WINAPI WebViewClearHistory(
    HWND hWndHost
);
```

The **WebViewClearHistory** function clears the navigation history for the current session.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function clears both the profile's stored browsing history and the navigation history for the current WebView instance. Internally, it uses the WebView2 profile APIs to remove stored history and related download entries, and then resets the back/forward navigation stack. The effect is similar to clearing the browser history in a browser, where visited pages are removed from the user's history, and the in-memory list of sites you can go back or forward to is discarded.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewCreateWindow Function

```
HWND WINAPI WebViewCreateWindow(
   LPCTSTR lpszUrl,
   WEBVIEWEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **WebViewCreateWindow** function creates a new window which hosts an instance of the browser control.

Parameters

lpszUrl

A null-terminated string which specifies the initial URL the browser should navigate to after the window has been created. If this parameter is NULL or an empty string, the browser instance will be created with a blank page. The only schemes permitted are `https://`, `http://` and `file://`. If a domain name is specified without a scheme, it will default to using `https://`.

lpEventProc

A callback function which will be invoked whenever browser events occur. If the application does not need to process events, this parameter can be NULL. The callback function will be invoked in the context of a separate thread which hosts the browser control, not the thread which calls this function. For more information, refer to the WebViewEventProc and WebView Events documentation.

dwParam

An optional parameter which can be used to provide additional context to the event handler. This user-defined value is passed back to the callback function when an event occurs. If this information is not required, this parameter can be zero.

Return Value

If the function succeeds, the return value is the handle of the window which contains the browser control. If the function fails, the return value is NULL. To get extended error information, call **WebViewGetLastError**.

Remarks

This function creates a top-level host window and a WebView runtime on a dedicated UI thread owned by the library. It returns after the window and control have been created and any navigation to the initial URL proceeds asynchronously. The returned window handle can be managed with normal Win32 APIs (such as **ShowWindow**), but you should destroy it with **WebViewDestroyWindow** rather than calling **DestroyWindow** directly. This ensures the browser resources are released correctly. If you specify an event handler, it will receive the normal attach and detach events associated with creating a browser session.

This function requires the single-threaded apartment (STA) COM model. During initialization the library calls **CoInitializeEx** as needed and if your process has already initialized COM as MTA (`COINIT_MULTITHREADED`), a browser instance cannot be created. This requirement comes directly from the Edge WebView2 control which cannot be created in an MTA COM application.

Event callbacks are invoked on the thread that owns the browser window, not the thread that calls **WebViewCreateWindow**. This is typically the internal UI thread that runs the message loop for the control. Avoid updating shared globals from both your main thread and the browser thread without

synchronization. If you need to communicate back to your main UI, use **PostMessage** or **SendMessage** to send application-defined messages to the window, or use an event, critical section, or message queue rather than directly changing the shared state.

By default the browser instance is created with WEBVIEW_OPTION_ENABLE_DEFAULT, enabling common features such as accelerator keys, the context menu, status text, zoom control, audio playback, JavaScript execution, and script dialogs. This gives a familiar, browser-like experience without additional configuration. If you need a more locked-down view (for kiosk or embedded scenarios), use **WebViewCreateWindowEx** to specify different options.

The function can be used from a console application. You do not need to create a message pump on your main thread; the library's hosting thread runs the necessary loop for the browser window. GUI applications can also call this function to create a modeless browser window that you control like any other top-level window.

The window title is automatically updated to reflect the title of the current page as navigation completes.

Example

```
#include "cstools12.h"
#include <stdio.h>

// WebView event handler for navigation and security events
static VOID CALLBACK WebViewEvents(HWND hWnd, UINT uEvent, WPARAM wParam, LPARAM
lParam, DWORD_PTR dwParam)
{
    switch (uEvent)
    {
    case WEBVIEW_EVENT_NAVIGATION_STARTING:
        OutputDebugString(_T("[WebView] Navigation starting\n"));
        break;

    case WEBVIEW_EVENT_NAVIGATION_COMPLETED:
        if (wParam)
            OutputDebugString(_T("[WebView] Navigation completed\n"));
        else
            OutputDebugString(_T("[WebView] Navigation failed\n"));
        break;

    case WEBVIEW_EVENT_SECURITY_CHANGED:
        OutputDebugString(_T("[WebView] Security changed\n"));
        break;
    }
}

int _tmain(int argc, TCHAR *argv[])
{
    if (!WebViewInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Unable to initialize the WebView API, error 0x%08lx\n"),
WebViewGetLastError());
        return 1;
    }

    // Create a top-level browser window
    HWND hBrowser = WebViewCreateWindow(_T("https://example.com"), WebViewEvents,
0);
```

```
    if (!hBrowser)
    {
        _tprintf(_T("Unable to create a WebView window\n"));
        return 2;
    }

    TCHAR szCmdLine[1024];
    TCHAR *pszCmd;
    TCHAR *pszArg;

    // Read commands from standard input to control the browser
    while (pszCmd = _getts_s(szCmdLine, _countof(szCmdLine)))
    {
        // Trim any leading whitespace
        while (*pszCmd && _istspace(*pszCmd))
            pszCmd++;

        // Look for any arguments to the command
        pszArg = _tcschr(pszCmd, _T(' '));
        if (pszArg)
            *pszArg++ = TCHAR('\0');

        if (_tcsicmp(pszCmd, _T("url")) == 0)
        {
            // The URL command will navigate to a new URL
            if (pszArg && _tcslen(pszArg) > 0)
            {
                if (!WebViewNavigateUrl(hBrowser, WEBVIEW_NAVIGATE_DEFAULT,
pszArg))
                {
                     DWORD dwError = WebViewGetLastError();
                     _tprintf(_T("WebViewNavigateUrl failed with error 0x%08lx\n"),
dwError);
                }
            }
            else
            {
                _tprintf(_T("This command requires a URL\n"));
            }
        }
        else if (_tcsicmp(pszCmd, "quit") == 0)
        {
            // Exit the loop, closing the browser window
            break;
        }
    }

    // Destroy the browser window and wait for it to close
    WebViewDestroyWindow(hBrowser);
    WebViewWaitUntilClosed(hBrowser, INFINITE);

    return 0;
}
```

WebViewCreateWindowEx Function

```
HWND WINAPI WebViewCreateWindowEx(
   LPCTSTR lpszTitle,
   DWORD dwStyle,
   LPRECT lpPosition,
   DWORD dwOptions,
   LPCTSTR lpszUrl,
   LPCTSTR lpszLanguage,
   LPCTSTR lpszDataFolder,
   WEBVIEWEVENTPROC lpEventProc,
   DWORD dwParam
);
```

The **WebViewCreateWindowEx** function creates a new window which hosts an instance of the browser control. This extended version of the function allows the developer to provide additional options, an alternate display language and specify an optional folder where the browser will store session data.

Parameters

lpszTitle

A null-terminated string which specifies the text displayed in the title bar. This parameter may be NULL or an empty string, in which case the title bar is set to the title of the document currently being displayed in the browser and will be automatically updated with subsequent navigations.

dwStyle

An unsigned integer which specifies the window style. This is the same windows style used with the **CreateWindowEx** function. If the value is zero, it will default to using the `WS_OVERLAPPEDWINDOW` style which creates an overlapped window with a caption, system menu and a minimize and maximize button. Some style bitflags will be ignored, such as the `WS_CHILD` style which cannot be applied to this window. This function can only be used to create an application window.

lpPosition

A pointer to a **RECT** structure which defines the position and size of the window. If all structure member values are `>= 0`, their values are passed directly to **CreateWindowEx**. If the top or left values are -1, a default position will be used. For example, if the structure is defined as `{ -1, -1, 800, 600 }` it would create an 800 x 600 window at a default position on the display. If the left or right values are -1, default values are used for the width or height. If all values are negative, the position and size of the window will use default values. If this parameter is NULL, the window will be positioned in the center of the current display with a width and height set to half the display area.

dwOptions

One or more option bitflags. For more information, refer to the WebView Options documentation. Most applications should not use a value of zero for this parameter. If no options are specified, the browser instance will be created with a very restrictive set of permissions that can prevent many websites from functioning correctly.

lpszUrl

A null-terminated string which specifies the initial URL the browser should navigate to after the window has been created. If this parameter is NULL or an empty string, the browser instance will be created with a blank page. The only schemes permitted are `https://`, `http://` and `file://`. If a domain name is specified without a scheme, it will default to using `https://`.

lpszLanguage

A null-terminated string which specifies an alternate language to use when the browser displays a context menu or dialogs. This value can be a standard language tag in BCP-47 format (such as "en-US") or it can be a string which specifies a hexadecimal Windows locale identifier (such as "0x0409"). It is recommended you use the language tag whenever possible, as Microsoft is deprecating the use of locale identifiers (LCIDs) and their associated APIs. If this parameter is a NULL pointer or an empty string, the browser will use the current default language for the local user.

lpszDataFolder

A folder name where the user profile data will be stored. This is the location where the browser will cache viewed pages, store cookies and form data, and where scripts may store session data. This value may be just a name (such as the name of the application) or an absolute path. If the folder name contains environment variables surrounded in percent (%) symbols, they will be replaced with their value in the current user's environment. If folder name does specify an absolute path, the profile will be stored in the current user's LocalAppData folder. If this parameter is NULL or an empty string, a temporary profile will be created for the session and then automatically deleted when the session ends.

lpEventProc

A callback function which will be invoked whenever browser events occur. If the application does not need to process events, this parameter can be NULL. The callback function will be invoked in the context of a separate thread which hosts the browser control, not the thread which calls this function. For more information, refer to the WebViewEventProc and WebView Events documentation.

dwParam

An optional parameter which can be used to provide additional context to the event handler. This user-defined value is passed back to the callback function when an event occurs. If this information is not required, this parameter can be zero.

Return Value

If the function succeeds, the return value is the handle of the window which contains the browser control. If the function fails, the return value is NULL. To get extended error information, call **WebViewGetLastError**.

Remarks

This function creates a top-level host window and a WebView runtime on a dedicated UI thread owned by the library. It returns after the window and control have been created and any navigation to the initial URL proceeds asynchronously. The returned window handle can be managed with normal Win32 APIs (such as **ShowWindow**), but you should destroy it with **WebViewDestroyWindow** rather than calling **DestroyWindow** directly. This ensures the browser resources are released correctly. If you specify an event handler, it will receive the normal attach and detach events associated with creating a browser session.

This function requires the single-threaded apartment (STA) COM model. During initialization the library calls **CoInitializeEx** as needed and if your process has already initialized COM as MTA (`COINIT_MULTITHREADED`), a browser instance cannot be created. This requirement comes directly from the Edge WebView2 control which cannot be created in an MTA COM application.

The dwOptions parameter enables you to specify what features are enabled in the browser. It is recommended that most applications use `WEBVIEW_OPTION_ENABLE_DEFAULT` which enables functionality which is most commonly found in web browsers. If you want your host application to exchange messages with scripts executing in the browser, you should also specify the

`WEBVIEW_OPTION_ENABLE_MESSAGES` options. This option must be enabled to use **WebViewPostMessage** and **WebViewGetMessage** functions.

When clicking on a link would normally open that page in a new tab or browser window, it will be redirected to the primary browser window by default. This ensures that the browser control retains focus and all events are within the context of that window. If you wish to permit the creation of popup windows and/or support the creation of new browser windows (for example, if a link target is "_blank") then specify the `WEBVIEW_OPTION_ENABLE_NEW_WINDOWS` option. Note that if you permit the creation of new popup windows, it can shift focus away from your main browser window. There is no mechanism in the API to enumerate the child popup windows and they are independent of the window you have created.

By default, the browser will use the language associated with the current user's locale. If you specify an alternate language, this also affects what languages the browser includes with the **Accept-Language** request header. This will provide hints to the website as to what language is preferred when it returns content to the browser. However, it does not guarantee that a website will return content in that language and will not automatically cause a page to be translated from one language to another.

If you pass NULL or an empty string for the *lpszDataFolder* parameter, the library creates a temporary, per-session user-data folder under the current user's `LocalAppData` folder. That folder is flagged as temporary and is automatically deleted when you detach the WebView from the window via **WebViewDetachWindow**. If you pass a relative path (such as "MyApp"), the library creates or uses that folder beneath `%LocalAppData%\WebView`, creating a folder path like `%LocalAppData%\WebView\MyApp`.

If you pass a fully qualified path as the *lpszDataFolder* parameter, it will use that path. However, it will not accept paths to unsafe locations and will return an error if your application does not have permission to create a folder in that location. If there are environment variables surrounded by percent (%) symbols, those variables will be expanded when the folder path is resolved. If you enable privacy mode with `WEBVIEW_OPTION_ENABLE_PRIVACY`, the library will ensure the profile is unique to the session by appending a GUID to the base folder and treating it as temporary. The **WebViewGetUserDataFolder** function can be used to obtain the full path to the data folder being used.

When multiple WebView instances point at the same user-data folder, they share a single WebView2 profile created with that folder path. In this configuration the browser cache, cookies, history, and site storage are persisted under that folder and are reused across windows and processes, which speeds up subsequent navigations and preserves sign-in/session state. The library passes your folder directly to WebView2 when creating the environment, so any instance using that same path participates in the same profile, and you can clear portions of that profile at runtime via the provided helpers for cache, history, and cookies.

Event callbacks are invoked on the thread that owns the browser window, not the thread that calls **WebViewCreateWindowEx**. This is typically the internal UI thread that runs the message loop for the control. Avoid updating shared globals from both your main thread and the browser thread without synchronization. If you need to communicate back to your main UI, use **PostMessage** or **SendMessage** to send application-defined messages to the window, or use an event, critical section, or message queue rather than directly changing the shared state.

The function can be used from a console application. You do not need to create a message pump on your main thread; the library's hosting thread runs the necessary loop for the browser window. GUI applications can also call this function to create a modeless browser window that you control like any other top-level window.

Example

```
#include "cstools12.h"
#include <stdio.h>

// WebView event handler for navigation and security events
static VOID CALLBACK WebViewEvents(HWND hWnd, UINT uEvent, WPARAM wParam, LPARAM
lParam, DWORD_PTR dwParam)
{
    switch (uEvent)
    {
    case WEBVIEW_EVENT_NAVIGATION_STARTING:
        OutputDebugString(_T("[WebView] Navigation starting\n"));
        break;

    case WEBVIEW_EVENT_NAVIGATION_COMPLETED:
        if (wParam)
            OutputDebugString(_T("[WebView] Navigation completed\n"));
        else
            OutputDebugString(_T("[WebView] Navigation failed\n"));
        break;

    case WEBVIEW_EVENT_SECURITY_CHANGED:
        OutputDebugString(_T("[WebView] Security changed\n"));
        break;
    }
}

int _tmain(int argc, TCHAR *argv[])
{
    if (!WebViewInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Unable to initialize the WebView API, error 0x%08lx\n"),
WebViewGetLastError());
        return 1;
    }

    // Create a top-level browser window
    LPCTSTR pszAppTitle = _T("MyWebView");
    LPCTSTR pszInitialUrl = _T("https://example.com");
    LPCTSTR pszDataFolder = _T("MyTestApp");
    DWORD dwOptions = WEBVIEW_OPTION_ENABLE_DEFAULT;
    RECT rcPos = { -1, -1, 1200, 800 };

    HWND hBrowser = WebViewCreateWindowEx(
                            pszAppTitle,          // Window title
                            WS_OVERLAPPEDWINDOW,  // Window style
                            &rcPos,               // Initial position
                            dwOptions,            // Creation options
                            pszInitialUrl,        // Initial URL
                            NULL,                 // Default language
                            pszDataFolder,        // User data folder
                            WebViewEvents, 0);    // Event callback
    if (!hBrowser)
    {
        _tprintf(_T("Unable to create a WebView window\n"));
        return 2;
    }
```

```
    TCHAR szCmdLine[1024];
    TCHAR *pszCmd;
    TCHAR *pszArg;

    // Read commands from standard input to control the browser
    while (pszCmd = _getts_s(szCmdLine, _countof(szCmdLine)))
    {
        // Trim any leading whitespace
        while (*pszCmd && _istspace(*pszCmd))
            pszCmd++;

        // Look for any arguments to the command
        pszArg = _tcschr(pszCmd, _T(' '));
        if (pszArg)
            *pszArg++ = TCHAR('\0');

        if (_tcsicmp(pszCmd, _T("url")) == 0)
        {
            // The URL command will navigate to a new URL
            if (pszArg && _tcslen(pszArg) > 0)
            {
                if (!WebViewNavigateUrl(hBrowser, WEBVIEW_NAVIGATE_DEFAULT,
pszArg))
                {
                     DWORD dwError = WebViewGetLastError();
                     _tprintf(_T("WebViewNavigateUrl failed with error 0x%08lx\n"),
dwError);
                }
            }
            else
            {
                _tprintf(_T("This command requires a URL\n"));
            }
        }
        else if (_tcsicmp(pszCmd, "quit") == 0)
        {
            // Exit the loop, closing the browser window
            break;
        }
    }

    // Destroy the browser window and wait for it to close
    WebViewDestroyWindow(hBrowser);
    WebViewWaitUntilClosed(hBrowser, INFINITE);

    return 0;
}
```

WebViewDestroyWindow Function

```
BOOL WINAPI WebViewDestroyWindow(
    HWND hWndHost
);
```

The **WebViewDestroyWindow** function closes the window and releases all browser resources.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function closes a browser window which was created using the **WebViewCreateWindow** or **WebViewCreateWindowEx** function. It is recommended that you always use this function to close the window rather than posting a **WM_CLOSE** message because it ensures resources for the window, such as its icons, are released correctly. The process of destroying the window does not occur immediately and when this function returns it is not guaranteed the browser child window and its associated processes have completely stopped. Use the **WebViewWaitUntilClosed** function if you wish to wait for the cleanup process to complete.

This function will cause the **WEBVIEW_EVENT_WINDOW_DETACHED** event to fire as part of the normal process of destroying the window. If you implement a handler for this event, you should never delay this process by attempting to show a dialog or request input from the user (for example, by displaying a message box). At the point this event is fired, the browser objects have already been disposed and there is no way to prevent the process from completing.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewDetachWindow Function

```
BOOL WINAPI WebViewDetachWindow(
    HWND hWndHost
);
```

The **WebViewDetachWindow** function releases the resources allocated for the browser session.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function is used to detach the browser instance from a window that it was previously attached to using either the **WebViewAttachWindow** or **WebViewAttachWindowEx** functions. This function should always be called when the browser is no longer needed and the host window is being destroyed. If the window handle was created using the **WebViewCreateWindow** or **WebViewCreateWindowEx** function, calling this function has the same effect as calling the **WebViewDestroyWindow** function.

This function will cause the `WEBVIEW_EVENT_WINDOW_DETACHED` event to fire as part of the normal process of detaching from the window. If you implement a handler for this event, you should never delay this process by attempting to show a dialog or request input from the user (for example, by displaying a message box). At the point this event is fired, the browser objects have already been disposed and there is no way to prevent the process from completing.

If there is a navigation in progress at the time this function is called, it will be canceled. If there are one or more file downloads in progress, the transfers will be aborted.

The current thread will block while it waits for the WebView2 browser process to shutdown gracefully. If the browser becomes non-responsive, this function will wait several seconds before forcibly terminating the child process and continuing with the cleanup process. If a temporary user profile was specified or a private browsing session was created, this function will also clear the browser cache and remove the user data folder that was created for the session.

WebViewDisableEvents Function

```
BOOL WINAPI WebViewDisableEvents(
    HWND hWndHost
);
```

The **WebViewDisableEvents** function disables event handling for the specified browser.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function removes the currently installed event handler for the specified host window and clears the user parameter. After it returns, the application will not receive any further browser events until **WebViewEnableEvents** is called again with a valid handler. Use this to permanently stop participating in event notifications (for example, during shutdown or when detaching the browser control from the host). Unlike temporarily freezing events, this function completely clears the callback handler for the browser instance.

If you only need to pause notifications temporarily, such as when presenting a modal dialog, performing a batch of UI updates, or executing several programmatic navigations back-to-back, freezing events is the recommended approach. Disabling events should be reserved for longer-term or terminal states, typically when the application is in the process of closing down.

You should not call **WebViewDisableEvents** from inside an event handler. Disabling callbacks while you are actively processing an event can lead to subtle reentrancy issues and missed cleanup. If you need to suspend notifications from within an event, call **WebViewFreezeEvents** instead, complete your work, and then unfreeze when you are ready to resume event handling.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

WebViewEnableEvents, WebViewEventProc, WebViewFreezeEvents

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebViewEnableEvents Function

```
BOOL WINAPI WebViewEnableEvents(
   HWND hWndHost,
   WEBVIEWEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **WebViewEnableEvents** function enables event handling for the specified browser.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpEventProc

A callback function which will be invoked whenever browser events occur. This parameter cannot be NULL. The callback function will be invoked in the context of a separate thread which hosts the browser control, not the thread which calls this function. For more information, refer to the WebViewEventProc and WebView Events documentation.

dwParam

An optional parameter which can be used to provide additional context to the event handler. This user-defined value is passed back to the callback function when an event occurs. If this information is not required, this parameter can be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewEnableEvents** function assigns or replaces the callback function that receives browser events for the specified host window. It can be used after the browser has been attached to start receiving notifications or to change event handlers at runtime. The change takes effect immediately and subsequent events will be invoked using the new handler.

Event delivery is serialized by the library and this call safely updates the event handler. You cannot specify a NULL pointer as the event handler; if you need to disable events, use the **WebViewDisableEvents** function. If events were previously frozen with **WebViewFreezeEvents**, calling this function with a new event handler will automatically unfreeze event notifications.

When using this function from within a C++ class, the event callback must be declared as a static function with the **__stdcall** (or **CALLBACK**) calling convention. This is required because the library calls the handler just as it would with any Win32 API callback function, without knowledge of C++ instance objects. Non-static member functions include a hidden **this** pointer parameter, which makes their signature incompatible with the expected **WEBVIEWEVENTPROC** type. A common pattern is to pass the object's ***this*** pointer as the ***dwParam*** value, then cast it back inside the static callback function to access the instance. This preserves object-oriented design while still meeting the calling convention requirements of the API.

WebViewEnumDownloads Function

```
INT WINAPI WebViewEnumDownloads(
    HWND hWndHost,
    DWORD dwStatus,
    LPDWORD lpdwFileList,
    INT nMaxFiles
);
```

The **WebViewEnumDownloads** function enumerates the file identifiers for downloads during the current session.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwStatus

A value which specifies the status of the downloads to enumerate. If this value is zero, the function will enumerate all downloads. If this parameter is one of the values listed below, only those downloads which match the specified status will be enumerated. For example, if this parameter is `WEBVIEW_DOWNLOAD_COMPLETED` then only those file downloads which have completed will be enumerated.

Name	Description
WEBVIEW_DOWNLOAD_STARTED	The file download has started and is in-progress.
WEBVIEW_DOWNLOAD_COMPLETED	The file download has completed successfully.
WEBVIEW_DOWNLOAD_CANCELED	The file download has been canceled.
WEBVIEW_DOWNLOAD_FAILED	The file download failed due to a network error or other problem.

lpdwFileList

A pointer to an array of DWORD values which specify the unique file identifier associated with the download. The identifiers can be passed to the **WebViewGetDownloadInfo** function to get detailed information about a specific download. This parameter can be NULL, in which case it will be ignored and the function will return the number of downloaded files.

nMaxFiles

The maximum number of file identifiers which can be copied into the *lpdwFileList* array. If the *lpdwFileList* parameter is NULL this value should be zero.

Return Value

If the function succeeds, the return value is the number of files downloaded during the current session. If there have been no downloads, or if the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewEnumDownloads** function can be used to obtain the identifiers for one or more file downloads that have occurred during the current browser session. Each identifier returned by this function uniquely corresponds to a download and can be used with functions such as **WebViewGetDownloadInfo** or **WebViewGetDownloadPath** to obtain detailed information about

the file.

If the *dwStatus* parameter is set to zero, the function enumerates all downloads regardless of their state. Otherwise, only downloads that match the specified status value are included in the enumeration. This allows applications to filter the results to include only downloads that are currently in progress, those that completed successfully, or those that were canceled or failed.

When the *lpdwFileList* parameter is not NULL, the function copies up to *nMaxFiles* identifiers into the specified array. If the number of matching downloads exceeds the array size, only the first *nMaxFiles* identifiers are returned, but the return value will still reflect the total number of matching downloads. This enables the application to first call the function with a NULL pointer to determine how many downloads are available, and then allocate an appropriately sized buffer before retrieving the identifiers.

The enumeration includes both active and completed downloads. If the host window is detached or destroyed, the list of downloads is cleared and further enumeration will return zero results.

Example

```
// Get the total number of downloads
INT nTotal = WebViewEnumDownloads(hWndHost, 0, NULL, 0);

if (nTotal <= 0)
{
    _tprintf(_T("No downloads found.\n"));
    return;
}

// Allocate a buffer for the identifiers
DWORD *pIds = (DWORD*)malloc(nTotal * sizeof(DWORD));
if (!pIds)
    return;

INT nCount = WebViewEnumDownloads(hWndHost, 0, pIds, nTotal);

// Enumerate each download and print basic info
for (INT nIndex = 0; nIndex < nCount; nIndex++)
{
    WEBVIEW_DOWNLOAD_INFO fileInfo = { sizeof(fileInfo) };

    if (WebViewGetDownloadInfo(hWndHost, pIds[nIndex], &fileInfo))
    {
        _tprintf(_T("Download %u: %s (%llu/%llu bytes)\n"),
                 fileInfo.dwFileId,
                 fileInfo.szFileName,
                 fileInfo.uiBytesCopied.QuadPart,
                 fileInfo.uiBytesTotal.QuadPart);
    }
}

free(pIds);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebViewEventProc Function

```
VOID CALLBACK WebViewEventProc(
    HWND hWndHost,
    UINT uEventId,
    WPARAM wParam,
    LPARAM lParam,
    DWORD_PTR dwParam
);
```

The **WebViewEventProc** function is an application-defined callback function that processes events generated by the browser.

Parameters

hWndHost

Handle to the window attached to the browser session.

uEventId

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the WebView Events documentation.

wParam

An integer value that depends on the event context. This value is commonly used by an event to indicate success (1) or failure (0). It may also be used to indicate a transition in state. Refer to the events documentation for information about how this parameter may be used by a specific event.

lParam

An integer value that depends on the event context. This value is commonly used by an event to provide a status code or error code, depending whether the operation which raised the event succeeded or failed. Refer to the events documentation for information about how this parameter may be used by a specific event.

dwParam

A user-defined integer value which was provided when the event callback was specified. This is typically used to provide additional context to the event or associate the event with a specific object. If this user-defined parameter was not specified when the browser window was attached or created, this value will be zero.

Return Value

None.

Remarks

The library invokes the callback function whenever an event occurs. Applications are not required to implement event handlers for each event, and may choose to not provide any event handlers by passing NULL as the callback function parameter. A minimal implementation would typically create handlers for the `WEBVIEW_EVENT_NAVIGATION_STARTING` event which notifies the application when the browser is beginning to navigate to a new location, and the `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event which indicates the navigation has completed.

When you attach a browser instance to an existing window, the callback function is always invoked on the same UI thread that owns that window, ensuring events are processed in the context of the caller's thread. However, if you create a new browser window using the **WebViewCreateWindow** function, a different thread manages the top-level window and message loop, and in that case the callback

function is invoked on the thread that owns the browser window rather than the thread that created it. This distinction is important when your application accesses shared data or resources from within the event handler. To avoid race conditions or undefined behavior, ensure that access to shared state is synchronized using mutexes, critical sections, or other appropriate synchronization primitives.

It is important to keep event handlers responsive. Because events are raised on the UI thread, long-running work in an event handler can block the user interface and stall navigation. Where possible, defer heavy operations to background threads. Avoid displaying modal dialogs or message boxes from within event handlers. Also note that some events may fire multiple times during a single navigation. For example, the security state can transition through several levels (unknown, neutral, secure, or warning) before settling on a final value. Applications should be written to handle these changes incrementally.

After the browser has been attached to a window, it is possible to change the event handler using the **WebViewEnableEvents** function. This changes the event handler for the browser instance, and from that point forward all event notifications will be routed to the new handler.

If you are implementing the callback function in a language other than C/C++ it must use the **__stdcall** calling convention, not the **__cdecl** calling convention. The parameters **WPARAM**, **LPARAM**, and **DWORD_PTR** used with the event callback are defined by the Windows API as integer types whose size depends on the target platform. For 32-bit applications, these types are 32-bit values; for 64-bit applications, they expand to 64-bit values. This design allows the parameters to hold either numeric values or pointer values in a way that is natural for the platform.

For applications written in C or C++, the compiler automatically adjusts these types based on whether you are building a 32-bit or 64-bit target. However, when calling the API from other languages (such as C#, Delphi, or VB), it is important to define these parameters as pointer-sized integers rather than fixed 32-bit integers. In .NET, for example, the correct type is **IntPtr**, which automatically maps to 32 or 64 bits depending on the runtime. In Delphi, you should use **NativeInt** or **NativeUInt**. Using a fixed 32-bit type in a 64-bit build can lead to truncated values or incorrect pointer conversions, while using a 64-bit type in a 32-bit build can cause calling convention mismatches.

When defining an event handler within a C++ class, the event callback must be declared as a static function with the **__stdcall** calling convention. This is required because the library calls the handler just as it would with any Win32 API callback function, without knowledge of C++ instance objects. Non-static member functions include a hidden **this** pointer parameter, which makes their signature incompatible with the expected **WEBVIEWEVENTPROC** type. A common pattern is to pass the object's ***this*** pointer as the ***dwParam*** value, then cast it back inside the static callback function to access the instance. This preserves object-oriented design while still meeting the calling convention requirements of the API.

WebViewExecute Function

```
INT WINAPI WebViewExecute(
   HWND hWndHost,
   LPCTSTR lpszJavaScript,
   LPTSTR lpszResult,
   INT nMaxLength
);
```

The **WebViewExecute** function executes JavaScript and returns the result synchronously.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszJavaScript

A null-terminated string which specifies the JavaScript that should be executed in the context of the current page being viewed. This parameter is required and cannot be NULL.

lpszResult

A string buffer which will contain the result returned by the script, either as a JSON object or a JSON string value. If this parameter is NULL, the function will not copy the result but will return the total number of characters in the response, not including the terminating null.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null. If the ***lpszResult*** parameter is NULL, this parameter should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the result buffer, not including the terminating null. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewExecute** function evaluates a JavaScript expression within the context of the currently loaded page and returns the result synchronously. Unlike **WebViewAsyncExecute**, this function blocks the current thread while waiting for the script to complete. If the web page is non-responsive, this function will timeout after approximately two seconds.

If you wish to dynamically allocate a string buffer for the response, you can call this function with the ***lpszResult*** parameter as NULL and the ***nMaxLength*** parameter as zero. The function will return the number of characters in the response, not including the terminating null. You can allocate the buffer and then call **WebViewGetResult** which will copy the response into the buffer you provide. Because script execution is dispatched to the underlying WebView2 control, this function will fail if navigation is still in progress. Applications should wait for the `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event before invoking script execution.

Example

```
// Execute a simple script that returns a string
INT nLength = WebViewExecute(hWndHost, _T("document.title"), NULL, 0);

if (nLength > 0)
{
```

```
    // Allocate a buffer large enough to hold the result
    LPTSTR lpszResult = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
    if (lpszResult)
    {
        // Retrieve the result of the script execution
        if (WebViewGetResult(hWndHost, lpszResult, nLength + 1))
        {
            _tprintf(_T("Page title is: %s\n"), lpszResult);
        }
        free(lpszResult);
    }
}
else
{
    _tprintf(_T("Script execution failed\n"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebViewFindWindow Function

```
HWND WINAPI WebViewFindWindow(
    HWND hWndParent,
    LPCTSTR lpszSearch,
    DWORD dwFlags,
    LPDWORD lpdwThreadId
);
```

The **WebViewFindWindow** function locates the associated host or child window handle for a browser instance.

Parameters

hWndParent

Handle to the parent window. If this parameter is NULL it will search all top-level windows. If this parameter is not NULL, it must be a valid window handle and the function will only match against a window which is a child window of the specified handle.

lpszSearch

An optional null-terminated string which specifies a URL. The function will only match those browser windows which have navigated to the specified URL. A simple case-insensitive substring search is performed, but will only match windows created by the current process. If this parameter is NULL or an empty string, the function will not match against any specific URL.

dwFlags

This parameter is reserved for future use and should always be zero. Future versions may expand this to support additional types of matching, such as document titles or more advanced search expressions.

lpdwThreadId

An optional parameter which is a pointer to an unsigned integer value that will contain the thread ID for the browser instance if a matching window is found. If no browser is found, this value will be set to zero. If this information is not required, this parameter can be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewFindWindow** function can be used to locate the window handle for an existing WebView2 instance that was created by the calling process. This is useful if the application needs to re-establish a reference to a previously created browser window, for example when handling messages or coordinating multiple windows.

If a parent window handle is specified, the function will restrict its search to that window and its children. This is the most efficient approach when the caller already knows the expected parent container. If the parameter is NULL, all top-level windows owned by the process are searched. An optional URL string can also be provided to limit results to windows whose current location contains the specified substring. The search is case-insensitive and only applies to windows created by the current process.

The function only returns a single matching window handle. If multiple instances could match the criteria, the particular instance returned is not guaranteed and the caller should design accordingly.

When both the parent handle and search string are NULL, the function simply locates the first available WebView2 instance owned by the current thread.

If the optional ***lpdwThreadId*** parameter is supplied, it will receive the thread identifier that owns the WebView2 instance. This can be used when thread affinity is important, such as posting messages directly to the UI thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebViewFreezeEvents Function

```
BOOL WINAPI WebViewFreezeEvents(
    HWND hWndHost,
    BOOL bFreezeEvents
);
```

The **WebViewEnableEvents** function suspends or re-enables event notifications for the specified browser.

Parameters

hWndHost

Handle to the window attached to the browser session.

bFreezeEvents

An integer value which specifies if event handling should be frozen. If the value is non-zero, browser events will be suspended until they are re-enabled. If the value is zero, browser events will be re-enabled if an event handler has been defined.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function toggles a per-instance switch for event delivery. When events are frozen, the browser continues to operate normally and still generates events internally, but your application will not be notified of them. The events are not queued while frozen; they are discarded. For developers familiar with COM controls, this mirrors the behavior of `IOleControl::FreezeEvents`. When you unfreeze, only new events that occur after unfreezing will be delivered.

Event freezing can be useful when:

- You are running scripted or programmatic operations that would otherwise flood your event handler, such as multiple page redirects or rapid **WebViewAsyncExecute** calls.
- You are making a series of user interface changes and want to avoid reentrant updates. For example, temporarily stopping focus and/or size change events while moving or resizing controls.
- You are showing a modal dialog or performing work where event reentrancy could complicate state management.
- You need to suppress event-driven logic during controlled navigation, such as "silently" reloading a document or navigating to a new location.

Freezing does not alter browser state, navigation, or timers; it only affects your application's callback. To resume normal notifications, call this function with the ***bFreezeEvents*** parameter as zero. Freezing events will not affect calls to **WebViewWaitForEvent**. Because freezing events does not prevent browser events from occurring, they are still processed internally and you can wait for a specific event to complete.

If you discover that subsequent notifications within an event handler would interfere with your application's workflow, it is safe to freeze events from within the handler. After completing the

operation, unfreeze events (for example, by posting an application-defined message or using a timer) so events resume normally. You should avoid calling **WebViewDisableEvents** from within an event handler, use freezing instead.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetAllOptions Function

```
BOOL WINAPI WebViewGetAllOptions(
    HWND hWndHost,
    LPDWORD lpdwOptions
);
```

The **WebViewGetAllOptions** function returns the current option flags for the instance.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpdwOptions

A pointer to an unsigned integer which will contain the browser options for the current session. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function returns the options for the current session. For more information about the options available, review the WebView Options documentation. Always check the return value from this function; the option bitflags are only valid if this function returns a non-zero (TRUE) value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetBackgroundColor Function

```
BOOL WINAPI WebViewGetBackgroundColor(
   HWND hWndHost,
   COLORREF *lprbgBackground
);
```

The **WebViewGetBackgroundColor** function returns the background color used behind the page content.

Parameters

hWndHost

Handle to the window attached to the browser session.

lprbgBackground

A pointer to an integer which will contain the current background color as an RGB value.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The background color specifies the fill used by the browser window when there is no content to display or the document itself does not define a background. This value only applies to the WebView host surface and does not affect page transparency. The alpha channel is ignored, and the color is treated as fully opaque. By default, the background color for new browser instances will be white.

A **COLORREF** is a 32-bit value used by the Windows API to represent an RGB color. The low-order byte specifies the red component, the next byte the green component, and the third byte the blue component, in the format **0x00BBGGRR**. The high-order byte is unused and should be zero. Note that **COLORREF** is specific to the Windows API and is not the same as the OLE color system (**OLE_COLOR**). OLE uses a slightly different encoding that allows system color values to be specified, which are resolved at runtime. Developers should be careful not to confuse the two.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetBrowserVersion Function

```
INT WINAPI WebViewGetBrowserVersion(
    LPDWORD lpdwVersionMS,
    LPDWORD lpdwVersionLS,
    LPTSTR lpszVersion,
    INT nMaxLength
);
```

The **WebViewGetBrowserVersion** function returns the installed browser runtime version information.

Parameters

lpdwVersionMS

A pointer to an unsigned integer which contains the major and minor version numbers. This parameter may be NULL.

lpdwVersionLS

A pointer to an unsigned integer which contains the build and release version numbers. This parameter may be NULL.

lpszVersion

A null-terminated string buffer which will contain the version as a printable string. This parameter may be NULL, in which case the version string is not copied but the function will still return the length of the version string if successful. If this parameter is NULL, the ***nMaxLength*** parameter should have a value of zero.

nMaxLength

An integer which specifies the maximum number of characters which may be copied into the string buffer, including the terminating null. If the ***lpszVersion*** parameter is NULL, this parameter should be zero.

Return Value

If the function succeeds, the return value is the length of the version string, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetBrowserVersion** function returns the version information for the installed Microsoft Edge WebView2 Runtime. This is the runtime that hosts the embedded browser control, and it is separate from the version of the Edge browser that may be installed on the system. The function can provide the version number as two 32-bit values (major/minor and build/revision), and optionally as a formatted string for display purposes. This function is useful for diagnostics, logging, or when an application requires a specific minimum runtime version to support certain features. If the WebView2 Runtime is not installed or cannot be located, the function will fail and return zero.

The version values returned by ***lpdwVersionMS*** and ***lpdwVersionLS*** can be used with the `HIWORD` and `LOWORD` macros to extract the individual components of the version number (for example, major, minor, build, and revision). The printable version string will match the same four-part format commonly shown in Edge and WebView2 documentation (e.g., "`126.0.2592.113`").

The result is independent of whether a WebView window has already been created or attached. It only reflects the version of the installed runtime and does not indicate whether the runtime is currently in use. For cases where you only need to check if a runtime is available, use the

WebViewRuntimeAvailable function instead.

Example

```
DWORD dwVerMS = 0, dwVerLS = 0;
TCHAR szVersion[64] = {0};

INT nLength = WebViewGetBrowserVersion(&dwVerMS, &dwVerLS, szVersion,
_countof(szVersion));
if (nLength > 0)
{
    WORD wMajor = HIWORD(dwVerMS);
    WORD wMinor = LOWORD(dwVerMS);
    WORD wBuild = HIWORD(dwVerLS);
    WORD wRevision = LOWORD(dwVerLS);

    _tprintf(_T("WebView2 Runtime Version: %s\n"), szVersion);
    _tprintf(_T("Major=%hu Minor=%hu Build=%hu Revision=%hu\n"), wMajor, wMinor,
wBuild, wRevision);
}
else
{
    _tprintf(_T("Unable to determine WebView2 Runtime version (Error 0x%lx)\n"),
WebViewGetLastError());
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetChildWindow Function

```
HWND WINAPI WebViewGetChildWindow(
     HWND hWndHost
);
```

The **WebViewGetChildWindow** function returns the handle of the internal browser child window.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is a window handle. If the function fails, the return value is NULL. To get extended error information, call **WebViewGetLastError**.

Remarks

The value returned by this function is the handle to the internal child window that hosts the WebView control. Applications should treat this handle as an implementation detail and avoid sending messages or altering window styles directly. The control manages this child window and relies on its state for proper operation. Interfering with the child window (for example, by subclassing it, changing its parent, or destroying it) can cause undefined behavior and application instability.

This function is primarily provided to support advanced scenarios where access to the native window handle is unavoidable, such as integrating with APIs that require a child window handle. In most cases, developers should use the higher-level functions in the WebView API instead of interacting with the child window directly.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetContentType Function

```
INT WINAPI WebViewGetContentType(
   HWND hWndHost
   LPTSTR lpszContentType,
   INT nMaxLength
);
```

The **WebViewGetContentType** function returns the content type for the current page.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszContentType

A string buffer which will contain the MIME content type of the resource returned by the web server. The buffer must be large enough to contain the entire content type string including the terminating null character. If this parameter is NULL, the content type will not be copied but the function will return the length of the `Content-Type` header value.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the buffer, including the terminating null. If the *lpszContentType* parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the return value is the length of the `Content-Type` header value. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetContentType** function returns the MIME type reported by the server in the `Content-Type` response header for the most recent navigation. This value reflects the server's indication of what kind of content is being delivered, such as "`text/html`", "`application/pdf`", or "`image/png`". The returned string is preserved until the next navigation begins, even if the document is cleared or headers are reset.

It is important to note that not all servers will provide a `Content-Type` header. Some intentionally omit this information in combination with a `X-Content-Type-Options: nosniff` header as a security measure to prevent the client from "sniffing" or inferring the type. In such cases, **WebViewGetContentType** will return an empty string. Applications should be prepared for this scenario and not assume a value will always be available.

This function is a convenience wrapper around the underlying response header and is useful for distinguishing whether the WebView is rendering standard HTML or other document types. If more detailed information is needed about the response, developers can enumerate the response headers directly using **WebViewGetFirstHeader** and **WebViewGetNextHeader**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

Unicode: Implemented as Unicode and ANSI versions

WebViewGetCurrentUrl Function

```
BOOL WINAPI WebViewGetCurrentUrl(
    HWND hWndHost,
    LPTSTR lpszUrl,
    INT nMaxLength
);
```

The **WebViewGetCurrentUrl** function returns the URL for the current document.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszUrl

A string buffer which will contain the current URL when the function returns. If this parameter is NULL, the function will not copy anything into the buffer but will return the length of the URL, not including the terminating null character. If a buffer is provided, it must be large enough to contain the entire URL.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null. If the ***lpszUrl*** parameter is NULL this value should be zero.

Return Value

If the function succeeds, the return value is the length of the current URL, not including the terminating null. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetCurrentUrl** function retrieves the URL associated with the current document loaded in the browser instance. The URL value is available as soon as navigation begins to a new location, so it can be queried during or after the navigation process. This allows applications to obtain the destination address immediately, even before the page has fully loaded or rendered its content.

Note that the current URL may differ from the value originally passed to **WebViewNavigateUrl**. The browser engine can normalize the address, such as adjusting letter case, expanding relative paths, or adding default components like a trailing slash. In addition, the current URL can change multiple times during the course of a navigation if the server issues one or more HTTP redirects before the final document is retrieved. For this reason, the URL returned by this function should be treated as the authoritative location of the content currently being displayed.

This function differs from examining the document itself (for example, by executing a script to query `document.URL`) because it reflects the navigation state maintained internally by the control. Applications should use this function to reliably track the current location of the browser instance.

If the **WebViewSetDocumentText** function was called to change the current document, the URL returned by this function will typically be `"data:text/html"` which indicates it is a local data source.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetDocumentText Function

```
INT WINAPI WebViewGetDocumentText(
    HWND hWndHost
    LPTSTR lpszText,
    INT nMaxLength
);
```

The **WebViewGetDocumentText** function returns the current document text.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszText

A string buffer which will contain the current document text when the function returns. If this parameter is NULL, the function will not copy anything into the buffer but will return the length of the text, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null. If the ***lpszText*** parameter is NULL this value should be zero.

Return Value

If the function succeeds, the return value is the length of the document text in characters, not including the terminating null. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetDocumentText** function retrieves the HTML markup for the current document loaded in the browser. This includes the complete contents of the `<html>` element, such as the `<head>` and `<body>` sections, rather than just the visible text.

The text returned will reflect the current state of the document at the time the function is called. If the page has been dynamically modified by scripts after it was initially loaded, those changes will be included. The value may be large, particularly for complex pages, and applications should allocate a buffer of sufficient size by first calling the function with a NULL pointer to determine the required length.

This function should only be called after navigation has completed. If called while a page is still loading, the results may be incomplete or empty. When the content is provided by a local file or string, the returned HTML will be the original content that was passed to the control. The returned text is raw HTML and may contain scripts, style definitions, and markup that are not directly suitable for display in a plain-text context.

If a blank page is currently being displayed, such as when navigating to `about:blank` or by setting the current document text to an empty string, this function can still return a value. Internally, the browser creates a blank page using the markup `"<html><head></head><body></body></html>"` and that is what this function will return.

There are two versions of this function, one that returns 8-bit text (**WebViewGetDocumentTextA**) and one that returns 16-bit Unicode text (**WebViewGetDocumentTextW**). The correct version of the function is called based on your project settings and whether the `UNICODE` macro is defined. If you call

the ANSI version of this function, the text that is returned will always be UTF-8 encoded, regardless of the current locale. If the document contains anything other than ASCII characters, it is recommended that you use the Unicode version of this function.

The **WebViewGetFilteredText** function can be used to obtain a filtered version of the text with the HTML markup removed.

Example

```
INT nLength = WebViewGetDocumentText(hWndHost, NULL, 0);
if (nLength > 0)
{
    LPTSTR pszBuffer = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
    if (!pszBuffer)
    {
        // Virtual memory exhausted
        return;
    }

    nLength = WebViewGetDocumentText(hWndHost, pszBuffer, nLength + 1);
    if (nLength > 0)
    {
         // Write the document HTML to standard output
        _putts(pszBuffer);
        _puttc(_T('\n'), stdout);
    }

    free(pszBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetDocumentTitle Function

```
INT WINAPI WebViewGetDocumentTitle(
    HWND hWndHost,
    LPTSTR lpszTitle,
    INT nMaxLength,
);
```

The **WebViewGetDocumentTitle** function returns the document title.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszTitle

A string buffer which will contain the current document title when the function returns. If this parameter is NULL, the function will not copy anything into the buffer but will return the length of the title, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null. If the ***lpszTitle*** parameter is NULL this value should be zero.

Return Value

If the function succeeds, the return value is the length of the document title in characters, not including the terminating null. If the document does not have a title or the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetDocumentTitle** function returns the current title of the document loaded in the browser. This corresponds to the contents of the `<title>` element in the document's `<head>` section, if one is defined.

The title is not fixed at the time the page is first loaded. A script running in the document can modify the `<title>` element dynamically, and some web applications use this technique to reflect state changes (for example, to indicate new messages or status updates). Because of this, the value returned by this function may change over the lifetime of the page. If the document does not explicitly define a title, the function may return an empty string. Applications that display document titles should be prepared to handle this case.

If the browser window was created using **WebViewCreateWindow** or **WebViewCreateWindowEx** without a specific title, the application title will be automatically changed to reflect the current document title. This does not happen if the browser window is attached to an existing window or if an application title was specified when the window was created. If you wish to manually update a top-level window title with the current document title, call this function in response to a `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event and then call the **SetWindowText** function to change the text in the window's title bar.

If the current document does not have a title, this function will return zero and the last error code will be set to `NO_ERROR`. If the ***lpszTitle*** parameter is not NULL, it will be set to an empty string when the function returns. This is not uncommon if the **WebViewSetDocumentText** function is called to change the current document and the text does not contain HTML markup or does not include a `<title>` tag.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetDownloadInfo Function

```
BOOL WINAPI WebViewGetDownloadInfo(
   HWND hWndHost
   DWORD dwFileId,
   WEBVIEW_DOWNLOAD_INFO *lpInfo
);
```

The **WebViewGetDownloadInfo** function returns information about the status of the specified download.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwFileId

An unsigned integer value which uniquely identifies the download. This value cannot be zero.

lpInfo

A pointer to a `WEBVIEW_DOWNLOAD_INFO` structure which will contain information about the specified download when the function returns. The *dwSize* member of this structure must be initialized to the size of the structure prior to being passed to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function returns information about a specific download and is typically called in the context of a download event handler. The *dwFileId* parameter identifies the download to be queried. This identifier can be obtained either through download-related event notifications, where it is provided as the *lParam* value, or by calling the **WebViewEnumDownloads** function to enumerate active and completed downloads.

The file identifier should be treated as an opaque value. While it is guaranteed to be unique for the lifetime of the client session, the underlying implementation simply assigns sequential values. Applications must not depend on this behavior, as the specific numbering scheme may change in future versions. Because the identifiers are only unique within a single session, they cannot be used after the browser instance has been detached or destroyed. If you need to track downloads across sessions, you should use the file name or URL rather than the internal identifier.

Information is returned in the `WEBVIEW_DOWNLOAD_INFO` structure, which includes the download status, number of bytes copied, total size, elapsed time, file name, and the source URL. If the specified identifier does not correspond to a valid download, the function will fail.

If you are only interested in the name of the local file used for the specified download, you can use the **WebViewGetDownloadPath** function.

Example

```
// Get the total number of downloads
INT nTotal = WebViewEnumDownloads(hWndHost, 0, NULL, 0);

if (nTotal <= 0)
```

```
{
    _tprintf(_T("No downloads found.\n"));
    return;
}

// Allocate a buffer for the identifiers
DWORD *pIds = (DWORD*)malloc(nTotal * sizeof(DWORD));
if (!pIds)
    return;

INT nCount = WebViewEnumDownloads(hWndHost, 0, pIds, nTotal);

// Enumerate each download and print basic info
for (INT nIndex = 0; nIndex < nCount; nIndex++)
{
    WEBVIEW_DOWNLOAD_INFO fileInfo = { sizeof(fileInfo) };

    if (WebViewGetDownloadInfo(hWndHost, pIds[nIndex], &fileInfo))
    {
        _tprintf(_T("Download %u: %s (%llu/%llu bytes)\n"),
                 fileInfo.dwFileId,
                 fileInfo.szFileName,
                 fileInfo.uiBytesCopied.QuadPart,
                 fileInfo.uiBytesTotal.QuadPart);
    }
}

free(pIds);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetDownloadPath Function

```
INT WINAPI WebViewGetDownloadPath(
    HWND hWndHost,
    DWORD dwFileId,
    LPTSTR lpszFilePath,
    INT nMaxLength
);
```

The **WebViewGetDownloadPath** function returns the complete path of the local file for the specified download.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwFileId

An unsigned integer value which uniquely identifies the download. This value cannot be zero.

lpszFilePath

A null-terminated string buffer which will contain the full path to the local file. If this parameter is NULL, the file path is not copied but the function will return the length of the file path, not including the terminating null character. It is recommended that this buffer be large enough to store `MAX_PATH` (260) characters.

nMaxLength

An integer value which specifies the maximum number of characters which may be copied into the string buffer, including the terminating null. If the ***lpszFilePath*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the length of the local file name, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function returns the complete path to the file that will be created or overwritten during the download. The file path returned by this function is always an absolute path which ensures that the application does not need to resolve relative paths or expand environment variables. The path returned may refer to a file that has not yet been created or fully written if the download is still in progress. Applications should check the download status with **WebViewGetDownloadInfo** before assuming the file is complete and ready to use.

The ***dwFileId*** parameter uniquely identifies the download within the current client session. This identifier can be obtained from download-related event notifications or by calling **WebViewEnumDownloads**. As with other functions that use file identifiers, applications should treat this value as opaque and only valid for the lifetime of the session.

If the provided string buffer is too small, the function will return the required length of the file path, not including the terminating null character. The caller can use this information to allocate a sufficiently large buffer and call the function again. There are both ANSI and Unicode versions of this function and the correct version is called based on how the project is configured. If the **WebViewGetDownloadPathA** function is called, the file path will always be returned as a UTF-8

encoded string regardless of the current locale.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetErrorString Function

```
INT WINAPI WebViewGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **WebViewGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **WebViewGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetFilteredText Function

```
INT WINAPI WebViewGetFilteredText(
   HWND hWndHost,
   LPTSTR lpszFilteredText,
   INT nMaxLength
);
```

The **WebViewGetFilteredText** function filters HTML formatting from the current document and returns plain text in a string buffer.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszFilteredText

A null-terminated string buffer which will contain the filtered text. If this parameter is NULL and the *nMaxLength* parameter is zero, the function will return the number of characters required to store the filtered text, not including the terminating null character.

nMaxLength

The maximum number of characters which can be copied into the *lpszFilteredText* string buffer. If this value is zero, no characters will be copied to the buffer and the function will return the length of the filtered text, not including the terminating null character. This can be used to determine how much memory should be allocated for the string.

Return Value

If the function succeeds, it will return the number of characters copied into the string buffer, not including the terminating null character. If the *lpszFilteredText* parameter is NULL and *nMaxLength* is zero, the function will return the number of characters in the filtered text without copying any characters. If the function fails, or there is no text in the input buffer, the function will return zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetFilteredText** function filters the HTML markup from the document text and returns output suitable for display in text-only environments. HTML tags are removed and entities are converted to their canonical Unicode equivalent. When filtering markup from the text, the function will:

- Remove all leading and trailing whitespace from the text, including newlines.
- Remove script, style, and other non-visible or unsafe elements.
- Convert common tag structures, such as lists and headers, into readable plain text.
- Extract and filter hyperlinks and image alt text, ignoring internal links to other sections.
- Remove any embedded credentials in hyperlinks.
- Decode common HTML entities such as `&trade` and `&copy`, as well as numeric entities like `&#x20.`

The function will remove extraneous whitespace within the text, but will attempt to maintain the structure of ordered and unordered lists. It does not parse the style information or Javascript that may be included in the HTML content. If a paragraph uses a style that would normally prevent it from being rendered in a browser (e.g.: the visibility attribute set to "hidden"), it is ignored and the text will be included in the output. If there are sections which contain preformatted text, such as text inside

`<pre>...</pre>` or `<code>...</code>` tags, individual line and paragraph breaks will be preserved.

This function will not remove Unicode characters from the input text. If the HTML markup includes any entities which are represented as Unicode, such as `½` which represents "½", they will be returned in the output string buffer as Unicode characters. If the ANSI version of this function is called, Unicode will always be returned as UTF-8 encoded characters.

Example

```
INT nLength = WebViewGetFilteredText(hWndHost, NULL, 0);
if (nLength > 0)
{
    LPTSTR pszFiltered = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
    if (!pszFiltered )
    {
        // Virtual memory exhausted
        return;
    }

    nLength = WebViewGetFilteredText(hWndHost, pszFiltered, nLength + 1);
    if (nLength > 0)
    {
         // Write the plain text to standard output
        _putts(pszFiltered);
        _puttc(_T('\n'), stdout);
    }

    free(pszFiltered);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetFirstHeader Function

```
BOOL WINAPI WebViewGetFirstHeader(
    HWND hWndHost,
    LPTSTR lpszHeaderName,
    INT nMaxNameLen,
    LPTSTR lpszHeaderValue,
    INT nMaxValueLen
);
```

The **WebViewGetFirstHeader** function begins enumerating response headers and return the first name/value pair.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszHeaderName

A string buffer which will contain the name of the first header returned by the server. If this parameter is NULL it will be ignored.

nMaxNameLen

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderName* string buffer, including the terminating null. If the *lpszHeaderName* parameter is NULL this value should be zero.

lpszHeaderValue

A string buffer which will contain the value of the first header returned by the server. If this parameter is NULL, it will be ignored.

nMaxValueLen

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderValue* string buffer, including the terminating null. If the *lpszHeaderValue* parameter is NULL this value should be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The response headers exposed by this function correspond to the most recent completed navigation for the specified browser instance. Callers typically use this function to start an enumeration and then call **WebViewGetNextHeader** repeatedly until it returns FALSE to indicate there are no more headers to enumerate.

Header names are case-insensitive by definition. This function will usually return header names as lower-case values, but applications should never depend on the casing and should compare names case-insensitively. The header names and values are returned exactly as enumerated internally by the WebView2 control.

Some response headers can appear multiple times in a message. For list-valued headers (those defined by the HTTP specifications to be comma-joinable), the implementation may return a single entry with a comma-separated value (e.g., `Accept-Language`, `Cache-Control`, etc.). Other headers

must not be combined; for example, each **Set-Cookie** header is returned as a separate name/value pair and will be seen multiple times during enumeration, each with a single cookie value. Code that depends on specific headers should be prepared for either a single combined value or multiple discrete occurrences of the same header name, depending on the header's semantics.

Enumeration reflects a snapshot of the headers for that response. Beginning a new navigation or calling **WebViewClearHeaders** invalidates the current enumeration. Only one header enumeration can be active per browser instance at a time. The enumeration state is not thread-safe, and any access to the response headers should be synchronized across different threads.

If the provided buffers are too small, the header names and values will be truncated to the available space specified by the maximum length parameters. In most cases, a header name is not going to exceed 256 characters and a header value will normally not exceed 5120 characters. Most header values are relatively short, but some headers such as **Set-Cookie** can return much longer values.

This function cannot be called while the browser is in the process of navigating to a new location. It will also fail if the current document is a local file or if the document text was set dynamically using **WebViewSetDocumentText**. There are no response headers available in a local context.

Example

```
TCHAR szName[WEBVIEW_MAX_HEADER_NAME];
TCHAR szValue[WEBVIEW_MAX_HEADER_VALUE];

if (WebViewGetFirstHeader(hWndHost,
                          szName, _countof(szName),
                          szValue, _countof(szValue)))
{
    do
    {
        _tprintf(_T("%s: %s\n"), szName, szValue);
    }
    while (WebViewGetNextHeader(hWndHost,
                                szName, _countof(szName),
                                szValue, _countof(szValue)));
}
else
{
    DWORD dwError = WebViewGetLastError();
    _tprintf(_T("No headers available (error 0x%lx)\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetFocus Function

```
BOOL WINAPI WebViewGetFocus(
    HWND hWndHost,
    BOOL *lpbHasFocus
);
```

The **WebViewGetFocus** function returns whether the browser has focus.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpbHasFocus

A pointer to a BOOL which will contain TRUE (non-zero) if the browser window has focus and FALSE (zero) if it does not have focus. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetFocus** function queries whether the browser control currently has input focus. This is useful for determining if keyboard input will be directed to the content area of the browser or handled by the host window. The focus state can change dynamically as the user interacts with the application, and applications that track focus should also monitor the `WEBVIEW_EVENT_FOCUS_CHANGED` event.

This function only reports the focus state of the embedded browser, not of the host window itself. For example, a host window may be the active foreground window, but if another control within the host has focus, the browser will not be considered focused. To explicitly give focus to the browser, call **WebViewSetFocus**.

Example

```
BOOL bHasFocus = FALSE;

if (WebViewGetFocus(hWndHost, &bHasFocus))
{
    if (!bHasFocus)
    {
        // Give the browser control focus if it does not have it
        WebViewSetFocus(hWndHost);
    }
}
else
{
    // Handle error
    DWORD dwError = WebViewGetLastError();
    _tprintf(_T("WebViewGetFocus failed, error=0x%lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetHeader Function

```
INT WINAPI WebViewGetHeader(
   HWND hWndHost,
   LPCTSTR lpszHeaderName,
   LPCTSTR lpszHeaderValue,
   INT nMaxLength
);
```

The **WebViewGetHeader** function returns the value of a specific response header by name.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszHeaderName

A null-terminated string which specifies the response header name. This value is not case-sensitive but must match the complete header name. This parameter cannot be NULL.

lpszHeaderValue

A string buffer which will contain the value of the specified header. If this parameter is NULL then nothing will be copied but the function will return the length of the header value, not including the terminating null.

nMaxLength

The maximum number of characters which may be copied into the string buffer, including the terminating null. If the ***lpszHeaderValue*** parameter is NULL this value should be zero.

Return Value

If the function succeeds, the return value is the length of the header value, not including the terminating null. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetHeader** function retrieves the value of a specific HTTP response header returned by the server. Header names are matched in a case-insensitive manner, with leading and trailing whitespace automatically trimmed before comparison. If multiple values are present for the specified header name, the behavior depends on the type of header:

- For headers that must not be combined (such as `Set-Cookie` and `Proxy-Authenticate`), only the first value encountered is returned.
- For all other headers, multiple values are joined together and returned as a single comma-separated string, as defined by the HTTP specification.

For headers such as `Set-Cookie`, which may legitimately occur multiple times with distinct values, **WebViewGetHeader** will only return the first occurrence. If your application needs to process each value individually, you should use **WebViewGetFirstHeader** and **WebViewGetNextHeader** to enumerate all response headers rather than relying on this function.

If the ***lpszHeaderValue*** parameter is NULL, the function returns the number of characters required to store the complete header value, excluding the terminating null. This enables applications to dynamically allocate a buffer of the correct size before retrieving the actual value.

Response headers are only available after navigation has completed. Calling this function while a navigation is still in progress, or when displaying local file or data content, will fail.

The maximum recommended length for a header name is **WEBVIEW_MAX_HEADER_NAME** (256 characters) and for a header value is **WEBVIEW_MAX_HEADER_VALUE** (5120 characters). These limits are intended as practical guidelines, not absolute restrictions.

Example

```
 INT nLength = WebViewGetHeader(hWndWebView, _T("Content-Type"), NULL, 0);
if (nLength <= 0)
{
    _tprintf(TEXT("Unable to get Content-Type header (error 0x%lx)\n"),
WebViewGetLastError());
    return;
}

LPTSTR lpszValue = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
if (!lpszValue)
{
    _tprintf(_T("Out of memory\n"));
    return;
}

if (WebViewGetHeader(hWndWebView, _T("Content-Type"), lpszValue, nLength + 1) > 0)
{
    _tprintf(_T("Content-Type: %s\n"), lpszValue);
}
else
{
    _tprintf(_T("Failed to retrieve Content-Type (error 0x%lx)\n"),
WebViewGetLastError());
}

free(lpszValue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetHeaderCount Function

```
BOOL WINAPI WebViewGetHeaderCount(
    HWND hWndHost
    DWORD dwHeaderType,
    LONG *lpnCount
);
```

The **WebViewGetHeaderCount** function returns the number of headers defined for the specified header type.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwHeaderType

An unsigned integer which specifies the type of header being checked. It may be one of the following values.

Name	Description
WEBVIEW_HEADERS_REQUEST	The number of custom headers submitted with a request.
WEBVIEW_HEADERS_RESPONSE	The number of headers returned by the server.

lpnCount

A pointer to an integer which will contain the number of headers when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function can be used to determine the number of custom request headers which have been set, or the number of headers returned by the server in response to a navigation. To enumerate the available response headers, use the **WebViewGetFirstHeader** and **WebViewGetNextHeader** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetHttpStatus Function

```
INT WINAPI WebViewGetHttpStatus(
    HWND hWndHost
);
```

The **WebViewGetHttpStatus** function returns the HTTP status code from the last completed navigation.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is a non-zero status code. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function returns the HTTP status code from the server response associated with the last completed navigation. These codes are defined by the HTTP standard and indicate the outcome of the request:

- **100-199**: Informational responses indicating the request is in progress.
- **200-299**: Successful responses, with 200 (OK) being the most common.
- **300-399**: Redirects, such as 301 (Moved Permanently) or 302 (Found).
- **400-499**: Client errors, such as 403 (Forbidden) or 404 (Not Found).
- **500-599**: Server errors, such as 500 (Internal Server Error) or 503 (Service Unavailable).

It is important to note that this value is only meaningful once navigation has completed. During a series of redirects, the status code may change multiple times; the value returned will be from the final response that completed navigation. A return value of **0** indicates the HTTP status code is unavailable. It may also return zero when the browser has navigated to a local file or when HTML content has been supplied directly using the **WebViewSetDocumentText** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetInterface Function

```
BOOL WINAPI WebViewGetInterface(
   HWND hWndHost,
   UINT_PTR lpInterface
);
```

The **WebViewGetInterface** function returns a raw COM interface pointer to the WebView2 browser control.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpInterface

A pointer to the COM interface for the browser control.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetInterface** function returns the underlying **ICoreWebView2** COM interface pointer that is associated with the specified browser instance. This function is provided for advanced scenarios where direct access to the WebView2 SDK is required. Most applications will not need to call this function and should instead use the higher-level functions in this API.

If the function succeeds, the interface pointer is returned through the *lpInterface* parameter. The pointer is not reference-counted on return. If your code intends to use the **ICoreWebView2** interface directly, you *must* increment the reference count by calling `AddRef` before wrapping it in a smart pointer such as `ComPtr<ICoreWebView2>`. Failure to do so can result in undefined behavior if the browser instance is later detached or destroyed.

Because this function exposes the raw COM interface, any code that uses it must include the Microsoft.Web.WebView2 SDK headers and link against the appropriate libraries. This introduces a dependency on the WebView2 SDK that is not otherwise required when using this library.

In most cases, this function is only used to determine whether a browser instance has been attached to a host window, treating the returned `UINT_PTR` value as opaque. Developers who choose to interact with the **ICoreWebView2** interface directly should be familiar with COM programming practices, including reference counting and apartment threading rules.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

WebViewAttachWindow, WebViewCreateWindow, WebViewInitialize

WebViewGetLastError Function

```
DWORD WINAPI WebViewGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **WebViewGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **WebViewSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE or NULL. Those functions which call **WebViewSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetMessage Function

```
BOOL WINAPI WebViewGetMessage(
    HWND hWndHost.
    LPTSTR lpszMessage,
    INT nMaxLength
);
```

The **WebViewGetMessage** function retrieves the next pending message sent from the current document.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszMessage

A null-terminated string buffer which will contain the message sent from the current document. If this parameter is NULL, the message will not be copied and the function will return the length of the message, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the ***lpszMessage*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters in the message, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetMessage** function retrieves the most recent message sent from script code running in the browser. This is typically used to enable interaction between the web content displayed in the browser and the host application. For example, a page might use notify the application when a user completes a form, clicks a button, or when some script logic produces a result that the native application needs to act upon. This provides a simple and secure channel for exchanging data between the web page and the host, without requiring the page to reload or navigate to a new URL.

Messages are sent from JavaScript using the following method:

```
window.chrome.webview.postMessage(value);
```

When a script in the browser sends a message, the `WEBVIEW_EVENT_MESSAGE_RECEIVED` event will fire and your event handler should call this function to retrieve the value posted by the script. The `value` parameter can be any JSON-serializable object or a simple string. The format of the message depends on the type of value that was posted:

- If the message was a structured JavaScript object or array, it will be returned as a JSON object string using a format like `{"key":"value"}`.
- If the message was a string, it will be returned as a JSON-formatted string with surrounding quotes and any special characters escaped, such as `"Hello\nWorld"`.

Applications that need to process these messages should parse the result as JSON to properly distinguish between plain strings and structured data.

Important: Message passing is disabled by default. To enable this functionality, the browser must be created or attached with the `WEBVIEW_OPTION_ENABLE_MESSAGES` flag. If this option is not specified, no messages will be received and this function will not return any content.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetNavigationStatus Function

```
BOOL WINAPI WebViewGetNavigationStatus(
    HWND hWndHost
    LPDWORD lpdwFlags,
    LPDWORD lpdwError
);
```

The **WebViewGetNavigationStatus** function returns the current navigation state.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpdwFlags

A pointer to an unsigned integer which may contain one of more status bitflags. This parameter may be NULL if the status flags are not required.

Name	Description
WEBVIEW_NAVIGATION_REDIRECTED	The navigation was the result of an HTTP redirect.
WEBVIEW_NAVIGATION_USER_INITIATED	Navigation began from a user gesture rather than being initiated by a script.
WEBVIEW_NAVIGATION_LOCAL_DATA	Content was served using local data rather than a full network fetch.

lpdwError

A pointer to a unsigned integer which will contain one of the following error codes. This parameter may be NULL if the error code is not required.

Name	Description
WEBVIEW_ERROR_NONE	No error.
WEBVIEW_ERROR_CERTIFICATE_COMMON_NAME	Certificate common name mismatch.
WEBVIEW_ERROR_CERTIFICATE_EXPIRED	Certificate is expired.
WEBVIEW_ERROR_INVALID_CLIENT_CERTIFICATE	Invalid or untrusted client certificate.
WEBVIEW_ERROR_CERTIFICATE_REVOKED	Certificate has been revoked.
WEBVIEW_ERROR_INVALID_CERTIFICATE	Certificate is invalid for another reason.
WEBVIEW_ERROR_SERVER_UNREACHABLE	Cannot reach the server/host.
WEBVIEW_ERROR_TIMEOUT	Operation timed out.
WEBVIEW_ERROR_INVALID_SERVER_RESPONSE	Server returned an invalid or unexpected response.
WEBVIEW_ERROR_CONNECTION_ABORTED	Connection aborted by the

	server or network.
WEBVIEW_ERROR_CONNECTION_RESET	Connection was reset.
WEBVIEW_ERROR_DISCONNECTED	Disconnected during the operation.
WEBVIEW_ERROR_CANNOT_CONNECT	Failed to establish a connection.
WEBVIEW_ERROR_HOST_NAME_NOT_RESOLVED	DNS resolution failed for the host.
WEBVIEW_ERROR_OPERATION_CANCELED	Operation was canceled by the user or host.
WEBVIEW_ERROR_REDIRECT_FAILED	Redirection failed.
WEBVIEW_ERROR_UNEXPECTED_ERROR	An unexpected error occurred.
WEBVIEW_ERROR_CREDENTIALS_REQUIRED	Authentication credentials are required.
WEBVIEW_ERROR_PROXY_AUTHENTICATION_REQUIRED	Proxy authentication is required.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetNavigationStatus** function provides detailed information about the current state of navigation for the specified WebView instance. It can be used to determine if a navigation is still in progress, whether it completed successfully, or if it was canceled or failed due to an error condition. The status flags returned in ***lpdwFlags*** can be combined to indicate additional context about the navigation, such as whether it was initiated by the user, if the content was served from local data rather than fetched over the network, or if the navigation resulted from an HTTP redirect.

Developers may find this function most useful in the following situations:

- After handling a `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event, to check if the navigation was successful.
- Before retrying or redirecting a failed request, to determine the specific cause of failure.
- When logging diagnostic information about connectivity or certificate errors.
- To distinguish between user-initiated cancellation, network timeouts, or security errors.
- To detect when content was provided from local data rather than fetched remotely.

The error code returned in ***lpdwError*** provides additional detail when a navigation fails or is blocked. These values cover a wide range of conditions, including invalid or expired certificates, connectivity issues, unreachable hosts, proxy authentication failures, and other network-related problems. If ***lpdwError*** is `WEBVIEW_ERROR_NONE`, the most recent navigation completed without error.

When navigation involves local files or HTML provided directly to the browser via **WebViewSetDocumentText**, the function will typically return `WEBVIEW_ERROR_NONE` and may set `WEBVIEW_NAVIGATION_LOCAL_DATA` in the status flags. This allows the application to detect that the content was not fetched over the network.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetNavigationTime Function

```
BOOL WINAPI WebViewGetNavigationTime(
    HWND hWndHost,
    LPDWORD lpdwElapsed,
    LPBOOL lpbNavigating
);
```

The **WebViewFunctionName** function returns the elapsed time for the last navigation.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpdwElapsed

A pointer to an unsigned integer which will contain the number of milliseconds elapsed since the current navigation has started.

lpbNavigating

A pointer to an integer which is updated when the function returns. It will contain a non-zero value if the browser is in the process of navigating to a new location. If the browser has completed navigation or the last navigation was canceled, this value will be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetNavigationTime** function measures how long the most recent navigation has taken, reported in milliseconds. If a navigation is currently in progress, the elapsed time represents the duration since the navigation began. If the navigation has already completed, the elapsed time represents the total duration of that navigation. If no navigation has occurred, the elapsed time will be zero.

This function can be used for diagnostics, performance monitoring, or implementing application-level timeouts. For example, an application may track whether a page is taking unusually long to load and decide to cancel the navigation, notify the user, or retry the request. Combined with **WebViewGetNavigationStatus**, it provides a way to determine both the state and timing of navigation operations.

Typical usage scenarios for this function include:

- Measuring page load times for performance profiling or telemetry.
- Implementing a custom navigation timeout by checking the elapsed time in a periodic timer.
- Providing user feedback, such as displaying how long a page has been loading.
- Logging navigation duration along with success or failure status for diagnostic purposes.

The *lpbNavigating* parameter indicates whether a navigation is currently in progress when the function is called. This allows developers to distinguish between a completed navigation (where the elapsed time is final) and an in-progress navigation (where the elapsed time is still increasing).

It is important to note that the reported time is based on the browser's internal navigation start and completion timestamps. It reflects the overall duration of the navigation process as observed by the

browser, not fine-grained network-level timings such as DNS lookup, TCP connection, or TLS handshake. For most application scenarios this high-level timing is sufficient to evaluate page load performance and detect unusual delays.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetNextHeader Function

```
BOOL WINAPI WebViewGetNextHeader(
   HWND hWndHost,
   LPTSTR lpszHeaderName,
   INT nMaxNameLen,
   LPTSTR lpszHeaderValue,
   INT nMaxValueLen
);
```

The **WebViewGetNextHeader** function returns the next name/value pair in a response header enumeration.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszHeaderName

A string buffer which will contain the name of the first header returned by the server. If this parameter is NULL it will be ignored.

nMaxNameLen

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderName* string buffer, including the terminating null. If the *lpszHeaderName* parameter is NULL this value should be zero.

lpszHeaderValue

A string buffer which will contain the value of the first header returned by the server. If this parameter is NULL, it will be ignored.

nMaxValueLen

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderValue* string buffer, including the terminating null. If the *lpszHeaderValue* parameter is NULL this value should be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This function continues the enumeration that was started when the **WebViewGetFirstHeader** function was called. Repeatedly call **WebViewGetNextHeader** until it returns zero (FALSE) indicating there are no more header values to return. The **WebViewGetLastError** function can be used to distinguish between an actual error condition and the end of the enumeration. If the last error code is `ST_ERROR_END_OF_DATA` then all response headers have been enumerated.

If the provided buffers are too small, the header names and values will be truncated to the available space specified by the maximum length parameters. In most cases, a header name is not going to exceed 256 characters and a header value will normally not exceed 5120 characters. Most header values are relatively short, but some headers such as `Set-Cookie` can return much longer values.

This function cannot be called while the browser is in the process of navigating to a new location. It will also fail if the current document is a local file or if the document text was set dynamically using

WebViewSetDocumentText. There are no response headers available in a local context.

Example

```
TCHAR szName[WEBVIEW_MAX_HEADER_NAME];
TCHAR szValue[WEBVIEW_MAX_HEADER_VALUE];

if (WebViewGetFirstHeader(hWndHost,
                          szName, _countof(szName),
                          szValue, _countof(szValue)))
{
    do
    {
        _tprintf(_T("%s: %s\n"), szName, szValue);
    }
    while (WebViewGetNextHeader(hWndHost,
                                szName, _countof(szName),
                                szValue, _countof(szValue)));
}
else
{
    DWORD dwError = WebViewGetLastError();
    _tprintf(_T("No headers available (error 0x%lx)\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetOption Function

```
BOOL WINAPI WebViewGetOption(
    HWND hWndHost,
    DWORD dwOption
    LPBOOL lpbEnabled
);
```

The **WebViewGetOption** function checks whether a specific option flag is enabled.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwOption

An unsigned integer which specifies the option to be checked. Refer to the WebView Options documentation for the list of available options. Only a single option may be specified; you cannot combine multiple option bitflags when calling this function.

lpbEnabled

A pointer to an integer which will be updated when the function returns. If the value is non-zero, the option has been enabled. If the value is zero, the option has not been enabled.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetOption** function is used to determine if a specific option has been enabled for the browser instance associated with the specified host window. Each option corresponds to an individual feature or behavior that can be enabled or disabled at creation time or later using **WebViewSetOption**.

This function only supports checking a single option value at a time. The *dwOption* parameter must specify exactly one option bitflag, such as `WEBVIEW_OPTION_ENABLE_SCRIPTING` or `WEBVIEW_OPTION_ENABLE_CONTEXT_MENU`. It is not valid to combine multiple bitflags with a bitwise OR. If you need to retrieve the complete set of enabled options, call **WebViewGetAllOptions**.

Note that not all options may be applicable after a window has been created. Some options only take effect at creation time and cannot be changed dynamically. For example, options related to profile isolation or privacy modes must be specified before the control is initialized.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetResult Function

```
BOOL WINAPI WebViewGetResult(
    HWND hWndHost,
    LPTSTR lpszResult,
    INT nMaxLength
);
```

The **WebViewGetResult** function returns the result from the most recent completed script execution.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszResult

A null-terminated string buffer which will contain the result from the script that was previously executed. If this parameter is NULL, the result will not be copied and the function will return the length of the string, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the ***lpszResult*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters in the result string, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetResult** function retrieves the result of the most recent JavaScript expression executed in the browser using either the **WebViewAsyncExecute** or **WebViewExecute** functions. The result is provided as a JSON-formatted string, which may be either a quoted string with escaped characters or a JSON object, depending on the value returned by the script. Applications that expect structured data should parse the returned string using a JSON parser.

Only the result from the most recently executed script is retained. Executing another script will overwrite the previous result, even if the value has not yet been retrieved. If your application needs to preserve earlier results, it should copy the returned string into its own buffer for later use.

When using **WebViewAsyncExecute**, the result is available once the `WEBVIEW_EVENT_SCRIPT_COMPLETED` event has been raised. Attempting to call **WebViewGetResult** before the event is delivered will return an empty string. When using **WebViewExecute**, the script is executed synchronously and the result is immediately available.

The maximum length of the result string is limited by the size of the buffer provided. If the ***lpszResult*** parameter is NULL, the function will return the required length of the result string in characters, not including the terminating null, which can be used to allocate a buffer of the appropriate size.

Example

```
// Execute a simple script that returns a string
INT nLength = WebViewExecute(hWndHost, _T("document.title"), NULL, 0);

if (nLength > 0)
```

```
{
    // Allocate a buffer large enough to hold the result
    LPTSTR lpszResult = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
    if (lpszResult)
    {
        // Retrieve the result of the script execution
        if (WebViewGetResult(hWndHost, lpszResult, nLength + 1))
        {
            _tprintf(_T("Page title is: %s\n"), lpszResult);
        }
        free(lpszResult);
    }
}
else
{
    _tprintf(_T("Script execution failed\n"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebViewGetSecurityInfo Function

```
BOOL WINAPI WebViewGetSecurityInfo(
   HWND hWndHost,
   WEBVIEW_SECURITY_INFO *lpSecurityInfo
);
```

The **WebViewGetSecurityInfo** function returns certificate and host security details for the last navigation.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpSecurityInfo

A pointer to a `WEBVIEW_SECURITY_INFO` structure which will contain information about the specified download when the function returns. The ***dwSize*** member of this structure must be initialized to the size of the structure prior to being passed to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetSecurityInfo** function retrieves details about the security state of the current page and populates a `WEBVIEW_SECURITY_INFO` structure. This includes the negotiated TLS protocol, cipher suite, certificate subject and issuer, and the validity period of the certificate. The function also reports an overall security level (***dwLevel***) and condition-specific flags (***dwFlags***) that identify issues such as expired certificates, mixed content, or weak cryptographic algorithms.

The information returned reflects the most recent navigation state. During navigation, these structure values may be provisional. For example, a page may initially appear secure but later be downgraded to a warning state if mixed content is detected. Applications should consider the values as advisory until a `WEBVIEW_EVENT_NAVIGATION_COMPLETED` notification confirms the final state.

The security level (***dwLevel***) is intended for user interface decisions, such as whether to display a lock icon. The flags (***dwFlags***) provide more granular context and may include multiple indicators at once. For instance, a site may be considered secure overall but still include a `WEBVIEW_SECURITY_FLAG_CERT_EXPIRED` flag if the certificate is past its validity period. Because the browser can revise its assessment as resources are loaded, applications that display security indicators should refresh their state after navigation completes. Do not assume that an initially secure status will remain unchanged for the life of the page. Conditions such as mixed content or blocked subresources may alter the security level after the main document is retrieved.

For plain HTTP or local content, the ***szProtocol*** and ***szCipher*** members will be empty, ***dwFlags*** will typically include `WEBVIEW_SECURITY_FLAG_UNENCRYPTED`, and the security level will be `WEBVIEW_SECURITY_LEVEL_INSECURE` or `WEBVIEW_SECURITY_LEVEL_NEUTRAL`. For HTTPS with a valid certificate, the protocol and cipher suite are reported, the subject and issuer strings identify the certificate, and the security level will be `WEBVIEW_SECURITY_LEVEL_SECURE`.

The subject and issuer members are provided for display or logging purposes only; certificate parsing and validation are handled internally by the browser engine. Likewise, the validity dates (***ftValidFrom*** and ***ftValidTo***) are exposed for simple checks but do not require applications to perform their own

certificate validation.

Before calling this function, the ***dwSize*** member of the structure must be initialized to the size of the structure. This ensures compatibility with future versions of the library if additional fields are introduced. If the size does not match, the function will fail or only initialize the subset of fields it recognizes.

Both ANSI (A) and Unicode (W) variants are available. When compiling with UNICODE defined, string members are UTF-16 encoded; otherwise, they are UTF-8 encoded. The **WebViewGetSecurityInfo** macro resolves to the appropriate version based on the project's character set.

If you are only interested in determining the current security level of the connection you can use the **WebViewGetSecurityLevel** function.

Example

```
// Map security level to text
static LPCTSTR SecLevelToText(DWORD level)
{
    switch (level)
    {
    case WEBVIEW_SECURITY_LEVEL_SECURE: return _T("SECURE");
    case WEBVIEW_SECURITY_LEVEL_WARNING: return _T("WARNING");
    case WEBVIEW_SECURITY_LEVEL_INSECURE: return _T("INSECURE");
    case WEBVIEW_SECURITY_LEVEL_NEUTRAL: return _T("NEUTRAL");
    default: return _T("UNKNOWN");
    }
}

// Print a FILETIME value as YYYY-MM-DD HH:MM:SS
static void PrintFileTime(LPCTSTR label, const FILETIME* pft)
{
    if (!pft || (pft->dwLowDateTime == 0 && pft->dwHighDateTime == 0))
    {
        _tprintf(_T("%s: (not available)\n"), label);
        return;
    }

    FILETIME lft = {0};
    SYSTEMTIME st = {0};

    if (FileTimeToLocalFileTime(pft, &lft) && FileTimeToSystemTime(&lft, &st))
    {
        _tprintf(_T("%s: %04u-%02u-%02u %02u:%02u:%02u\n"),
                 label,
                 (unsigned)st.wYear,
                 (unsigned)st.wMonth,
                 (unsigned)st.wDay,
                 (unsigned)st.wHour,
                 (unsigned)st.wMinute,
                 (unsigned)st.wSecond);
    }
    else
    {
        _tprintf(_T("%s: (conversion failed)\n"), label);
    }
}

// Build and print a readable flag list
```

```
static void PrintSecurityFlags(DWORD dwFlags)
{
    if (dwFlags == WEBVIEW_SECURITY_FLAG_NONE)
    {
        _tprintf(_T("Flags: NONE (0x%08lX)\n"), dwFlags);
        return;
    }

    _tprintf(_T("Flags: 0x%08lX"), dwFlags);

WebViewGetSecurityLevel Function

```
BOOL WINAPI WebViewGetSecurityLevel(
    HWND hWndHost,
    LPDWORD lpdwLevel
);
```

The **WebViewGetSecurityLevel** function returns the evaluated security level for the last navigation.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpdwLevel

A pointer to an unsigned integer which will contain the security level when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetSecurityLevel** function provides a simplified way to obtain the current security state of the page displayed in the browser. This value is an overall assessment of the page's security status and is primarily intended for use in user interface logic, such as whether to display a lock icon or warning indicator. The security level does not provide detailed diagnostic information; if your application requires additional context such as certificate details, protocol version, or specific security flags, you should call **WebViewGetSecurityInfo** instead.

The possible values returned in the ***lpdwLevel*** parameter correspond to the security level constants:

- `WEBVIEW_SECURITY_LEVEL_UNKNOWN`: The security state could not be determined.
- `WEBVIEW_SECURITY_LEVEL_INSECURE`: The page was retrieved over plain HTTP or the certificate is invalid.
- `WEBVIEW_SECURITY_LEVEL_WARNING`: The page uses weak encryption or contains mixed content.
- `WEBVIEW_SECURITY_LEVEL_NEUTRAL`: Local content or the browser is in a transitional state.
- `WEBVIEW_SECURITY_LEVEL_SECURE`: The page was retrieved using HTTPS with a valid certificate.

Because the browser engine may revise the security assessment as additional resources are loaded, the level can change over the course of a navigation. For example, a page may initially appear secure, but once mixed content is detected the level will be downgraded to `WEBVIEW_SECURITY_LEVEL_WARNING.` Applications should refresh their indicators when they receive a `WEBVIEW_EVENT_SECURITY_CHANGED` notification or after navigation has completed.

The level values are ordered, with higher values indicating stronger security. Applications should avoid upgrading an observed level within the same navigation, since subsequent checks may legitimately lower the assessment.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGetTimeout Function

```
INT WINAPI WebViewGetTimeout(
    HWND hWndHost
);
```

The **WebViewGetTimeout** function returns the number of seconds the client will wait for the navigation to complete.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. A value of zero specifies no timeout period has been specified.

Remarks

The **WebViewGetTimeout** function retrieves the current navigation timeout value, expressed in seconds. This value determines how long the library will wait for a navigation request to complete before it is considered to have failed due to a timeout condition.

If the timeout value is set to zero, the control uses the built-in timeouts defined by the underlying WebView2 browser engine. These internal timeouts are adaptive and depend on network conditions, DNS resolution, and connection establishment. In practice, this allows the browser to determine how long to wait before treating a navigation as unresponsive. For most applications, leaving the timeout set to zero provides behavior consistent with the Microsoft Edge browser.

If a non-zero timeout value has been set, navigation will be canceled if the specified number of seconds elapses without the page load completing. This provides a deterministic limit on how long a navigation attempt is allowed to continue before the operation fails. However, specifying a very long timeout value does not guarantee that navigation will continue for that entire duration, since the WebView2 engine may still enforce its own internal limits and terminate the request earlier.

Requirements

WebViewGetUserAgent Function

```
BOOL WINAPI WebViewGetUserAgent(
    HWND hWndHost,
    LPTSTR lpszUserAgent,
    INT nMaxLength,
);
```

The **WebViewGetUserAgent** function returns the current User-Agent value for this instance.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszUserAgent

A null-terminated string buffer which will contain the User-Agent string for the current session. If this parameter is NULL, the string will not be copied and the function will return the length of the string, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the *lpszUserAgent* parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters in the User-Agent string, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetUserAgent** function retrieves the current User-Agent string used by this browser instance. This value is the exact string sent in the User-Agent header of outgoing HTTP requests and is determined by the underlying Microsoft Edge WebView2 runtime unless explicitly changed with **WebViewSetUserAgent**. The returned value can be used for informational purposes, such as logging the client identity or displaying diagnostic information to the user. It is also useful if your application needs to preserve the default User-Agent string before setting a custom one.

If the *lpszUserAgent* parameter is `NULL`, the function returns the length of the string in characters. This allows the caller to allocate a buffer of the appropriate size before retrieving the value. When a valid buffer is provided, the string copied to it will always be null-terminated.

The User-Agent value applies to the entire lifetime of the browser instance. Once it has been changed, all subsequent navigations will use the new string until explicitly reset or the instance is destroyed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebViewGetUserDataFolder Function

```
INT WINAPI WebViewGetUserDataFolder(
    HWND hWndHost,
    LPTSTR lpszDataFolder,
    INT nMaxLength,
);
```

The **WebViewGetUserDataFolder** function returns the full path to the user data folder for the current session.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszDataFolder

A null-terminated string buffer which will contain the path to user data folder for the session. If this parameter is NULL, the string will not be copied and the function will return the length of the path, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the ***lpszDataFolder*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters in the User-Agent string, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **User Data Folder** (UDF) is the WebView2 profile directory that Chromium uses to persist browsing state for this instance. It contains the browser cache, cookies, localStorage/IndexedDB data, service worker state, visited link history, site permissions, and other profile data. Each ***distinct*** folder path corresponds to a distinct browser profile. Multiple WebView2 instances that point to the same folder will share the same profile (and therefore share cookies, storage, and authentication state). Using different folder paths isolates profiles.

The user data folder is chosen when the WebView instance is created or attached via **WebViewAttachWindowEx** or **WebViewCreateWindowEx** and cannot be changed afterwards. If your application needs to switch profiles (for example, to use a different folder), you must destroy the current instance and create a new one with the desired folder.

If your application does not specify a folder or uses an empty string as the folder path, the library creates a unique per-session folder under the current user's local profile. This is an ***ephemeral profile*** that is not intended to be reused across browser instances. By default, this temporary folder is removed when the instance is detached; if the process terminates unexpectedly, the folder may remain and can be safely deleted later.

In contrast, specifying an explicit, persistent folder (for example, a subdirectory under `%LocalAppData%\WebView\YourApp`) gives you a shared profile that persists across sessions and can be reused by multiple WebView2 instances to enable single sign-on, shared cookies, and faster subsequent navigations due to caching. Use this approach when you want consistent, long-lived browser state.

The reported folder path is always an absolute, normalized local path. Environment variables in the path you supply at creation time are expanded; forward slashes are normalized to backslashes and relative names are resolved beneath the current user's local application data folder. The library rejects invalid or unsafe locations (e.g.: device names, system directories, UNC or extended path prefixes, or root drive targets) and will create intermediate directories as needed for valid paths. For multithreaded applications, you should use explicit absolute paths rather than relying on the process current directory.

Important: The user data folder is managed internally by the the WebView2 runtime, and your application should never attempt to modify, move, or delete any of the files it contains while a browser instance is active. The contents are in use by the rendering engine and interfering with them can result in data corruption or unexpected behavior. If you need to remove or relocate a profile, ensure that all browser instances using that folder have been completely closed. If you want to delete certain data, such as cookies or the browser history, use the functions provided specifically for that purpose.

You can call **WebViewGetUserDataFolder** at any time after the instance has been created to discover which profile directory is in use. Passing ***lpszDataFolder*** as `NULL` returns the required buffer length so you can allocate a buffer of the appropriate size; the returned length does not include the terminating null character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewGetZoomLevel Function

```
BOOL WINAPI WebViewGetZoomLevel(
    HWND hWndHost,
    INT *lpnPercent
);
```

The **WebViewGetZoomLevel** function return the current zoom level as a percentage.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpnPercent

A pointer to an integer which will contain the current zoom level as a percentage value when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGetZoomLevel** function returns the current zoom level of the browser window as an integer percentage value. A zoom level of **100** indicates that the page is being displayed at its normal size without any scaling applied. Values greater than **100** mean that the content is being magnified, and values less than **100** mean that the content is being reduced.

The zoom level is constrained by the limits defined for the control. By default, the minimum zoom level is **25** (25%) and the maximum zoom level is **400** (400%). Attempts to set values outside of this range using **WebViewSetZoomLevel** will be clamped to the supported range.

This function can be used to determine the current scaling when an application wants to preserve a user's preferred zoom level across sessions, or to query whether the content is being displayed at the default size. If the function fails, the contents of the ***lpnPercent*** parameter are undefined and should not be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebViewGoBack Function

```
BOOL WINAPI WebViewGoBack(
    HWND hWndHost
);
```

The **WebViewGoBack** function navigates backwards through the browser history.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGoBack** function navigates the browser to the previous page in its session history, if one is available. This is equivalent to selecting the Back button in a standard web browser. If there is no previous entry in the history list, the function will succeed but no navigation will occur. The availability of backward navigation can be determined by handling the `WEBVIEW_EVENT_HISTORY_CHANGED` event and checking for the `WEBVIEW_MOVE_BACKWARD_ENABLED` flag.

Calling **WebViewClearHistory** will remove the session history for the browser instance. After the history has been cleared, calling **WebViewGoBack** will have no effect until new pages have been visited.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewGoForward Function

```
BOOL WINAPI WebViewGoForward(
    HWND hWndHost
);
```

The **WebViewGoForward** function navigates forwards through the browser history.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewGoForward** function navigates the browser to the next page in its session history, if one is available. This is equivalent to selecting the Forward button in a standard web browser.

If there is no forward entry in the history list, the function will succeed but no navigation will occur. The availability of forward navigation can be determined by handling the `WEBVIEW_EVENT_HISTORY_CHANGED` event and checking for the `WEBVIEW_MOVE_FORWARD_ENABLED` flag.

Calling **WebViewClearHistory** will remove the session history for the browser instance. After the history has been cleared, calling **WebViewGoForward** will have no effect until new pages have been visited.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewInEvent Function

```
BOOL WINAPI WebViewInEvent();
```

The **WebViewInEvent** function determines if the current thread is executing code within an event handler.

Parameters

None.

Return Value

If the current thread is executing code within the context of an event handler, the return value is non-zero; otherwise the return value is zero.

Remarks

The **WebViewInEvent** function checks a thread-local flag that is set whenever your code is executing inside an event handler. This allows an application to determine if the current call stack is the result of an event callback (for example, a navigation completed event or a message received event) rather than code executing on its own.

Knowing whether you are inside a event handler can be useful for several reasons:

- **Reentrancy detection**. Certain API functions should not be called while an event is still being processed, since this can cause re-entrant behavior or unexpected state changes in the underlying WebView2 control. For example, it is not permitted to attempt another navigation or reset the browser state while inside a navigation event handler.
- **Thread marshalling**. Event handlers are typically invoked on the UI thread associated with the WebView instance. By checking this function, the application can decide whether it needs to marshal an operation to the browser's thread or whether it is already executing in the correct context.
- **Application logic**. In some cases you may want to avoid triggering further navigation, script execution, or message posting in direct response to a particular event. This function lets you distinguish between code running in an event handler versus code running elsewhere in your application.

The return value from this function is only valid for the calling thread. Each thread maintains its own state, so a worker thread will always return FALSE unless it is actively executing a event callback on that thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewInitialize Function

```
BOOL WINAPI WebViewInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **WebViewInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **WebViewInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **WebViewUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **WebViewInitialize** or **WebViewUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

The calling thread must be in a single-threaded apartment (STA). During initialization the library calls **CoInitializeEx** as needed and if your process has already initialized COM as MTA (`COINIT_MULTITHREADED`), initialization will fail. This requirement comes directly from the Edge WebView2 control which cannot be created in an MTA COM application.

Before calling this function, applications may optionally call **WebViewRuntimeAvailable** to determine if the Microsoft Edge WebView2 runtime is installed and meets the minimum required version. This can be useful during application startup to provide a clear error message or guidance to the user if the runtime is missing or out of date, rather than attempting to initialize the control and handling the

failure afterward.

On modern versions of Windows, the WebView2 runtime is included as part of the operating system and is serviced through Windows Update. However, on older or unsupported versions of Windows the runtime may not be present by default and must be installed separately. In these cases, your application needs to detect the missing runtime and prompt the user to install it.

The latest WebView2 runtime version officially supported on Windows 7 and Windows 8/8.1 is version 109.0.1518.140, released January 2023. After version 109, no further updates, new features, or fixes have been provided for those operating systems. Although this library supports Windows 7 and Windows 8, these platforms are not recommended because they no longer receive security updates for the browser.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewIsVisible Function

```
BOOL WINAPI WebViewIsVisible(
    HWND hWndHost
);
```

The **WebViewIsVisible** function determines if the browser window is currently visible.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the browser window is visible, the return value is non-zero. If the window is not visible or has been closed, the return value is zero.

Remarks

The **WebViewIsVisible** function checks whether the browser window is currently visible. A return value of **TRUE** means that the browser window is being displayed. A return value of **FALSE** indicates that the window has been hidden using the **WebViewShowWindow** function or the window was closed.

This function only reports on the visibility state that was explicitly set through the API. It does not reflect other factors that might affect whether the browser content is actually visible to the user, such as the host window being minimized, overlapped by another window, or located off screen.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewKeyEventHandled Function

```
BOOL WINAPI WebViewKeyEventHandled(
    HWND hWndHost,
    BOOL bHandled
);
```

The **WebViewKeyEventHandled** function sets an accelerator key event as handled.

Parameters

hWndHost

Handle to the window attached to the browser session.

bHandled

An integer which specifies if the accelerator key event was handled by the application. A non-zero value indicates the application has handled the accelerator key event and the WebView2 control should not process the event. A value of zero specifies that the browser should handle the accelerator key using it's normal, default behavior.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewKeyEventHandled** function is used in conjunction with the **WebViewEventProc** callback when the application receives a `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS` event. By calling this function and specifying that the key event has been handled, the application can prevent the browser from processing the key itself.

This mechanism is useful when you want to disable or override the default behavior of certain keys within the embedded browser. For example, you may wish to prevent the user from pressing **F12** to open the developer tools, block function keys that have meaning in your application, or intercept combinations such as **Ctrl+P** or **Ctrl+S** to substitute your own print or save functionality.

If *bHandled* is non-zero, the event is considered handled by the host application and WebView2 will not process the key. If *bHandled* is zero, the key is passed through and processed normally according to the browser's default behavior. This function should typically be called during the event handler for `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS`.

Note that this function only affects accelerator key events when the `WEBVIEW_OPTION_ENABLE_ACCELERATORS` option has been specified when creating or attaching the WebView. It does not apply to ordinary text input within form fields or content editable regions in the page.

Example

```
VOID CALLBACK EventHandler(HWND hWndHost, UINT uEvent, WPARAM wParam, LPARAM
lParam, DWORD_PTR dwParam)
{
    if (uEvent == WEBVIEW_EVENT_ACCELERATOR_KEYPRESS)
    {
        // wParam contains flags (WEBVIEW_ACCELERATOR_KEY_DOWN/UP/SYSTEM)
        // lParam contains the virtual-key code
        UINT vkCode = (UINT)lParam;
```

```
        if (vkCode == VK_F3) // Intercept the F3 key
        {
            // Mark the event as handled so WebView2 won't process it
            WebViewKeyEventHandled(hWndHost, TRUE);
            return;
        }
    }

    // Other events can be handled here as needed
}
```

Requirements

WebViewNavigateUrl Function

```
BOOL WINAPI WebViewNavigateUrl(
    HWND hWndHost
    DWORD dwFlags,
    LPCTSTR lpszUrl
);
```

The **WebViewNavigateUrl** function navigates to the specified URL or local file path.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwFlags

An unsigned integer which specifies additional options for how the navigation will be performed.

Value	Description
WEBVIEW_NAVIGATE_DEFAULT	Use the default navigation behavior. The specified URL or local file path is normalized and used without additional restrictions.
WEBVIEW_NAVIGATE_SAFE_URL	Perform additional safety checks on the input before navigation. This will reject unsafe or malformed URLs, filter out potentially harmful schemes, and block traversal sequences (such as `../../`) in local paths. This option is recommended when the URL or path is provided by external or untrusted input.

lpszUrl

A null-terminated string which specifies the URL or local file to navigate to. Any leading and trailing whitespace will be removed and the URL will be normalized to ensure that it specifies a valid location. If the URL only specifies a domain name (such as `"example.com"`) the browser will default to using a secure connection. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewNavigateUrl** function accepts both standard web URLs such as `https://www.example.com/` and local file paths which are automatically normalized and converted into `file://` URLs. This allows an application to load either remote web content or content from the local filesystem.

When a local file path is specified, the function validates the path to ensure that it refers to a valid, absolute file system location and is not under restricted system folders (such as the Windows or Program Files directories). Relative paths are resolved against the current working directory, but it is recommended that applications provide absolute paths to avoid ambiguity in multithreaded or service-hosted environments.

File names and paths are normalized before navigation. Illegal or reserved device names (such as `CON`,

AUX, or **NUL**) and paths containing invalid characters will be rejected. UNC paths and extended-length paths using the **\\?** prefix are not supported. If the path points to a valid file, it will be loaded into the WebView using the appropriate **file://** URL form.

If the *dwFlags* parameter specifies **WEBVIEW_NAVIGATE_SAFE_URL**, the URL or path will undergo additional checks to ensure that it does not contain unsafe schemes, fragments, or traversal sequences. This is useful when the application accepts untrusted input that may be used for navigation.

Note that navigation to local files is supported, but applications should exercise caution when mixing remote and local content, as this may have cross-origin security implications. If your application needs to load dynamic HTML content, consider using **WebViewSetDocumentText** instead.

This function only supports navigation to standard web and local resources. Valid URL schemes are limited to **http://**, **https://**, **file://**, and **about:blank**. Other protocols or custom application schemes are not supported and will cause the function to fail. This includes the **edge://settings/profile** page or any other internal configuration settings for the Edge browser. If your application needs to handle such protocols, you should implement a custom handler to intercept those links and handle them externally.

Requirements

WebViewNormalizeUrl Function

```
INT WINAPI WebViewNormalizeUrl(
   LPCTSTR lpszUrl,
   DWORD dwFlags,
   LPTSTR lpszNormalized,
   INT nMaxLength
);
```

The **WebViewNormalizeUrl** function parses and normalizes a URL into a safe, navigable form.

Parameters

lpszUrl

A null-terminated string which specifies the URL to be normalized. This parameter cannot be NULL or an empty string.

dwFlags

Specifies one or more bit flags that control how the URL is normalized. A value of zero specifies that only standard normalization will be performed, such as removing any leading and trailing whitespace and ensuring the URL does not contain any illegal characters. Multiple flags may be combined using a bitwise or operator.

Value	Description
URL_FLAG_DEFAULT_HTTPS	When no URL scheme is provided and no scheme is otherwise required, select `https://` by default. If an explicit port is present, port 443 selects `https` and any other port selects `http`. Explicit input schemes are preserved.
URL_FLAG_REQUIRE_HTTP	When no scheme is provided, force `http://`. If the input already specifies a scheme, it is preserved.
URL_FLAG_REQUIRE_HTTPS	When no scheme is provided, force `https://`. If the input already specifies a scheme, it is preserved.
URL_FLAG_REJECT_LOCALHOST	Reject URLs that specify `localhost` as the host name.
URL_FLAG_REJECT_IPV4	Reject URLs that specify a numeric IPv4 address (for example, `192.0.2.1`) as the host.
URL_FLAG_REJECT_IPV6	Reject URLs that specify a bracketed IPv6 address (for example, `[2001:db8::1]`) as the host.
URL_FLAG_ASCII_HOSTNAME	Host names are checked to ensure that they only contain legal ASCII characters. Unicode host names are converted to ASCII (punycode) before validation, and the host name is normalized to lowercase.
URL_FLAG_ESCAPE_PATH	Percent-encode the path component as needed. Non-ASCII characters are encoded as UTF-8 and then percent-encoded per byte. Valid `%HH` sequences are preserved and upper-cased. The path is also normalized by removing duplicate slashes and collapsing `.` and `..` segments of the path.
URL_FLAG_ESCAPE_QUERY	Percent-encode the query and fragment tail as needed. The first `?` is treated as the start of the tail and characters commonly

	used in queries (such as **&**, **=**, **+**, **;**, **#**) are permitted unescaped. Non-ASCII characters are encoded as UTF-8 and then percent-encoded.
URL_FLAG_VALIDATE_UTF8	Applicable to projects using a multi-byte character set. Require the URL to use UTF-8 encoding and fail if the function encounters an invalid Unicode character. When this flag is not specified, and the URL does not use UTF-8 encoding, the function attempts to normalize the URL using the active code page.
URL_FLAG_REJECT_LOCAL_FILES	Reject absolute local and UNC paths and existing **file://** URLs. When specified, UNC paths are also rejected and unsafe file extensions are not allowed.
URL_FLAG_REJECT_UNC_PATHS	When local file normalization is permitted, reject UNC paths (for example, **\\server\share**). Files paths which use a mapped drive to a network share will be allowed.
URL_FLAG_ALLOW_UNSAFE_FILES	When converting local/UNC paths to **file://** URLs or normalizing existing **file://** URLs, permit any file extension. If this option is not specified, only a common set of safe, renderable file types are allowed. This includes HTML files, text files and common image formats.

lpszNormalized

A null-terminated string buffer which will contain the normalized URL when the function returns. This parameter may be NULL, in which case the function returns the number of characters required to store the normalized URL. If a buffer is provided, it must be large enough to contain the entire URL.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null character. If this parameter is zero, the function will return the number of characters required to store the normalized URL and no characters will be copied into the buffer.

Return Value

An integer which specifies the length of the normalized URL, not including the terminating null character. A return value of zero indicates the URL could not be normalized, either due to an invalid URL or the output buffer not being large enough to store the complete URL. Call the **WebViewGetLastError** function for more information about the cause of the failure.

Remarks

The **WebViewNormalizeUrl** function parses and normalizes a candidate URL without navigating. In most cases you do not need to call this function directly because **WebViewNavigateUrl** already performs basic normalization internally before it passes the URL to the browser. Use **WebViewNormalizeUrl** when you want to enforce additional policy restrictions with the option flags, or notify users of clear validation failures before attempting navigation.

Normalization includes, depending on the flags you choose:

- Scheme defaults and enforcement. If the input omits a scheme, you can default to HTTPS (**URL_FLAG_DEFAULT_HTTPS**) or require http:// or https:// explicitly using

`URL_FLAG_REQUIRE_HTTP` or `URL_FLAG_REQUIRE_HTTPS`. If the normalizer cannot accept the scheme under your selected policy, the call fails. The same default behavior is applied with **WebViewNavigateUrl**.

- Hostname policy. You may reject localhost, numeric IPv4, or bracketed IPv6 literals, or enforce ASCII hostnames (Unicode hostnames are converted to Punycode and lower-cased). The host parsing also ensures the input isn't a Windows path accidentally pasted in place of a URL.
- Path and query normalization. Paths may be percent-encoded as needed, duplicate slashes removed, and path traversal segments are collapsed; queries and fragments may be percent-encoded while preserving common query delimiters.
- Local file handling. Absolute local and UNC paths or existing file:// URLs can be converted to a normalized file:// form unless you explicitly reject them with `URL_FLAG_REJECT_LOCAL_FILES` (and optionally the `URL_FLAG_REJECT_UNC_PATHS` option). If you intend to only permit web content, enable these reject flags. At navigation time the library also tracks whether the target is a local file.
- If your project uses the multi-byte character set instead of Unicode, and `URL_FLAG_VALIDATE_UTF8` is specified, the function will fail if the URL contains any invalid UTF-8 encoding. Without this flag, if the function detects invalid UTF-8 characters, it will attempt to validate the URL using the active code page. It is recommended that applications use UTF-8 or UTF-16 Unicode whenever possible.

This function validates and normalizes URLs but does not expand redirects, verify server reachability, or fetch headers. Use it to block undesired inputs before navigation (such as disallowing bare IPs or local files), or to present a user-friendly, fully qualified URL.

Example

```
// Match the safe normalization options and forbid local files
DWORD dwNormFlags =
    URL_FLAG_DEFAULT_HTTPS |
    URL_FLAG_ASCII_HOSTNAME |
    URL_FLAG_ESCAPE_PATH |
    URL_FLAG_ESCAPE_QUERY |
    URL_FLAG_REJECT_LOCAL_FILES |
    URL_FLAG_REJECT_UNC_PATHS;

// If normalization or navigation fails, save the last error code
DWORD dwError = NO_ERROR;

// Check how long the normalized URL will be
INT nLength = WebViewNormalizeUrl(pszUserInput, dwNormFlags, NULL, 0);
if (nLength <= 0)
    dwError = WebViewGetLastError();

if (dwError == NO_ERROR)
{
    // Allocate buffer and normalize again
    LPTSTR pszNormalizedUrl = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));

    if (!pszNormalizedUrl)
         return; // Failed; virtual memory exhausted

    nLength = WebViewNormalizeUrl(pszUserInput, dwNormFlags, pszNormalizedUrl,
nLength + 1);
```

```
    if (nLength <= 0)
    {
        dwError = WebViewGetLastError();
    }
    else
    {
        // Navigate using the normalized URL
        if (!WebViewNavigateUrl(hWeb, WEBVIEW_NAVIGATE_DEFAULT, pszNormalizedUrl))
            dwError = WebViewGetLastError();
    }

    free(pszNormalizedUrl);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewPostMessage Function

```
BOOL WINAPI WebViewPostMessage (
    HWND hWndHost,
    LPCTSTR lpszMessage
);
```

The **WebViewPostMessage** function posts a string or JSON message to the current page.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszMessage

A null-terminated string which contains the message to be sent to the current page. This parameter cannot be NULL or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewPostMessage** function sends a message from the host application to the currently loaded page using the WebView2 messaging channel. The call is asynchronous: if it is invoked from a thread other than the thread that created the browser instance, the function marshals the request to the UI thread and returns immediately, with delivery performed later on that thread. Internally, this posts a private window message to the host window; when handled, it forwards the text using the `ICoreWebView2::PostWebMessageAsString` method.

For a page to receive messages from the host, web messaging must be enabled. When the `WEBVIEW_OPTION_ENABLE_MESSAGES` option is set, the wrapper enables web messages in the control settings (exposing `window.chrome.webview` to the script) and wires the corresponding message events. If this option is not enabled, the page will not see the messaging object and cannot receive messages.

On the JavaScript side, the page subscribes to messages using the standard listener pattern. Messages posted with this function are delivered as strings to the page's handler:

```
window.chrome.webview.addEventListener('message', (event) => {
 // event.data is the string posted by WebViewPostMessage
 const text = event.data;
 // If you know the string is JSON, you can parse it explicitly
 // const obj = JSON.parse(text);
});
```

Because delivery is asynchronous, there is no built-in acknowledgement and ordering is not guaranteed across navigations. If the page navigates or reloads after you call **WebViewPostMessage**, a listener registered on the previous document will not receive later messages.

Messages are Unicode strings and you should avoid sending very large payloads. For large data transfers, consider using application-level protocols rather than embedding large content in a single message. This function is primarily intended to enable your host application to notify the web page the user has taken some action which should be reflected in the browser. The web page can send

messages back to your application using `window.chrome.webview.postMessage(value)` and you can receive those messages using the **WebViewGetMessage** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewPrintDocument Function

```
BOOL WINAPI WebViewPrintDocument(
    HWND hWndHost,
    DWORD dwOptions
);
```

The **WebViewPrintDocument** function displays the browser print dialog for the current document.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwOptions

An unsigned integer which specifies how the print dialog should be displayed.

Value	Description
WEBVIEW_PRINT_DIALOG_DEFAULT	Use Edge's print preview dialog, equivalent to the **Ctrl+P** experience. This dialog provides preview capabilities and additional print options.
WEBVIEW_PRINT_DIALOG_SYSTEM	Use the native system print dialog. This dialog allows the user to select a printer and set standard options, but does not provide a preview of the document.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewPrintDocument** function displays the print dialog for the currently loaded document. The dialog is shown asynchronously and the function will return once the print user interface has been invoked. This function does not perform the printing operation itself; it only initiates the print workflow and allows the user to select a printer, adjust preferences, and confirm printing.

This function can only be called after navigation has completed and the current document is fully loaded. If navigation is still in progress when the function is called, it will fail with an error indicating that the operation is in progress. This function only supports interactive printing through a user interface. If you need to programmatically export the document without user interaction, use the **WebViewSaveDocument** function instead.

It is recommended that most applications use the default dialog. The `WEBVIEW_PRINT_DIALOG_SYSTEM` option shows a simplified print dialog provided by browser. This is not the same dialog exposed by the Windows Common Controls API through the **PrintDlg** or **PrintDlgEx** functions, and it may differ in appearance and available options depending on the platform and version of the WebView2 runtime.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewRedrawWindow Function

```
BOOL WINAPI WebViewRedrawWindow(
    HWND hWndHost
);
```

The **WebViewRedrawWindow** function forces the host window and browser control to redraw.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewRedrawWindow** function reloads the current document and forces both the host window and the embedded WebView2 child window to repaint themselves. This differs from **WebViewReloadDocument**, which simply reloads the page (similar to pressing **F5**) but does not explicitly invalidate and redraw the hosting window.

Internally, this function clears the browser cache and then forces a redraw by updating the control bounds and notifying the browser that the parent window has changed. If the host window itself is visible, it is also invalidated and updated to ensure that the client area is repainted.

Because this function performs multiple operations that can be relatively expensive, applications should generally prefer **WebViewReloadDocument** unless a complete repaint of both the control and the host window is required. For example, it can be used if rendering artifacts are visible after a resize or when switching between different DPI contexts.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewClearCache, WebViewReloadDocument, WebViewResetBrowser

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebViewReloadDocument Function

```
BOOL WINAPI WebViewReloadDocument(
    HWND hWndHost,
    BOOL bClearCache
);
```

The **WebViewReloadDocument** function reloads the current document and optionally clears the cache.

Parameters

hWndHost

Handle to the window attached to the browser session.

bClearCache

An integer which indicates if the document cache for the session should be cleared. A non-zero value specifies the cache should be cleared; zero specifies the cache should not be cleared.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewReloadDocument** function refreshes the currently loaded page, similar to pressing **F5** in a web browser. If the ***bClearCache*** parameter is non-zero, the document cache is also cleared before reloading, ensuring that all resources are fetched again from the server instead of being served from the local cache.

This function is generally preferred over **WebViewRedrawWindow** when an application only needs to reload the content without forcing the host window and browser control to repaint. It provides a lightweight way to refresh the page and optionally reset cached resources, without the overhead of a full redraw of the hosting window.

An application would typically use this function in response to a user action or when it needs to ensure the latest version of a document is displayed after cached data may have become stale.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

WebViewClearCache, WebViewRedrawWindow

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebViewResetBrowser Function

```
BOOL WINAPI WebViewResetBrowser(
    HWND hWndHost
);
```

The **WebViewResetBrowser** function resets the embedded runtime control.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewResetBrowser** function clears the state of the current browser session and restores it to its default configuration. This includes discarding cached content, navigation history, and any data associated with the last document. The control is then navigated to an empty `about:blank` page and the zoom level is reset to its default value.

Internally, this function releases cached strings such as the most recent message, script result, and document text, clears the current HTTP status and security information, removes cached data, and clears the session history. A navigation to **about:blank** is performed, and the host window is invalidated to ensure that the client area is repainted. The call blocks until the navigation has completed or the operation times out.

Because this function performs a complete reset of the WebView2 control, it should be used in situations where the browser needs to be returned to a known, clean state (for example, when reinitializing a session or preparing the control for a new task). Applications that only need to refresh the current document should use **WebViewReloadDocument** or **WebViewRedrawWindow** instead, as they are lighter-weight operations.

This function cannot be called while a navigation is already in progress. Attempting to do so will fail with an error code indicating that the operation is in progress. As with other navigation-related functions, it must be called on the thread that owns the browser window, or the request will be marshaled back to the UI thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewClearCache, WebViewRedrawWindow, WebViewReloadDocument

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebViewRuntimeAvailable Function

```
BOOL WINAPI WebViewRuntimeAvailable();
```

The **WebViewRuntimeAvailable** function determines whether the required runtime is installed and available.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewRuntimeAvailable** function checks whether the Microsoft Edge WebView2 runtime is installed and meets the minimum required version for this library. If the runtime is available, the function returns `TRUE`; otherwise, it returns `FALSE` and sets the last error code to indicate whether the runtime is missing or is an unsupported version. If the runtime is not installed, the last error code will be set to `ST_ERROR_WEBVIEW2_NOT_INSTALLED`. If the installed runtime is older than the minimum supported version (currently `102.0.1245.22`), the last error code will be set to `ST_ERROR_INVALID_WEBVIEW2_VERSION`.

This function is one of the few API functions that can be called before **WebViewInitialize**. It allows an application to check for the availability of the WebView2 runtime at startup, and optionally provide a more helpful error message to the user before attempting to create or attach a browser control. Developers may wish to call this function during application startup or installation checks. For example, if the runtime is not present or is too old, the application can inform the user that they must install or update the Microsoft Edge WebView2 runtime in order to use features which require embedded web content.

If the function succeeds, it only guarantees that the required runtime is installed and is a sufficient version. It does not initialize or configure the runtime; that process occurs when **WebViewInitialize** is called.

Example

```
INT APIENTRY wWinMain(HINSTANCE hInstance, HINSTANCE hPrevInstance, LPWSTR
lpCmdLine, INT nCmdShow)
{
    if (!WebViewRuntimeAvailable())
    {
        DWORD dwError = WebViewGetLastError();

        if (dwError == ST_ERROR_WEBVIEW2_NOT_INSTALLED)
        {
            MessageBoxW(NULL,
                        L"The Microsoft Edge WebView2 runtime is not installed.\n"
                        L"Please install it to continue.",
                        L"MyApp", MB_ICONERROR | MB_OK);
        }
        else
        {
            MessageBoxW(NULL,
                        L"The installed Microsoft Edge WebView2 runtime is too
```

```
old.\n"
                        L"Please update to the latest version.",
                        L"MyApp", MB_ICONERROR | MB_OK);
        }

        return 0; // Exit application
    }

    // Safe to initialize the library and create a WebView2 control
    if (!WebViewInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        MessageBoxW(NULL,
                    L"Unable to initialize the SocketTools WebView library",
                    L"MyApp", MB_ICONERROR | MB_OK);
        return 0;
    }

    // Create your main window, attach the browser, etc.

    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebViewSaveDocument Function

```
BOOL WINAPI WebViewSaveDocument(
    HWND hWndHost
    UINT uFileType
    LPCTSTR lpszFileName
);
```

The **WebViewSaveDocument** function saves the current document to a local file.

Parameters

hWndHost

Handle to the window attached to the browser session.

uFileType

An unsigned integer which specifies the format the document should be saved as.

Value	Description
WEBVIEW_FILE_TYPE_DEFAULT	Save using a format inferred from the file extension. If the file extension is not recognized, the contents will be saved as plain text. For example, if you specify a file name with the `.html` extension, it will be saved in HTML format. If the file name has a `.pdf` extension, it will be saved as a PDF.
WEBVIEW_FILE_TYPE_TEXT	Saves the current document as plain text. The HTML tags are removed and entities are converted to their UTF-8 equivalent. Extraneous whitespace within the text will be removed, but the overall structure of ordered and unordered lists will be preserved. Choose this format if you wish to save only the text content of a document.
WEBVIEW_FILE_TYPE_HTML	Saves the current document as a UTF-8 encoded HTML file. This includes the complete source for the page, but does not include any of the additional assets such as images. Choose this format if you wish to save the document as an editable HTML file.
WEBVIEW_FILE_TYPE_JSON	Saves the current document as a JSON formatted string. The string will be quoted and reserved characters will be escaped. Choose this format if you wish to preserve the HTML document as a JSON string for logging or embedding in a JSON object.
WEBVIEW_FILE_TYPE_MHTML	Saves the current document as a single-file web archive (MHTML) that inlines the HTML content and all of the resources it references. This format calls the DevTools `Page.captureSnapshot` method in the browser and writes the returned data to disk. MHTML is useful for offline archiving since it combines images, styles and scripts together in a single file.
WEBVIEW_FILE_TYPE_PDF	Saves the current document as a PDF file which produces

	a paginated document suitable for printing and distribution. This is functionally similar to using the browser to print to a PDF, but does not display a dialog to the user.
WEBVIEW_FILE_TYPE_JPEG	Save the current document view as a JPEG image. JPEG is a widely used image format optimized for photographs and complex images with smooth gradients. It uses lossy compression to significantly reduce file size while maintaining acceptable visual quality.
WEBVIEW_FILE_TYPE_PNG	Save the current document view as a PNG image. PNG is a lossless image format designed for crisp detail and high fidelity, especially in graphics with sharp edges, text, or flat colors. Although PNG files are typically larger than JPEGs, they preserve exact image data without quality loss.
WEBVIEW_FILE_TYPE_WEBP	Save the current document view as a WebP image. WebP is a modern image format developed by Google that supports both lossy and lossless compression, as well as transparency and animation. It delivers smaller file sizes compared to JPEG and PNG while maintaining comparable or better visual quality.

lpszFileName

A null-terminated string which specifies the name of the local file. If the path includes environment variables enclosed in percent (%) symbols, the variables will be expanded. This parameter cannot be NULL and must specify a valid file path. The file name cannot specify a device, folder name or system file. If the file is marked as read-only, the function will fail.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSaveDocument** function saves the current page to a local file in the format specified by the *uFileType* parameter. The operation is synchronous, processing messages while the browser completes the action, and only returns once the document has been created or the operation has failed. A temporary file is created during the save process and then moved into place, replacing any existing file. This ensures that an existing file will not be changed unless the browser indicates the save operation was successful. Saving is not permitted while a navigation is in progress, and attempts to do so will fail with an error.

The file name specified must be valid, and environment variables in the path are expanded before use. When `WEBVIEW_FILE_TYPE_DEFAULT` is specified, the format is inferred from the file extension. For example, `.html` or `.htm` will save the document as HTML, `.pdf` will create a PDF file and `.png` will save the page as a PNG image. If no recognized extension is present, the page will be saved as plain text by default.

When saving the current document as plain text, the HTML markup will be removed and it will be saved as a UTF-8 encoded text file. When saving as HTML, the function saves the complete HTML source for the page. The JSON format also saves the HTML markup, but encodes it as a quoted JSON

string with reserved characters escaped. Note that all text-related formats are saved using UTF-8 multi-byte encoding without a byte order mark (BOM). The text will not be automatically converted to the current user's locale. Most modern text editors automatically recognize UTF-8 encoding, but some legacy applications may assume the text is localized to the current code page.

The MHTML option creates a single-file archive which contains the page content and all of its resources such as images, style sheets, and scripts. This format is often used for offline archiving or sharing since everything is contained in one file. Saving as PDF renders the page into a paginated print-style format suitable for distribution. These formats all operate on the complete document, including content that extends beyond the visible area.

By contrast, saving as an image (JPEG, PNG, or WebP) captures only the visible viewport of the page at the time the function is called. Content that requires scrolling will not be included in the saved image. PNG is lossless and preserves transparency, while JPEG and WebP use compression to produce smaller files. WEBP generally offers better quality at a reduced size compared to JPEG, but support for the format may vary between applications. If you want a pixel-perfect representation of the current page as it appears on the screen, particularly if it contains a lot of text, it is recommended that you use the PNG format.

Because this function blocks the current thread until the save completes, it may take a noticeable amount of time to return if the current document is very large. If the function is called from a worker thread, the request is marshaled to the UI thread that manages the browser control. For applications with a graphical interface, it is recommended that you display the standard hourglass (or other busy indicator) while the save is in progress to provide a visual cue to the user.

If you want a copy of the HTML or plain text contents of the current page without saving it to a file, use the **WebViewGetDocumentText** or **WebViewGetFilteredText** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewSetBackgroundColor Function

```
BOOL WINAPI WebViewSetBackgroundColor(
    HWND hWndHost,
    COLORREF rgbBackground
);
```

The **WebViewSetBackgroundColor** function changes the background color used behind the page content.

Parameters

hWndHost

Handle to the window attached to the browser session.

rgbBackground

An integer value which specifies the background color.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The background color specifies the fill used by the browser window when there is no content to display or the document itself does not define a background. This value only applies to the WebView host surface and does not affect page transparency. The alpha channel is ignored, and the color is treated as fully opaque.

It is important to note that this setting does not override the background defined by the currently loaded page. If the page specifies its own background color or image, that content will take precedence and may obscure the configured color. For example, setting the background to white will not force web pages to appear white unless the page itself has transparent regions.

Applications can use this function to provide a consistent appearance for empty or loading views, but should not rely on the background color as a substitute for page styling. When a browser instance is first created, the default background color is white.

A **COLORREF** is a 32-bit value used by the Windows API to represent an RGB color. The low-order byte specifies the red component, the next byte the green component, and the third byte the blue component, in the format **0x00BBGGRR**. The high-order byte is unused and should be zero. Note that **COLORREF** is specific to the Windows API and is not the same as the OLE color system (**OLE_COLOR**). OLE uses a slightly different encoding that allows system color values to be specified, which are resolved at runtime. Developers should be careful not to confuse the two.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewSetBounds Function

```
BOOL WINAPI WebViewSetBounds(
    HWND hWndHost,
    INT xPos,
    INT yPos,
    INT nWidth,
    INT nHeight
);
```

The **WebViewSetBounds** function sets the position and size of the browser child window.

Parameters

hWndHost

Handle to the window attached to the browser session.

xPos

The x-position of the child window. This is a client area coordinate of the host window, not a screen position.

yPos

The y-position of the child window. This is a client area coordinate of the host window, not a screen position.

nWidth

The width of the child window. This is expressed in device units for the host window's client area.

nHeight

The height of the child window. This is expressed in device units for the host window's client area.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSetBounds** function updates the position and size of the embedded browser window relative to the client area of the host window. It calls the ***put_Bounds*** method on the underlying WebView2 controller to resize the child window that renders the web content. The specified coordinates and dimensions must fall within the client area of the host window associated with the browser instance. Attempting to specify bounds outside of the host window will result in clipping or the control being partially hidden.

The *nWidth* and *nHeight* parameters are device units, the same pixel units that the Win32 API uses with functions like **MoveWindow** and **SetWindowPos**. If the host window was created as a per-monitor DPI-aware window, the values your application gets with a `WM_SIZE` message are already scaled for the current DPI and you should just pass those values directly to this function. If your application is not DPI-aware, Windows will attempt to scale the values for you through DPI virtualization. It is important to note that these values are not logical units like Twips and they are not independent of DPI scaling.

Typically this function is called from within a `WM_SIZE` or `WM_MOVE` message handler so that the browser control resizes and repositions itself along with the parent window. You can also call this function directly to dock the browser into a specific portion of the host window's client area, such as

aligning it within a child frame or panel.

In most applications it is sufficient to call this function in response to a **WM_SIZE** message so the browser control resizes along with the client area of the host window. However, in a per-monitor DPI-aware application it may also be useful to call this function when handling **WM_MOVE**. This is because moving a top-level window between monitors can trigger a DPI change even if the window size itself does not change. Reapplying the bounds in response to **WM_MOVE** ensures the control is correctly adjusted to the new scaling factor. For applications that are not DPI-aware, handling **WM_MOVE** is generally unnecessary since the client area origin remains at (0,0) and Windows applies DPI virtualization automatically.

Calling **WebViewSetBounds** does not affect the visibility of the browser window. To hide or show the control, use the **WebViewShowWindow** function, and to query its visibility, use **WebViewIsVisible**.

Example

```
 LRESULT CALLBACK WndProc(HWND hWnd, UINT uMsg, WPARAM wParam, LPARAM lParam)
{
    switch (uMsg)
    {
    case WM_CREATE:
        // Attach a browser to this window as its host
        WebViewAttachWindow(hWnd, _T("https://www.example.com"), NULL, 0);
        return 0;

    case WM_SIZE:
        {
            RECT rcClient;
            GetClientRect(hWnd, &rcClient);

            // Resize the browser to occupy the full client area
            WebViewSetBounds(hWnd,
                             rcClient.left,
                             rcClient.top,
                             rcClient.right - rcClient.left,
                             rcClient.bottom - rcClient.top);
        }
        return 0;

    case WM_DESTROY:
        // Detach the browser instance from the window
        WebViewDetachWindow(hWnd);
        PostQuitMessage(0);
        return 0;
    }

    return DefWindowProc(hWnd, uMsg, wParam, lParam);
}
```

Requirements

WebViewSetDocumentText Function

```
BOOL WINAPI WebViewSetDocumentText(
    HWND hWndHost,
    LPCTSTR lpszText
);
```

The **WebViewSetDocumentText** function replaces the current document with the specified HTML or plain text.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszText

A null-terminated string which specifies the HTML or plain text that should replace the current document. If this parameter is NULL the current document will be cleared.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSetDocumentText** function replaces the currently displayed content with the specified HTML or plain text. If the text does not contain any markup, it will be wrapped in HTML as preformatted text and displayed using the default monospaced font. If the *lpszText* parameter is `NULL` or an empty string, the browser will display a blank page.

The string passed to this function is normally rendered directly by the browser. If the string is very large (over 256 KiB), the library will first write the text to a local temporary file and then instruct the browser to navigate to that file. This is done to work around limitations in the Edge WebView2 control when handling long inline strings. The temporary file will be automatically deleted when it is no longer needed.

There are two versions of this function, one that accepts 8-bit text (**WebViewSetDocumentTextA**) and one that accepts 16-bit Unicode text (**WebViewSetDocumentTextW**). The correct version of the function is called based on your project settings and whether the `UNICODE` macro is defined. If you call the ANSI version of this function, it expects the text will be UTF-8 encoded. If the text contains anything other than ASCII characters, it is recommended that you use the Unicode version of this function.

Important: It is possible to embed markup that references images, scripts, or other resources located on the Internet. While this is supported, you should be aware of potential risks when combining local content with external resources. This can create mixed-content scenarios and introduce cross-origin or security issues. Applications that render untrusted content should avoid linking to remote resources and ensure that the HTML provided is properly validated.

Example

In this example, the function replaces the current page with a basic HTML document. The `<img>` tag references an external image from a website. This is supported, but as noted above, applications should carefully consider the security implications of mixing local content with external resources.

```
// Replace the current document with a simple HTML page
```

```
LPCTSTR pszHtml =
    _T("<html><head><title>Hello</title></head>")
    _T("<body><h1>Hello, world!</h1>")
    _T("<p>This content was created dynamically.</p>")
    _T("<img src=\"https://example.com/logo.png\" alt=\"Logo\"/>")
    _T("</body></html>");

if (!WebViewSetDocumentText(hWndHost, pszHtml))
{
    DWORD dwError = WebViewGetLastError();
    // Handle the error
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewSetDownloadPath Function

```
BOOL WINAPI WebViewSetDownloadPath(
    HWND hWndHost,
    DWORD dwFileId,
    LPCTSTR lpszFilePath
);
```

The **WebViewSetDownloadPath** function changes the location of the local file for the specified download.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwFileId

An unsigned integer value which uniquely identifies the download. This value cannot be zero.

lpszFilePath

A null-terminated string which specifies the new path for the downloaded file. This value may be a `file://` URL or it may specify a local file path. If the path contains environment variables surrounded with percent (%) symbols, the variables will be expanded. This parameter cannot be NULL or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The specified path may be provided as either a file:// URL or a local file system path. If a file:// URL is given, it will be converted to a local path before use. Environment variables enclosed in percent signs (such as `%TEMP%`) are expanded automatically. If the path refers to an existing directory rather than a file name, the original file's base name is preserved and the file will be created in that directory. This allows applications to easily redirect a download into a specific folder without changing the file name.

The function always normalizes the provided path. If a relative path is specified, it is resolved against the current working directory of the process. Because this can lead to unpredictable results in multithreaded applications, it is strongly recommended that applications always provide absolute paths. By default, downloaded files are typically stored in the current user's Downloads folder.

Several restrictions are enforced on the path to help ensure safety and compatibility. Device names such as `CON`, `PRN`, or `NUL` are not permitted. Downloads cannot be redirected into system folders such as the Windows folder or Program File folder. The path cannot contain reserved characters, and files that are marked as read-only will not be overwritten. If any of these conditions are detected, the function will fail with an error.

This function can only be called within a handler for the `WEBVIEW_EVENT_DOWNLOAD_STARTING` event. Once the download has begun, the local file path cannot be changed. If you wish to move the file after it has been downloaded, you can use the **WebViewGetDownloadPath** function to obtain its current location and then use a function like **MoveFileEx** to move the file to a new folder.

Note that you should avoid showing modal dialogs such as the common "Save File" dialog within event handlers. Because the browser events are raised within the context of the WebView2 UI thread,

displaying a dialog asking the user for a new download location can prevent the control from processing its internal message loop, potentially leading to stalled downloads.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewSetFocus Function

```
BOOL WINAPI WebViewSetFocus(
    HWND hWndHost
);
```

The **WebViewSetFocus** function changes focus to the browser control.

Parameters

hWndHost

Handle to the window attached to the browser session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSetFocus** function gives input focus to the embedded browser control. Once focus has been set, keyboard input such as typing or navigation keys will be directed to the content displayed by the control rather than to other controls in the host window. This is equivalent to the user clicking inside the browser area.

Setting focus does not make the host window itself the active foreground window. If the host window is not active, input will still not be directed to the browser until the window is activated by the user or programmatically. Applications that need to determine whether the browser currently has focus can call **WebViewGetFocus**.

Example

```
BOOL bHasFocus = FALSE;

if (WebViewGetFocus(hWndHost, &bHasFocus))
{
    if (!bHasFocus)
    {
        // Give the browser control focus if it does not have it
        WebViewSetFocus(hWndHost);
    }
}
else
{
    // Handle error
    DWORD dwError = WebViewGetLastError();
    _tprintf(_T("WebViewGetFocus failed, error=0x%lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewSetHeader Function

```
BOOL WINAPI WebViewSetHeader (
   HWND hWndHost,
   LPCTSTR lpszHeaderName,
   LPCTSTR lpszHeaderValue
);
```

The **WebViewSetHeader** function sets a request header value to be included with subsequent navigations.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszHeaderName

A null-terminated string which specifies the name of the request header value to set or change.

lpszHeaderValue

A null-terminated string which specifies the value of the header. If this value is NULL or an empty string, the request header will be removed.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSetHeader** function adds or updates a custom request header that will be included with subsequent navigations. Request header names are not case-sensitive, and any leading or trailing whitespace is ignored. If the specified header value is NULL or an empty string, the header will be removed from the current list of custom headers. These changes only affect future requests; they do not modify headers already sent for the current navigation.

Certain standard headers are controlled by the underlying WebView2 control and may be ignored if set programmatically. Examples include `Host`, `Referer`, `Origin`, `User-Agent`, and most authentication headers. Attempting to override these may have no effect. For headers that can be set, the specified values will be merged with the default request headers used by WebView2 when making requests. If you wish to change the `User-Agent` header value, use the **WebViewSetUserAgent** function.

When defining custom request headers, it is recommended to use names prefixed with X- (for example, `X-Application-ID` or `X-Request-Token`). This convention helps distinguish application-specific headers from those defined by the HTTP standard, and reduces the likelihood of conflicts with headers that are managed internally by WebView2 or intermediaries such as proxies and gateways. While most modern systems will accept arbitrary header names, following this convention improves compatibility and avoids unexpected behavior.

If you need to clear all custom request headers that have been set, call **WebViewClearHeaders** with the `WEBVIEW_HEADERS_REQUEST` option.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

WebViewSetIcon Function

```
BOOL WINAPI WebViewSetIcon(
   HWND hWndHost,
   HINSTANCE hResInst,
   LPCTSTR lpszIconName,
   UINT uResId,
   DWORD dwFlags
);
```

The **WebViewSetIcon** function sets custom large and small icons for the host window.

Parameters

hWndHost

Handle to the window attached to the browser session.

hResInst

Handle to the module instance that contains the icon resource. If this parameter is NULL, the ***lpszIconName*** parameter should specify the path to an icon file.

lpszIconName

A null-terminated string that specifies the name of the icon resource or a path to an icon file. If this parameter is not NULL, it takes precedence over ***uResId***.

uResId

An unsigned integer which specifies the numeric identifier of the icon resource within the module. This is used when ***lpszIconName*** is NULL.

dwFlags

An unsigned integer which specifies which icons to update. This must be one or more of the values shown in the following table.

Value	Description
WEBVIEW_ICON_BIG	Update the large window icon.
WEBVIEW_ICON_SMALL	Update the small window icon.
WEBVIEW_ICON_BOTH	Update both large and small icons.
WEBVIEW_ICON_DPI_AWARE	Choose the system-recommended small icon size for the current DPI when possible.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSetIcon** function updates the large and/or small icons associated with the host window created using the **WebViewCreateWindow** or **WebViewCreateWindowEx** function. This is equivalent to sending the `WM_SETICON` message to the host window, but automatically handles both the large and small icons and supports DPI-aware sizing when requested.

If the ***hRetInst*** parameter is not NULL, either a string resource name (***lpszIconName***) or a numeric resource identifier (***uResId***) can be specified to identify the icon. If both are provided, the string

resource name takes precedence. The resource must exist in the module instance specified by *hResInst*. If neither *lpszIconName* nor *uResId* resolves to a valid icon, the function fails.

if the *hResInst* parameter is NULL, the *lpszIconName* parameter must specify the name of a file which contains the icon and the *uResId* parameter is ignored. It is recommended that you provide an absolute path to the icon file. If the path includes environment variables surrounded with percent (%) symbols, those variables will be automatically expanded. The file must use the standard Windows icon format.

The *dwFlags* parameter determines which icons are updated. You can set the large icon (used in the Alt-Tab interface and title bar), the small icon (shown in the window caption and taskbar), or both. If `WEBVIEW_ICON_DPI_AWARE` is specified, the system will choose an appropriate small icon size based on the current display scaling.

Windows icons are stored in the standard `.ico` file format, which can contain one or more images at different resolutions and color depths. When you compile icons into your application's resources and reference them by name or identifier, Windows will automatically select the most appropriate image for the current display settings. This allows a single icon resource to provide 16x16, 32x32, 48x48, or higher-resolution images within the same file.

The operating system chooses which image to use based on context and DPI scaling. For example, a 16x16 version may be displayed in a window caption or taskbar, while a 32x32 or 48x48 version may be shown in the Alt-Tab interface or Windows Explorer. If `WEBVIEW_ICON_DPI_AWARE` is specified, the system can pick a small-icon size that best matches the current DPI rather than always defaulting to 16x16.

Calling this function does not destroy the icon resource itself; ownership remains with the module that loaded it. If you dynamically create icons at runtime using **CreateIcon** or **LoadImage**, you are responsible for releasing them with **DestroyIcon** if they are no longer needed.

This function can only be used with windows created by this library, it cannot be used with windows you attach the browser to using the **WebViewAttachWindow** or **WebViewAttachWindowEx** functions.

Example

```
// Define the path to the application's icon file
LPCTSTR pszIconFile = _T("%LocalAppData%\\MyApp\\MyApp.ico");

HWND hWnd = WebViewCreateWindow(_T("about:blank"), NULL, 0);
if (hWnd)
{
    // Set both large and small icons for the WebView host window
    WebViewSetIcon(
        hWnd,
        NULL,
        pszIconFile,
        0,
        WEBVIEW_ICON_BOTH | WEBVIEW_ICON_DPI_AWARE
    );
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

WebViewSetLastError Function

```
VOID WINAPI WebViewSetLastError(
    DWORD dwErrorCode
);
```

The **WebViewSetLastError** function sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE or NULL. Those functions which call **WebViewSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **WebViewGetLastError** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

WebViewGetErrorString, WebViewGetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebViewSetOption Function

```
BOOL WINAPI WebViewSetOption(
    HWND hWndHost,
    DWORD dwOption,
    BOOL bEnable
);
```

The **WebViewSetOption** function enables or disables a specific option.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwOption

An unsigned integer which specifies the option to be changed. Refer to the WebView Options documentation for the list of available options. Only a single option may be specified; you cannot combine multiple option bitflags when calling this function.

bEnable

An integer value which specifies if the option should be enabled. If this value is non-zero, the option is enabled. If the value is zero, the option is disabled.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSetOption** function enables or disables a single option for the browser instance attached to the specified host window. Each option corresponds to a specific feature or behavior such as scripting, zoom controls, developer tools, or privacy settings. Only one option bitflag may be specified in the ***dwOption*** parameter when calling this function. It is not valid to combine multiple option flags with a bitwise OR. If you need to change the state of multiple options, call this function once for each option you want to modify.

Some options can be changed dynamically at runtime, while others only take effect during creation of the browser control. For example, options related to scripting, dialogs, or developer tools can typically be toggled while the control is active. In contrast, options that affect the user data folder, profile isolation, or privacy mode must be set at creation time using **WebViewAttachWindowEx** or **WebViewCreateWindowEx**. Attempting to change those options will fail once the browser control has been created.

If the function succeeds, the option state will be updated immediately. The application can verify the new state by calling **WebViewGetOption** or by retrieving all current options with **WebViewGetAllOptions**. If the function fails, no changes are made and extended error information can be obtained with **WebViewGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewSetTimeout Function

```
INT WINAPI WebViewSetTimeout(
    HWND hWndHost,
    INT nTimeout
);
```

The **WebViewSetTimeout** function sets the number of seconds the browser will wait for a response from the server.

Parameters

hWndHost

Handle to the window attached to the browser session.

nTimeout

The number of seconds to wait for the navigation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WEBVIEW_ERROR. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSetTimeout** function specifies the maximum number of seconds that the library should wait for a navigation request to complete. This timeout begins when navigation starts and ends when the navigation completes or fails.

If the timeout period is set to zero, the library does not enforce its own timer and instead relies on the default timeouts implemented by the WebView2 engine. These built-in timeouts automatically handle conditions such as slow DNS resolution, stalled connections, or unreachable servers, and generally behave in the same way as the Microsoft Edge browser.

If a non-zero timeout period is specified, the control will cancel the navigation if the internal timer exceeds that value and the page has not finished loading. When this occurs, the navigation is stopped and a timeout error is reported through the standard navigation event notifications. This allows applications to fail fast in cases where a site is not responding, rather than waiting for the browser's adaptive timeouts to expire.

Note that specifying a very large timeout value will not force the browser to wait indefinitely. The WebView2 engine may still apply its own internal maximums and terminate the navigation earlier if it decides the request cannot succeed. Applications should select timeout values that balance responsiveness and reliability.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewSetUserAgent Function

```
BOOL WINAPI WebViewSetUserAgent(
    HWND hWndHost,
    LPCTSTR lpszUserAgent
);
```

The **WebViewSetUserAgent** function changes the default User-Agent string for this instance.

Parameters

hWndHost

Handle to the window attached to the browser session.

lpszUserAgent

A null-terminated string which specifies the new User-Agent header value for subsequent requests. If this parameter is NULL or an empty string, the User-Agent header will revert back to the default value used by the Edge WebView2 control.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSetUserAgent** function sets the string that will be sent in the User-Agent header for all subsequent HTTP requests made by this browser instance. This function should always be used to modify the User-Agent header value; you should not set the header directly using the **WebViewSetHeader** function.

Applications may want to override the default User-Agent in several scenarios:

- Requesting a mobile or tablet version of a site by providing a User-Agent string that identifies as a mobile browser.
- Emulating a different browser for testing purposes.
- Including custom product tokens identifying the host application to the server.

The general format of a User-Agent string follows the conventions described in RFC 9110:

```
User-Agent: product / version (comment) [ product / version ... ]
```

For example, a typical User-Agent string might look like:

```
Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like
Gecko) Chrome/140.0.0.0 Safari/537.36 Edg/140.0.0.0
```

This value is global to the instance. Once changed, it will remain in effect until explicitly reset or until the browser window is destroyed. When setting a custom User-Agent value, developers should ensure it is a syntactically valid string. Some websites may reject requests or provide degraded functionality if the value is malformed or omits key tokens.

If you want to change the User-Agent string to identify your application, it is recommended that you append your application name and version to the default value.

Example

```
// First, get the length of the current User-Agent string
```

```
INT nLength = WebViewGetUserAgent(hWndHost, NULL, 0);
if (nLength <= 0)
{
    _tprintf(_T("Unable to get User-Agent string (error 0x%lx)\n"),
WebViewGetLastError());
    return;
}

// Allocate a buffer large enough to append the application name and version;
// note the leading space in the name to separate it from other tokens
const TCHAR szAppId[] = _T(" MyApp/1.0");

INT nTotalLength = nLength + (INT)_tcslen(szAppId) + 1;
LPTSTR lpszUserAgent = (LPTSTR)malloc(nTotalLength * sizeof(TCHAR));

if (!lpszUserAgent)
    return;

// Retrieve the current User-Agent value from the browser
if (WebViewGetUserAgent(hWndHost, lpszUserAgent, nTotalLength) <= 0)
{
    _tprintf(_T("Failed to copy User-Agent string (error 0x%lx)\n"),
WebViewGetLastError());
    free(lpszUserAgent);
    return;
}

// Append our application identifier to the User-Agent string
_tcscat_s(lpszUserAgent, nTotalLength, szAppId);

// Update the User-Agent header with the new value
if (!WebViewSetUserAgent(hWndHost, lpszUserAgent))
{
    _tprintf(_T("Failed to update the User-Agent string (error 0x%lx)\n"),
WebViewGetLastError());
}
else
{
    _tprintf(_T("User-Agent successfully updated to:\n%s\n"), lpszUserAgent);
}

free(lpszUserAgent);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebViewSetZoomLevel Function

```
BOOL WINAPI WebViewSetZoomLevel(
    HWND hWndHost,
    INT nPercent
);
```

The **WebViewSetZoomLevel** function changes the current browser zoom level.

Parameters

hWndHost

Handle to the window attached to the browser session.

nPercent

An integer which specifies the zoom level as a percentage. The minimum zoom level is 25 and the maximum is 400.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewSetZoomLevel** function changes the zoom level of the current browser window to the specified percentage. A zoom level of **100** represents the default size with no scaling applied. Larger values magnify the content, while smaller values reduce it.

The zoom percentage is constrained by the limits defined for the control. The minimum supported zoom level is **25** (25%) and the maximum is **400** (400%). If a value outside of this range is specified, it will be clamped to the nearest valid zoom level.

Changing the zoom level affects how the page content is displayed but does not alter the underlying document. This is equivalent to adjusting the zoom in a standard web browser. The new zoom level applies to the current browser instance and will remain in effect until it is changed again, or the instance is destroyed.

If the function fails, the zoom level remains unchanged. To query the current zoom level, call **WebViewGetZoomLevel**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WebViewShowWindow Function

```
BOOL WINAPI WebViewShowWindow(
    HWND hWndHost,
    BOOL bVisible
);
```

The **WebViewShowWindow** function shows or hides the browser window.

Parameters

hWndHost

Handle to the window attached to the browser session.

bVisible

An integer value which specifies if the browser window should be displayed. If this value is non-zero the browser will be shown. If the value is zero, the browser window will be hidden.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewShowWindow** function changes the visibility state of the browser control. When the browser was created as a top-level window using **WebViewCreateWindow** or **WebViewCreateWindowEx**, this function internally calls the standard **ShowWindow** API to show or hide the entire browser window. The window will be restored or hidden according to the value of the *bVisible* parameter.

When the browser is embedded in an existing host window using **WebViewAttachWindow** or **WebViewAttachWindowEx**, the function does not change the visibility of the parent window. Instead, it sends an internal message to the control to show or hide the child window which contains the WebView2 browser. This enables the host application to toggle the visibility of the browser control independently of other controls in the same window.

This function does not destroy the browser instance or unload its current content. Hiding the browser simply makes it invisible; it can be shown again without requiring a reload of the current document. The current visibility state can be queried using the **WebViewIsVisible** function.

Hiding the browser window can also provide performance benefits in scenarios where the application does not need to display the page contents for a period of time. While background tasks such as script execution and network activity continue as normal, the browser will not spend resources on rendering or updating the visual output when the control is not visible. This can reduce CPU and GPU usage, particularly when the page is dynamic or graphically intensive.

Calling this function has no effect if the handle passed in *hWndHost* is not currently associated with an active browser session. If the window is minimized or closed, the function will not restore it; it only changes the visible state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewUninitialize Function

```
VOID WINAPI WebViewUninitialize();
```

The **WebViewUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **WebViewInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **WebViewUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages.

There should be a call to **WebViewUninitialize** for every successful call to **WebViewInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated when the reference count for the library is zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

WebViewWaitForEvent Function

```
BOOL WINAPI WebViewWaitForEvent(
    HWND hWndHost
    UINT uEventId,
    DWORD dwMilliseconds
);
```

The **WebViewWaitForEvent** function waits until a specific event occurs or the timeout period expires.

Parameters

hWndHost

Handle to the window attached to the browser session.

uEventId

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the WebView Events documentation.

dwMilliseconds

The number of milliseconds to wait for the event to occur. If this amount of time elapses, the function returns. If this value is zero, the function will return successfully if the last event handled matches the ***uEventId*** parameter. This can be used to effectively poll the browser to determine if the specified event has occurred. This value may be **INFINITE** in which case the function will not return until the event occurs.

Return Value

If the function succeeds, the return value is non-zero. If the function fails or the timeout period is exceeded, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewWaitForEvent** function suspends the calling thread until the specified event is raised or the timeout interval expires. While waiting, this function continues to process the thread's Windows message queue. This ensures that the user interface remains responsive and that event callbacks are able to execute on the correct thread.

Because messages are dispatched while this function blocks, application code must be written with the possibility of reentrancy in mind. That is, another message handler or event callback may run before **WebViewWaitForEvent** returns. If your application maintains shared state, you should use appropriate synchronization (critical sections, mutexes, etc.) to ensure it remains consistent.

This function should generally be called from the same thread that created the browser instance. Calling it from a worker thread that does not own a message loop may prevent events from being delivered. If you require a fully non-blocking design, you should use the event callback function specified when creating or attaching the browser window, rather than waiting synchronously.

You should not call **WebViewWaitForEvent** from within an event handler. Doing so can result in unexpected behavior, as the function will attempt to wait for additional events and dispatch messages while another event is already being processed. This may lead to subtle reentrancy issues or even deadlocks depending on the event ordering. Event handlers should return promptly, and synchronous waits should be performed only outside of callback contexts.

Note that if ***dwMilliseconds*** is set to **INFINITE**, the function will not return until the event occurs. To avoid unresponsive behavior, it is recommended you use a finite timeout value unless you are certain

the event will always be signaled within a reasonable period.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

WebViewAttachWindow, WebViewCreateWindow, WebViewEventProc, WebViewWaitUntilClosed

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebViewWaitUntilClosed Function

```
BOOL WINAPI WebViewWaitUntilClosed(
    HWND hWndHost,
    DWORD dwMilliseconds
);
```

The **WebViewWaitUntilClosed** function waits until the host window is closed or destroyed.

Parameters

hWndHost

Handle to the window attached to the browser session.

dwMilliseconds

The number of milliseconds to wait for the browser window to close. If this amount of time elapses, the function returns. If this value is zero, the function will not enter a wait state and returns immediately. This value may be `INFINITE` in which case the function will not return until the window is closed.

Return Value

If the browser window has been closed, the return value is non-zero. If the timeout period has been exceeded or the function fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

The **WebViewWaitUntilClosed** function blocks the calling thread until the browser window created by **WebViewCreateWindow** or **WebViewCreateWindowEx** has been closed or destroyed, or until the specified timeout interval has elapsed. Internally, this function waits on the thread handle associated with the WebView2 instance using the `WaitForSingleObject` function.

This function can only be used with browser windows that were created by this API. It is not valid to call this function with a window handle that was attached using **WebViewAttachWindow** or **WebViewAttachWindowEx**. Attempting to do so will cause the function to fail.

Unlike **WebViewWaitForEvent**, this function does not process any Windows messages while it is waiting. As a result, it should not be used by applications that have a message loop, such as GUI programs that create windows with menus, controls, or dialog boxes. Because messages are not dispatched, the application's user interface may become unresponsive if this function is called from the primary UI thread.

This function is intended primarily for use in console applications or background worker threads, where it may be necessary to determine when the browser window has been closed by the user. GUI applications should use the **WebViewEventProc** callback to detect the `WEBVIEW_EVENT_WINDOW_DETACHED` event instead of calling this function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebView Data Structures

- WEBVIEW_DOWNLOAD_INFO
- WEBVIEW_SECURITY_INFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WEBVIEW_DOWNLOAD_INFO

The **WEBVIEW_DOWNLOAD_INFO** structure contains information about the current state of a file download.

```
typedef struct _WEBVIEW_DOWNLOAD_INFO
{
    DWORD dwSize;
    DWORD dwFileId;
    DWORD dwStatus;
    ULARGE_INTEGER uiBytesTotal;
    ULARGE_INTEGER uiBytesCopied;
    DWORD dwTimeElapsed;
    TCHAR szFileName[260];
    TCHAR szFileUrl[2048];
} WEBVIEW_DOWNLOAD_INFO, *LPWEBVIEW_DOWNLOAD_INFO;
```

Members

dwSize

Specifies the size of the structure in bytes. This member must be initialized by the caller.

dwFileId

A unique identifier assigned to the download. This value can be used with functions such as **WebViewGetDownloadInfo** and **WebViewCancelDownload** to query or manage the download.

dwStatus

Indicates the current state of the download. This will be one of the following values:

Name	Description
WEBVIEW_DOWNLOAD_STARTED	The file download has started and is in-progress.
WEBVIEW_DOWNLOAD_COMPLETED	The file download has completed successfully.
WEBVIEW_DOWNLOAD_CANCELED	The file download has been canceled.
WEBVIEW_DOWNLOAD_FAILED	The file download failed due to a network error or other problem.

uiBytesTotal

The total size of the file, in bytes, as reported by the server. If the server did not provide the file size, this value may be zero.

uiBytesCopied

The number of bytes that have been downloaded so far. If the download has completed, this value will be equal to ***uiBytesTotal***. If the total size is unknown, this value still reflects the number of bytes received.

dwTimeElapsed

The elapsed time for the download, in milliseconds. For completed downloads this is the total time from start to finish. For active downloads this is the time since the download began. If the download has not started, this value is zero.

szFileName

A null-terminated string which specifies the local file name associated with the download. If the application has not changed the file path using **WebViewSetDownloadPath**, this will be the

default file name assigned by the browser. Typically the file will be stored in the current user's Downloads folder.

szFileUrl

A null-terminated string which specifies the URL of the file being downloaded. This is the fully qualified resource location provided to the browser.

Remarks

This structure provides detailed information about the progress and final state of a download managed by the browser. Before calling a function that populates this structure, such as **WebViewGetDownloadInfo**, the caller must set the ***dwSize*** member to the size of the structure. This ensures that applications remain compatible if new fields are added in future updates.

The ***uiBytesTotal*** and ***uiBytesCopied*** members allow applications to report download progress or log completed downloads. If the total file size is not known, ***uiBytesTotal*** will be zero and applications should base their progress reporting on the number of bytes copied alone.

The ***dwFileId*** member can be obtained from **WebViewEnumDownloads**, and is required to retrieve download information or to cancel a pending download.

Both ANSI (A) and Unicode (W) versions of this structure are provided. Applications that call **WebViewGetDownloadInfoW** will populate the wide-character members of the structure (such as ***szFileName*** and ***szFileUrl***) with UTF-16 encoded text. Applications that call **WebViewGetDownloadInfoA** will receive the ANSI version of the structure, where those same members are returned as UTF-8 encoded strings. The default **WEBVIEW_DOWNLOAD_INFO** macro maps to one or the other depending on whether the UNICODE preprocessor symbol is defined at compile time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h.
Unicode: Implemented as Unicode and ANSI versions

WEBVIEW_SECURITY_INFO

The **WEBVIEW_SECURITY_INFO** structure contains information about the current state of a secure connection.

```
typedef struct _WEBVIEW_SECURITY_INFO
{
    DWORD dwSize;
    DWORD dwFlags;
    DWORD dwLevel;
    TCHAR szProtocol[32];
    TCHAR szCipher[64];
    TCHAR szSubject[128];
    TCHAR szIssuer[128];
    FILETIME ftValidFrom;
    FILETIME ftValidTo;
} WEBVIEW_SECURITY_INFO, *LPWEBVIEW_SECURITY_INFO;
```

Members

dwSize

Specifies the size of the structure in bytes. This member must be initialized by the caller.

dwFlags

A bitmask that provides additional detail about the connection and certificate state. One or more values may be set to indicate conditions such as unencrypted content, use of weak algorithms, or general certificate errors. It may be one or more of the security flags listed below.

Name	Description
WEBVIEW_SECURITY_FLAG_NONE	No additional security indicators.
WEBVIEW_SECURITY_FLAG_UNENCRYPTED	Content is not encrypted.
WEBVIEW_SECURITY_FLAG_INSECURE	Site is insecure using outdated protocols or weak ciphers.
WEBVIEW_SECURITY_FLAG_CERT_WEAK	The certificate uses weak signatures.
WEBVIEW_SECURITY_FLAG_CERT_ERROR	The certificate is invalid. This is a general error condition.
WEBVIEW_SECURITY_FLAG_CERT_EXPIRED	The certificate expired but is otherwise valid.
WEBVIEW_SECURITY_FLAG_UNSAFE	The site is considered potentially unsafe (it failed reputation checks).

dwLevel

Overall security level for the current page. This is a summarized assessment intended for UI decisions, such as showing a lock icon or warning. It maps to one of the security level values listed below.

Name	Description
WEBVIEW_SECURITY_LEVEL_UNKNOWN	The security state could not be determined.
WEBVIEW_SECURITY_LEVEL_INSECURE	The page was retrieved using plain HTTP or the site has an invalid certificate.

WEBVIEW_SECURITY_LEVEL_WARNING	The page contains mixed content or only weak encryption is available.
WEBVIEW_SECURITY_LEVEL_NEUTRAL	Local content or the browser is in a transitional/loading state.
WEBVIEW_SECURITY_LEVEL_SECURE	The page was retrieved using HTTPS and the site has a valid certificate.

szProtocol

A null-terminated string that names the negotiated security protocol, such as `"TLS 1.3"` or `"TLS 1.2"`. For plain HTTP and local content, this string is empty.

szCipher

A null-terminated string that identifies the selected cipher suite, such as `"TLS_AES_128_GCM_SHA256"`. This string is empty if the site is not secure or local content is being displayed.

szSubject

A null-terminated string which contains the certificate subject. Typically this includes the common name (CN) and/or subject alternative name which matches the hostname.

szIssuer

A null-terminated string which specifies the certificate issuer. This is normally the name of the Certificate Authority (CA) which provided the certificate.

ftValidFrom

The date and time when the certificate was issued. This is represented as a standard FILETIME structure.

ftValidTo

The date and time when the certificate expires. This is represented as a standard FILETIME structure.

Remarks

The security information reflects the state of the last navigation. During navigation, values can be provisional; the final, authoritative values are available after the navigation completes. The ***dwLevel*** value is an assessment that may be adjusted by the engine for conditions such as mixed content, weak ciphers, or certificate problems. The ***dwFlags*** field provides the underlying reasons and may have multiple bitflags set. Applications should check for combinations (for example, a page might be secure overall but also report a warning flag if subresources were blocked).

For plain HTTP (unencrypted) pages, ***dwLevel*** is typically `WEBVIEW_SECURITY_LEVEL_INSECURE`. The ***szProtocol*** and ***szCipher*** members are empty strings and ***dwFlags*** will include `WEBVIEW_SECURITY_FLAG_UNENCRYPTED`. For HTTPS with a valid certificate, ***dwLevel*** is typically `WEBVIEW_SECURITY_LEVEL_SECURE`, and other members identify the negotiated TLS version and cipher suite. If the certificate is expired or otherwise invalid, the security level is downgraded and the corresponding certificate flags are set.

The ***szSubject*** and ***szIssuer*** strings are for display and logging purposes; certificate parsing and validation is handled by the browser. The validity timestamps (***ftValidFrom*** and ***ftValidTo***) are provided to enable simple checks, but applications do not need to implement certificate validation logic themselves.

Set the ***dwSize*** member to the actual size of the structure before calling **WebViewGetSecurityInfo**. If the caller passes a different size than expected, the function will fail or only populate the fields known to that size.

Both ANSI (`A`) and Unicode (`W`) variants are provided. When compiling with `UNICODE` defined, the `TCHAR` strings are UTF-16. In ANSI builds, they are UTF-8. The **WebViewGetSecurityInfo** macro resolves to the appropriate version based on the project's character set.

Because the browser can update security state as additional resources are loaded, applications that display a security indicator should refresh it on navigation completion events. Treat the security level as ordered and do not "upgrade" a previously observed state during the same navigation unless a later callback provides a higher confidence result. Note that it's also possible for the security level to be `WEBVIEW_SECURITY_LEVEL_SECURE` during navigation, but may be downgraded to `WEBVIEW_SECURITY_LEVEL_WARNING` when navigation completes due to mixed content in the page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h.
Unicode: Implemented as Unicode and ANSI versions

CWebView Constants

Name	Value	Description
Options		
WEBVIEW_OPTION_ENABLE_NOTHING	0	No options enabled. This is very restrictive and will not permit the use of JavaScript.
WEBVIEW_OPTION_ENABLE_ACCELERATORS	0x00001	Enables common keyboard accelerators (e.g., Ctrl+L, F5). Accelerator key events are surfaced via `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS`.
WEBVIEW_OPTION_ENABLE_CONTEXT_MENU	0x00002	Shows the built-in right-click context menu. Clear this to fully suppress the menu.
WEBVIEW_OPTION_ENABLE_STATUSBAR	0x00004	Displays status text (e.g., link targets, loading state) in the bottom-left status area.
WEBVIEW_OPTION_ENABLE_ZOOM_CONTROL	0x00008	Allows user zoom (Ctrl+Plus/Minus, Ctrl+mouse-wheel). If disabled, zoom remains fixed unless set by API.
WEBVIEW_OPTION_ENABLE_AUDIO	0x00010	Permits audio playback in the WebView. Disable to mute at the engine level.
WEBVIEW_OPTION_ENABLE_AUTOFILL	0x00020	Enables form autofill suggestions where available.
WEBVIEW_OPTION_ENABLE_PASSWORD_AUTOSAVE	0x00040	Allows the engine to offer saving website passwords/credentials.
WEBVIEW_OPTION_ENABLE_PRIVACY	0x00080	Enable private browsing
WEBVIEW_OPTION_ENABLE_SCRIPTING	0x00100	Enables JavaScript execution. Disabling blocks script evaluation and script-initiated behaviors.
WEBVIEW_OPTION_ENABLE_DIALOGS	0x00200	Allows script dialogs (alert/confirm/prompt) and related UI. Disable to suppress script-driven dialogs.
WEBVIEW_OPTION_ENABLE_DEVTOOLS	0x00400	Permits opening Developer Tools (e.g., F12). Disable to block DevTools access.
WEBVIEW_OPTION_ENABLE_NEW_WINDOWS	0x00800	Allows the creation of new popup windows
WEBVIEW_OPTION_ENABLE_MESSAGES	0x01000	Enables `window.chrome.webview.postMessage` communication from the page to the host.
WEBVIEW_OPTION_ENABLE_EXTERNAL_DROP	0x02000	Allows external drag-and-drop (e.g., files from Explorer) into the WebView surface.
WEBVIEW_OPTION_RESTRICT_NAVIGATION	0x10000	Blocks navigations after the initial page

		load unless explicitly permitted by the host.
WEBVIEW_OPTION_RESTRICT_DOWNLOADS	0x20000	Blocks attempts to download files through the browser.
WEBVIEW_OPTION_EXCLUSIVE_PROFILE	0x40000	Require exclusive use of the user data folder
WEBVIEW_OPTION_TRANSPARENT_BACKGROUND	0x80000	Renders with a transparent background where content allows; the host window should support composition.
WEBVIEW_OPTION_ENABLE_DEFAULT	0x0031F	Convenience preset enabling the most common interactive features for typical app scenarios.
Navigation Flags		
WEBVIEW_NAVIGATION_REDIRECTED	0x0001	The navigation was the result of an HTTP redirect.
WEBVIEW_NAVIGATION_USER_INITIATED	0x0002	Navigation began from a user gesture rather than being initiated by a script.
WEBVIEW_NAVIGATION_LOCAL_DATA	0x1000	Content was served using local data rather than a full network fetch.
Accelerator Key Flags		
WEBVIEW_ACCELERATOR_KEY_DOWN	0x0001	Indicates an accelerator key-down event.
WEBVIEW_ACCELERATOR_KEY_UP	0x0002	Indicates an accelerator key-up event.
WEBVIEW_ACCELERATOR_KEY_SYSTEM	0x0004	Indicates a system key event using the Alt key, similar to `WM_SYSKEY`.
History Movement Flags		
WEBVIEW_MOVE_BACKWARD_ENABLED	0x0001	Backward navigation is currently available.
WEBVIEW_MOVE_FORWARD_ENABLED	0x0002	Forward navigation is currently available.
Navigation Error Codes		
WEBVIEW_ERROR_NONE	0	No error.
WEBVIEW_ERROR_CERTIFICATE_COMMON_NAME	1	Certificate common name mismatch.
WEBVIEW_ERROR_CERTIFICATE_EXPIRED	2	Certificate is expired.
WEBVIEW_ERROR_INVALID_CLIENT_CERTIFICATE	3	Invalid or untrusted client certificate.
WEBVIEW_ERROR_CERTIFICATE_REVOKED	4	Certificate has been revoked.
WEBVIEW_ERROR_INVALID_CERTIFICATE	5	Certificate is invalid for another reason.
WEBVIEW_ERROR_SERVER_UNREACHABLE	6	Cannot reach the server/host.
WEBVIEW_ERROR_TIMEOUT	7	Operation timed out.
WEBVIEW_ERROR_INVALID_SERVER_RESPONSE	8	Server returned an invalid or unexpected response.

WEBVIEW_ERROR_CONNECTION_ABORTED	9	Connection aborted by the server or network.
WEBVIEW_ERROR_CONNECTION_RESET	10	Connection was reset.
WEBVIEW_ERROR_DISCONNECTED	11	Disconnected during the operation.
WEBVIEW_ERROR_CANNOT_CONNECT	12	Failed to establish a connection.
WEBVIEW_ERROR_HOST_NAME_NOT_RESOLVED	13	DNS resolution failed for the host.
WEBVIEW_ERROR_OPERATION_CANCELED	14	Operation was canceled by the user or host.
WEBVIEW_ERROR_REDIRECT_FAILED	15	Redirection failed.
WEBVIEW_ERROR_UNEXPECTED_ERROR	16	An unexpected error occurred.
WEBVIEW_ERROR_CREDENTIALS_REQUIRED	17	Authentication credentials are required.
WEBVIEW_ERROR_PROXY_AUTHENTICATION_REQUIRED	18	Proxy authentication is required.
Events		
WEBVIEW_EVENT_WINDOW_ATTACHED	1	WebView attached to the host window. This is the first event that fires after the browser is created.
WEBVIEW_EVENT_WINDOW_DETACHED	2	WebView detached from the host window. This is the last event that fires before the browser is destroyed.
WEBVIEW_EVENT_FOCUS_CHANGED	3	WebView focus changed. The ***wParam*** value indicates if focus was gained (1) or lost (0).
WEBVIEW_EVENT_ACCELERATOR_KEYPRESS	4	Accelerator key event. The ***wParam*** value is the virtual-key code and ***lParam*** is the accelerator flags.
WEBVIEW_EVENT_NAVIGATION_STARTING	5	Navigation starting. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the navigation flags.
WEBVIEW_EVENT_NAVIGATION_COMPLETED	6	Navigation completed. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the error code.
WEBVIEW_EVENT_SECURITY_CHANGED	7	Security level changed. The ***wParam*** is the security level and ***lParam*** is the security flags.
WEBVIEW_EVENT_HISTORY_CHANGED	8	Back/forward availability changed. The ***wParam*** value is the history movement flags.
WEBVIEW_EVENT_DOWNLOAD_STARTING	9	A download has been initiated. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the file ID.
WEBVIEW_EVENT_DOWNLOAD_COMPLETED	10	A download has completed. The ***wParam*** value indicates success (1) or failure (0)

		and *lParam* is the file ID.
WEBVIEW_EVENT_MESSAGE_RECEIVED	11	Message received from a script on the page.
WEBVIEW_EVENT_SCRIPT_COMPLETED	12	Script execution completed. The *wParam* value indicates success (1) or failure (0) and *lParam* is the user-defined parameter.
Status Flags		
WEBVIEW_STATUS_SESSION_IDLE	0	No navigation in progress, the browser is in an idle state.
WEBVIEW_STATUS_NAVIGATING	0x0001	Currently navigating to a new location.
WEBVIEW_STATUS_NAVIGATION_ERROR	0x0002	The navigation failed due to an error.
WEBVIEW_STATUS_NAVIGATION_CANCELED	0x0004	The navigation was canceled by the user or host.
WEBVIEW_STATUS_NAVIGATION_TIMEOUT	0x0008	The navigation exceeded the configured timeout period.
WEBVIEW_STATUS_NAVIGATION_BLOCKED	0x0010	The navigation was blocked by policy.
WEBVIEW_STATUS_CONNECTION_FAILED	0x0100	The connection attempt failed or hostname was invalid.
WEBVIEW_STATUS_CONNECTION_ABORTED	0x0200	The connection was aborted or reset.
WEBVIEW_STATUS_SECURITY_WARNING	0x1000	The page includes insecure/mixed content or weak encryption was detected.
Icon Flags		
WEBVIEW_ICON_BIG	0x0001	Update the large window icon.
WEBVIEW_ICON_SMALL	0x0002	Update the small window icon.
WEBVIEW_ICON_BOTH	0x0003	Update both large and small icons.
WEBVIEW_ICON_DPI_AWARE	0x0100	Choose the system-recommended small icon size for the current DPI when possible.
Navigate Flags		
WEBVIEW_NAVIGATE_DEFAULT	0	Default navigation behavior.
WEBVIEW_NAVIGATE_SAFE_URL	0x0001	Applies additional URL safety checks and normalization before navigating.
Header Type Flags		
WEBVIEW_HEADERS_REQUEST	0x0001	Specifies custom request headers supplied by the client.
WEBVIEW_HEADERS_RESPONSE	0x0002	Specifies headers returned by the server in the last response.

Print Dialog Flags		
WEBVIEW_PRINT_DIALOG_DEFAULT	0	Use Edge's print preview dialog, equivalent to the Ctrl+P experience.
WEBVIEW_PRINT_DIALOG_SYSTEM	0x0001	Use the native system print dialog. Does not include print preview.
File Types (Save Document)		
WEBVIEW_FILE_TYPE_DEFAULT	0	Save using a format inferred from the file extension.
WEBVIEW_FILE_TYPE_TEXT	1	Save the document as a plain text file.
WEBVIEW_FILE_TYPE_HTML	2	Save the document as an HTML file.
WEBVIEW_FILE_TYPE_JSON	3	Save the document as JSON formatted string with reserved characters encoded.
WEBVIEW_FILE_TYPE_MHTML	4	Save the document as an MHTML single-file archive which includes all page assets.
WEBVIEW_FILE_TYPE_PDF	5	Save the document as a PDF file.
WEBVIEW_FILE_TYPE_JPEG	101	Save the current view as a JPEG image.
WEBVIEW_FILE_TYPE_PNG	102	Save the current view as a PNG image.
WEBVIEW_FILE_TYPE_WEBP	103	Save the current view as a WEBP image.
Download Status		
WEBVIEW_DOWNLOAD_STARTED	1	The file download has started and is in-progress.
WEBVIEW_DOWNLOAD_COMPLETED	2	The file download has completed successfully.
WEBVIEW_DOWNLOAD_CANCELED	3	The file download has been canceled.
WEBVIEW_DOWNLOAD_FAILED	4	The file download failed due to a network error or other problem.
Zoom		
WEBVIEW_ZOOM_MIN_PERCENT	25	Minimum zoom level as a percentage.
WEBVIEW_ZOOM_MAX_PERCENT	400	Maximum zoom level as a percentage.
WEBVIEW_ZOOM_DEFAULT	100	Default zoom level as a percentage.
Security Levels		
WEBVIEW_SECURITY_LEVEL_UNKNOWN	0	The security state could not be determined.
WEBVIEW_SECURITY_LEVEL_INSECURE	1	The page was retrieved using plain HTTP or the site has an invalid certificate.
WEBVIEW_SECURITY_LEVEL_WARNING	2	The page contains mixed content or only weak encryption is available.
WEBVIEW_SECURITY_LEVEL_NEUTRAL	3	Local content or the browser is in a

		transitional/loading state.
WEBVIEW_SECURITY_LEVEL_SECURE	4	The page was retrieved using HTTPS and the site has a valid certificate.
WEBVIEW_SECURITY_LEVEL_LOW	1	Alias of `WEBVIEW_SECURITY_LEVEL_WARNING`.
WEBVIEW_SECURITY_LEVEL_HIGH	4	Alias of `WEBVIEW_SECURITY_LEVEL_SECURE`.
Security Flags		
WEBVIEW_SECURITY_FLAG_NONE	0	No additional security indicators.
WEBVIEW_SECURITY_FLAG_UNENCRYPTED	0x0001	Content is not encrypted.
WEBVIEW_SECURITY_FLAG_INSECURE	0x0002	Site is insecure using outdated protocols or weak ciphers.
WEBVIEW_SECURITY_FLAG_CERT_WEAK	0x0004	The certificate uses weak signatures.
WEBVIEW_SECURITY_FLAG_CERT_ERROR	0x0008	The certificate is invalid. This is a general error condition.
WEBVIEW_SECURITY_FLAG_CERT_EXPIRED	0x0010	The certificate expired but is otherwise valid.
WEBVIEW_SECURITY_FLAG_UNSAFE	0x0020	The site is considered potentially unsafe (it failed reputation checks).

WebView Events

The library reports state changes and notifications through a user-defined callback function which is specified when a browser instance is created or attached to a window. For more information, refer to the **WebViewEventProc** function. It is not required for an application to implement handlers for each event. When there is no event handler for a specific event, the browser takes its default action for that event. For example, if your application does not implement a handler for the `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS` event then all accelerator key events are processed normally by the browser control.

Event Constants

Name	Description
WEBVIEW_EVENT_WINDOW_ATTACHED	This event is raised after the WebView2 control has been successfully attached to the specified host window. At this point the browser environment has been created, the controller has been initialized, and the browser instance is ready to accept navigation requests and configuration changes. Applications often use this event to perform initialization tasks such as setting a custom user agent, applying option flags, or starting the first navigation to a default URL. The event confirms that the control is operational and that subsequent API calls will succeed. The *wParam* value indicates success (1) or failure (0). If the browser could not be attached to the window, the *lParam* value will contain the HRESULT code returned by the browser's COM interface.
WEBVIEW_EVENT_WINDOW_DETACHED	This event occurs when the WebView2 control has been detached from its host window, either because the host window is being destroyed or because the application explicitly requested detachment. After this event has fired, the instance is no longer valid and should not be used for navigation or script execution. Applications typically use this event to clean up resources associated with the WebView, save state, or update their user interface to reflect that the browser view is no longer available. Any references to the WebView instance should be considered invalid after detachment.
WEBVIEW_EVENT_FOCUS_CHANGED	This event is raised whenever the browser window gains or loses keyboard focus relative to its host window. The *wParam* value indicates if focus was gained (1) or lost (0). This allows the application to track when user input is directed to the embedded browser versus other controls in the window. For example, you might use this event to update menu state, adjust shortcut key handling, or provide visual cues when the browser window is active.
WEBVIEW_EVENT_ACCELERATOR_KEYPRESS	This event is raised when the user presses an accelerator key combination such as the arrow keys, Page Up and Page Down, Insert, Delete, or other keys that the embedded

	browser normally handles. The ***wParam*** value is the virtual-key code and ***lParam*** is the accelerator flags. The event gives your application a chance to intercept these keystrokes before they are processed by the browser. This is especially useful when you want to provide custom navigation, prevent certain keys from being used, or integrate the control with application-level keyboard shortcuts. To prevent the default behavior being taken by the browser, call the **WebViewKeyEventHandled** function from within this event.
WEBVIEW_EVENT_NAVIGATION_STARTING	This event is fired when a new navigation request begins. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the navigation flags. The event is raised before any network request is made, ensuring that no data is sent until the handler has had a chance to approve or deny the navigation. The **WebViewGetNavigationUrl** function can be called to determine the new URL the browser is navigating to and the **WebViewCancelNavigation** function can be used to prevent the navigation.
WEBVIEW_EVENT_NAVIGATION_COMPLETED	This event is raised when a navigation request has finished loading. It is triggered regardless of whether the navigation succeeded or failed, with the ***wParam*** value indicating success (1) or failure (0). If the navigation has failed, the ***lParam*** value is the error code. Applications typically handle this event to update their UI once the content has loaded, or to implement custom error handling when navigation fails. Because the event always fires, even on errors, it is a reliable notification point for the end of a navigation sequence.
WEBVIEW_EVENT_SECURITY_CHANGED	This event occurs when the security level of the current connection changes. The ***wParam*** value is the security level and ***lParam*** is the security flags. For example, the level may change from neutral to secure once a certificate has been validated, or from secure to warning if mixed content is detected. Additional information about the state of the connection can be obtained by calling the **WebViewGetSecurityInfo** function. Applications often use this event to update visual indicators such as a padlock icon or to apply additional security-related policies. It is important to note that this event may be raised multiple times during a single navigation, and earlier values should be discarded in favor of the most recent state.
WEBVIEW_EVENT_HISTORY_CHANGED	This event occurs whenever the browsing history changes. The ***wParam*** value is the history movement flags. Navigating to a new page, using the **WebViewGoBack** or **WebViewGoForward** functions, or programmatically calling navigation functions can trigger this event. Your application can respond by enabling or disabling UI elements such as toolbar buttons depending on whether it is possible to go

	back or forward.
WEBVIEW_EVENT_DOWNLOAD_STARTING	This event occurs when a file download is initiated either by a user clicking on a link or navigating to a URL which specifies content that cannot be rendered in the browser. The *wParam* value indicates success (1) or failure (0) and *lParam* is the unique file identifier which can be used to identify the specific download. This identifier can be used with the **WebViewGetDownloadInfo** function to obtain information about the download in progress.
WEBVIEW_EVENT_DOWNLOAD_COMPLETED	This event occurs when a file download has completed. The *wParam* value indicates success (1) or failure (0) and *lParam* is the unique file identifier. If the file download is canceled, it is considered to be a failed download. The **WebViewGetDownloadInfo** function can be used to obtain information about the download, such as the total number of bytes copied, how much time elapsed and the full path of the local file that was created.
WEBVIEW_EVENT_MESSAGE_RECEIVED	This event occurs when a message is posted from JavaScript code in the web page using `window.chrome.webview.postMessage`. The message is delivered as a string, which can be retrieved using the **WebViewGetMessage** function. The message may include structured data such as JSON or it may be a simple JSON formatted string. This event provides a two-way communication channel between the page content and the host application, allowing developers to implement hybrid scenarios where the web page can notify the native host of user actions, requests, or state changes. If messages are not enabled, this event will not be raised.
WEBVIEW_EVENT_SCRIPT_COMPLETED	This event is raised when a script execution initiated by the application completes. The *wParam* value indicates success (1) or failure (0) and *lParam* is the user-defined parameter provided when the **WebViewAsyncExecute** function was called. The **WebViewGetResult** function can be called to obtain the result of the script execution. If the script contained errors or could not be executed, the status will reflect a failure condition. Applications typically use this event to retrieve values from the page, execute custom logic in response to script results, or detect when asynchronous script operations have finished. Because script execution is asynchronous, this event is the definitive way to know when a script call has finished.

Remarks

Some events, such as `WEBVIEW_EVENT_NAVIGATION_STARTING` and `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS`, allow your application to influence behavior by canceling an action or handling a keypress. Others, like `WEBVIEW_EVENT_HISTORY_CHANGED` or `WEBVIEW_EVENT_SECURITY_CHANGED`, are informational and allow you to update user interface

elements or record state.

If your application does not enable specific options (such as allowing scripts, dialogs, or message passing), the corresponding events will not be raised. For example, if messages are disabled, the `WEBVIEW_EVENT_MESSAGE_RECEIVED` event will never occur. This makes it important to configure options appropriately for the scenarios you wish to support.

Whois Protocol Library

Request registration information for an Internet domain name.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSWHOV12.DLL
Version	12.0.3024.1286
LibID	A3CFB881-EB11-4A10-95A2-C357BF955F74
Import Library	CSWHOV12.LIB
Dependencies	None
Standards	RFC 954

Overview

The Whois protocol library provides an interface for requesting registration information for an Internet domain name. When a domain name is registered, the organization that registers the domain must provide certain contact information along with technical information such as the primary name servers for that domain. The library provides an API for requesting that information and returning it to the program so that it can be displayed or processed. This library would be most commonly used to query the Whois server at **whois.internic.net** to obtain information about a specific Internet domain name or an administrative contact at that domain.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing

applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Whois Protocol Functions

Function	Description
WhoisAsyncConnect	Connect asynchronously to the specified server
WhoisAttachThread	Attach the specified client handle to another thread
WhoisCancel	Cancel the current blocking operation
WhoisConnect	Connect to the specified server
WhoisDisableEvents	Disable asynchronous event notification
WhoisDisableTrace	Disable logging of network function calls
WhoisDisconnect	Disconnect from the current server
WhoisEnableEvents	Enable asynchronous event notification
WhoisEnableTrace	Enable logging of network function calls to a file
WhoisEventProc	Callback function that processes events generated by the client
WhoisFreezeEvents	Suspend or resume event handling by the calling process
WhoisGetErrorString	Return a description for the specified error code
WhoisGetLastError	Return the last error code
WhoisGetStatus	Return the current client status.
WhoisGetTimeout	Return the number of seconds until an operation times out
WhoisInitialize	Initialize the library and validates the specified license key at runtime
WhoisIsBlocking	Determine if the client is blocked, waiting for information
WhoisIsConnected	Determine if the client is connected to the server
WhoisIsReadable	Determine if there is data available to be read from the server
WhoisRead	Read data returned by the server
WhoisRegisterEvent	Register an event callback function
WhoisSearch	Search for the specified record
WhoisSetLastError	Set the last error code
WhoisSetTimeout	Set the number of seconds until an operation times out
WhoisUninitialize	Terminate use of the library by the application

WhoisAsyncConnect Function

```
HCLIENT WINAPI WhoisAsyncConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwReserved,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **WhoisAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **WhoisConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwReserved

A reserved parameter. This value should always be zero.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this parameter is NULL, then a synchronous (blocking) connection will be established with the server.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **WhoisGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has

occurred. The *wParam* parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **WhoisDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

WhoisAttachThread Function

```
DWORD WINAPI WhoisAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **WhoisAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **WhoisAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **WhoisAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **WhoisCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **WhoisUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisConnect, WhoisDisconnect, WhoisUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WhoisCancel Function

```
INT WINAPI WhoisCancel(
   HCLIENT hClient
);
```

The **WhoisCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

When the **WhoisCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisIsBlocking

WhoisConnect Function

```
HCLIENT WINAPI WhoisConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwReserved
);
```

The **WhoisConnect** function is used to establish a connection with the specified server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **WhoisConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

WhoisDisableEvents Function

```
INT WINAPI WhoisDisableEvents(
    HCLIENT hClient
);
```

The **WhoisDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

WhoisDisableTrace Function

```
BOOL WINAPI WhoisDisableTrace();
```

The **WhoisDisableTrace** function disables the logging of network function calls file.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

WhoisDisconnect Function

```
INT WINAPI WhoisDisconnect(
   HCLIENT hClient
);
```

The **WhoisDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

WhoisEnableEvents Function

```
INT WINAPI WhoisEnableEvents(
    HCLIENT hClient,
    HWND hEventWnd,
    UINT uEventMsg
);
```

The **WhoisEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **WhoisRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a

	connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To cancel asynchronous notification and return the client to a blocking mode, use the **WhoisDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisDisableEvents, WhoisFreezeEvents, WhoisRegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WhoisEnableTrace Function

```
BOOL WINAPI WhoisEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **WhoisEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

WhoisEventProc Function

```
VOID CALLBACK WhoisEventProc(
    HCLIENT hClient,
    UINT nEventId,
    DWORD dwError,
    DWORD_PTR dwParam
);
```

The **WhoisEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hClient

The handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **WhoisRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **WhoisRegisterEvent** function. The **WhoisEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisDisableEvents, WhoisEnableEvents, WhoisFreezeEvents, WhoisRegisterEvent

WhoisFreezeEvents Function

```
INT WINAPI WhoisFreezeEvents(
    HCLIENT hClient,
    BOOL bFreeze
);
```

The **WhoisFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisGetErrorString Function

```
INT WINAPI WhoisGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **WhoisGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **WhoisGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

WhoisGetLastError, WhoisSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WhoisGetLastError Function

```
DWORD WINAPI WhoisGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **WhoisSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **WhoisGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **WhoisSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WHOIS_ERROR. Those functions which call **WhoisSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisGetErrorString, WhoisSetLastError

WhoisGetStatus Function

```
INT WINAPI WhoisGetStatus(
   HCLIENT hClient
);
```

The **WhoisGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

The **WhoisGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
WHOIS_STATUS_IDLE	The client is current idle and not sending or receiving data.
WHOIS_STATUS_CONNECT	The client is establishing a connection with the server.
WHOIS_STATUS_READ	The client is reading data from the server.
WHOIS_STATUS_WRITE	The client is writing data to the server.
WHOIS_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WhoisGetTimeout Function

```
INT WINAPI WhoisGetTimeout(
   HCLIENT hClient
);
```

The **WhoisGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisInitialize Function

```
BOOL WINAPI WhoisInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **WhoisInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WhoisGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **WhoisInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **WhoisUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **WhoisInitialize** or **WhoisUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

WhoisIsBlocking Function

```
BOOL WINAPI WhoisIsBlocking(
    HCLIENT hClient
);
```

The **WhoisIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns TRUE. If the client is not performing a blocking operation, or the client handle is invalid, the function returns FALSE.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **WhoisIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisCancel, WhoisGetStatus, WhoisIsConnected, WhoisIsReadable

WhoisIsConnected Function

```
BOOL WINAPI WhoisIsConnected(
    HCLIENT hClient
);
```

The **WhoisIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisGetStatus, WhoisIsBlocking, WhoisIsReadable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WhoisIsReadable Function

```
BOOL WINAPI WhoisIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **WhoisIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisGetStatus, WhoisIsBlocking, WhoisIsConnected

WhoisRead Function

```
INT WINAPI WhoisRead(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **WhoisRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

When **WhoisRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

WhoisRegisterEvent Function

```
INT WINAPI WhoisRegisterEvent(
   HCLIENT hClient,
   UINT nEventId,
   WHOISEVENTPROC lpfnEvent,
   DWORD_PTR dwParam
);
```

The **WhoisRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One or more of the following values may be used:

Value	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpfnEvent

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WhoisEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86

(32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **WhoisRegisterEvent** function associates a callback function with a specific event. The event handler is an **WhoisEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisSearch Function

```
INT WINAPI WhoisSearch(
   HCLIENT hClient,
   LPCTSTR lpszKeyword,
   UINT nSearchType
);
```

The **WhoisSearch** function submits the specified keyword to the server.

Parameters

hClient

Handle to the client session.

lpszKeyword

Points to a string which specifies the query keyword. It may be a handle, name or mailbox.

nSearchType

The type of search being performed. One of the following values may be used:

Value	Description
WHOIS_SEARCH_ANY	Search for any record that matches the specified keyword.
WHOIS_SEARCH_HANDLE	Search only for handles that match the specified keyword.
WHOIS_SEARCH_MAILBOX	Search only for mailboxes that match the specified keyword.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WhoisSetLastError Function

```
VOID WINAPI WhoisSetLastError(
    DWORD dwErrorCode
);
```

The **WhoisSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WHOIS_ERROR. Those functions which call **WhoisSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **WhoisGetLastError** function. The use of **WhoisGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisGetErrorString, WhoisGetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WhoisSetTimeout Function

```
INT WINAPI WhoisSetTimeout(
   HCLIENT hClient,
   UINT nTimeout
);
```

The **WhoisSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is WHOIS_ERROR. To get extended error information, call **WhoisGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

WhoisGetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WhoisUninitialize Function

```
VOID WINAPI WhoisUninitialize();
```

The **WhoisUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **WhoisInitialize** call before it can call any of the other the library functions. When it has finished using the library, the application must call **WhoisUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **WhoisUninitialize** for every successful call to **WhoisInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

SocketWrench Windows Sockets Library

A general purpose TCP/IP networking library for developing client and server applications.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSWSKV12.DLL
Version	12.0.3024.1286
LibID	99EEE601-E935-4266-B046-771A823DB47D
Import Library	CSWSKV12.LIB
Dependencies	None
Standards	RFC 768, RFC 791, RFC 793

Overview

At the core of all of the SocketTools networking libraries is the Windows Sockets API. This provides a low level interface for sending and receiving data over the Internet or a local intranet using the Transmission Control Protocol (TCP) and/or User Datagram Protocol (UDP). The SocketWrench library provides a simpler interface to the Windows Sockets API, without sacrificing features or functionality. Using SocketWrench, you can easily create client and server applications while avoiding many of the mundane tasks and common problems that developers face when building Internet applications.

This class library supports secure connections using the TLS 1.2 and TLS 1.3 protocols and can also be used to create secure, customized server applications. Both implicit and explicit TLS connections are supported, enabling the class to work with a wide variety of client and server applications without requiring third-party encryption libraries.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on

ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SocketWrench Library Functions

Function	Description
InetAbort	Abort the connection and immediately close the socket
InetAccept	Accept a connection request from a remote host
InetAcceptEx	Accept a client connection on a listening socket with additional options
InetAsyncAccept	Accept an asynchronous connection request from a remote host
InetAsyncAcceptEx	Accept a non-blocking connection on a listening socket
InetAsyncConnect	Connect asynchronously to the specified server
InetAsyncConnectEx	Connect asynchronously to the specified server
InetAsyncListen	Listen for client connections on an asynchronous socket
InetAsyncListenEx	Listen for client connections on an asynchronous socket with additional options
InetAttachSocket	Attach the socket handle to the specified process
InetAttachThread	Attach the specified socket to another thread
InetCancel	Cancel a blocking operation
InetClientBroadcast	Write data to all other clients that are connected to the same server
InetCompareAddress	Compare two IP addresses to determine if they are identical
InetConnect	Connect to the specified server
InetConnectEx	Connect to the specified server with additional connection information
InetConnectUrl	Connect to the specified server using a URL
InetCreateSecurityCredentials	Create a new security credentials structure
InetDeleteSecurityCredentials	Delete a previously created security credentials structure
InetDetachSocket	Detach the socket handle from the current process
InetDisableEvents	Disable asynchronous event notification
InetDisableSecurity	Disable secure communication with the remote host
InetDisableTrace	Disable logging of network function calls
InetDisconnect	Disconnect from the current server
InetEnableEvents	Enable asynchronous event notification
InetEnableSecurity	Enable secure communication with the remote host
InetEnableTrace	Enable logging of network function calls to a file
InetEnumHostAliases	Return a byte array that contains all the aliases for a specified host
InetEnumNetworkAddresses	Return the list of network addresses that are configured for the local host
InetEnumServerClients	Returns a list of active client sessions established with the specified server
InetEnumServerClientsByAddress	Returns a list of active client sessions that match the specified IP address
InetEventProc	Callback method that processes events generated on the socket
InetFindClientMoniker	Returns a handle to the client socket which matches the specified moniker
InetFlush	Flush the send and receive buffers
InetFormatAddress	Convert an IP address in binary format into a printable string
InetFreezeEvents	Suspend or resume event handling by the application
InetGetAdapterAddress	Return the IP or MAC assigned to the specified network adapter

InetGetAddress	Convert an IP address string to a binary format
InetGetAddressFamily	Return the address family for the specified IP address
InetGetBlockingSocket	Return the handle for the socket which is blocked in the current thread
InetGetDefaultHostFile	Return the fully qualified path name of the host file on the local system
InetGetClientData	Returns the application defined data associated with the specified client session
InetGetClientHandle	Returns the handle for a specific client session based on its ID number
InetGetClientId	Returns the unique ID number assigned to the specified client session
InetGetClientIdleTime	Returns the amount of time the specified client session has been idle
InetGetClientMoniker	Returns the string alias associated with the specified client session
InetGetClientPriority	Returns the current priority for the specified client session
InetGetClientServer	Returns a socket handle to the server for the specified client socket
InetGetClientServerById	Returns a socket handle to the server for the specified session identifier
InetGetClientThreadId	Returns the thread ID for the specified client session
InetGetClientThreads	Returns the number of client session threads created by the server
InetGetErrorString	Return a description for the specified error code
InetGetExternalAddress	Return the external IP address assigned to the local system
InetGetHostAddress	Return the IP address assigned to the specified hostname
InetGetHostFile	Return the name of the host file
InetGetHostName	Return the hostname assigned to the specified IP address
InetGetLastError	Return the last error code
InetGetLocalAddress	Return the local IP address and port number for a socket
InetGetLocalName	Return the hostname assigned to the local system
InetGetLockedServer	Return the handle to the server which has been locked
InetGetMemoryUsage	Return the amount of memory allocated for the network connection
InetGetOption	Return the current socket options
InetGetPeerAddress	Return the IP address of the peer that the socket is connected to
InetGetPhysicalAddress	Return the media access control (MAC) address for the primary network adapter
InetGetSecurityInformation	Return information about the security characteristics of a connection
InetGetServerClient	Return the handle for the last client connection accepted by the server
InetGetServerData	Returns the application defined data associated with the specified server
InetGetServerPriority	Return the current priority assigned to the specified server
InetGetServerStackSize	Return the initial size of the stack allocated for threads created by the server
InetGetServerStatus	Returns the status of the specified server
InetGetServerThreadId	Returns the thread ID for the specified server
InetGetServiceName	Return the service name associated with a specified port number
InetGetServicePort	Return the port number associated with a service name
InetGetStatus	Report what sort of socket operation is in progress
InetGetStreamInfo	Return information about the current stream read or write operation
InetGetThreadClient	Return the handle for the client session that is being managed by the specified thread
InetGetTimeout	Return the timeout interval for blocking operations, in seconds

InetGetUrlHostName	Return the host name and port number specified in a URL
InetGetVpnAdapter	Return the name of the active Virtual Private Network adapter
InetHostNameToUnicode	Converts the canonical form of a host name to its Unicode version
InetInitialize	Initialize the library and validate the specified user license key at runtime
InetIsAddressNull	Determine if the specified IP address is a null address
InetIsAddressRoutable	Determine if the specified IP address is routable over the Internet
InetIsBlocking	Determine if the socket is performing a blocking operation
InetIsClosed	Determine if the remote host has closed its socket
InetIsConnected	Determine if the socket is connected to a remote host
InetIsListening	Determine if the socket is listening for a connection
InetIsProtocolAvailable	Determine if the specified protocol and address family are supported
InetIsReadable	Determine if date can be read from the remote process
InetIsUrgent	Determine if there is any out-of-band (OOB) data available to be read
InetIsWritable	Determine if data can be written to the remote process
InetListen	Listen for client connections on the specified socket
InetListenEx	Listen for client connections on the specified socket with additional options
InetMatchHostName	Match a host name against of list of addresses including wildcards
InetNormalizeHostName	Return the canonical form of a host name
InetPeek	Read data from the socket without removing it from the socket buffer
InetRead	Read data from the socket
InetReadEx	Read data from the socket, with extended functionality
InetReadLine	Read a line of data from the socket, storing it in a string buffer
InetReadStream	Read a stream of data from the socket
InetRegisterEvent	Register an event callback function
InetReject	Reject a pending client connection request
InetServerAsyncNotify	Enable or disable asynchronous notification of changes in server status
InetServerBroadcast	Write data to all active clients currently connected to the specified server
InetServerLock	Lock the specified server, causing all other client threads to block until it is unlocked
InetServerRestart	Restart the server, terminating all active client sessions
InetServerResume	Resume accepting client connections on the specified server
InetServerStart	Begin listening for client connections on the specified address and port
InetServerStop	Stop listening for connections and terminate all client sessions
InetServerStopEx	Stop listening for connections and wait for the server to terminate
InetServerSuspend	Suspend accepting client connections on the specified server
InetServerSuspendEx	Suspend accepting client connections and optionally reject or disconnect clients
InetServerThrottle	Limit the number of active client connections, connections per address and connection rate
InetServerUnlock	Unlock the specified server, allowing other client threads to resume execution
InetSetClientData	Associate application defined data with the specified client session
InetSetClientMoniker	Associate a unique string alias with the specified client session

InetSetClientPriority	Set the priority for the specified client session
InetSetServerData	Associate application defined data with the specified server
InetSetServerPriority	Change the priority assigned to the specified server
InetSetServerStackSize	Change the initial size of the stack allocated for threads created by the server
InetSetHostFile	Specify the name of an alternate host table
InetSetLastError	Set the last error code
InetSetOption	Set one or more options for the current socket
InetSetTimeout	Set the interval used when waiting for a blocking operation to complete
InetShutdown	Disable reception or transmission of data
InetStoreStream	Read a stream of data from the remote host and store it in a file
InetUninitialize	Terminate use of the library by the application
InetValidateCertificate	Validate the specified security certificate is installed on the local system
InetValidateHostName	Validate the specified host name and return the resolved IP address
InetWrite	Write data to the socket
InetWriteEx	Write data to the socket, with extended functionality
InetWriteLine	Write a line of data to the socket, terminated with a carriage-return and linefeed
InetWriteStream	Write a stream of data to the socket

InetAbort Function

```
INT WINAPI InetAbort(
   SOCKET hSocket
);
```

Immediately close the socket without waiting for any remaining data to be written out.

Parameters

hSocket

Handle to the socket.

Return Value

If the function succeeds, the return value is 0. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetAbort** function should only be used when the connection must be closed immediately before the application terminates. This function should only be used to abort client connections and should not be used with passive (listening) sockets. Server applications that need to abort an incoming client connection should use the **InetReject** function.

In most cases, the application should call the **InetDisconnect** function to gracefully close the connection to the remote host. Aborting the connection will discard any buffered data and may cause errors or result in unpredictable behavior.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetAccept Function

```
SOCKET WINAPI InetAccept(
   SOCKET hSocket,
   UINT nTimeout
);
```

The **InetAccept** function is used to accept a pending client connection.

This function has been deprecated and is included for backwards compatibility. Use the **InetServerStart** function to create a server application.

Parameters

hSocket

Handle to the listening socket.

nTimeout

The number of seconds that the server will wait for the connection to complete before failing the operation.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

When a connection is accepted by the server, the original listening socket continues to listen for more connections. The socket handle returned by **InetAccept** should be used to exchange information with the client.

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and accept the connection by calling **InetAccept** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

To accept a secure connection, use the **InetAcceptEx** function and specify the INET_OPTION_SECURE option.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetAcceptEx Function

```
SOCKET WINAPI InetAcceptEx(
   SOCKET hSocket,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **InetAcceptEx** function is used to accept a pending client connection.

This function has been deprecated and is included for backwards compatibility. Use the **InetServerStart** function to create a server application.

Parameters

hSocket

Handle to the socket.

nTimeout

The number of seconds that the server will wait for a client connection before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.
INET_OPTION_INLINE	This option controls how urgent (out-of-band) data is handled when reading data from the socket. If set, urgent data is placed in the data stream along with non-urgent data.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has stopped the server.
INET_OPTION_SECURE	This option determines if a secure connection is negotiated with the remote host.
INET_OPTION_SECURE_FALLBACK	This option specifies the server should permit the use of less secure cipher suites for compatibility with legacy clients. If this option is specified, the server will

	allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This may be NULL, unless ***dwOptions*** includes INET_OPTION_SECURE. When INET_OPTION_SECURE is used, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

When a connection is accepted by the server, the original listening socket continues to listen for more connections. The socket handle returned by **InetAcceptEx** should be used to exchange information with the client.

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and accept the connection by calling **InetAcceptEx** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The ***dwOptions*** argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetAsyncAccept Function

```
SOCKET WINAPI InetAsyncAccept(
    SOCKET hSocket,
    UINT nTimeout,
    HWND hEventWnd,
    UINT uEventMsg
);
```

The **InetAsyncAccept** function is used to accept a pending client connection.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Use the **InetServerStart** function to create a server application.

Parameters

hSocket

Handle to the listening socket.

nTimeout

The number of seconds that the server will wait for the connection to complete before failing the operation. This value is used only if ***hWnd*** is NULL.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

When a connection is accepted by the server, the original listening socket continues to listen for more connections. The socket handle returned by **InetAsyncAccept** should be used to exchange information with the client.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the socket handle. One or more of the following event identifiers may be sent:

Value	Description
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some of

	the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetAsyncAcceptEx Function

```
SOCKET WINAPI InetAsyncAcceptEx(
   SOCKET hSocket,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **InetAsyncAcceptEx** function is used to accept a pending client connection.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Use the **InetServerStart** function to create a server application.

Parameters

hSocket

Handle to the listening socket.

nTimeout

The number of seconds that the server will wait for a client connection before failing the operation. This value is only used with blocking connections.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.
INET_OPTION_INLINE	This option controls how urgent (out-of-band) data is handled when reading data from the socket. If set, urgent data is placed in the data stream along with non-urgent data.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has stopped

	the server.
INET_OPTION_SECURE	This option determines if a secure connection is negotiated with the remote host.
INET_OPTION_SECURE_FALLBACK	This option specifies the server should permit the use of less secure cipher suites for compatibility with legacy clients. If this option is specified, the server will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This may be NULL, unless dwOptions includes INET_OPTION_SECURE. When INET_OPTION_SECURE is used, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

When a connection is accepted by the server, the original listening socket continues to listen for more connections. The socket handle returned by **InetAsyncAccept** or **InetAsyncAcceptEx** should be used to exchange information with the client.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the socket handle. One or more of the following event identifiers may be sent:

Value	Description
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.

INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.

It is recommended that you only establish an asynchronous connection if you understand the implications of doing so. In most cases, it is preferable to create a synchronous connection and create threads for each additional session if more than one active client session is required.

The ***dwOptions*** argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetAsyncConnect Function

```
SOCKET WINAPI InetAsyncConnect(
   LPCTSTR lpszHostName,
   UINT nPort,
   UINT nProtocol,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **InetAsyncConnect** function is used to establish a connection with a server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **InetConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

Parameters

lpszHostName

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nPort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Value	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for a response before failing the current operation.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is constructed by using the bitwise Or operator with any of the following values:

Value	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be

	enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_DONTROUTE	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_RESERVEDPORT	This option specifies the socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the TLS protocol.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the ***lpCredentials*** parameter. If the ***lpCredentials*** parameter is NULL, the connection will default to using TLS 1.2 and the strongest cipher suites available. Older versions of Windows prior to Windows 7 and Windows Server 2008 R2 only support TLS 1.0 and secure connections will automatically downgrade on those platforms.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.

INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure. This parameter is only used if INET_OPTION_SECURE is specified for a TCP connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

When this function is called with UDP as the specified protocol, it does not actually establish a connection. Instead, it simply establishes a default destination IP address and port that is used with subsequent **InetRead** and **InetWrite** calls.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the socket handle. One or more of the following event identifiers may be sent:

Value	Description
INET_EVENT_CONNECT	The connection to the remote host has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.

INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.

To cancel asynchronous notification and return the socket to a blocking mode, use the **InetDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetAsyncConnectEx Function

```
SOCKET WINAPI InetAsyncConnectEx(
   LPCTSTR lpszHostName,
   UINT nPort,
   UINT nProtocol,
   UINT nTimeout,
   DWORD dwOptions,
   LPCTSTR lpszLocalAddress,
   UINT nLocalPort,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **InetAsyncConnectEx** function is used to establish a connection with a server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **InetConnectEx** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

Parameters

lpszHostName

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nPort

The port number the server is listening on; a value of zero specifies that the default port number should be used.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Value	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for a response before failing the current operation.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are recognized:

Value	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_DONTROUTE	This option specifies default routing should not be used. This option should not be specified unless absolutely necessary.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_RESERVEDPORT	This option specifies the socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the TLS protocol.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the ***lpCredentials*** parameter. If the ***lpCredentials*** parameter is NULL, the connection will default to using TLS 1.2 and the strongest cipher suites available. Older versions of Windows prior to Windows 7 and Windows Server 2008 R2 only support TLS 1.0 and secure connections will automatically downgrade on those platforms.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will

	allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

lpszLocalAddress

A null-terminated string that specifies the local IP address that the socket should be bound to. If this parameter is NULL, then an appropriate address will automatically be used. A specific address should only be used if it is required by the application.

nLocalPort

The local port number that the socket should be bound to. If this parameter is set to zero, then an appropriate port number will automatically be used. A specific port number should only be used if it is required by the application.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure. This parameter is only used if INET_OPTION_SECURE is specified for a TCP connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the socket handle. One or more of the following event identifiers may be sent:

Value	Description
INET_EVENT_CONNECT	The connection to the remote host has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetAsyncListen Function

```
SOCKET WINAPI InetAsyncListen(
   LPCTSTR lpszLocalAddress,
   UINT nLocalPort,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **InetAsyncListen** function creates an listening socket.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Use the **InetServerStart** function to create a server application.

Parameters

lpszLocalAddress

A null-terminated string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The socket option INET_OPTION_REUSEADDRESS is enabled by default when calling the **InetAsyncListen** function. This allows an application to re-use a local address and port number when

creating the listening socket. If this behavior is not desired, use the **InetAsyncListenEx** function instead.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the socket handle. One or more of the following event identifiers may be sent:

Value	Description
INET_EVENT_ACCEPT	The process has received a connection request from a client and should accept the connection using the **InetAsyncAccept** function. This event is only generated for server applications which have created an asynchronous socket using the **InetAsyncListen** function.

To cancel asynchronous notification and return the socket to a blocking mode, use the **InetDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetAsyncListenEx Function

```
SOCKET WINAPI InetAsyncListenEx(
   LPCTSTR lpszLocalAddress,
   UINT nLocalPort,
   UINT nBacklog,
   DWORD dwOptions,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **InetAsyncListenEx** function creates an listening socket.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Use the **InetServerStart** function to create a server application.

Parameters

lpszLocalAddress

A null-terminated string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

nBacklog

The maximum length of the queue allocated for pending client connections. A value of zero specifies that the size of the queue should be set to a maximum reasonable value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are supported:

Value	Description
INET_OPTION_NONE	No option specified. If the address and port number are in use by another application or a closed socket which was listening on this port is still in the TIME_WAIT state, the function will fail.
INET_OPTION_REUSEADDRESS	This option enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable an application to close the listening socket and

	immediately reopen it without getting an error that the address is in use.
INET_OPTION_EXCLUSIVE	This option specifies the local address and port number is for the exclusive use by the current process, preventing another application from forcibly binding to the same address. If another process has already bound a socket to the address provided by the caller, this function will fail.
INET_OPTION_RESERVEDPORT	This option specifies the listening socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges and firewall rules that will permit a client to establish a connection with the service.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has stopped the server.

hEventWnd

The handle to the event notification window. This window receives messages which notify the application of various asynchronous socket events that occur.

uEventMsg

The message identifier that is used when an asynchronous socket event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to the socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

If the INET_OPTION_REUSEADDRESS option is not specified, an error may be returned if a listening socket was recently created for the same local address and port number. By default, once a listening socket is closed there is a period of time that all applications must wait before the address can be reused (this is called the TIME_WAIT state). The actual amount of time depends on the operating system and configuration parameters, but is typically two to four minutes. Specifying this option enables an application to immediately re-use a local address and port number that was previously in use.

If the INET_OPTION_EXCLUSIVE option is specified, the local address and port number cannot be used by another process until the listening socket is closed. This can prevent another application from forcibly binding to the same listening address as your server. This option can be useful in determining whether or not another process is already bound to the address you wish to use, but it may also

prevent your server application from restarting immediately, regardless if the INET_OPTION_REUSEADDRESS option has also been specified.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the socket handle. One or more of the following event identifiers may be sent:

Value	Description
INET_EVENT_ACCEPT	An incoming client connection is pending. The connection will be assigned to a new socket. This event is only generated if the socket is in asynchronous mode.

To cancel asynchronous notification and return the socket to a blocking mode, use the **InetDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetAttachSocket Function

```
SOCKET WINAPI InetAttachSocket(
    SOCKET hSocket
    DWORD dwProcessId
);
```

The **InetAttachThread** function attaches the specified socket handle to another thread.

Parameters

hSocket

Handle to the socket.

dwProcessId

The process ID for the process that currently owns the socket handle. This value may be zero to specify the current process.

Return Value

If the function succeeds, the return value is the handle to the attached socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetAttachSocket** function enables an application to attach an external socket handle to the current thread and initializes it for use by the library. An external socket is any socket handle created directly by the Windows Sockets API or by a third-party library. If the ***dwProcessId*** parameter is zero or specifies the current process ID, then the function checks to see if the socket was created by this library. If it was, then its owner context is switched to the current thread; if the socket was created externally, then it is initialized for use by the library and attached to the current thread.

If the ***dwProcessId*** parameter specifies another process, the socket will be duplicated into the current process, attached to the current thread and the original socket handle will be closed in the other process. This enables an application to effectively take control of a connection created by another process. The original socket handle must be inheritable by the by the current process and must be an actual Windows socket handle, not a pseudo-handle. This functionality is only supported on Windows NT 4.0 and later versions of the operating system with the Microsoft TCP/IP stack. Note that Layered Service Providers (LSPs) may interfere with the ability to inherit handles across processes.

The attached socket is initialized in a blocking state, even if was originally using asynchronous socket events. If the application requires that the socket use events, it must explicitly call **InetEnableEvents** using the handle returned by this function.

In most cases, the handle returned by this function will be the same value as the ***hSocket*** parameter, however an application should never make the assumption that this will be the case. If **InetAttachSocket** returns a socket handle that has a different value than the ***hSocket*** parameter, this indicates that the original handle has been destroyed and should never be used in subsequent function calls.

This function should never be used with a secure socket connection because the attached socket will not have the security context required to encrypt and decrypt the data exchanged with the remote host.

Example

To demonstrate how to pass sockets between processes, this example will use two programs; one

acting as a server to listen for client connections and accept them, the other inheriting the client socket and echoing back anything the client sends. The first program will create the listening socket, and when a client connects, it will call **CreateProcess** to create a new child process to handle that connection.

```
SOCKET hServer;
SOCKET hClient;

// Initialize the library

if (!InetInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    return;

// Listen for incoming client connections

if ((hServer = InetListen(NULL, nLocalPort)) == INVALID_SOCKET)
    return;

while (TRUE)
{
    hClient = InetAccept(hServer, 10);

    if (hClient == INVALID_SOCKET)
    {
        // If InetAccept has timed-out, then simply loop back and attempt
        // to continue accepting connections; otherwise, exit the loop

        if (InetGetLastError() != ST_ERROR_OPERATION_TIMEOUT)
            break;
    }
    else
    {
        STARTUPINFO si;
        PROCESS_INFORMATION pi;
        CHAR szCommandLine[512];
        BOOL bResult;

        // Detach the socket, which will free the memory that the library
        // has allocated for it without actually destroying the socket handle;
        // the child process will close the handle in this process when it
        // attaches to it
        InetDetachSocket(hClient, 0);

        // Initialize the STARTUPINFO structure
        ZeroMemory(&si, sizeof(si));

        // Create the command line arguments, passing the current
        // process ID and socket handle to the new process

        wsprintf(szCommandLine, "%s %lu %lu",
                 lpszAppName,
                 (DWORD)GetCurrentProcessId(),
                 (DWORD)hClient);

        // Create the child process

        bResult = CreateProcess(NULL,
                                szCommandLine,
                                NULL, NULL,
```

```
                                    TRUE,
                                    CREATE_DEFAULT_ERROR_MODE,
                                    NULL, NULL,
                                    &si, &pi);

        if (!bResult)
            InetDisconnect(hClient);
    }
}

InetDisconnect(hServer);
InetUninitialize();
```

The second program attaches to the socket handle that was passed to it by the parent process. It goes into a loop, reading any data sent to it by the client and sending the same data back. When the client disconnects, the **InetRead** function will return 0, it will exit the loop and the process will terminate.

```
SOCKET hSocket;
SOCKET hClient;
DWORD dwProcessId;

// Initialize the library

if (!InetInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    return;

// Process command line arguments that were passed to us
// by the server process

dwProcessId = (DWORD)atol(argv[1]);
hClient = (SOCKET)atol(argv[2]);

// Attach to the hClient socket that the server passed
// to us; this will close the socket in the server process

hSocket = InetAttachSocket(hClient, dwProcessId);

if (hSocket != INVALID_SOCKET)
{
    BYTE cBuffer[512];
    int nRead;

    do
    {
        // Read any data sent to us by the client
        nRead = InetRead(hSocket, cBuffer, sizeof(cBuffer));

        // Echo the data we have read back to the client
        if (nRead > 0)
            InetWrite(hSocket, cBuffer, nRead);
    }
    while (nRead > 0);

    InetDisconnect(hSocket);
}

InetUninitialize();
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

InetAttachThread Function

```
DWORD WINAPI InetAttachThread(
    SOCKET hSocket
    DWORD dwThreadId
);
```

The **InetAttachThread** function attaches the specified socket handle to another thread.

Parameters

hSocket

Handle to the socket.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the socket handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

When a socket handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in an application to create the socket, and then pass that handle to another worker thread. The **InetAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **InetAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **InetCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **InetUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetCancel Function

```
INT WINAPI InetCancel(
   SOCKET hSocket
);
```

The **InetCancel** function cancels a blocking operation.

Parameters

hSocket

Handle to the socket.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

When the **InetCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

This function is typically called from within an event handler to signal that the current blocking operation should stop. It may also be used to cancel a blocking operation that is occurring on another thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetClientBroadcast Function

```
INT WINAPI InetClientBroadcast(
    SOCKET hClient,
    LPBYTE lpBuffer,
    INT cbBuffer
);
```

The **InetClientBroadcast** function sends data to all other clients that are connected to the same server.

Parameters

hClient

The socket handle.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server clients.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of clients that the data was sent to. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetClientBroadcast** function sends the contents of the buffer to all other clients that are connected to the same server as the specified client. This function will block until all clients have been sent a copy of the data. There is no guarantee in which order the clients will receive and process the data that has been broadcast.

This function can only be used with client sessions created as part of the server interface and cannot be used with standard sockets created using the **InetConnect** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetCompareAddress Function

```
BOOL WINAPI InetCompareAddress(
   LPINTERNET_ADDRESS lpAddress1,
   LPINTERNET_ADDRESS lpAddress2
);
```

The **InetCompareAddress** function compares two Internet addresses in a binary format.

Parameters

lpAddress1

A pointer to an INTERNET_ADDRESS structure that contains the first IP address to be compared.

lpAddress2

A pointer to an INTERNET_ADDRESS structure that contains the second IP address to be compared.

Return Value

If the function succeeds and the two addresses are identical, the return value is non-zero. If the function fails or the two addresses are not identical, the return value is zero. If either parameter is NULL, or the address family for the two addresses are not the same, the last error code will be updated. If the addresses are valid and in the same address family, but are not identical, the last error code will be set to NO_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetHostAddress, InetGetLocalAddress, InetGetPeerAddress, INTERNET_ADDRESS

InetConnect Function

```
SOCKET WINAPI InetConnect(
   LPCTSTR lpszHostName,
   UINT nRemotePort,
   UINT nProtocol,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **InetConnect** function is used to establish a connection with a server.

Parameters

lpszHostName

A null-terminated string which specifies the host name or IP address of the system you want to connect with. This parameter cannot be a URL and must only specify the name of the remote host. If this parameter is NULL or an empty string, the function will fail with an error indicating the host name is invalid.

nRemotePort

The port number used to establish the connection. Valid port numbers range in value from 1 through 65535 and a value outside if this range will cause the function to fail. Port numbers in the range of 49152 and 65535 are referred to as dynamic ports and are generally reserved for private use by client applications. You cannot specify a port number of zero when establishing an outbound connection.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Value	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for the connection to complete before failing the current operation.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is constructed by using the bitwise Or operator with any of the following values:

Value	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_DONTROUTE	This option specifies default routing should not be

	used. This option should not be specified unless absolutely necessary.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_RESERVEDPORT	This option specifies the socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the TLS protocol.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the ***lpCredentials*** parameter. If the ***lpCredentials*** parameter is NULL, the connection will default to using TLS 1.2 or later and the strongest cipher suites available.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6

	address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure. This parameter is only used if INET_OPTION_SECURE is specified for a TCP connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The ***lpszHostName*** parameter must specify a valid host name or IP address. Host names are resolved into an IP address by first checking the local hosts file and if the name is not found, a name server query will be performed to determine the IP address. If the Unicode version of this function is called and the host name includes non-ASCII characters, the host name will be automatically converted to an ASCII compatible format. Refer to the **InetNormalizeHostName** function for more information. To establish a connection using a URL rather than a host name, use the **InetConnectUrl** function.

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **InetConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you use the INET_OPTION_SECURE option to enable a secure connection, the connection will always use implicit TLS. This means a secure session will be initiated immediately after the socket connection has been established with the server. A common example of a service which uses implicit TLS is the HTTPS protocol. Another type of secure connection is one that uses explicit TLS. This is when the client establishes a normal (non-secure) connection with the server and then explicitly switches to using a secure connection, typically by sending a command. If the server you are connecting to requires explicit TLS, you should not specify the INET_OPTION_SECURE option. Instead, connect without this option and then call the **InetEnableSecurity** function when you are ready to initiate the TLS handshake.

The ***dwOptions*** argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected

behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

When this function is called with UDP as the specified protocol, it does not actually establish a connection in the same way that a TCP stream connection is created. Instead, it simply establishes a default destination IP address and port that is used with subsequent **InetRead** and **InetWrite** calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetConnectEx Function

```
SOCKET WINAPI InetConnectEx(
   LPCTSTR lpszHostName,
   UINT nRemotePort,
   UINT nProtocol,
   UINT nTimeout,
   DWORD dwOptions,
   LPCTSTR lpszLocalAddress,
   UINT nLocalPort,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **InetConnectEx** function is used to establish a connection with a server.

Parameters

lpszHostName

A null-terminated string which specifies the host name or IP address of the system you want to connect with. This parameter cannot be a URL and must only specify the name of the remote host. If this parameter is NULL or an empty string, the function will fail with an error indicating the host name is invalid.

nRemotePort

The port number used to establish the connection. Valid port numbers range in value from 1 through 65535 and a value outside if this range will cause the function to fail. Port numbers in the range of 49152 and 65535 are referred to as dynamic ports and are generally reserved for private use by client applications. You cannot specify a port number of zero when establishing an outbound connection.

nProtocol

The protocol to be used when establishing the connection. This may be one of the following values:

Value	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This is the default protocol.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. Note that UDP is unreliable in that there is no way for the sender to know that the receiver has actually received the datagram.

nTimeout

The number of seconds to wait for the connection to complete before failing the operation.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is constructed by using the bitwise Or operator with any of the following values:

Value	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for

	stream sockets.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_RESERVEDPORT	This option specifies the socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using either the TLS protocol.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The specific version of TLS and other security related options are provided in the ***lpCredentials*** parameter. If the ***lpCredentials*** parameter is NULL, the connection will default to using TLS 1.2 or later and the strongest cipher suites available.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a

	connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

lpszLocalAddress

A null-terminated string that specifies the local IP address that the socket should be bound to. If this parameter is NULL, then an appropriate address will automatically be used. A specific address should only be used if it is required by the application.

nLocalPort

The local port number that the socket should be bound to. If this parameter is set to zero, then an appropriate port number will automatically be used. A specific port number should only be used if it is required by the application.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure. This parameter is only used if INET_OPTION_SECURE is specified for a TCP connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The ***lpszHostName*** parameter must specify a valid host name or IP address. Host names are resolved into an IP address by first checking the local hosts file and if the name is not found, a name server query will be performed to determine the IP address. If the Unicode version of this function is called and the host name includes non-ASCII characters, the host name will be automatically converted to an ASCII compatible format. Refer to the **InetNormalizeHostName** function for more information. To establish a connection using a URL rather than a host name, use the **InetConnectUrl** function.

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **InetConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

If you use the INET_OPTION_SECURE option to enable a secure connection, the connection will always use implicit TLS. This means a secure session will be initiated immediately after the socket connection has been established with the server. A common example of a service which uses implicit TLS is the HTTPS protocol. Another type of secure connection is one that uses explicit TLS. This is when the client establishes a normal (non-secure) connection with the server and then explicitly switches to using a secure connection, typically by sending a command. If the server you are connecting to requires explicit TLS, you should not specify the INET_OPTION_SECURE option. Instead, connect without this option and then call the **InetEnableSecurity** function when you are ready to initiate the TLS handshake.

The ***dwOptions*** argument can be used to specify the threading model that is used by the library when

a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

When this function is called with UDP as the specified protocol, it does not actually establish a connection in the same way that a TCP stream connection is created. Instead, it simply establishes a default destination IP address and port that is used with subsequent **InetRead** and **InetWrite** calls.

InetConnectUrl Function

```
SOCKET WINAPI InetConnectUrl(
    LPCTSTR lpszUrl,
    UINT nTimeout,
    DWORD dwOptions
);
```

The **InetConnectUrl** function is used to establish a TCP connection with a server using the information provided in a URL.

Parameters

lpszUrl

A null-terminated string which specifies a URL used when establishing the connection. This parameter cannot be NULL or point to an empty string. If a non-standard URI scheme is used, the port number must be explicitly specified or the function will fail. See the remarks below for more information on the format supported by this function.

nTimeout

The number of seconds to wait for the connection to complete before failing the current operation. If this value is zero, a default timeout period will be used.

dwOptions

An unsigned integer used to specify one or more socket options. This parameter is constructed by using the bitwise Or operator with any of the following values:

Value	Description
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This option is not necessary for most connections, particularly when the client will not be connected to the server for an extended period of time.
INET_OPTION_NODELAY	This option disables the Nagle algorithm. By default, small amounts of data written to the socket are buffered, increasing efficiency and reducing network congestion. However, this buffering can negatively impact the responsiveness of certain applications. This option disables this buffering and immediately sends data packets as they are written to the socket.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.
INET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects secure

	connections using the TLS protocol.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the remote host. The connection will always default to using TLS 1.2 or later and the strongest cipher suites available on the client platform. This option may be automatically enabled if the URL scheme specifies a service which requires a secure connection. See the remarks below for more information.
INET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
INET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
INET_OPTION_FREETHREAD	This option specifies the socket returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the socket is synchronized across multiple threads.

Return Value

If the function succeeds, the return value is a handle to a socket. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetConnectUrl** function provides a simplified interface which can be used to establish a connection using a URL. This function can only be used to establish connections using TCP and does not currently support the use of URLs to connect with a service which uses UDP. The general format of the URL should look like this:

```
[scheme]:// [[username : password] @] hostname [:port] / [path;parameters
...]
```

This function recognizes most standard URI schemes which use this format. The host name and port number specified in the URL will be used to establish a connection and the remaining information will be discarded. If the URL does not explicitly specify a port number, the default port number associated with the scheme will be used as the default value. For example, consider the following:

```
https://www.example.com
```

In this example, there is no port number specified; instead, the default port for the **https://** scheme would be used, which is port 443. The host name **www.example.com** would be resolved into an IP

address and the connection established on port 443. This function will also recognize a simpler format which only includes the host name and port number without a URI scheme, such as:

```
www.example.com:443
```

When used in this way, the port number must always be provided. Without a URI scheme or an explicit port number, the function cannot determine what port number should be used when establishing the connection. The same also applies if a custom, non-standard URI scheme is provided which is not recognized.

If the URI scheme specifies a secure protocol which requires implicit TLS, this function will automatically enable the INET_OPTION_SECURE option. For example, providing a URL which uses the **https://** scheme will automatically enable a secure connection regardless if the *dwOptions* parameter includes that option. If a URI scheme is used in conjunction with a port number associated with a secure service, security will also be enabled for that connection. For example:

```
http://www.example.com:443
```

The standard **http://** scheme is used which does not indicate a secure connection. However, since port 443 is the standard port designated for a secure HTTP connection, a secure connection will be enabled by default, even if INET_OPTION_SECURE has not been specified by the caller. Alternatively, if a custom port number is specified in the URL or the scheme is not recognized as one which requires implicit TLS, security options will not be automatically enabled for the connection.

The host name portion of the URL can be specified as either a domain name or an IP address. Because an IPv6 address can contain colon characters, you must enclose the entire address in bracket [] characters. If this is not done, this function will return an error indicating the port number is invalid. For example, the URL `https://[2001:db8:0:0:1::128]/` uses an IPv6 host address and this would be considered valid. Without the brackets, this URL would not be accepted.

Important: The URL provided to this function will only be used to establish a connection with a server. This is a general purpose function which does not enable support for any particular application protocol and all implementation details are the responsibility of your application. If you require higher-level support for a specific Internet protocol, the SocketTools API provides comprehensive collection of higher-level functions which can be used to access those services.

If you use the INET_OPTION_SECURE option to enable a secure connection, the connection will always use implicit TLS. This means a secure session will be initiated immediately after the socket connection has been established with the server. A common example of a service which uses implicit TLS is the HTTPS protocol. Another type of secure connection is one that uses explicit TLS. This is when the client establishes a normal (non-secure) connection with the server and then explicitly switches to using a secure connection, typically by sending a command. If the server you are connecting to requires explicit TLS, you should not specify the INET_OPTION_SECURE option. Instead, connect without this option and then call the **InetEnableSecurity** function when you are ready to initiate the TLS handshake.

To prevent this function from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **InetConnectUrl** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **InetAttachThread** function.

Specifying the INET_OPTION_FREETHREAD option enables any thread to call any function using the socket handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the socket is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same socket handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

InetCreateSecurityCredentials Function

```
BOOL WINAPI InetCreateSecurityCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **InetCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **InetDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **InetGetLastError** function.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **InetConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
InetCreateSecurityCredentials(SECURITY_PROTOCOL_DEFAULT,
                              CREDENTIAL_STORE_CURRENT_USER,
                              NULL,
                              NULL,
                              strCertStore,
                              strCertName,
                              NULL,
                              &lpSecCred);

hAcceptSocket = InetAsyncAcceptEx(hListenSocket,
                                  nTimeout,
                                  dwOptions,
                                  lpSecCred,
                                  hEventWnd,
                                  uEventMsg);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetDeleteSecurityCredentials Function

```
VOID WINAPI InetDeleteSecurityCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **InetDeleteSecurityCredentials** function deletes an existing SECURITYCREDENTIALS structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer value will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)
    InetDeleteSecurityCredentials(&lpSecCred);
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been established.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetDetachSocket Function

```
BOOL WINAPI InetDetachSocket(
    SOCKET hSocket
    DWORD dwThreadId
);
```

The **InetDetachSocket** function detaches the specified socket from the current process.

Parameters

hSocket

Handle to the socket.

dwThreadId

The ID of the thread that owns the socket handle. A value of zero specifies that the current thread is the owner.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetDetachSocket** function will release the memory that the library has allocated for the socket without destroying the socket handle. After the function returns, the socket can no longer be used with other functions in the library, however the socket handle remains valid. This is typically used when passing a socket handle between processes, where the parent process detaches the socket prior to creating the child process. The child then calls **InetAttachSocket** to attach the socket handle to its own process.

This function should never be used with a secure socket connection because detaching a secure socket will force the security context for that session to be released. If the socket is attached to another process, it will not have the security context originally created when the connection was established and will be unable to encrypt or decrypt the data stream.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetAttachThread, InetAttachSocket, InetDisconnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetDisableEvents Function

```
INT WINAPI InetDisableEvents(
    SOCKET hSocket
);
```

The **InetDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hSocket

The socket handle.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetEnableEvents, InetFreezeEvents, InetRegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetDisableSecurity Function

```
INT WINAPI InetDisableSecurity(
    SOCKET hSocket,
    DWORD dwReserved
);
```

The **InetDisableSecurity** function disables a secure session with the remote host.

Parameters

hSocket

The socket handle.

dwReserved

Reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetDisableSecurity** function disables a secure session, with subsequent calls to **InetRead** and **InetWrite** sending and receiving unencrypted data. It is important to note that because this function sends a shutdown message to terminate the secure session, this may cause connection to be closed by the remote host.

This function does not close the socket. Use the **InetDisconnect** function to close the socket and release the resources allocated for the current session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetCreateSecurityCredentials, InetDeleteSecurityCredentials, InetEnableSecurity

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetDisableTrace Function

```
BOOL WINAPI InetDisableTrace();
```

The **InetDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetDisconnect Function

```
INT WINAPI InetDisconnect(
    SOCKET hSocket
);
```

The **InetDisconnect** function terminates the connection, closing the socket and releasing the memory allocated for the session.

Parameters

hSocket

The socket handle.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

Once the connection has been terminated, the socket handle is no longer valid and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new connection is established. An application should always consider the socket handle to be opaque and never depend on it being a specific value.

After a socket is closed, it will go into a TIME-WAIT state which prevents an application from using the same source and destination address and port numbers bound to that socket for a brief period of time, typically two to four minutes. This is normal behavior designed to prevent delayed or misrouted packets of data from being read by a subsequent connection. This can have an impact on an application that rapidly connects and disconnects over a short period of time because it can exhaust the pool of ephemeral ports.

If this function is called using a server socket handle returned by the **InetServerStart** function, all active client connections will be disconnected, the listening socket will be closed and the server thread will terminate. If this function is called with a client socket handle allocated by the server, it will terminate the client connection and the thread that manages it.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetEnableEvents Function

```
INT WINAPI InetEnableEvents(
    SOCKET hSocket,
    HWND hEventWnd,
    UINT nEventMsg
);
```

The **InetEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **InetRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hSocket

The socket handle.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

nEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the socket handle. One or more of the following event identifiers may be sent:

Value	Description
INET_EVENT_ACCEPT	The process has received a connection request from a client and should accept the connection using the **InetAsyncAccept** function. This event is only generated for server applications which have created an asynchronous socket using the **InetAsyncListen** function.
INET_EVENT_CONNECT	The connection to the remote host has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will also be posted if an error has occurred.
INET_EVENT_DISCONNECT	The remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to read by the calling process. No additional

	messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	The process can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_TIMEOUT	The process has timed-out waiting for a blocking operation to complete. This event is only generated for synchronous sockets.
INET_EVENT_CANCEL	The application has canceled a blocking operation. This event is fired once an operation has been terminated by the **InetCancel** function, and control has been returned to the calling process.

This function cannot be used with sockets that are created by the SocketWrench server interface. Those sockets are managed separately in their own thread, and event notifications are handled inside the callback function specified when the server is created using the **InetServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetDisableEvents, InetFreezeEvents, InetRegisterEvent

InetEnableSecurity Function

```
INT WINAPI InetEnableSecurity(
   SOCKET hSocket,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **InetEnableSecurity** function enables a secure session with the remote host.

Parameters

hSocket

The socket handle.

dwOptions

An unsigned integer value that specifies additional security options. It may have a value of zero or one of the following options:

Value	Description
INET_SECURE_CLIENT	The certificate specified by the ***lpCredentials*** parameter will be used as a client certificate, and the application will begin to negotiate the secure session as a client by initiating the handshake with the server. The certificate that is used must be a valid client certificate with a private key associated with it. If the ***lpCredentials*** parameter is NULL, then a secure client session will be initiated without a client certificate.
INET_SECURE_SERVER	The certificate specified by the ***lpCredentials*** parameter will be used as a server certificate, and the application will wait for the remote host to initiate the handshake that establishes the parameters of the secure session. The certificate that is used must be a valid server certificate and have a private key associated with it. The ***lpCredentials*** parameter cannot be NULL if this option is specified.

lpCredentials

Pointer to a SECURITYCREDENTIALS structure. This parameter may be NULL, in which case no client credentials will be provided. If client credentials are required, the structure members ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the SECURITYCREDENTIALS structure.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetEnableSecurity** function enables a secure communications session with the remote host, automatically negotiating the encryption algorithm and validating the certificate. This function is useful if the application needs to establish a standard connection to the remote host and then negotiate a secure connection at a later point (this is known as explicit TLS). If the function succeeds, all subsequent calls to **InetRead** and **InetWrite** to receive and send data will be encrypted.

If the *dwOptions* parameter has a value of zero and the socket was created using **InetConnect** or related functions to establish a client connection, then **InetEnableSecurity** will initiate the handshake with the remote host to establish a secure session. If the **InetAccept** or related functions were used to accept a connection from a client, then the function will block and wait for the client to initiate the handshake.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetEnableTrace Function

```
BOOL WINAPI InetEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **InetEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetEnumHostAliases Function

```
INT WINAPI InetEnumHostAliases(
   LPCTSTR lpszHostName,
   INT nAddressFamily,
   LPTSTR lpszHostAliases,
   INT nMaxLength
);
```

The **InetEnumHostAliases** function returns a collection of null-terminated strings which contain the aliases for a specified host.

Parameters

lpszHostName

A null-terminated string which specifies a host name or IP address. This parameter cannot be NULL and must specify a valid host name.

nAddressFamily

An integer which specifies the address family which should be used when resolving the host name or IP address. It may be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	If the host name specifies an IP address, it will be resolved based on the format of the string. For compatibility, host names are resolved to IPv4 addresses by default but if there is only an IPv6 address assigned to the host name, it will be used.
INET_ADDRESS_IPV4	Specifies the host name should be resolved using an IPv4 address.
INET_ADDRESS_IPV6	Specifies the host name should be resolved using an IPv6 address.

lpszHostAliases

A null-terminated string buffer which will contain the aliases for the specified. If this parameter is NULL, the function will return the number of characters which would be copied into the buffer.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the buffer, including the terminating null characters. If the ***lpszHostAliases*** parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is the number of characters copied to the string, including the terminating null characters which indicate the end of each host alias. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If there are multiple aliases for the host name, each name will be terminated with a null character, with an extra null character indicating the end of the list of aliases.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetEnumNetworkAddresses Function

```
INT WINAPI InetEnumNetworkAddresses(
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddressList,
   INT nMaxAddresses
);
```

The **InetEnumNetworkAddresses** function returns the list of network addresses that are configured for the local host.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this function. It may be one of the following values:

Value	Description
INET_ADDRESS_ANY	Return both IPv4 or IPv6 addresses assigned to the local host, depending on how the system is configured and which network interfaces are enabled. This option is only recommended for applications that require support for IPv6 connections.
INET_ADDRESS_IPV4	Return only the IPv4 addresses assigned to the local host. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Return only the IPv6 addresses assigned to the local host. All bytes in the ***ipNumber*** array are significant. This option is only recommended for those applications that require support for IPv6 connections.

lpAddressList

A pointer to an array of INTERNET_ADDRESS structures that will contain the IP address of each local network interface. This parameter may be NULL, in which case the method will only return the number of available addresses.

nMaxAddresses

Maximum number of addresses to be returned. If the ***lpAddressList*** parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the return value is the number of network addresses that are configured for the local host. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the ***nAddressFamily*** parameter is specified as INET_ADDRESS_ANY, the application must be prepared to accept IPv6 addresses returned by this function. On Windows Vista and later versions of the operating system, IPv6 support is enabled and the local network adapter will have IPv6 addresses assigned to them by default. For legacy applications that only recognize IPv4 addresses, the

nAddressFamily parameter should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

This function will ignore addresses that are bound to a disabled interface, as well as those addresses bound to a virtual loopback interface. For example, although the loopback address 127.0.0.1 is a valid network address, it will not be included in list of addresses returned by this function.

The first IPv4 or IPv6 address returned by this function is typically the address assigned to the primary network adapter on the local system. However, your application should not depend on addresses being returned in any particular order. If the system has dial-up networking or virtualization software installed, this function may also include the IP addresses assigned to any virtualized network adapters installed by that software.

Example

```
INTERNET_ADDRESS *lpAddressList = NULL;
INT nAddressCount = InetEnumNetworkAddresses(INET_ADDRESS_IPV4, NULL, 0);

if (nAddressCount > 0)
{
    // Allocate memory for the array of IP addresses
    lpAddressList = (INTERNET_ADDRESS *)LocalAlloc(LPTR, nAddressCount *
sizeof(INTERNET_ADDRESS));

    if (lpAddressList == NULL)
    {
        // Virtual memory exhausted
        return;
    }

    // Populate the array with the addresses
    nAddressCount = InetEnumNetworkAddresses(INET_ADDRESS_IPV4, lpAddressList,
nAddressCount);
}

_tprintf(_T("There are %d local network addresses assigned\n"), nAddressCount);

// Display each IP address assigned to the local system
for (INT nIndex = 0; nIndex < nAddressCount; nIndex++)
{
    TCHAR szValue[64];

    // Convert the IP address to a printable string
    InetFormatAddress(lpAddressList + nIndex, szValue, 64);
    _tprintf(_T("%d: %s\n"), nIndex, szValue);
}

// Free the memory allocated for the IP address list
if (lpAddressList != NULL)
    LocalFree((HLOCAL)lpAddressList);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetEnumServerClients Function

```
INT WINAPI InetEnumServerClients(
    SOCKET hServer,
    SOCKET *lpClients,
    INT nMaxClients
);
```

The **InetEnumServerClients** function returns a list of active client sessions established with the specified server.

Parameters

hServer

Handle to the server socket.

lpClients

Pointer to an array of socket handles which identifies all client connections. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client socket handles to be returned. If the ***lpClients*** parameter is NULL, this parameter should be specified with a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server. A return value of zero indicates that there are no active client sessions. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the ***nMaxClients*** parameter is less than the number of active client connections, the function will fail. To dynamically determine the number of active connections, call the function with the ***lpClients*** parameter with a value of NULL, and the ***nMaxClients*** parameter with a value of zero. To enumerate the active clients that match a specific IP address, use the **InetEnumServerClientsByAddress** function.

This function will not enumerate clients that have disconnected from the server, even if the session thread is still active. If the server is in the process of shutting down, this function will return zero, indicating no active client sessions, even though there may be clients that are still in the process of disconnecting from the server. To determine the actual number of client sessions regardless of their status, use the **InetGetClientThreads** function.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using **InetListen** or **InetListenEx**.

Example

```
INT nMaxClients = InetEnumServerClients(hServer, NULL, 0);

if (nMaxClients > 0)
{
    SOCKET *lpClients = NULL;

    // Allocate memory for client sockets
```

```
    lpClients = (SOCKET *)LocalAlloc(LPTR, nMaxClients * sizeof(SOCKET));
    if (lpClients == NULL)
    {
        // Virtual memory has been exhausted
        return;
    }

    nMaxClients = InetEnumServerClients(hServer, lpClients, nMaxClients);
    if (nMaxClients == INET_ERROR)
    {
        // Unable to obtain list of connected clients
        return;
    }

    for (INT nClient = 0; nClient < nMaxClients; nClient++)
    {
        // Perform some action with each client socket
        SOCKET hClient = lpClients[nClient];
    }

    // Free memory allocated for client sockets
    LocalFree((HLOCAL)lpClients);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetEnumServerClientsByAddress, InetGetClientThreads, InetServerBroadcast, InetServerStart

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetEnumServerClientsByAddress Function

```
INT WINAPI InetEnumServerClientsByAddress(
   SOCKET hServer,
   LPINTERNET_ADDRESS lpAddress,
   SOCKET *lpClients,
   INT nMaxClients
);
```

The **InetEnumServerClientsByAddress** function returns a list of active client sessions established with the specified server that match the specified IP address.

Parameters

hServer

Handle to the server socket.

lpAddress

Pointer to an INTERNET_ADDRESS structure that specifies the client IP address. If this parameter is NULL, then all active client sessions will be enumerated.

lpClients

Pointer to an array of socket handles which identifies all client connections that match the specified IP address. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client socket handles to be returned. If the ***lpClients*** parameter is NULL, this parameter should be specified with a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server that match the specified IP address. A return value of zero indicates that no clients have connected from the specified IP address. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the ***nMaxClients*** parameter is less than the number of active client connections that match the specified address, the function will fail. To dynamically determine the number of active connections, call the function with the ***lpClients*** parameter with a value of NULL, and the ***nMaxClients*** parameter with a value of zero. If the ***lpAddress*** parameter is NULL, this function will return a list of all active clients connected to the server and is effectively the same as calling the **InetEnumServerClients** function. If an address is provided, it must be a valid IP address in a supported address family.

This function will not enumerate clients that have disconnected from the server, even if the session thread is still active. If the server is in the process of shutting down, this function will return zero, indicating no active client sessions, even though there may be clients that are still in the process of disconnecting from the server.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using **InetListen** or **InetListenEx**.

Example

```
INTERNET_ADDRESS ipAddress;
```

```
if (InetGetPeerAddress(hSocket, &ipAddress, NULL) == INET_ERROR)
{
    // Unable to get the peer IP address for the socket
    return;
}

// Determine the number of clients that have the same IP address
INT nMaxClients = InetEnumServerClientsByAddress(hServer, &ipAddress, NULL, 0);

if (nMaxClients > 0)
{
    SOCKET *lpClients = NULL;

    // Allocate memory for client sockets
    lpClients = (SOCKET *)LocalAlloc(LPTR, nMaxClients * sizeof(SOCKET));
    if (lpClients == NULL)
    {
        // Virtual memory has been exhausted
        return;
    }

    nMaxClients = InetEnumServerClientsByAddress(hServer, &ipAddress, lpClients,
nMaxClients);
    if (nMaxClients == INET_ERROR)
    {
        // Unable to obtain list of connected clients
        return;
    }

    for (INT nClient = 0; nClient < nMaxClients; nClient++)
    {
        // Perform some action with each client socket
        SOCKET hClient = lpClients[nClient];
    }

    // Free memory allocated for client sockets
    LocalFree((HLOCAL)lpClients);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetEventProc Function

```
VOID CALLBACK InetEventProc(
   SOCKET hSocket,
   UINT nEvent,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **InetEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hSocket

The socket handle.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the InetRegisterEvent function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **InetRegisterEvent** function. The **InetEventProc** function is a placeholder for the application-defined function name.

If the callback function is being used with the **InetServerStart** function, the function will be called in the context of the thread that is currently managing the server or client session. You must ensure that any access to global or static variables is synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself. If you need to manage state information for a specific client, then use the **InetGetClientData** and **InetSetClientData** functions which will allow you to access application defined data for that client session in a thread-safe manner.

When this callback function is used for event notifications from the server interface, the *hSocket* parameter specifies the client socket handle, except for the INET_EVENT_ACCEPT event, in which case the handle references the server socket handle. To obtain the handle of the client connection that was just accepted, use the **InetGetServerClient** function. To obtain the handle to the server using the client socket handle, use the **InetGetClientServer** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetDisableEvents, InetEnableEvents, InetFreezeEvents, InetGetClientServer, InetGetServerClient

InetFindClientMoniker Function

```
SOCKET WINAPI InetFindClientMoniker(
    SOCKET hServer,
    LPCTSTR lpszMoniker
);
```

The **InetFindClientMoniker** function returns a handle to the client socket which matches the specified moniker.

Parameters

hServer

A handle to the server.

lpszMoniker

A null-terminated string which specifies the client moniker to search for. This parameter cannot be NULL and cannot specify an empty string.

Return Value

If the function succeeds, the return value is the handle to the client socket for the session that matches the specified moniker. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session using the **InetSetClientMoniker** function. This function will search all active client sessions for the server, and returns the socket handle to the client that matches the specified moniker. If there is no match, an error will be returned.

The moniker can be any string value, however monikers are not case sensitive and may not contain embedded null characters. The maximum length of a moniker is 127 characters.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using **InetListen** or **InetListenEx**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetFlush Function

```
INT WINAPI InetFlush(
   SOCKET hSocket
);
```

The **InetFlush** function flushes the internal send and receive buffers used by the socket.

Parameters

hSocket

The socket handle.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetFlush** function will flush any data waiting to be read or written to the remote host . It is important to note that this function is not similar to flushing data to a disk file; it does not ensure that a specific block of data has been written to the socket. For example, you should never call this function immediately after calling **InetWrite** or prior to calling **InetDisconnect**.

An application never needs to use **InetFlush** under normal circumstances. This function is only to be used when the application needs to immediately return the socket to an inactive state with no pending data to be read or written. Calling this function may result in data loss and should only be used if you understand the implications of discarding any data which has been sent by the remote host.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetFormatAddress Function

```
INT WINAPI InetFormatAddress(
   LPINTERNET_ADDRESS lpAddress,
   LPTSTR lpszAddress,
   INT cchAddress
);
```

The **InetFormatAddress** function converts a numeric IP address to a printable string. The format of the string depends on whether an IPv4 or IPv6 address is specified.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure which specifies the numeric IP address that should be converted to a string.

lpszAddress

A null-terminated string buffer that will contain the formatted IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length.

cchAddress

The maximum number of characters that can be copied into the address buffer.

Return Value

If the function succeeds, the return value is the length of the IP address string. If the function fails, the return value is INET_ERROR, meaning that the IP address could not be converted into a string. Typically this indicates that the pointer to the INTERNET_ADDRESS structure is invalid, or the data does not specify a valid IP address family.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetFreezeEvents Function

```
INT WINAPI InetFreezeEvents(
    SOCKET hSocket,
    BOOL bFreeze
);
```

The **InetFreezeEvents** function is used to suspend and resume event handling.

Parameters

hSocket

Socket handle.

bFreeze

A non-zero value specifies that event handling should be suspended. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if event handling has been suspended, and four read events occur, only one of those read events will be posted to the application when even handling is resumed. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetAdapterAddress Function

```
INT WINAPI InetGetAdapterAddress(
    INT nAdapterIndex,
    INT nAddressType,
    LPTSTR lpszAddress,
    INT nMaxLength
);
```

Return the IP or MAC assigned to the specified network adapter.

Parameters

nAdapterIndex

An integer value that identifies the network adapter.

nAddressType

An integer value which specifies the type of address that should be returned:

Value	Description
INET_ADAPTER_IPV4	The address string will contain the primary IPv4 unicast address assigned to the network adapter.
INET_ADAPTER_IPV6	The address string will contain the primary IPv6 unicast address assigned to the network adapter.
INET_ADAPTER_MAC	The address string will contain the media access control (MAC) address assigned to the network adapter.

lpszAddress

A string buffer that will contain the IP or MAC address assigned to the adapter. This parameter cannot be NULL and it is recommended that it be at least 64 characters in length to provide enough space for any address type.

nMaxLength

The maximum number of characters that can be copied into the string buffer, including the terminating null character. If the buffer is too small to store the complete address, this function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied to the string buffer, not including the terminating null character. A return value of zero indicates that the requested address type has not been assigned to the adapter. If the function fails, the return value is INET_ERROR and this typically indicates that either the adapter index is invalid or the string buffer is not large enough to store the complete address. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetAdapterAddress** function will return the IPv4, IPv6 or MAC address assigned to a specific network adapter. The primary network adapter has an index value of zero, and it increments for each adapter that is configured on the local system.

The media access control (MAC) address is a 48 bit or 64 bit value that is assigned to each network interface and is used for identification and access control. All network devices on the same subnet must be assigned their own unique MAC address. Unlike IP addresses which may be assigned

dynamically and can be frequently changed, MAC addresses are considered to be more permanent because they are usually assigned by the device manufacturer and stored in firmware. Note that in some cases it is possible to change the address assigned to a device, and virtual network interfaces may have configurable MAC addresses.

This function returns the MAC address string as sequence of hexadecimal values separated by a colon. An example of a 48 bit MAC address would be "01:23:45:67:89:AB". Note that some virtual network adapters may not have a MAC address assigned to them, in which case this function would return zero.

This function will ignore network adapters that have been disabled, as well as those that are bound to a virtual loopback interface. If the system has dial-up networking or virtualization software installed, this function may also return IP addresses assigned to a virtualized network adapters installed by that software.

Example

```
// Display the IPv4 address assigned to each network adapter
for (INT nIndex = 0;; nIndex++)
{
    TCHAR szAddress[64];
    INT cchAddress;

    cchAddress = InetGetAdapterAddress(nIndex, INET_ADAPTER_IPV4, szAddress, 64);

    if (cchAddress == INET_ERROR)
        break;

    _tprintf(_T("Adapter %d: %s\n"), nIndex, szAddress);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetGetAddress Function

```
INT WINAPI InetGetAddress(
   LPCTSTR lpszAddress,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);
```

The **InetGetAddress** function converts an IP address string to binary format.

Parameters

lpszAddress

A null-terminated string which specifies an IP address. This function recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address specified by the ***lpszAddress*** parameter. It may be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on the value of the ***lpszAddress*** parameter.
INET_ADDRESS_IPV4	Specifies that the address should be in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero. If the ***lpszAddress*** parameter does not specify a valid IPv4 address string, this function will fail.
INET_ADDRESS_IPV6	Specifies that the address should be in IPv6 format. All bytes in the ***ipNumber*** array are significant. If the ***lpszAddress*** parameter does not specify a valid IPv6 address string, this function will fail.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the ***nAddressFamily*** parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible that an IPv6 address string has been specified. For legacy applications that only recognize IPv4 addresses, the ***nAddressFamily*** member should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned and any attempt to specify an IPv6 address string would result in an error.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system,

use the **InetIsProtocolAvailable** function. If an IPv6 stack is not installed, this function will fail if the *lpszAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetFormatAddress, InetIsAddressNull, InetIsAddressRoutable, InetIsProtocolAvailable, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetAddressFamily Function

```
INT WINAPI InetGetAddressFamily(
   LPCTSTR lpszAddress,
);
```

Return the address family for the specified IP address.

Parameters

lpszAddress

A null-terminated string which specifies an IP address. This function recognizes the format for both IPv4 and IPv6 format addresses.

Return Value

If the function succeeds, the return value is the address family for the specified IP address and may be one of the values listed below. If the function fails, the return value is INET_ADDRESS_UNKNOWN. To get extended error information, call **InetGetLastError**.

Value	Description
INET_ADDRESS_IPV4	The address passed to the function is a valid IPv4 address.
INET_ADDRESS_IPV6	The address passed to the function is a valid IPv6 address.

Remarks

The **InetGetAddressFamily** function returns the address family associated with the specified IP address string. This can be used to determine if a string specifies a valid IPv4 or IPv6 address that can be passed to other functions such as **InetConnect**. Note that this function will not attempt to resolve hostnames, it will only accept IP addresses.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **InetIsProtocolAvailable** function. If an IPv6 stack is not installed, this function will fail if the *lpszAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetIsAddressNull, InetIsAddressRoutable, InetIsProtocolAvailable, INTERNET_ADDRESS

InetGetBlockingSocket Function

```
SOCKET InetGetBlockingSocket();
```

The **InetGetBlockingSocket** function returns the handle for the socket in the current thread which is currently blocking, if there is one.

Parameters

None.

Return Value

If the function succeeds, the return value is the handle for the socket in the current thread which is currently blocking. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetClientData Function

```
BOOL WINAPI InetGetClientData(
    SOCKET hClient,
    LPVOID *lppvData
);
```

The **InetGetClientData** function returns the application defined data associated with the specified client session.

Parameters

hClient

The client socket handle.

lppvData

Pointer to a void pointer which will contain an application defined value associated with the client session.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the client session could not be retrieved. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientData** function is used to retrieve the application defined data that was previously associated with a client session using the **InetSetClientData** function. This is typically used to associate a pointer to a data structure or a class instance with a specific client handle.

This function can only be used with client socket handles created using the server interface. It cannot be used with socket handles created using the **InetConnect** or **InetAccept** functions. If the socket handle is invalid, or does not reference a client socket handle created by the server, the *lppvData* pointer passed to this function will be initialized to a value of NULL and the function will return a value of zero.

If this function is called with a valid socket handle and there is no data associated with the socket, the function will return a non-zero value and the *lppvData* pointer will be returned with a NULL value. Before dereferencing the pointer returned by this function, the application should always check the return value to ensure the function succeeded and make sure that the pointer is not NULL.

Example

```
UINT *pnValue1 = (UINT *)LocalAlloc(LPTR, sizeof(UINT));
UINT *pnValue2 = NULL;

*pnValue1 = 1234;

if (InetSetClientData(hClient, pnValue1) == FALSE)
{
    // Unable to associate the data with this session
    return;
}

if (InetGetClientData(hClient, &pnValue2) == FALSE)
{
```

```
    // Unable to retrieve the data associated with this session
    return;
}

// *pnValue2 == 1234
printf("The value of user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetClientHandle Function

```
SOCKET WINAPI InetGetClientHandle(
    SOCKET hServer,
    UINT nClientId
);
```

The **InetGetClientHandle** function returns the handle for a specific client session based on its ID number.

Parameters

hServer

Handle to the server socket.

nClientId

An unsigned integer value which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is the socket handle for the specified client session. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be obtained by calling the **InetGetClientId** function and used by the application to identify that client session. The **InetGetClientHandle** function can then be used to used to obtain the client socket handle for the session, based on that client ID.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetClientId, InetGetClientMoniker, InetSetClientMoniker, InetGetServerClient, InetGetThreadClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetClientId Function

```
UINT WINAPI InetGetClientId(
    SOCKET hClient
);
```

The **InetGetClientId** function returns the unique ID number assigned to the specified client session.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is an unsigned integer value which uniquely identifies the client session. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

Each client connection that is accepted by the server is assigned a unique numeric value. This value can be obtained by calling the **InetGetClientId** function and used by the application to identify that client session. The **InetGetClientHandle** function can then be used to used to obtain the client socket handle for the session, based on that client ID. It is important to note that the actual value of the client ID should be considered opaque. It is only guaranteed that the value will be greater than zero, and that it will be unique to the client session.

While it is possible for a client socket handle to be reused by the operating system, client IDs are unique throughout the life of the server session and are never duplicated.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetClientIdleTime Function

```
DWORD WINAPI InetGetClientIdleTime(
     SOCKET hClient
);
```

Returns the number of milliseconds that the specified client session has been idle.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is an unsigned integer value which specifies the number of milliseconds the client session has been idle. If the function fails, the return value is INFINITE. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientIdleTime** function will return the number of milliseconds that have elapsed since data was exchanged with the client. The elapsed time is limited to the resolution of the system timer, which is typically in the range of 10 milliseconds to 16 milliseconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetClientMoniker Function

```
INT WINAPI InetGetClientMoniker(
   SOCKET hSocket,
   LPTSTR lpszMoniker,
   INT nMaxLength
);
```

The **InetGetClientMoniker** function returns the moniker associated with the specified client session.

Parameters

hSocket

Handle to the client socket.

lpszMoniker

Pointer to a string buffer that will contain the moniker for the specified client session when the function returns.

nMaxLength

The maximum number of characters that may be copied into the string buffer. The buffer must be large enough to store the moniker and a terminating null character. The maximum length of a moniker is 127 characters.

Return Value

If the function succeeds, the return value is the number of characters in the moniker string. A return value of zero specifies that no moniker was assigned to the socket. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. A moniker can be assigned to the client session using the **InetSetClientMoniker** function. This function will return the moniker that was previously assigned to the client, if any. To obtain the socket handle associated with a given moniker, use the **InetFindClientMoniker** function.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetGetClientPriority Function

```
INT WINAPI InetGetClientPriority(
    SOCKET hClient
);
```

The **InetGetClientPriority** function returns the current priority for the specified client session.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is the priority for the specified client session. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientPriority** function can be used to determine the current priority assigned to the specified client session. The client priority is inherited from the priority specified when the server is started using the **InetServerStart** function. It may be one of the following values:

Value	Description
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the client session. It is typically used with lightweight services running in the background that are designed for few client connections. The client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. The client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the client session and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The client thread will be given higher scheduling priority and will be more responsive to network events. It is not recommended that this priority be used on a system with a single processor.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetClientServer Function

```
SOCKET WINAPI InetGetClientServer(
    SOCKET hClient
);
```

The **InetGetClientServer** function returns a socket handle to the server for the specified client socket.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientServer** function returns the handle to the server that created the client session. The **InetGetClientServerById** function can be used to obtain the server handle using the client session ID rather than the client socket handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetClientServerById Function

```
SOCKET WINAPI InetGetClientServerById(
     UINT nClientId
);
```

The **InetGetClientServerById** function returns a socket handle to the server for the specified client session identifier.

Parameters

nClientId

Client session identifier.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientServerById** function returns the handle to the server that created the client session using the client's unique identifier. The **InetGetClientServer** function can be used to obtain the server handle using the client socket handle rather than the client session ID. This function is typically used in conjunction with the INET_NOTIFY_CONNECT notification message to obtain the handle to the server that generated the event using the client ID passed in the ***wParam*** message parameter.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetClientThreadId Function

```
DWORD WINAPI InetGetClientThreadId(
     SOCKET hClient
);
```

The **InetGetClientThreadId** function returns the thread ID for the specified client session.

Parameters

hClient

Handle to the client socket.

Return Value

If the function succeeds, the return value is an unsigned integer value which identifies the thread that was created to manage the client session. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The thread ID returned by this function can be used with the **OpenThread** function to obtain a handle to the thread. Until the thread terminates, the thread identifier uniquely identifies the thread throughout the system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetClientThreads Function

```
INT WINAPI InetGetClientThreads(
    SOCKET hServer
);
```

Returns the number of client session threads created by the server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the number of client session threads that have been created by the server. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetClientThreads** function returns the number of threads that are managing client sessions for the specified server. If there are no clients connected to the server, this function will return a value of zero. Because this function returns the number of session threads, the value returned will include those clients that are in the process of disconnecting from the server but their session thread has not yet terminated. This differs from the **InetEnumServerClients** function which will only enumerate active clients.

If you wish to determine when the last client has disconnected from the server, call this function within an event handler for the INET_EVENT_DISCONNECT event. If the function returns a value greater than one, then there are other client sessions that are either connected or in the process of terminating.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetDefaultHostFile Function

```
INT WINAPI InetGetDefaultHostFile(
    LPTSTR lpszFileName,
    INT nMaxLength
);
```

The **InetGetDefaultHostFile** function returns the fully qualified path name of the host file on the local system. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **InetGetHostAddress** and **InetGetHostNames** function. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

The location of the default host file depends on the operating system. For Windows 95/98 and Windows Me the file is stored in C:\Windows\hosts and for Windows NT and later versions the file is stored in C:\Windows\system32\drivers\etc\hosts. Regardless of platform, there is no filename extension and this file may or may not exist on a given system.

Parameters

lpszFileName

Pointer to a string buffer that will contain the fully qualified file name to the default host file. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is length of the string. A return value of zero indicates that the default host file could not be determined for the current platform. To get extended error information, call **InetGetLastError**.

Remarks

This function only returns the default location of the host file and does not determine if the file actually exists. It is not required that a host file be present on the system.

The default host file is processed before performing a nameserver lookup when resolving a hostname into an IP address, or an IP address into a hostname.

To specify an alternate local host file, use the **InetSetHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetGetErrorString Function

```
INT WINAPI InetGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **InetGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the InetGetLastError function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetGetExternalAddress Function

```
INT WINAPI InetGetExternalAddress(
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);
```

The **InetGetExternalAddress** function returns the external IP address for the local system.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this function. It may be one of the following values:

Value	Description
INET_ADDRESS_ANY	Return any external IP address available. IPv4 addresses will be preferred over IPv6 for backwards compatibilty.
INET_ADDRESS_IPV4	Specifies that the external address should be in IPv4 format.
INET_ADDRESS_IPV6	Specifies that the external address should be in IPv6 format. If the local system does not have IPv6 enabled, the function will fail.

lpAddress

A pointer to an INTERNET_ADDRESS structure which contains the external IP address of the local system when the function returns.

Return Value

If the function succeeds, the return value is zero and the INTERNET_ADDRESS structure contains the external IP address for the local host in binary form. If the function fails, it will return INET_ERROR and the *ipFamily* member of the INTERNET_ADDRESS structure will be set to INET_ADDRESS_UNKNOWN. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetExternalAddress** function returns the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **InetGetLocalAddress** function will only return the IP address for the local system on the LAN side of the network unless a connection has already been established to a remote host. The **InetGetExternalAddress** function can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router.

An application should always check the return value in case there is an error. Never assume that the return value is always a valid address. The function may be unable to determine the external IP address for the local system for a number of reasons, particularly if it is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the function is able to obtain a valid external address for the local host, that address will be cached by the library. If you are using a VPN (Virtual Private Network), this function will return the external IP address for the VPN adapter and not your local network connection. The **InetGetVpnAdapter** function can be used to obtain information about the active VPN adapter.

Calling this function may cause the current thread to block until the external IP address can be resolved and should never be used in conjunction with asynchronous socket connections. If you need to call this function in an application which uses asynchronous sockets, it is recommended that you create a background worker thread and call this function from within that thread.

To convert the address from its binary form into a string, use the **InetFormatAddress** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetFormatAddress, InetGetHostAddress, InetGetLocalAddress, InetGetPeerAddress, InetGetVpnAdapter, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetHostAddress Function

```
INT WINAPI InetGetHostAddress(
   LPCTSTR lpszHostName,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);
```

The **InetGetHostAddress** function resolves the specified host name into an IP address in binary format.

Parameters

lpszHostName

The name of the host to resolve; this may be a fully-qualified domain name or an IP address. This function recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Value	Description
INET_ADDRESS_ANY	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on how the host name can be resolved. By default, a preference will be given for returning an IPv4 address. However, if the host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the ***ipNumber*** array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address of the specified host.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This function can also be used to convert an address in dot notation to a binary format. If the function must perform a DNS lookup to resolve the hostname, the calling thread will block. To ensure future compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the ***ipFamily*** member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

The *nAddressFamily* parameter is used to specify a preference for the type of address returned,

however it is possible that a host may not have an IPv4 or IPv6 address record, in which case this function will fail. Although IPv4 is still the most common address used at this time, an application should not assume that because a given host name does not have an IPv4 address, that the host name is invalid.

If the *nAddressFamily* parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible for a host name to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* member should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **InetIsProtocolAvailable** function. If an IPv6 stack is not installed, this function will fail if the *lpszHostName* parameter specifies an host that only has an IPv6 (AAAA) DNS record.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetGetHostName, InetGetLocalAddress, InetGetLocalName, InetGetPeerAddress, InetIsProtocolAvailable, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetHostFile Function

```
INT WINAPI InetGetHostFile(
   LPTSTR lpszFileName,
   INT nMaxLength
);
```

The **InetGetHostFile** function returns the name of the host file previously set using the **InetSetHostFile** function. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **InetGetHostAddress** and **InetGetHostNames** function.

Parameters

lpszFileName

Pointer to a string buffer that will contain the host file name. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null character.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is length of the string. A return value of zero indicates that no host file has been specified or the function was unable to determine the file name. To get extended error information, call **InetGetLastError**. If the last error is zero, this indicates that no host file name has been specified for the current thread. If the last error is non-zero, this indicates the reason that the function failed.

Remarks

This function only returns the name of the host file that is cached in memory for the current thread. The contents of the file on the disk may have changed after the file was loaded into memory. To reload the host file or clear the cache, call the **InetSetHostFile** function.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

The host file returned by this function may be different than the default host file for the local system. To determine the file name for the default host file, use the **InetGetDefaultHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetGetDefaultHostFile, InetGetHostAddress, InetGetHostName, InetSetHostFile

InetGetHostName Function

```
INT WINAPI InetGetHostName(
   LPINTERNET_ADDRESS lpAddress,
   LPTSTR lpszHostName,
   INT cchHostName
);
```

The **InetGetHostName** function performs a reverse lookup, returning the host name associated with a given IP address.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure which specifies the IP address that should be resolved into a host name.

lpszHostName

The buffer that will contain the host name. It is recommended that this buffer be at least 256 characters in length to accommodate the longest possible fully qualified domain name.

cchHostName

The maximum number of characters that can be copied into the buffer.

Return Value

If the function succeeds, the return value is the length of the hostname. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the function must perform a reverse DNS lookup to resolve the IP address into a host name, the calling thread will block. This function requires that the host have a PTR record, otherwise it will fail. Because many hosts do not have a PTR record, calling this function frequently may have a negative impact on the overall performance of the application.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **InetIsProtocolAvailable** function. If an IPv6 stack is not installed, this function will fail if the *lpAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetGetLastError Function

```
DWORD WINAPI InetGetLastError();
```

Parameters

None.

Return Value

Functions set this value by calling the InetSetLastError function. The return value section of each reference page notes the conditions under which the function sets the last-error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **InetGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **InetSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those functions which call **InetSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetErrorString, InetSetLastError

InetGetLocalAddress Function

```
INT WINAPI InetGetLocalAddress(
   SOCKET hSocket,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress,
   UINT *lpnPort
);
```

The **InetGetLocalAddress** function returns the local IP address and port number for the specified socket.

Parameters

hSocket

The socket handle.

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on the type of connection that was established. If the ***hSocket*** parameter is INVALID_SOCKET, a preference will be given for returning an IPv4 address. However, if the local host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the ***ipNumber*** array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address of the local host. If the ***hSocket*** parameter is specified as INVALID_SOCKET, this function will attempt to determine the IP address of the local host assigned by the system. If the address is not required, this parameter may be NULL.

lpnPort

A pointer to an unsigned integer that will contain the local port number. If the ***hSocket*** parameter specifies a valid socket, this parameter will be set to the local port that the socket was bound to. If the ***hSocket*** parameter is specified as INVALID_SOCKET, this parameter is ignored. If the port number is not required, this parameter may be NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

To ensure future compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the ***ipFamily*** member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

If the ***nAddressFamily*** parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible for the local host to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the ***nAddressFamily*** member should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

If the system is connected to the Internet through a local network and/or uses a router that performs Network Address Translation (NAT), the **InetGetLocalAddress** function will return the local, non-routable IP address assigned to the system. To determine the public IP address has been assigned to the system, you should use the **InetGetExternalAddress** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetExternalAddress, InetGetHostAddress, InetGetHostName, InetGetLocalName, InetGetPeerAddress, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetLocalName Function

```
INT WINAPI InetGetLocalName(
   LPTSTR lpszHostName,
   INT cchHostName
);
```

The **InetGetLocalName** function returns the hostname assigned to the local system.

Parameters

lpszHostName

The buffer that will contain the hostname.

cchHostName

The maximum number of characters that can be copied into the address buffer.

Return Value

If the function succeeds, the return value is the length of the hostname. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetGetLockedServer Function

```
SOCKET WINAPI InetGetLockedServer(
    LPDWORD lpdwThreadId
);
```

The **InetGetLockedServer** function unlocks the specified server, allowing other server threads to resume execution.

Parameters

lpdwThreadId

A pointer to an unsigned integer which identifies the thread that established the server lock. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds, the return value is the handle to the locked server. If no server is in a locked state, the function will return a value of INVALID_SOCKET.

Remarks

The **InetGetLockedServer** function can be used to determine if there is a server in a locked state. If there is, the function will return a handle to the server and will identify the thread which established the lock. This function may be called from any thread, however only the thread which established the server lock may interact with the server or release the lock.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetMemoryUsage Function

```
BOOL WINAPI InetGetMemoryUsage(
   SOCKET hSocket,
   ULARGE_INTEGER *lpMemUsage
);
```

Return the amount of memory allocated for the network connection.

Parameters

hSocket

The socket handle.

lpMemUsage

A pointer to a ULARGE_INTEGER variable which will specify how much memory has been allocated for the socket. This parameter will be initialized to a value of zero by the function and updated with the total number of bytes allocated.

Return Value

If the function succeeds, the return value is non-zero and the memory usage value will be updated. If the socket handle does not specific a socket created by the library, the return value is zero. Call the **InetGetLastError** function to determine the cause of the failure.

Remarks

This function returns the amount of memory allocated for the socket. It enumerates all heap allocations made by the process and returns the total number of bytes allocated for the specific socket handle. If the ***hSocket*** parameter value is INVALID_SOCKET, the function will calculate the amount of memory allocated for all sockets created by the library. This value only reflects the amount of memory explicitly allocated by this library and does not reflect the total working set size of the process, or memory allocated by any other libraries. To determine the working set size for the process, refer to the Win32 **GetProcessWorkingSetSize** and **GetProcessMemoryInfo** functions.

This function forces the current thread into a locked state, and all network operations will block until the function returns. Because this function enumerates all heaps created for the process, it can be an expensive operation, particularly when a large number of connections have been established. Frequent use of this function can significantly degrade the performance of the application. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active network connections. If the value returned by the function remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetOption Function

```
INT WINAPI InetGetOption(
   SOCKET hSocket,
   DWORD dwOption,
   LPBOOL lpbEnabled
);
```

The **InetGetOption** function is used to determine if a specific socket option has been enabled.

Parameters

hSocket

The socket handle.

dwOption

An unsigned integer used to specify one of the socket options. These options cannot be combined. The following values are recognized:

Value	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.

lpbEnabled

A pointer to a boolean flag. If the option is enabled, the flag is set to a non-zero value, otherwise it is set to a value of zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetPeerAddress Function

```
INT WINAPI InetGetPeerAddress(
   SOCKET hSocket,
   LPINTERNET_ADDRESS lpAddress,
   UINT *lpnPort
);
```

The **InetGetPeerAddress** function returns the peer IP address and remote port number for the specified socket.

Parameters

hSocket

The socket handle.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address of the remote host that the socket is connected to.

lpnPort

A pointer to an unsigned integer that will contain the remote port that the socket is connected to.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If this function is called by a server application in response to a INET_EVENT_ACCEPT event, it will return the IP address and port number for the client that is attempting to establish the connection. If the peer address is unavailable, the *ipFamily* member of the INTERNET_ADDRESS structure will be zero. To convert the IP address to a printable string, use the **InetFormatAddress** function.

It is not recommended that you use the port number for anything other than informational and logging purposes. Server applications should not make any assumptions about the specific port number or range of port numbers that a client is using when establishing a connection to the server. The ephemeral port number that a client is bound to can vary based on the client operating system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetFormatAddress, InetGetHostAddress, InetGetHostName, InetGetLocalAddress, InetGetLocalName, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetPhysicalAddress Function

```
BOOL WINAPI InetGetPhysicalAddress(
    LPTSTR lpszAddress,
    UINT nMaxLength
);
```

Return the media access control (MAC) address for the primary network adapter.

Parameters

lpszAddress

A string buffer that will contain the address in a printable format when the function returns. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetPhysicalAddress** function returns the media access control (MAC) address for the primary network adapter. This is a 48 bit or 64 bit address that is assigned to each network interface and is used for identification and access control. All network devices on the same subnet must be assigned their own unique MAC address. Unlike IP addresses which may be assigned dynamically and can be frequently changed, MAC addresses are considered to be more permanent because they are usually assigned by the device manufacturer and stored in firmware. Note that in some cases it is possible to change the address assigned to a device, and virtual network interfaces may have configurable MAC addresses.

This function returns the MAC address as a printable string, with each byte of the address as a two-digit hexadecimal value separated by a colon. The string buffer passed to the function should be at least 20 characters long to accommodate the address and terminating null character. An example of a 48 bit address would be "01:23:45:67:89:AB". If the local system is multi-homed (having more than one network adapter) then this function will return the MAC address for the primary network adapter.

This function is provided for backwards compatibility with previous versions of the library and it is recommended that new applications use the **InetGetAdapterAddress** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetGetSecurityInformation Function

```
BOOL WINAPI InetGetSecurityInformation(
   SOCKET hSocket,
   LPSECURITYINFO lpSecurityInfo
);
```

The **InetGetSecurityInformation** function fills a structure with information about the security characteristics of a connection.

Parameters

hSocket

Handle to the socket.

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;

securityInfo.dwSize = sizeof(SECURITYINFO);
if (InetGetSecurityInformation(hClient, &securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
```

```
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetGetServerClient Function

```
SOCKET WINAPI InetGetServerClient(
    SOCKET hServer
);
```

The **InetGetServerClient** function returns the handle for the last client connection accepted by the server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the handle to the last client connection that was accepted by the server. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerClient** function can be used inside the service event handler to determine the client connection that was just accepted by the server. This would typically be used in conjunction with the INET_EVENT_ACCEPT handler, enabling the application to obtain the handle of the new client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetServerData Function

```
BOOL WINAPI InetGetServerData(
    SOCKET hServer,
    LPVOID *lppvData
);
```

The **InetGetServerData** function returns the application defined data associated with the specified server.

Parameters

hServer

The server socket handle.

lppvData

Pointer to a void pointer which will contain an application defined value associated with the server.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the server could not be retrieved. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerData** function is used to retrieve the application defined data that was previously associated with a server using the **InetSetServerData** function. This is typically used to associate a pointer to a data structure or a class instance with a specific instance of a server.

This function can only be used with socket handles created using **InetServerStart** function. It cannot be used with socket handles created using the **InetListen** or **InetListenEx** functions. If the socket handle is invalid, or does not reference a server handle, the *lppvData* pointer passed to this function will be initialized to a value of NULL and the function will return a value of zero.

If this function is called with a valid socket handle and there is no data associated with the socket, the function will return a non-zero value and the *lppvData* pointer will be returned with a NULL value. Before dereferencing the pointer returned by this function, the application should always check the return value to ensure the function succeeded and make sure that the pointer is not NULL.

Example

```
UINT *pnValue1 = (UINT *)LocalAlloc(LPTR, sizeof(UINT));
UINT *pnValue2 = NULL;

*pnValue1 = 1234;

if (InetSetServerData(hServer, pnValue1) == FALSE)
{
    // Unable to associate the data with this server
    return;
}

if (InetGetServerData(hServer, &pnValue2) == FALSE)
{
    // Unable to retrieve the data associated with this server
    return;
}
```

```
// *pnValue2 == 1234
printf("The value of user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetServerPriority Function

```
INT WINAPI InetGetServerPriority(
    SOCKET hServer
);
```

The **InetGetServerPriority** function returns the current priority for the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the priority for the specified server. If the function fails, the return value is INET_PRIORITY_INVALID. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerPriority** function can be used to determine the current priority assigned to the specified server. It will be one of the following values:

Value	Description
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetServerStackSize Function

```
DWORD WINAPI InetGetServerStackSize(
     SOCKET hServer
);
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerStackSize** function returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetServerStatus Function

```
INT WINAPI InetGetServerStatus(
    SOCKET hServer
);
```

The **InetGetServerStatus** function returns the current status of the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the status for the specified server. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetServerStatus** function can be used to determine the current status for the specified server. It may be one of the following values:

Value	Description
INET_SERVER_INACTIVE	The server is currently inactive.
INET_SERVER_STARTED	The server has initialized and is preparing to listen for client connections.
INET_SERVER_LISTENING	The server is actively listening for incoming client connections.
INET_SERVER_SUSPENDED	The server has been suspended and is no longer accepting client connections.
INET_SERVER_SHUTDOWN	The server has been stopped and is in the process of terminating all active client connections.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetServerThreadId Function

```
DWORD WINAPI InetGetServerThreadId(
     SOCKET hServer
);
```

The **InetGetServerThreadId** function returns the thread ID for the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is an unsigned integer value which identifies the thread that was created to manage the server. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The thread ID returned by this function can be used with the **OpenThread** function to obtain a handle to the thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetServiceName Function

```
BOOL WINAPI InetGetServiceName(
   UINT nServicePort,
   LPTSTR lpszServiceName,
   INT nMaxLength
);
```

The **InetGetServiceName** function returns the service name associated with a specified port number.

Parameters

nServicePort

Port number associated with some network service.

lpszServiceName

A null-terminated string buffer that will contain the name of the service associated with the specified port number. This string should be at least 32 characters long.

nMaxLength

An integer value which specifies the maximum number of characters that can be copied into the string buffer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetGetServicePort

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetServicePort Function

```
UINT WINAPI InetGetServicePort(
   LPCTSTR lpszServiceName
);
```

The **InetGetServicePort** function returns the port number associated with a service name.

Parameters

lpszServiceName

A null-terminated string which specifies the name of the service to return the port number for.

Return Value

If the function succeeds, the return value is the port number associated with a service name. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetGetServiceName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetStatus Function

```
INT WINAPI InetGetStatus(
   SOCKET hSocket
);
```

The **InetGetStatus** function is used to report what sort of socket operation is in progress.

Parameters

hSocket

The socket handle.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The return value is one of the following values:

Value	Description
INET_STATUS_UNUSED	No connection has been established.
INET_STATUS_IDLE	The socket is idle and not in a blocked state
INET_STATUS_LISTEN	The socket is listening for inbound connections from a client
INET_STATUS_CONNECT	The socket is establishing a connection with a server
INET_STATUS_ACCEPT	The socket is accepting a connection from a client
INET_STATUS_READ	Data is being read from the socket
INET_STATUS_WRITE	Data is being written to the socket
INET_STATUS_FLUSH	The socket is being flushed; all data in the receive buffers is being discarded
INET_STATUS_DISCONNECT	The socket is disconnecting from the remote host

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified socket.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetStreamInfo Function

```
BOOL WINAPI InetGetStreamInfo(
   SOCKET hSocket,
   LPINETSTREAMINFO lpStreamInfo
);
```

The **InetGetStreamInfo** function fills a structure with information about the current stream I/O operation.

Parameters

hSocket

Handle to the socket.

lpStreamInfo

A pointer to an INETSTREAMINFO structure which contains information about the status of the network stream.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetStreamInfo** function returns information about the current streaming socket operation, including the average number of bytes transferred per second and the estimated amount of time until the operation completes. If there is no operation currently in progress, this function will return the status of the last successful streaming read or write performed by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified socket.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetReadStream, InetStoreStream, InetWriteStream, INETSTREAMINFO

InetGetThreadClient Function

```
SOCKET WINAPI InetGetThreadClient(
    DWORD dwThreadId
);
```

The **InetGetThreadClient** function returns the socket handle for the client session that is being managed by the specified thread.

Parameters

dwThreadId

An unsigned integer value which identifies the thread managing the client session. If this parameter has a value of zero, then the client handle for the current thread is returned.

Return Value

If the function succeeds, the return value is the socket handle for the specified client session. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetThreadClient** is used to obtain the socket handle for the client session that is being managed by the specified thread. If the specified thread ID is zero, then the function will return the client socket for the current thread, otherwise it will search the internal table of all active client sessions and return the handle to the session that is being managed by that thread.

This function will fail if the thread ID does not specify an active client session thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetGetTimeout Function

```
INT WINAPI InetGetTimeout(
    SOCKET hSocket
);
```

The **InetGetTimeout** function returns the timeout interval for blocking operations, in seconds.

Parameters

hSocket

Handle to the socket.

Return Value

If the function succeeds, the return value is the timeout interval for blocking operations, in seconds. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetSetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetGetUrlHostName Function

```
INT WINAPI InetGetUrlHostName(
   LPCTSTR lpszUrl,
   DWORD dwReserved,
   LPTSTR lpszHostName,
   INT nMaxLength,
   UINT *lpnHostPort,
   UINT *lpnProtocol,
   DWORD *lpdwOptions
);
```

The **InetGetUrlHostName** function returns the host name and port number specified in a URL.

Parameters

lpszUrl

A null-terminated string which specifies a URL. This parameter cannot be NULL or point to an empty string. If a non-standard URI scheme is used, the port number must be explicitly specified or the function will fail. See the remarks below for more information on the format supported by this function.

dwReserved

An unsigned integer value reserved for internal use. This value should always be zero.

lpszHostName

Pointer to the string buffer that will contain the canonical form of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer and must be large enough to store the complete host name.

nMaxLength

The maximum number of characters that can be copied to the *lpszHostName* string buffer. This parameter cannot be zero, and must include the terminating null character.

lpnHostPort

Pointer to an unsigned integer value which will contain the port number specified in the URL. This parameter value will always be initialized by the function with a value of zero. If this parameter is NULL, it will be ignored and no port information will be returned.

lpnProtocol

Pointer to an unsigned integer value which will contain the protocol associated with the URI scheme. This parameter value will always be initialized by the function with a value of zero. If this parameter is NULL, it will be ignored and no protocol information will be returned.

lpdwOptions

Pointer to an unsigned integer value which will contain any socket options required to establish a connection based on the URI scheme or specified port. This parameter value will always be initialized by the function with a value of zero. If this parameter is NULL, it will be ignored.

Return Value

If the function succeeds, the return value is the number of characters copied into the *lpszHostName* buffer. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetGetUrlHostName** function will extract the host name and port number from a URL and return the canonical form of the host name. If the *lpnHostPort*, *lpnProtocol* and *lpdwOptions* parameters have been specified, they will contain the port number, protocol and additional connection options associated with the URL scheme.

The general format of the URL should look like this:

```
[scheme]:// [[username : password] @] hostname [:port] / [path;parameters
...]
```

This function recognizes most standard URI schemes which use this format. The host name and port number specified in the URL will be used to establish a connection and the remaining information will be discarded. If the URL does not explicitly specify a port number, the default port number associated with the scheme will be used as the default value. For example, consider the following:

```
https://www.example.com/
```

In this example, there is no port number specified; instead, the default port for the **https://** scheme would be used, which is port 443. This function will also recognize a simpler format which only includes the host name and port number without a URI scheme, such as:

```
www.example.com:443
```

If the *lpszUrl* parameter only specifies a host name without a URI scheme or port number, this function will ignore the *lpnHostPort, lpnProtocol* and *lpdwOptions* parameters and return the canonical form of the host name in the *lpszHostName* string argument.

The host name portion of the URL can be specified as either a domain name or an IP address. Because an IPv6 address can contain colon characters, you must enclose the entire address in bracket [] characters. If this is not done, the function will return an error indicating the port number is invalid. For example, the URL `https://[2001:db8:0:0:1::128]/` uses an IPv6 host address and this would be considered valid. Without the brackets, this URL would not be accepted.

If the URL uses an IP address instead of a host name, this function will return a copy of that IP address in the *lpszHostName* string provided by the caller. The function will not attempt to resolve the IP address into a host name, however you can use the **InetGetHostName** function to perform a reverse DNS lookup if required.

The only URI schemes currently supported by this function use TCP stream connections. In practical terms, this means the *lpnProtocol* parameter will always return with the value INET_PROTOCOL_TCP when the function is successful. If the function fails, this value will be INET_PROTOCOL_NONE.

Although this function performs checks to ensure that the *lpszUrl* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the host name. To check if the host name exists and has a valid IP address, use the **InetValidateHostName** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetGetVpnAdapter Function

```
BOOL WINAPI InetGetVpnAdapter(
   LPTSTR lpszAdapterName,
   INT nMaxLength,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);
```

The **InetGetVpnAdapter** function returns the name of the active VPN adapter.

Parameters

lpszAdapterName

A null-terminated string buffer which will contain the name of the active VPN adapter if one is found. If a VPN was not detected, the buffer will contain an empty string when the function returns. This parameter may be NULL if the adapter name is not required.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character. If this value is zero, the ***lpszAdapterName*** parameter is ignored.

nAddressFamily

An integer value which identifies the type of IP address to return. It may be one of the following values:

Value	Description
INET_ADDRESS_ANY	Return the IP address for the adapter in either IPv4 or IPv6 format, depending on how the host name can be resolved. By default, a preference will be given for returning an IPv4 address. However, if the adapter only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the adapter address should be returned in IPv4 format. The first four bytes of the ***ipNumber*** member of the INTERNET_ADDRESS structure are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the adapter address should be returned in IPv6 format. All bytes in the ***ipNumber*** member of the INTERNET_ADDRESS structure are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address assigned to the VPN adapter when the function returns. This parameter may be NULL if this information is not required. If this parameter is NULL, the value of the ***nAddressFamily*** parameter is ignored.

Return Value

If the function succeeds, the return value is non-zero if an active VPN adapter was found. If no VPN adapter was detected, this function will return zero.

Remarks

The **InetGetVpnAdapter** function provides a best-effort method to detect if the system is currently using a Virtual Private Network (VPN) connection. The detection logic is based on identifying active network adapters with names or descriptions that match known VPN software or common VPN adapter naming conventions, while explicitly excluding adapters associated with virtualization platforms (such as Hyper-V, VMware, and VirtualBox), loopback interfaces, and other non-VPN virtual adapters.

Because there is no industry standard for how VPN clients are identified at the network adapter level, this function uses a heuristic approach and cannot guarantee detection in every scenario. Some VPN clients may use custom adapter names or attempt to obscure their presence, and new VPN software may not be recognized until the internal detection list is updated. There is also a small chance that non-VPN software using similar naming conventions could result in a false positive.

The result of this function should be treated as a hint for diagnostic or troubleshooting purposes. It should not be used to restrict access to your application or deny service to users based solely on the possible presence of a VPN connection. If you specify an address family and the ***lpAddress*** parameter is not NULL, it will contain the first IP address bound to the adapter interface. It is possible for VPN adapters to be bound to multiple IP addresses. The **InetFormatAddress** function can be used to convert the INTERNET_ADDRESS value to a printable string.

The adapter name returned by this function is the description of the detected VPN adapter, encoded as a UTF-8 string in the ANSI version of this function. If you require more detailed network information, consider using the **InetEnumNetworkAddresses** function. You can use the **InetGetExternalAddress** function to obtain the public-facing IP address allocated for the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetHostNameToUnicode Function

```
INT WINAPI InetHostNameToUnicode(
   LPCTSTR lpszHostName,
   LPTSTR lpszUnicodeName,
   INT nMaxLength
);
```

The **InetHostNameToUnicode** function converts the canonical form of a host name to its Unicode version.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero-length string.

lpszUnicodeName

Pointer to the string buffer that will contain the original Unicode version of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that can be copied to the ***lpszUnicodeName*** string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is INET_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **InetHostNameToUnicode** function will convert the encoded ASCII version of a host name to its Unicode version. Although any valid host name is accepted by this function, it is intended to convert a Punycode encoded host name to its original Unicode character encoding.

If the Unicode version of this function is used, the value returned in ***lpszUnicodeName*** will be a Unicode string using UTF-16 encoding. If the ANSI version of this function, the value returned will be a Unicode string using UTF-8 encoding. To display a UTF-8 encoded host name, your application will need to convert it to UTF-16 using the **MultiByteToWideChar** function.

Although this function performs checks to ensure that the ***lpszHostName*** parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the InetGetHostAddress function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetInitialize Function

```
BOOL WINAPI InetInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **InetInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**. All other functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **InetInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **InetUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **InetInitialize** or **InetUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetIsAddressNull Function

```
BOOL WINAPI InetIsAddressNull(
   LPINTERNET_ADDRESS lpAddress
);
```

The **InetIsAddressNull** function determines if the IP address is null.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure that contains the address to check.

Return Value

If the function succeeds and the IP address is null, or the ***lpAddress*** parameter is a NULL pointer, the return value is non-zero. If the function fails or the address is not null, the return value is zero. If the address family is not supported, the last error code will be updated. If the address is valid but not null, the last error code will be set to NO_ERROR.

Remarks

A null IP address is one where all bits for the address (32 bits for IPv4 or 128 bits for IPv6) are zero. This is a special address that is typically used when creating a passive socket that should listen for connections on all available network interfaces.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetAddress, InetIsAddressRoutable, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetIsAddressRoutable Function

```
BOOL WINAPI InetIsAddressRoutable(
   LPINTERNET_ADDRESS lpAddress
);
```

The **InetIsAddressRoutable** function determines if the IP address is routable over the Internet.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure that contains the address to check. This parameter cannot be NULL.

Return Value

If the function succeeds and the IP address is routable over the Internet, the return value is non-zero. If the function fails or the address is not routable, the return value is zero. If the parameter is NULL, or the address family is not supported, the last error code will be updated. If the address is valid but not routable, the last error code will be set to NO_ERROR.

Remarks

A routable IP address is one that can be reached by anyone over the public Internet. These are also commonly referred to as "public addresses" which are typically assigned to networks and individual hosts by an Internet service provider. There are also certain addresses that are not routable over the Internet, and used to address systems over a local network or private intranet. This function can be used to determine if a given IP address is public (routable) or private.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetIsBlocking Function

```
BOOL WINAPI InetIsBlocking(
    SOCKET hSocket
);
```

The **InetIsBlocking** function is used to determine if the socket is performing a blocking operation.

Parameters

hSocket

Socket handle.

Return Value

If the socket is currently performing a blocking operation, the function returns a non-zero value. If the socket is not performing a blocking operation, or the socket handle is invalid, the function returns zero.

Remarks

This function is typically used to determine if an open socket that is being used by another thread is currently blocked. A socket may block when waiting to receive data from a remote host or while data is actively being exchanged. Because there can only be one blocking socket operation per thread, this function can be used to determine if a function such as **InetRead** or **InetWrite** would fail because another thread is currently sending or receiving data on that socket. This socket handle that is passed to this function does not need to be owned by the current thread.

It is important to note that if this function returns a non-zero value, it does not guarantee that a subsequent read or write on the socket will succeed. The application should always check the return value from functions such as **InetRead** and **InetWrite** to ensure they were successful.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetIsClosed Function

```
BOOL WINAPI InetIsClosed(
   SOCKET hSocket
);
```

The **InetIsClosed** function is used to determine if the remote host has closed its socket.

Parameters

hSocket

Socket handle.

Return Value

If the remote host has closed its socket, the function returns a non-zero value. If the remote host has not closed its connection, or the socket handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetIsConnected, InetIsListening, InetIsReadable, InetIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetIsConnected Function

```
BOOL WINAPI InetIsConnected(
    SOCKET hSocket
);
```

The **InetIsConnected** function is used to determine if the socket is currently connected to a remote host.

Parameters

hSocket

Socket handle.

Return Value

If the socket is connected to a remote host, the function returns a non-zero value. If the socket is not connected, or the socket handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetIsListening Function

```
BOOL WINAPI InetIsListening(
    SOCKET hSocket
);
```

The **InetIsListening** function determines if the socket is listening for connection requests.

Parameters

hSocket

Socket handle.

Return Value

If the socket is being used to listen for connection requests, the function returns a non-zero value. If the socket is not listening or the socket handle is invalid, the function returns zero.

Remarks

The **InetIsListening** function determines if the socket is being used in a server application to actively listen for incoming connection requests from client applications. A listening socket can be created using either the **InetAsyncListen** or **InetListen** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetIsProtocolAvailable Function

```
BOOL WINAPI InetIsProtocolAvailable(
    INT nAddressFamily,
    INT nProtocol
);
```

The **InetIsProtocolAvailable** function determines if the operating system supports creating a socket for the specified address family and protocol.

Parameters

nAddressFamily

An integer which identifies the address family that should be checked. It should be one of the following values:

Value	Description
INET_ADDRESS_IPV4	Specifies that the function should determine if it can create an Internet Protocol version 4 (IPv4) socket. This requires that the system have an IPv4 TCP/IP stack bound to at least one network adapter on the local system. All Windows systems include support for IPv4 by default.
INET_ADDRESS_IPV6	Specifies that the function should determine if it can create an Internet Protocol version 6 (IPv6) socket. This requires that the system have an IPv6 TCP/IP stack bound to at least one network adapter on the local system. Windows XP and Windows Server 2003 includes support for IPv6, however it is not installed by default. Windows Vista and later versions include support for IPv6 and enable it by default.

nProtocol

An integer which identifies the protocol that should be checked. It should be one of the following values:

Value	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This requires that the system be capable of creating a stream socket using the specified address family.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. This requires that the system be capable of creating a datagram socket using the specified address family.

Return Value

If the system is capable of creating a socket using the specified address family and protocol, this function will return a non-zero value. If the combination of address family and protocol is not supported, this function will return a value of zero.

Remarks

The **InetIsProtocolAvailable** function is used to determine if the operating system supports creating a particular type of socket. Typically it is used by an application to determine if the system has an IPv6 TCP/IP stack installed and configured. By default, all Windows systems will have an IPv4 stack installed if the system has a network adapter. However, not all systems may have an IPv6 stack installed, particularly older Windows XP and Windows Server 2003 systems. Note that if an IPv6 stack is not installed, the library will not recognize IPv6 addresses and cannot resolve host names that only have an IPv6 (AAAA) record, even if the address or host name is valid.

Example

```
if (!InetIsProtocolAvailable(INET_ADDRESS_IPV6, INET_PROTOCOL_TCP))
{
    AfxMessageBox(_T("This system does not support IPv6"), MB_ICONEXCLAMATION);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetAddress, InetGetHostAddress, InetGetHostName

InetIsReadable Function

```
BOOL WINAPI InetIsReadable(
   SOCKET hSocket,
   DWORD dwTimeout,
   LPDWORD lpdwAvail
);
```

The **InetIsReadable** function is used to determine if data is available to be read from the socket.

Parameters

hSocket

Socket handle.

dwTimeout

Timeout value in milliseconds. If the socket cannot be read within this time period, the function will return a value of zero. A timeout value of zero specifies that the socket should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read.

Return Value

If the current thread can read data from the socket without blocking, the function returns a non-zero value. If the current thread cannot read any data without blocking, the function returns zero.

Remarks

On some platforms, the value returned in *lpdwAvail* will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

If the connection is secure, the value returned in *lpdwAvail* will reflect the number of bytes available in the encrypted data stream. The actual amount of data available to the application after it has been decrypted will vary.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetIsClosed, InetIsWritable, InetPeek, InetRead, InetReadLine, InetReadStream

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetIsUrgent Function

```
BOOL WINAPI InetIsUrgent(
   SOCKET hSocket
);
```

The **InetIsUrgent** function determines if there is any out-of-band (OOB) data available to be read.

Parameters

hSocket

Handle to the socket.

Return Value

If there is out-of-band data, the return value is non-zero. If there is no out-of-band data, or an error occurs the return value is zero. To determine if an error has occurred, use the **InetGetLastError** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetSetOption (INET_OPTION_INLINE)

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetIsWritable Function

```
BOOL WINAPI InetIsWritable(
    SOCKET hSocket,
    DWORD dwTimeout
);
```

The **InetIsWritable** function is used to determine if data can be written to the socket.

Parameters

hSocket

Socket handle.

dwTimeout

Timeout value in milliseconds. If the socket cannot be written to within this time period, the function will return a value of zero. A timeout value of zero specifies that the socket should be polled without blocking the current thread.

Return Value

If the current thread can write data to the socket within the timeout period, the function returns a non-zero value. The function will return zero if the socket send buffer is full.

Remarks

The **InetIsWritable** function cannot be used to determine the amount of data that can be sent to the remote host without blocking the current thread. A non-zero return value only indicates that the send buffer is not full and can accept some data. In most cases, it is recommended that larger blocks of data be broken into smaller logical blocks rather than attempting to send it all of the data at once. For very large streams of data, it is recommended that you use the **InetWriteStream** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetListen Function

```
SOCKET WINAPI InetListen(
   LPCTSTR lpszLocalAddress,
   UINT nLocalPort
);
```

The **InetListen** function creates a passive socket used to listen for connections from a client application.

This function has been deprecated and is included for backwards compatibility. Use the **InetServerStart** function to create a server application.

Parameters

lpszLocalAddress

A null-terminated string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

Return Value

If the function succeeds, the return value is a socket handle. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The socket option INET_OPTION_REUSEADDRESS is enabled by default when calling the **InetListen** function. This allows an application to re-use a local address and port number when creating the listening socket. If this behavior is not desired, use the **InetListenEx** function instead.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

After the listening socket has been created, the application should then call the **InetAccept** function to wait for a client to establish a connection. For servers that need to handle multiple simultaneous client connections, it is recommended that the asynchronous functions be used.

Example

```
SOCKET hServer = INVALID_SOCKET;
LPCTSTR lpszAddress = _T("192.168.0.48");
```

```
// Accept connections from clients that connect to
// address 192.168.0.48 on port 7000

hServer = InetListen(lpszAddress, 7000);
if (hServer == INVALID_SOCKET)
{
    DWORD dwError;
    TCHAR szError[256];

    dwError = InetGetLastError();
    InetGetErrorString(dwError, szError, 256);

    MessageBox(NULL, szError, NULL, MB_OK|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetAccept, InetAcceptEx, InetInitialize, InetListenEx, InetServerStart

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetListenEx Function

```
SOCKET WINAPI InetListenEx(
   LPCTSTR lpszLocalAddress,
   UINT nLocalPort,
   UINT nBacklog,
   DWORD dwOptions
);
```

The **InetListenEx** function creates a passive socket, and specifies the maximum number of connection requests that will be queued.

This function has been deprecated and is included for backwards compatibility. Use the **InetServerStart** function to create a server application.

Parameters

lpszLocalAddress

A null-terminated string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

nBacklog

The maximum length of the queue allocated for pending client connections. A value of zero specifies that the size of the queue should be set to a maximum reasonable value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are supported:

Value	Description
INET_OPTION_NONE	No option specified. If the address and port number are in use by another application or a closed socket which was listening on this port is still in the TIME_WAIT state, the function will fail.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable an application to close the listening socket and immediately reopen it without getting an error that the address is in use.
INET_OPTION_EXCLUSIVE	This option specifies the local address and port number is

	for the exclusive use by the current process, preventing another application from forcibly binding to the same address. If another process has already bound a socket to the address provided by the caller, this function will fail.
INET_OPTION_RESERVEDPORT	This option specifies the listening socket should be bound to an unused port number less than 1024, which is typically reserved for well-known system services. If this option is specified, the process may require administrative privileges and firewall rules that will permit a client to establish a connection with the service.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.

Return Value

If the function succeeds, the return value is a socket handle. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

If the INET_OPTION_REUSEADDRESS option is not specified, an error may be returned if a listening socket was recently created for the same local address and port number. By default, once a listening socket is closed there is a period of time that all applications must wait before the address can be reused (this is called the TIME_WAIT state). The actual amount of time depends on the operating system and configuration parameters, but is typically two to four minutes. Specifying this option enables an application to immediately re-use a local address and port number that was previously in use. Note that this does not permit more than one server to bind to the same address.

If the INET_OPTION_EXCLUSIVE option is specified, the local address and port number cannot be used by another process until the listening socket is closed. This can prevent another application from forcibly binding to the same listening address as your server. This option can be useful in determining whether or not another process is already bound to the address you wish to use, but it may also prevent your server application from restarting immediately, regardless if the INET_OPTION_REUSEADDRESS option has also been specified.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

After the listening socket has been created, the application should then call the **InetAccept** or **InetAcceptEx** function to wait for a client to establish a connection. For servers that need to handle multiple simultaneous client connections, it is recommended that the asynchronous functions be used.

Example

```
SOCKET hServer = INVALID_SOCKET;
LPCTSTR lpszAddress = _T("192.168.0.48");

// Accept connections from clients that connect to
// address 192.168.0.48 on port 7000 with a standard
// backlog of 5 connections

hServer = InetListenEx(lpszAddress,
                       7000,
                       INET_BACKLOG,
                       INET_OPTION_REUSEADDRESS);

if (hServer == INVALID_SOCKET)
{
    DWORD dwError;
    TCHAR szError[256];

    dwError = InetGetLastError();
    InetGetErrorString(dwError, szError, 256);

    MessageBox(NULL, szError, NULL, MB_OK|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetMatchHostName Function

```
BOOL WINAPI InetMatchHostName(
   LPCTSTR lpszHostName,
   LPCTSTR lpszHostMask
   BOOL bResolve
);
```

The **InetMatchHostName** function matches a host name against one more strings that may contain wildcards.

Parameters

lpszHostName

A null-terminated string which specifies the host name or IP address to match.

lpszHostMask

A null-terminated string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

bResolve

A boolean value which specifies if the host name or IP address should be resolved when matching the host against the mask string. If this parameter is non-zero, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is zero, then the match is made only against the host name string provided.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetMatchHostName** function provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the function would return a non-zero value indicating the host name matched the mask. However, if the mask string was "*.net" then the function would return zero, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

If an internationalized domain name (IDN) is specified, it will be converted internally to an ASCII string using Punycode encoding. The host mask will be matched against this encoded version of the host name, not its Unicode version.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

InetNormalizeHostName Function

```
INT WINAPI InetNormalizeHostName(
   LPCTSTR lpszHostName,
   LPTSTR lpszNormalized,
   INT nMaxLength
);
```

The **InetNormalizeHostName** function returns the canonical form of a host name in the specified buffer.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero-length string.

lpszNormalized

Pointer to the string buffer that will contain the canonical form of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer and must be large enough to store the complete host name.

nMaxLength

The maximum number of characters that can be copied to the ***lpszNormalized*** string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetNormalizeHostName** function will remove all leading and trailing whitespace characters from the host name and fold all upper-case characters to lower-case. If an internationalized domain name (IDN) containing Unicode characters is passed to this function, it will be converted to an ASCII compatible format for domain names.

The ***lpszHostName*** parameter should only specify a host name or IP address. If you want to support the use of URLs to establish a connection, use the **InetGetUrlHostName** function which has extended support for extracting the host name and port number specified in a URL.

If the Unicode version of this function is used, the host name will be converted from UTF-16 to UTF-8 and then processed. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended you use the Unicode version.

Although this function performs checks to ensure that the ***lpszHostName*** parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the **InetValidateHostName** function.

It is recommended that you use this function if your application needs to store the host name, and if accepts a host name as user input. It is not necessary to call this function prior to calling other SocketWrench functions which accept a host name as a parameter. Those functions already normalize the host name and perform checks to ensure it is in the correct format.

If the *lpszHostName* parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address. To determine if the IP address has a corresponding host name, use the **InetGetHostName** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetPeek Function

```
INT WINAPI InetPeek(
   SOCKET hSocket,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **InetPeek** function reads the specified number of bytes from the socket and copies them into the buffer, but it does not remove the data from the internal socket buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hSocket

The socket handle.

lpBuffer

Pointer to the buffer in which the data will be copied. This argument may be NULL, in which case no data is copied from the socket buffers, however the function will return the number of bytes available to read.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. If the ***lpBuffer*** parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes available to read from the socket. A return value of zero indicates that there is no data available to read at that time. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetPeek** function returns data that is available to read from the socket, up to the number of bytes specified. The data returned by this function is not removed from the socket buffers. It must be consumed by a subsequent call to the **InetRead** or **InetReadEx** function. The return value indicates the number of bytes that can be read in a single operation, up to the specified buffer size. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. Using this method in a loop to poll a non-blocking socket may cause the application to become non-responsive. To determine if there is data available to be read, use the **InetIsReadable** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetRead Function

```
INT WINAPI InetRead(
   SOCKET hSocket,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **InetRead** function reads the specified number of bytes from the socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hSocket

The socket handle.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the remote host has closed the connection and there is no more data available to be read. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetRead** function will read up to the specified number of bytes and store the data in the buffer provided by the caller. If there is no data available to be read at the time this function is called, the current thread will block until at least one byte of data becomes available, the timeout period elapses or an error occurs. This function will return if any amount of data is sent by the remote host, and will not block until the entire buffer has been filled. To avoid blocking the current thread, either create an asynchronous socket or use the **InetIsReadable** function to determine if there is data available to be read prior to calling this function.

The application should never make an assumption about the amount of data that will be available to read. TCP considers all data to be an arbitrary stream of bytes and does not impose any structure on the data itself. For example, if the remote host is sending data to the server in fixed 512 byte blocks of data, it is possible that a single call to the **Read** function will return only a partial block of data, or it may return multiple blocks combined together. It is the responsibility of the application to buffer and process this data appropriately.

For applications that are built using the Unicode character set, it is important to note that the buffer is an array of bytes, not characters. If the remote host is writing string data to the socket, it must be read as a stream of bytes and converted using the **MultiByteToWideChar** function. If the remote host is sending lines of text terminated with a linefeed or carriage return and linefeed pair, the **InetReadLine** function will return a line of text at a time and perform this conversion for you.

When **InetRead** is called and the socket is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is

available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetIsReadable, InetPeek, InetReadEx, InetWrite, InetWriteEx

InetReadEx Function

```
INT WINAPI InetReadEx(
   SOCKET hSocket,
   LPVOID lpvBuffer,
   INT cbBuffer,
   DWORD dwReserved,
   LPINTERNET_ADDRESS lpRemoteAddress,
   UINT *lpnRemotePort
);
```

The **InetReadEx** function reads the specified number of bytes from the socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hSocket

The socket handle.

lpvBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

dwReserved

Reserved parameter. This value must always be zero.

lpRemoteAddress

Pointer to an INTERNET_ADDRESS structure which will contain the IP address of the remote host that sent the data being read. If this information is not required, the parameter may be specified as NULL.

lpnRemotePort

Pointer to an unsigned integer which will contain the remote port number. If this information is not required, the parameter may be specified as NULL.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the remote host has closed the connection and there is no more data available to be read. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

When **InetReadEx** is called and the socket is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

This function extends the **InetRead** function to return additional information about the peer who sent the data being received. For a client TCP socket, the IP address and remote port are the same values that were used to establish the connection. For a server TCP socket, it is the IP address and port number of the client which sent the data. When reading data from a UDP socket, this is the IP address

and remote port of the peer that sent the datagram. This information can be used in conjunction with the **InetWriteEx** function to send a datagram back to that host.

InetReadLine Function

```
BOOL WINAPI InetReadLine(
   SOCKET hSocket,
   LPTSTR lpszBuffer,
   LPINT lpnLength
);
```

The **InetReadLine** function reads up to a line of data from the socket and returns it in a string buffer.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpszBuffer

Pointer to the string buffer that will contain the data when the function returns. The string will be terminated with a null byte, and will not contain the end-of-line characters.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the function returns, its value will updated with the actual length of the string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetReadLine** function reads data from the socket and copies into a specified string buffer. Unlike the **InetRead** function which reads arbitrary bytes of data, this function is specifically designed to return a single line of text data in a null-terminated string. When an end-of-line character sequence is encountered, the function will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **InetReadLine**. The function should only be used to read text, never binary data. In particular, the function will discard nulls, linefeed and carriage return control characters. The Unicode version of this function will return a Unicode string, however this function does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This function will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If this function is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **InetReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **InetRead** and **InetReadLine** function calls can be intermixed, however be aware that **InetRead**

will consume any data that has already been buffered by the **InetReadLine** function and this may have unexpected results.

Unlike the **InetRead** function, it is possible for data to be returned in the buffer even if the return value is zero. Applications should also check the value of the *lpnLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the function is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Example

```
TCHAR szBuffer[MAXBUFLEN];
INT nLength;
BOOL bResult;

do
{
    nLength = sizeof(szBuffer);
    bResult = InetReadLine(hSocket, szBuffer, &nLength);

    if (nLength > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = InetGetLastError();
if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The remote host has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetReadStream Function

```
BOOL WINAPI InetReadStream(
   SOCKET hSocket,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions,
   LPBYTE lpMarker,
   DWORD cbMarker,
   DWORD dwReserved
);
```

The **InetReadStream** function reads the socket data stream and stores the contents in the specified buffer.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpvBuffer

Pointer to the buffer that will contain or reference the data when the function returns. The actual argument depends on the value of the ***dwOptions*** parameter which specifies how the data stream will be stored.

lpdwLength

A pointer to an unsigned integer value which specifies the maximum length of the buffer and contains the number of bytes read when the function returns. This argument should should always point to an initialized value. If the lpvBuffer argument specifies a memory buffer, then this argument cannot point to an initialized value of zero; if any other type of stream buffer is used and the initialized value is zero, that indicates that all available data from the socket should be returned until the end-of-stream marker is encountered or the remote host disconnects.

dwOptions

An unsigned integer value which specifies both the stream buffer type and any options to be used when reading the data stream. One of the following stream types may be specified:

Value	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the ***lpvBuffer*** parameter. If the argument specifies a pointer to a global memory handle initialized to NULL, then the function will return a handle which references the data; otherwise, the function will consider the parameter a pointer to a block of pre-allocated memory which will contain the stream data when the function returns. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The ***lpvBuffer*** argument specifies a pointer to a pre-allocated block of memory which will contain the data read from the socket when the function returns. If this stream buffer type is used, the ***lpdwLength*** argument must point to an unsigned

	integer which has been initialized with the maximum length of the buffer.
INET_STREAM_HGLOBAL	The ***lpvBuffer*** argument specifies a pointer to a global memory handle. When the function returns, the handle will reference a block of memory that contains the stream data. The application should take care to make sure that the handle passed to the function does not currently reference a valid block of memory; it is recommended that the handle be initialized to NULL prior to calling this function.
INET_STREAM_HANDLE	The ***lpvBuffer*** argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read from the socket will be written to this handle using the WriteFile function.
INET_STREAM_SOCKET	The ***lpvBuffer*** argument specifies a socket handle. The data read from the socket specified by the ***hSocket*** argument will be written to this socket. The socket handle passed to this function must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either attach the socket using the InetAttachSocket function or use the INET_STREAM_HANDLE stream buffer type instead.
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being returned as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the source data stream; if the application is using a pre-allocated memory buffer, this must be considered before calling this function.

lpMarker

A pointer to an array of bytes which marks the end of the data stream. When this byte sequence is encountered by the function, it will stop reading and return to the caller. The buffer will contain all of the data read from the socket up to and including the end-of-stream marker. If this argument is NULL, then the function will continue to read from the socket until the maximum buffer size is reached, the remote host closes its socket or an error is encountered.

cbMarker

An unsigned integer value which specifies the length of the end-of-stream marker in bytes. If the *lpMarker* parameter is NULL, then this value must be zero.

dwReserved

A reserved parameter. This value must always be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetReadStream** function enables an application to read an arbitrarily large stream of data and store it in memory, write it to a file or even another socket. Unlike the **InetRead** method, which will return immediately when any amount of data has been read, **InetReadStream** will only return when the buffer is full as specified by the *lpdwLength* parameter, the logical end-of-stream marker has been read, the socket closed by the remote host or when an error occurs.

This function will force the thread to block until the operation completes. If this function is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **InetReadStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for data to be returned in the buffer even if the function returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the function is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the function return value.

Because **InetReadStream** can potentially cause the application to block for long periods of time as the data stream is being read, the function will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **InetRegisterEvent** function, and can obtain information about the current operation by calling the **InetGetStreamInfo** function.

Example

```
HGLOBAL hgblBuffer = NULL; // Return data in a global memory buffer
DWORD cbBuffer = 102400;   // Read up to 100K bytes
BOOL bResult;

bResult = InetReadStream(hSocket,
                         &hgblBuffer,
                         &cbBuffer,
                         INET_STREAM_HGLOBAL | INET_STREAM_CONVERT,
                         NULL, 0, 0);

if (bResult && cbBuffer > 0)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // Use data in the stream buffer
```

```
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

InetRegisterEvent Function

```
INT WINAPI InetRegisterEvent(
   SOCKET hSocket,
   UINT nEventId,
   INETEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **InetRegisterEvent** function registers a callback function for the specified event.

Parameters

hSocket

Socket handle.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. This parameter is ignored if the socket handle specifies a server created using the **InetServerStart** function. One or more of the following values may be used:

Value	Description
INET_EVENT_ACCEPT	A network event that indicates the process has received a connection request from a client and should accept the connection using the **InetAsyncAccept** function. This event is only generated for server applications which have created an asynchronous socket using the **InetAsyncListen** function.
INET_EVENT_CONNECT	A network event that indicates the connection to the remote host has completed.
INET_EVENT_DISCONNECT	A network event that indicates the remote host has closed the connection. The process should read any remaining data and disconnect.
INET_EVENT_READ	A network event which indicates data is available to read. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	A network event which indicates the application can send data to the remote host. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The application may attempt to retry the operation, or may disconnect from the remote host and report an error to the user.
INET_EVENT_CANCEL	The application has canceled a blocking operation. This event is fired once an operation has been terminated by the **InetCancel** function, and control has been returned to the

	calling process.

lpEventProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **InetEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled. This parameter cannot be NULL if the socket handle specifies a server created using the **InetServerStart** function.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetRegisterEvent** function associates a callback function with a specific event. The event handler is an **InetEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

This function can be used to change the callback function and user defined parameter for a server created using the **InetServerStart** function. However, it cannot be used with client sockets automatically created by the server interface. Those sockets are managed separately in their own thread, and individual client event notifications are not supported.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetReject Function

```
BOOL WINAPI InetReject(
   SOCKET hSocket
);
```

The **InetReject** function is used to reject a client connection request.

Parameters

hSocket

Handle to a listening socket.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetReject** function rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this function will immediately return with an error indicating that the operation would cause the thread to block.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetAbort, InetAccept, InetListen

InetServerAsyncNotify Function

```
BOOL WINAPI InetServerAsyncNotify(
    SOCKET hServer,
    HWND hWnd,
    UINT uMsg
);
```

Enable or disable asynchronous notification of changes in server status.

Parameters

hServer

The socket handle.

hWnd

A handle to the window whose window procedure will receive the notification message.

uMsg

The user-defined message that will be sent to the notification window.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerAsyncNotify** function is used by an application to enable or disable asynchronous notifications. The message window is typically the main UI window and these notifications are used signal to the application that it should update the user interface. If the *hWnd* parameter is not NULL, it must specify a valid window handle and the user-defined message must have a value of **WM_USER** or higher. The application cannot specify a notification message that is reserved by the operating system. The pseudo-handle **HWND_BROADCAST** cannot be specified as the notification window. If the *hWnd* parameter is NULL, notifications for the specified server will be disabled.

When asynchronous notifications are enabled for a server, the server will post the user-defined message to the window whenever there is a change in status or after a client has connected or disconnected from the server. The *wParam* message parameter will contain the notification message and the *lParam* message parameter will contain the handle to the server or the unique client ID. The following notification messages are defined:

Value	Description
INET_NOTIFY_STARTUP	This notification is sent when the server has started and is preparing to accept client connections. This notification is only sent once, and only if asynchronous notifications are enabled immediately after the **InetServerStart** function is called. This message will not be sent once the server has begun accepting client connections or when notification messages are disabled and then subsequently re-enabled at a later time. The *lParam* message parameter will specify the handle to the server.
INET_NOTIFY_LISTEN	This notification is sent when the server is listening for client connections. This notification message may be sent to the

	application multiple times over the lifetime of the server. If the server was suspended, this notification will be sent after the application calls the **InetServerResume** function to resume accepting client connections. The *lParam* message parameter will specify the handle to the server.
INET_NOTIFY_SUSPEND	This notification is sent when the server suspends accepting new connections because the application has called either the **InetServerSuspend** or **InetServerSuspendEx** function. This notification message may be sent to the application multiple times over the lifetime of the server. The *lParam* message parameter will specify the handle to the server.
INET_NOTIFY_RESTART	This notification is sent when the server is restarted using the **InetServerRestart** function. Note that the server socket handle provided by the *lParam* message parameter will specify the new socket handle of the restarted server instance, not the original socket handle. The *lParam* message parameter will specify the handle to the server.
INET_NOTIFY_CONNECT	This notification is sent when the server accepts a client connection and the thread that manages the client session has begun processing network events for that client. This message notification will not be sent if the client connection is rejected by the server. The *lParam* message parameter will specify the unique ID of the client that connected to the server.
INET_NOTIFY_DISCONNECT	This notification is sent when the client disconnects from the server and the client socket has been closed. This notification message may not occur for each client session that is forced to terminate as the result of the server being stopped using the **InetServerStop** function. The *lParam* message parameter will specify the unique ID of the client that disconnected from the server.
INET_NOTIFY_SHUTDOWN	This notification is sent when the server thread is in the process of terminating. At the time the application processes this notification message, the server handle in *lParam* will reference the defunct server and cannot be used with other server functions. The *lParam* message parameter will specify the handle to the server.

If asynchronous notifications are enabled, you should never use those notifications as a replacement for an event handler. When an event occurs, the callback function that handles the event is invoked in the context of the thread that manages the client session. The application should exchange data with the client within that event handler and not in response to a notification message. These notification messages should only be used to update the application UI in response to changes in the status of the server.

The INET_NOTIFY_CONNECT and INET_NOTIFY_DISCONNECT notifications are different from the other server notifications because the *lParam* message parameter does not specify the server handle, but rather the unique client ID associated with the session that connected to or disconnected from the server. If you need to obtain the handle to the client session using the ID, call the

InetGetClientHandle function. To obtain the server handle in response to the INET_NOTIFY_CONNECT message, use the **InetGetClientServerById** function. Note that at the time the application processes the INET_NOTIFY_DISCONNECT notification message, the client session will have already terminated.

This function can only be used with a handle returned by the **InetServerStart** function and cannot be used with sockets created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetServerBroadcast Function

```
INT WINAPI InetServerBroadcast(
    SOCKET hServer,
    LPBYTE lpBuffer,
    INT cbBuffer
);
```

The **InetServerBroadcast** function sends data to clients that are connected to the specified server.

Parameters

hServer

The socket handle.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server clients.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of clients that the data was sent to. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerBroadcast** function sends the contents of the buffer to all of the clients that are connected to the specified server. This function will block until all clients have been sent a copy of the data. There is no guarantee in which order the clients will receive and process the data that has been broadcast.

This function can only be used with a socket handle created using the **InetServerStart** function and cannot be used with sockets created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetServerLock Function

```
BOOL WINAPI InetServerLock(
    SOCKET hServer
);
```

The **InetServerLock** function locks the specified server, causing other client threads to block until it is unlocked.

Parameters

hServer

The socket handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerLock** function causes the specified server to enter a locked state where only the current thread may interact with the server and the clients that are connected to it. While a server is locked, all other threads will block when they attempt to perform a network operation. When the server is unlocked, the blocked threads will resume normal execution.

This function should be used carefully, and a server should never be left in a locked state for an extended period of time. It is meant to be used when the server process updates a global data structure and it must prevent any other threads from performing a network operation during the update. Only one server can be locked at any one time, and once a server has been locked, it can only be unlocked by the same thread.

The program should always check the return value from this function, and should never assume that the lock has been established. If more than one thread attempts to lock a server at the same time, there is no guarantee as to which thread will actually establish the lock. If a potential deadlock situation is detected, this function will fail and return a value of zero.

Every time the **InetServerLock** function is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to **InetServerLock** must be matched by an equal number of calls to the **InetServerUnlock** function. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetServerRestart Function

```
SOCKET WINAPI InetServerRestart(
    SOCKET hServer
);
```

The **InetServerRestart** function restarts the server, terminating all active client sessions.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is the new socket handle for the specified server. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerRestart** function will restart the specified server, terminating all active client sessions and recreating the listening socket. The socket handle that is returned by the function is the handle for the new listening socket, and the old handle value is no longer valid. If the function is unable to recreate the listening socket for any reason, the server thread is terminated.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetServerResume Function

```
BOOL WINAPI InetServerResume(
    SOCKET hServer
);
```

The **InetServerResume** function resumes accepting client connections on the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerResume** function instructs the server to resume accepting client connections. Any pending client connections that were requested while the server was suspended will be accepted.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetServerStatus, InetServerRestart, InetServerStart, InetServerStop, InetServerSuspend

InetServerStart Function

```
SOCKET WINAPI InetServerStart(
   LPCTSTR lpszLocalHost,
   UINT nLocalPort,
   UINT nBacklog,
   UINT nMaxClients,
   UINT nTimeout,
   UINT nPriority,
   DWORD dwOptions,
   INETEVENTPROC lpEventProc,
   DWORD_PTR dwEventParam,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **InetServerStart** function begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the callback function specified by the caller.

Parameters

lpszLocalHost

A null-terminated string which specifies the local hostname or IP address address that the socket should be bound to. If this parameter is NULL or an empty string, then an appropriate address will automatically be used. A specific address should only be used if it is required by the application.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero.

nBacklog

The maximum length of the queue allocated for pending client connections. A value of zero specifies that the size of the queue should be set to a maximum reasonable value. On Windows server platforms, the maximum value is large enough to queue several hundred pending connections.

nMaxClients

The maximum number of client connections that can be established with the server. A value of zero specifies that there should not be any fixed limit on the number of active client connections. This value can be adjusted after the server has been created by calling the **InetServerThrottle** function.

nTimeout

The number of seconds the server should wait for a client to perform a network operation. If the client does not exchange any information with the server within this period of time, a timeout event will occur. The timeout value affects all clients that are connected to the server.

nPriority

An integer value which specifies the priority for the server and all client sessions. The priority for a specific client session may be modified by calling the **InetSetClientPriority** function. This parameter may be one of the following values:

Value	Description
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. It is recommended that most

	applications use this priority.
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the client session. It is typically used with lightweight services running in the background that are designed for few client connections. The client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. The client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the client session and the thread will be given higher scheduling priority. It can be used when it is important for the client session thread to be highly responsive. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The thread will be given higher scheduling priority and will be more responsive to the remote host. It is not recommended that this priority be used on a system with a single processor.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are supported:

Value	Description
INET_OPTION_NONE	No option specified. If the address and port number are in use by another application or a closed socket which was listening on this port is still in the TIME_WAIT state, the function will fail.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable an application to close the listening socket and immediately reopen it without getting an error that the address is in use.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. Enabling this option will also help applications detect the physical loss of a network connection, such as an Ethernet cable being unplugged. This option does not guarantee that persistent

	connections will be maintained over long periods of time.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and combines smaller packets into a single larger packet when sending data to a remote host. Specifying this option can improve the responsiveness and overall throughput of applications that implement their own buffering and exchange large amounts of information.
INET_OPTION_NOINHERIT	This option prevents the server socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.
INET_OPTION_SECURE	This option specifies that a secure connection should be established with the client, where the client immediately initiates the TLS handshake when it connects to the server. To implement an explicit TLS session, where the client establishes a standard, non-secure connection and then sends a command to the server to initiate a secure session, you should not use this option. Instead, use the **InetEnableSecurity** function to selectively enable TLS for the client session.

lpEventProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **InetEventProc** callback function. This parameter cannot be NULL.

dwEventParam

A user-defined integer value that is passed to the callback function.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This may be NULL, unless the ***dwOptions*** parameter includes INET_OPTION_SECURE. When a secure session is specified, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a socket handle. If the function fails, the return value is INVALID_SOCKET. To get extended error information, call **InetGetLastError**.

Remarks

In most cases, the ***lpszLocalHost*** parameter should be a NULL pointer or an empty string. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

If the INET_OPTION_REUSEADDRESS option is not specified, an error may be returned if a listening socket was recently created for the same local address and port number. By default, once a listening socket is closed there is a period of time that all applications must wait before the address can be reused (this is called the TIME_WAIT state). The actual amount of time depends on the operating system and configuration parameters, but is typically two to four minutes. Specifying this option enables an application to immediately re-use a local address and port number that was previously in use. Note that this does not permit more than one server to bind to the same address.

When the event handler callback function is invoked by the server, it normally executes in the context of the worker thread that manages that client session. This means that even if you do not explicitly create any threads in your application, you must design your program to be thread-safe, with synchronized access to global objects and data. If your application has a user interface, only the main UI thread should attempt to modify controls. If you attempt to modify a control from a worker thread, such as adding a row to a listbox control, it can result the application becoming deadlocked. This means that you should not attempt to directly update the UI from within the event handler function. To enable asynchronous server notifications for a GUI application, use the **InetServerAsyncNotify** function.

The socket handle returned by this function references the listening socket that was created when the server was started. The service is managed in another thread, and all interaction with the server and active client connections are performed inside the event handler. To disconnect all active connections, close the listening socket and terminate the server thread, call the **InetServerStop** function.

Example

```
#define SERVER_PORT       7000
#define SERVER_CLIENTS    100

SOCKET hServer = INVALID_SOCKET;

// Accept connections from clients that connection on port 7000 with a default
// backlog of 5 connections and a maximum of 100 client connections.

hServer = InetServerStart(NULL,
                          SERVER_PORT,
                          INET_BACKLOG,
                          SERVER_CLIENTS,
                          INET_TIMEOUT,
                          INET_PRIORITY_NORMAL,
                          INET_OPTION_REUSEADDRESS,
                          MyEventHandler,
                          0,
                          NULL);

if (hServer == INVALID_SOCKET)
{
    DWORD dwError;
    TCHAR szError[256];
```

```
    dwError = InetGetLastError();
    InetGetErrorString(dwError, szError, 256);

    MessageBox(NULL, szError, NULL, MB_OK|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetServerStop Function

```
BOOL WINAPI InetServerStop(
    SOCKET hServer
);
```

The **InetServerStop** function signals the server to stop listening for connections and terminates all client sessions.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerStop** function signals the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The socket handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the socket handle to be opaque and never depend on it being a specific value.

If this function is called when there is one or more clients connected to the server, it will signal each client thread to terminate and then wait for the server thread to terminate. As the client sessions are terminated, the event handler will not be invoked. If you wish to ensure that all clients are disconnected normally before stopping the server, call the **InetServerSuspendEx** function with the INET_SUSPEND_DISCONNECT option and then stop the server after the last client has disconnected.

Because the **InetServerStop** function waits for the server thread to terminate, this function may cause your application to block. If this is not desirable, use the **InetServerStopEx** function which can perform the shutdown sequence asynchronously.

After the server thread has been terminated, the listening socket will go into a TIME-WAIT state which prevents an application from reusing the same address and port number bound to that socket for a brief period of time, typically two to four minutes. This is normal behavior designed to prevent delayed or misrouted packets of data from being read by a subsequent connection. To immediately start a new server using the same local address and port number, the option INET_OPTION_REUSEADDRESS must be specified when calling the **InetServerStart** function.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetServerStatus, InetServerRestart, InetServerStart, InetServerStopEx, InetServerSuspendEx

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetServerStopEx Function

```
BOOL WINAPI InetServerStopEx(
   SOCKET hServer,
   DWORD dwMilliseconds
);
```

The **InetServerStopEx** function signals the server to stop listening for connections and terminates all client sessions.

Parameters

hServer

Handle to the server socket.

dwMilliseconds

An unsigned integer value that specifies the number of milliseconds to wait for all active clients to disconnect and the server thread to terminate.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerStopEx** function signals the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The socket handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the socket handle to be opaque and never depend on it being a specific value.

Unlike the **InetServerStop** function, which waits for fixed period of time for the server thread to terminate, the **InetServerStopEx** allows the caller to determine how much time should be spent waiting for the clients to disconnect and the server thread to terminate. If the ***dwMilliseconds*** parameter has a value of INFINITE, the function will wait for an indefinite period of time until all clients have disconnected, the listening socket closed and the server thread has terminated. If the ***dwMilliseconds*** parameter has a value of zero, the function does not wait for the server to shutdown. Instead, it returns immediately and the shutdown process continues in the background.

If your application specifies a value of zero for the ***dwMilliseconds*** parameter, the event handler will be invoked with the INET_EVENT_DISCONNECT event as each client disconnects from the server during the shutdown process. If you depend on this event to perform some cleanup on a per-client basis, you must ensure that the application does not exit until the server thread has terminated. To perform a graceful shutdown of the server, it is recommended that you use the **InetServerSuspendEx** function and specify the INET_SUSPEND_DISCONNECT option. After all clients have disconnected, call the **InetServerStop** function to terminate the server thread.

After the server thread has been terminated, the listening socket will go into a TIME-WAIT state which prevents an application from reusing the same address and port number bound to that socket for a brief period of time, typically two to four minutes. This is normal behavior designed to prevent delayed or misrouted packets of data from being read by a subsequent connection. To immediately start a new server using the same local address and port number, the option INET_OPTION_REUSEADDRESS must be specified when calling the **InetServerStart** function.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetServerSuspend Function

```
BOOL WINAPI InetServerSuspend(
    SOCKET hServer
);
```

Suspend accepting client connections on the specified server.

Parameters

hServer

Handle to the server socket.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerSuspend** function instructs the server to suspend accepting new client connections. Any incoming client connections will be queued up to the maximum backlog value specified when the server was started. To resume accepting client connections, call the **InetServerResume** function.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **InetServerThrottle** function.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetServerStatus, InetServerRestart, InetServerResume, InetServerStart, InetServerStop, InetServerThrottle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetServerSuspendEx Function

```
BOOL WINAPI InetServerSuspendEx(
    SOCKET hServer,
    DWORD dwOptions
);
```

Suspend accepting client connections and optionally reject or disconnect clients.

Parameters

hServer

Handle to the server socket.

dwOptions

An unsigned integer that specifies one or more options.

Value	Description
INET_SUSPEND_DEFAULT	Specifies that the server should suspend accepting new connections. New incoming client connections will be queued and clients that have already established a connection to the server will remain connected.
INET_SUSPEND_REJECT	Specifies that the server should suspend accepting new connections and reject any new client connections. Clients that have already established a connection to the server will remain connected.
INET_SUSPEND_DISCONNECT	Specifies that the server should suspend accepting new connections and disconnect all active clients that are currently connected to the server. If the INET_SUSPEND_REJECT option is also specified, new client connections will be rejected by the server.
INET_SUSPEND_WAIT	Specifies that the function should wait for the clients to disconnect from the server rather than return immediately to the caller. This option is only meaningful when used in conjunction with INET_SUSPEND_DISCONNECT.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerSuspendEx** function instructs the server to suspend accepting new client connections. Additional options can be used to control how the server suspends connections. If you plan on suspending the server for any period of time greater than a few seconds, it is recommended that you specify the INET_SUSPEND_REJECT option so that clients are not forced to wait.

If the INET_SUSPEND_DISCONNECT option is specified, the server will signal each client to disconnect and will stop accepting new connections. The event handler will be invoked for each client that disconnects. If the INET_SUSPEND_WAIT option is also specified, the function will wait until the last client has disconnected from the server before returning to the caller. If there are a large number of

clients connected to the server, this process may cause the application to block for an extended period of time and appear to be non-responsive to the user. For this reason, you should not specify the INET_SUSPEND_WAIT option if the function is being called from the application's main UI thread.

To perform a graceful shutdown of the server, it is recommended that you call **InetServerSuspendEx** with the INET_SUSPEND_REJECT and INET_SUSPEND_DISCONNECT options. This will allow each client to disconnect from the server and the server will reject any new incoming connections. After the last client has disconnected from the server, call the **InetServerStop** function to complete the shutdown process. The **InetGetClientThreads** function can be used to determine if all client session threads have terminated.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetServerStatus, InetServerRestart, InetServerResume, InetServerStart, InetServerStop, InetServerThrottle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetServerThrottle Function

```
BOOL WINAPI InetServerThrottle(
   SOCKET hServer,
   UINT nMaxClients,
   UINT nMaxClientsPerAddress,
   DWORD dwConnectionRate
);
```

The **InetServerThrottle** function limits the number of active client connections, connections per address and connection rate.

Parameters

hServer

Handle to the server socket.

nMaxClients

A value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

nMaxClientsPerAddress

A value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is no limit on the number of client connections per address.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerThrottle** function is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **InetServerStart** function is called with the maximum number of clients set to 100, and then **InetServerThrottle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept

incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

The socket handle for the server must be one that was created by calling the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetServerUnlock Function

```
BOOL WINAPI InetServerUnlock(
    SOCKET hServer
);
```

The **InetServerUnlock** function unlock the specified server, allowing other client threads to resume execution.

Parameters

hServer

The socket handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetServerUnlock** function releases the lock on the specified server and allows any blocked threads to resume execution. Only one server may be locked at any one time, and only the thread which established the lock can unlock the server.

Every time the **InetServerLock** function is called, an internal lock counter is incremented, and the lock will not be released until the lock count drops to zero. This means that each call to **InetServerLock** must be matched by an equal number of calls to the **InetServerUnlock** function. Failure to do so will result in the server becoming non-responsive as it remains in a locked state.

The program should always check the return value from this function, and should never assume that the lock has been released. If a potential deadlock situation is detected, this function will fail and return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetSetClientData Function

```
BOOL WINAPI InetSetClientData(
    SOCKET hClient,
    LPVOID lpvData
);
```

The **InetSetClientData** function sets the application defined data associated with the specified client session.

Parameters

hClient

The client socket handle.

lpvData

Pointer to the application defined data associated with the specified client session.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the client session could not be modified. To get extended error information, call **InetGetLastError**.

Remarks

The **InetSetClientData** function is used to associate application defined data with a specific client session. This is typically used to associate a pointer to a data structure or a class instance with the client socket. The data can be retrieved using the **InetGetClientData** function.

You should never specify a pointer to a local variable or data structure that will go out of scope when the calling function exits. If you do this, the pointer will no longer be valid after the function exits and attempting to dereference that pointer at some later time can cause an exception to be thrown and terminate the program. You should always allocate a block of memory for the data using a function such as **HeapAlloc** or **LocalAlloc**. If you specify the address of a static or global data structure, you must use thread synchronization functions when dereferencing and modifying that structure.

This function can only be used with client socket handles created using the SocketWrench server interface. It cannot be used with socket handles created using the **InetConnect** or **InetAccept** functions.

Example

```
UINT *pnValue1 = (UINT *)LocalAlloc(LPTR, sizeof(UINT));
UINT *pnValue2 = NULL;

*pnValue1 = 1234;

if (InetSetClientData(hClient, pnValue1) == FALSE)
{
    // Unable to associate the data with this session
    return;
}

if (InetGetClientData(hClient, &pnValue2) == FALSE)
{
    // Unable to retrieve the data associated with this session
    return;
```

```
}

// *pnValue2 == 1234
printf("The value of user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetSetClientMoniker Function

```
INT WINAPI InetSetClientMoniker(
   SOCKET hSocket,
   LPCTSTR lpszMoniker
);
```

The **InetSetClientMoniker** function associates a unique string moniker with the specified client session.

Parameters

hSocket

Handle to the client socket.

lpszMoniker

Pointer to a string which specifies the moniker for the specified client socket. If this parameter is NULL or specifies an empty string, a moniker will no longer be associated with the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

A client moniker is a string which can be used to uniquely identify a specific client session aside from its socket handle. The **InetGetClientMoniker** function will return the moniker that was previously assigned to the client, if any. To obtain the socket handle associated with a given moniker, use the **InetFindClientMoniker** function.

Monikers are not case-sensitive, and they must be unique so that no client socket for a particular server can have the same moniker. The maximum length for a moniker is 127 characters.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetSetClientPriority Function

```
INT WINAPI InetSetClientPriority(
    SOCKET hClient,
    INT nPriority
);
```

The **InetSetClientPriority** function sets the current priority for the specified client session.

Parameters

hClient

Handle to the client session.

nPriority

An integer value which specifies the new priority for the client session. It may be one of the following values:

Value	Description
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. It is recommended that most applications use this priority.
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the client session. It is typically used with lightweight services running in the background that are designed for few client connections. The client thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the client session and meters the processor utilization for the client session. The client thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the client session and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The client thread will be given higher scheduling priority and will be more responsive to network events. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority for the specified client session. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **InetSetClientPriority** function can be used to change the current priority assigned to the specified client session. The client priority is inherited from the priority specified when the server is started using the **InetServerStart** function.

The socket handle for the client must be one that was created as part of the SocketWrench server interface, and cannot be a socket that was created using the **InetConnect** or **InetAccept** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetClientPriority, InetGetServerPriority, InetServerStart, InetSetServerPriority

InetSetHostFile Function

```
INT WINAPI InetSetHostFile(
   LPCTSTR lpszFileName
);
```

The **InetSetHostFile** function specifies the name of an alternate file to use when resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **InetGetHostAddress** and **InetGetHostNames** function. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

lpszFileName

Pointer to a string that specifies the name of the file. If the parameter is NULL, then the current host file is cleared from the cache and only the default host file will be used to resolve hostnames and addresses.

Return Value

If the function succeeds, the return value is the number of entries in the host file. A return value of INET_ERROR indicates failure. To get extended error information, call **InetGetLastError**.

Remarks

This function loads the file into memory allocated for the current thread. If the contents of the file have changed after the function has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, call this function again with the same file name. To remove the alternate host file from memory, specify a NULL pointer as the parameter.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

To determine if an alternate host file has been specified, use the **InetGetHostFile** function. A return value of zero indicates that no alternate host file has been cached for the current thread.

A system may have a default host file, which is used to resolve hostnames before performing a nameserver lookup. To determine the name of this file, use the **InetGetDefaultHostFile** function. It is not necessary to specify this default host file, since it is always used to resolve host names and addresses.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

InetSetLastError Function

```
VOID WINAPI InetSetLastError(
   DWORD dwErrorCode
);
```

The **InetSetLastError** function sets the last-error code for the caller. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last-error code for the caller.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those functions which call **InetSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the InetGetLastError function. The use of **InetGetLastError** is optional; an application can call it to find out the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetSetOption Function

```
INT WINAPI InetSetOption(
   SOCKET hSocket,
   DWORD dwOption,
   BOOL bEnabled
);
```

The **InetSetOption** function is used to enable or disable a specific socket option.

Parameters

hSocket

The socket handle.

dwOption

An unsigned integer used to specify one of the socket options. These options cannot be combined. The following values are recognized:

Value	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.

bEnabled

A boolean flag. If the flag is set to a non-zero value, the option is enabled. Otherwise the socket option is disabled.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

It is not recommend that you disable the Nagle algorithm by specifying the INET_OPTION_NODELAY flag unless it is absolutely required. Doing so can have a significant, negative impact on the performance of the application and network.

If if the INET_OPTION_KEEPALIVE option is enabled, keep-alive packets will start being generated five seconds after the socket has become idle with no data being sent or received. Enabling this option can be used by applications to detect when a physical network connection has been lost. However, it is recommended that most applications query the remote host directly to determine if the connection is still active. This is typically accomplished by sending specific commands to the server to query its status, or checking the elapsed time since the last response from the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetSetServerData Function

```
BOOL WINAPI InetSetServerData(
    SOCKET hServer,
    LPVOID lpvData
);
```

The **InetSetServerData** function sets the application defined data associated with the specified server.

Parameters

hServer

The socket handle.

lpvData

Pointer to the application defined data associated with the specified server.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates that application defined data for the server could not be modified. To get extended error information, call **InetGetLastError**.

Remarks

The **InetSetServerData** function is used to associate application defined data with a specific server. The data can be retrieved using the **InetGetServerData** function.

You should never specify a pointer to a local variable or data structure that will go out of scope when the calling function exits. If you do this, the pointer will no longer be valid after the function exits and attempting to dereference that pointer at some later time can cause an exception to be thrown and terminate the program. You should always allocate a block of memory for the data using a function such as **HeapAlloc** or **LocalAlloc**. If you specify the address of a static or global data structure, you must use thread synchronization functions when dereferencing and modifying that structure.

This function can only be used with server socket handles created using the **InetServerStart** function. It cannot be used with socket handles created using the **InetListen** or **InetListenEx** functions.

Example

```
UINT *pnValue1 = (UINT *)LocalAlloc(LPTR, sizeof(UINT));
UINT *pnValue2 = NULL;

*pnValue1 = 1234;

if (InetSetServerData(hServer, pnValue1) == FALSE)
{
    // Unable to associate the data with this server
    return;
}

if (InetGetServerData(hServer, &pnValue2) == FALSE)
{
    // Unable to retrieve the data associated with this server
    return;
}

// *pnValue2 == 1234
```

```
printf("The value of user defined data is %u\n", *pnValue2);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetSetServerPriority Function

```
INT WINAPI InetSetServerPriority(
    SOCKET hServer,
    INT nPriority
);
```

The **InetSetServerPriority** function sets the current priority for the specified server.

Parameters

hServer

Handle to the server socket.

nPriority

An integer value which specifies the new priority for the server. It may be one of the following values:

Value	Description
INET_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
INET_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
INET_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
INET_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
INET_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority assigned to the server. If the function fails, the return value is INET_PRIORITY_INVALID. To get extended error information, call **InetGetLastError**.

Remarks

The **InetSetServerPriority** function can be used to change the current priority assigned to the specified server. Client connections that are accepted after this function is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function. To modify the priority for an active client session, use the **InetSetClientPriority** function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

The socket handle for the server must be one that was created using the **InetServerStart** function, and cannot be a socket that was created using the **InetListen** or **InetListenEx** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetClientPriority, InetGetServerPriority, InetServerStart, InetSetClientPriority

InetSetServerStackSize Function

```
BOOL WINAPI InetSetServerStackSize(
    SOCKET hServer,
    DWORD dwStackSize
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetSetServerStackSize** function changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change the stack size unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetGetMemoryUsage, InetGetServerStackSize, InetServerStart

InetSetTimeout Function

```
INT WINAPI InetSetTimeout(
   SOCKET hSocket,
   UINT nTimeout
);
```

The **InetSetTimeout** function sets the interval that is used when waiting for a blocking operation to complete.

Parameters

hSocket

Handle to the socket.

nTimeout

Duration of timeout interval, in seconds. If a value over 1000 is specified, it is assumed that milliseconds are intended by the user, and the value actually used will be adjusted accordingly.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

InetShutdown Function

```
INT WINAPI InetShutdown(
   SOCKET hSocket,
   DWORD dwOption
);
```

The **InetShutdown** function is used to disable reception or transmission of data, or both.

Parameters

hSocket

The socket handle.

dwOption

An unsigned integer used to specify one of the shutdown options. These options cannot be combined. The following values are recognized:

Value	Description
INET_SHUTDOWN_READ	Disable reception of data.
INET_SHUTDOWN_WRITE	Disable transmission of data.
INET_SHUTDOWN_BOTH	Disable both reception and transmission of data.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This function is rarely needed. It is provided as an interface to the Windows Sockets **shutdown** function.

In some asynchronous applications, it may be desirable for a client to inform the server that no further communication is wanted, while allowing the client to read any residual data that may reside in internal buffers on the client side. **InetShutdown** accomplishes this because the socket handle is still valid after it has been called, although some or all communication with the remote host has ceased.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetDisconnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

InetStoreStream Function

```
BOOL WINAPI InetStoreStream(
   SOCKET hSocket,
   LPCTSTR lpszFileName,
   DWORD dwLength,
   LPDWORD lpdwCopied
   DWORD dwOffset,
   DWORD dwOptions
);
```

The **InetStoreStream** function reads the socket data stream and stores the contents in the specified file.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpszFileName

Pointer to a string which specifies the name of the file to create or overwrite.

dwLength

An unsigned integer which specifies the maximum number of bytes to read from the socket and write to the file. If this value is zero, then the function will continue to read data from the socket until the remote host disconnects or an error occurs.

lpdwCopied

A pointer to an unsigned integer value which will contain the number of bytes written to the file when the function returns.

dwOffset

An unsigned integer which specifies the byte offset into the file where the function will start storing data read from the socket. Note that all data after this offset will be truncated. A value of zero specifies that the file should be completely overwritten if it already exists.

dwOptions

An unsigned integer value which specifies one or more options. Programs can use a bitwise operator to combine any of the following values:

Value	Description
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data written to the file to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.

INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being written as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the source data stream. If the *dwOffset* parameter has a value of zero, the Unicode byte order mark (BOM) will be written to the beginning of the file.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetStoreStream** function enables an application to read an arbitrarily large stream of data and store it in a file. This function is essentially a simplified version of the **InetReadStream** function, designed specifically to be used with files rather than memory buffers or handles.

This function will force the thread to block until the operation completes. If this function is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **InetStoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **InetStoreStream** can potentially cause the application to block for long periods of time as the data stream is being read, the function will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **InetRegisterEvent** function, and can obtain information about the current operation by calling the **InetGetStreamInfo** function.

Example

```
DWORD dwCopied;
BOOL bResult;

bResult = InetStoreStream(hSocket,
                          lpszFileName,                          0,
                          &dwCopied,
                          0,
                          INET_STREAM_CONVERT);

if (bResult && dwCopied > 0)
{
    // The data has been written to the file
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetUninitialize Function

```
VOID WINAPI InetUninitialize();
```

The **InetUninitialize** function terminates the use of the library.

Parameters

None.

Return Value

None.

Remarks

An application is required to perform a successful **InetInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **InetUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **InetUninitialize** for every successful call to **InetInitialize** made by a process. In a multithreaded environment, operations for all threads are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

InetValidateCertificate Function

```
BOOL WINAPI InetValidateCertificate(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertPassword,
   LPCTSTR lpszCertName
);
```

The **InetValidateCertificate** function determines if the specified security certificate is installed on the local system.

Parameters

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the personal certificate store will be used as the default. This parameter may also specify the name of a certificate file in PKCS #12 (PFX) format.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertPassword

A null-terminated string which specifies the password associated with a certificate file. This parameter is only used if the ***lpszCertStore*** parameter specifies a certificate file, otherwise it is ignored. If the certificate file is not protected with a password, this parameter should be a NULL pointer or empty string.

lpszCertName

A null-terminated string which specifies the name of the certificate to validate. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This

comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

If you are checking the validity of a certificate installed in the local certificate store, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user.

It is possible to validate a certificate file rather than one stored in the local certificate store. The *lpszCertStore* member should specify the name of a file in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate file was created, it must be provided in with the *lpszCertPassword* parameter or this function will be unable to access the certificate.

This function can only validate certificate files in PFX format and cannot be used to validate a certificate file in another format, such as PEM (base64 encoded) or DER (binary).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetValidateHostName Function

```
BOOL WINAPI InetValidateHostName(
   LPCTSTR lpszHostName,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **InetValidateHostName** function determines if the specified host name is valid and returns its IP address.

Parameters

lpszHostName

A null-terminated string which specifies the host name. The function will fail If this parameter is NULL or an empty string.

lpszAddress

A null-terminated string buffer which will contain the IP address of the host. If specified, this string must be large enough to store the complete IP address, including the terminating null character. If this parameter is NULL or the ***nMaxLength*** parameter is zero, it will be ignored and the IP address will not be returned.

nMaxLength

An integer value that specifies the maximum number of characters which can be copied into the ***lpszAddress*** string buffer. The buffer must be large enough to store the complete address. Because this function can return either an IPv4 or IPv6 address, it is recommended the minimum length for the buffer to be 46 characters. If this parameter is zero, the ***lpszAddress*** parameter will be ignored.

Return Value

If the function succeeds, the host name is valid and the return value will be non-zero. If the function fails, the host name could not be resolved to an IP address and the return value will be zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetValidateHostName** function provides a convenient way to determine if a host name is valid by attempting to resolve the name into an IP address. It is similar to calling the **InetNormalizeHostName** function to obtain the canonical form of the host name, calling **InetGetAddress** to obtain the IP address and then calling **InetFormatAddress** to return the string representation of the host's IP address.

If the Unicode version of this function is used, any non-ASCII characters in the host name will be automatically encoded into a compatible format and then resolved to an IP address. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended you use the Unicode version.

The ***lpszHostName*** parameter can only specify a host name or IP address and cannot be a URL. If you want your application to support providing a URL in addition to a host name, use the **InetGetUrlHostName** function to extract the host name from the URL. You can then provide the host name to this function to obtain its IP address.

If the ***lpszHostName*** parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address. To determine if

the IP address has a corresponding host name, use the **InetGetHostName** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

InetWrite Function

```
INT WINAPI InetWrite(
   SOCKET hSocket,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **InetWrite** function sends the specified number of bytes to the remote host.

Parameters

hSocket

The socket handle.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the remote host.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the application to send the remaining data at some later point. For non-blocking connections, the program must wait for the INET_EVENT_WRITE asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetWriteEx Function

```
INT WINAPI InetWriteEx(
   SOCKET hSocket,
   LPVOID lpvBuffer,
   INT cbBuffer,
   DWORD dwReserved,
   LPINTERNET_ADDRESS lpRemoteAddress,
   UINT nRemotePort
);
```

The **InetWriteEx** function sends the specified number of bytes to the remote host.

Parameters

hSocket

The socket handle.

lpvBuffer

The pointer to the buffer which contains the data that is to be sent to the remote host.

cbBuffer

The number of bytes to send from the specified buffer.

dwReserved

Reserved parameter. This value must always be zero.

lpRemoteAddress

Pointer to an INTERNET_ADDRESS structure that specifies the address of the remote host that is to receive the data being written. For TCP stream sockets, this parameter must always be NULL or specify the same address that was used to establish the connection. For UDP datagram sockets, this may specify any valid IP address.

nRemotePort

The port number of the remote host that is to receive the data being written. For TCP stream sockets, this value must always be zero, or specify the same port number that was used to establish the connection. For UDP datagram sockets, this may specify any valid port number.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the application to send the remaining data at some later point. For non-blocking connections, the program must wait for the INET_EVENT_WRITE asynchronous notification message before it resumes sending data.

This function extends the **InetWrite** function to additional information about the destination IP address and port number for the data being written. For a client TCP connection, the IP address and remote port must be the same values that were used to establish the connection. When writing on a UDP socket, this is the IP address and remote port of the peer that will receive the datagram. This information can be used in conjunction with the **InetReadEx** function to send a datagram back to that host.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetWriteLine Function

```
BOOL WINAPI InetWriteLine(
   SOCKET hSocket,
   LPCTSTR lpszBuffer,
   LPINT lpnLength
);
```

The **InetWriteLine** function sends a line of text to the remote host, terminated by a carriage-return and linefeed.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the remote host. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetWriteLine** function writes a line of text to the remote host and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **InetWrite** function which writes arbitrary bytes of data to the socket, this function is specifically designed to write a single line of text data from a string.

If the ***lpszBuffer*** string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the ***lpnLength*** parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **InetWriteLine**. The function should only be used to send text, never binary data. In particular, the function will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this function will accept a Unicode string, however this function does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

This function will force the thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this function is called with

asynchronous events enabled, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **InetWriteLine** is blocked sending data to the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **InetWrite** and **InetWriteLine** function calls can be safely intermixed.

Unlike the **InetWrite** function, it is possible for data to have been written to the socket if the return value is zero. For example, if a timeout occurs while the function is waiting to send more data to the remote host, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the ***lpnLength*** argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

InetWriteStream Function

```
BOOL WINAPI InetWriteStream(
   SOCKET hSocket,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions
);
```

The **InetWriteStream** function writes data from the stream buffer to the specified socket.

Parameters

hSocket

The socket handle. The socket must reference a stream socket, not a datagram or raw socket. If the socket type is not valid, the function will return an error.

lpvBuffer

Pointer to the buffer that contains or references the data to be written to the socket. The actual argument depends on the value of the ***dwOptions*** parameter which specifies how the data stream will be accessed.

lpdwLength

A pointer to an unsigned integer value which specifies the size of the buffer and contains the number of bytes written when the function returns. This argument should should always point to an initialized value. If the ***lpvBuffer*** argument specifies a memory buffer or global memory handle, then this argument cannot point to an initialized value of zero.

dwOptions

An unsigned integer value which specifies the stream buffer type to be used when writing the data stream to the socket. One of the following stream types may be specified:

Value	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the ***lpvBuffer*** parameter. If the argument specifies a a global memory handle, then the function will write the data referenced by that handle; otherwise, the function will consider the parameter a pointer to a block of memory which contains data to be written. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The ***lpvBuffer*** argument specifies a pointer to a block of memory which contains the data to be written to the socket. If this stream buffer type is used, the ***lpdwLength*** argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HGLOBAL	The ***lpvBuffer*** argument specifies a global memory handle that references the data to be written to the socket. The handle must have been created by a call to the GlobalAlloc or GlobalReAlloc function. If this stream

	buffer type is used, the *lpdwLength* argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HANDLE	The *lpvBuffer* argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read using the ReadFile function with this handle will be written to the socket.
INET_STREAM_SOCKET	The *lpvBuffer* argument specifies a socket handle. The data read from the socket specified by this handle will be written to the socket specified by the *hSocket* parameter. The socket handle passed to this function must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either attach the socket using the InetAttachSocket function or use the INET_STREAM_HANDLE stream buffer type instead.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **InetWriteStream** function enables an application to write an arbitrarily large stream of data from memory or a file to the specified socket. Unlike the **InetWrite** function, which may not write all of the data in a single function call, **InetWriteStream** will only return when all of the data has been written or an error occurs.

This function will force the thread to block until the operation completes. If this function is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, write the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **InetWriteStream** is blocked sending data to the remote host, an error will occur. It is recommended that this function only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for some data to have been written even if the function returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was sent. For example, if a timeout occurs while the function is waiting to write more data, it will return zero; however, some data may have already been written to the socket prior to the error condition.

Because **InetWriteStream** can potentially cause the application to block for long periods of time as the data stream is being written, the function will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **InetRegisterEvent** function, and can obtain information about the current operation by calling the **InetGetStreamInfo** function.

Example

```
HANDLE hFile;
```

```
DWORD dwLength;

hFile = CreateFile(lpszFileName,
                   GENERIC_READ,
                   FILE_SHARE_READ,
                   NULL,
                   OPEN_EXISTING,
                   FILE_FLAG_SEQUENTIAL_SCAN,
                   NULL);

if (hFile == INVALID_HANDLE_VALUE)
    return;

dwLength = GetFileSize(hFile, NULL);

if (dwLength > 0)
{
    BOOL bResult = InetWriteStream(
                     hSocket,
                     hFile,
                     &dwLength,
                     INET_STREAM_HANDLE);
}

CloseHandle(hFile);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

INETSTREAMINFO

The INETSTREAMINFO structure contains information about the data stream being currently read or written.

```
typedef struct _INETSTREAMINFO
{
    DWORD   dwStreamThread;
    DWORD   dwStreamSize;
    DWORD   dwStreamCopied;
    DWORD   dwStreamMode;
    DWORD   dwStreamError;
    DWORD   dwBytesPerSecond;
    DWORD   dwTimeElapsed;
    DWORD   dwTimeEstimated;
} INETSTREAMINFO, *LPINETSTREAMINFO;
```

Members

dwStreamThread

Specifies the numeric ID for the thread that created the socket.

dwStreamSize

The maximum number of bytes that will be read or written. This is the same value as the buffer length specified by the caller, and may be zero which indicates that no maximum size was specified. Note that if this value is zero, the application will be unable to calculate a completion percentage or estimate the amount of time for the operation to complete.

dwStreamCopied

The total number of bytes that have been copied to or from the stream buffer.

dwStreamMode

A numeric value which specifies the stream operation that is current being performed. It may be one of the following values:

Value	Description
INET_STREAM_READ	Data is being read from the socket and stored in the specified stream buffer.
INET_STREAM_WRITE	Data is being written from the specified stream buffer to the socket.

dwStreamError

The last error that occurred when reading or writing the data stream. If no error has occurred, this value will be zero.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the operation is completed. This is based on the average number of bytes transferred per second and requires that a maximum stream buffer size be specified by the caller.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h

INTERNET_ADDRESS

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
    INT    ipFamily;
    BYTE   ipNumber[16];
} INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the ***ipNumber*** array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the ***ipNumber*** array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The INTERNET_ADDRESS structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the ***ipNumber*** array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the ***ipFamily*** member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

SocketWrench Library Error Codes

Value	Constant	Description
0x80042711	ST_ERROR_NOT_HANDLE_OWNER	Handle not owned by the current thread
0x80042712	ST_ERROR_FILE_NOT_FOUND	The specified file or directory does not exist
0x80042713	ST_ERROR_FILE_NOT_CREATED	The specified file could not be created
0x80042714	ST_ERROR_OPERATION_CANCELED	The blocking operation has been canceled
0x80042715	ST_ERROR_INVALID_FILE_TYPE	The specified file is a block or character device, not a regular file
0x80042716	ST_ERROR_INVALID_DEVICE	The specified device or address does not exist
0x80042717	ST_ERROR_TOO_MANY_PARAMETERS	The maximum number of function parameters has been exceeded
0x80042718	ST_ERROR_INVALID_FILE_NAME	The specified file name contains invalid characters or is too long
0x80042719	ST_ERROR_INVALID_FILE_HANDLE	Invalid file handle passed to function
0x8004271A	ST_ERROR_FILE_READ_FAILED	Unable to read data from the specified file
0x8004271B	ST_ERROR_FILE_WRITE_FAILED	Unable to write data to the specified file
0x8004271C	ST_ERROR_OUT_OF_MEMORY	Out of memory
0x8004271D	ST_ERROR_ACCESS_DENIED	Access denied
0x8004271E	ST_ERROR_INVALID_PARAMETER	Invalid argument passed to function
0x8004271F	ST_ERROR_CLIPBOARD_UNAVAILABLE	The system clipboard is currently unavailable
0x80042720	ST_ERROR_CLIPBOARD_EMPTY	The system clipboard is empty or does not contain any text data
0x80042721	ST_ERROR_FILE_EMPTY	The specified file does not contain any data
0x80042722	ST_ERROR_FILE_EXISTS	The specified file already exists
0x80042723	ST_ERROR_END_OF_FILE	End of file
0x80042724	ST_ERROR_DEVICE_NOT_FOUND	The specified device could not be found
0x80042725	ST_ERROR_DIRECTORY_NOT_FOUND	The specified directory could not be found
0x80042726	ST_ERROR_INVALID_BUFFER	Invalid memory address passed to function
0x80042728	ST_ERROR_NO_HANDLES	No more handles available to this process
0x80042733	ST_ERROR_OPERATION_WOULD_BLOCK	The specified operation would block the current thread
0x80042734	ST_ERROR_OPERATION_IN_PROGRESS	A blocking operation is currently in progress
0x80042735	ST_ERROR_ALREADY_IN_PROGRESS	The specified operation is already in progress
0x80042736	ST_ERROR_INVALID_HANDLE	Invalid handle passed to function
0x80042737	ST_ERROR_INVALID_ADDRESS	Invalid network address specified

0x80042738	ST_ERROR_INVALID_SIZE	Datagram is too large to fit in specified buffer
0x80042739	ST_ERROR_INVALID_PROTOCOL	Invalid network protocol specified
0x8004273A	ST_ERROR_PROTOCOL_NOT_AVAILABLE	The specified network protocol is not available
0x8004273B	ST_ERROR_PROTOCOL_NOT_SUPPORTED	The specified protocol is not supported
0x8004273C	ST_ERROR_SOCKET_NOT_SUPPORTED	The specified socket type is not supported
0x8004273D	ST_ERROR_INVALID_OPTION	The specified option is invalid
0x8004273E	ST_ERROR_PROTOCOL_FAMILY	Specified protocol family is not supported
0x8004273F	ST_ERROR_PROTOCOL_ADDRESS	The specified address is invalid for this protocol family
0x80042740	ST_ERROR_ADDRESS_IN_USE	The specified address is in use by another process
0x80042741	ST_ERROR_ADDRESS_UNAVAILABLE	The specified address cannot be assigned
0x80042742	ST_ERROR_NETWORK_UNAVAILABLE	The networking subsystem is unavailable
0x80042743	ST_ERROR_NETWORK_UNREACHABLE	The specified network is unreachable
0x80042744	ST_ERROR_NETWORK_RESET	Network dropped connection on remote reset
0x80042745	ST_ERROR_CONNECTION_ABORTED	Connection was aborted due to timeout or other failure
0x80042746	ST_ERROR_CONNECTION_RESET	Connection was reset by remote network
0x80042747	ST_ERROR_OUT_OF_BUFFERS	No buffer space is available
0x80042748	ST_ERROR_ALREADY_CONNECTED	Connection already established with remote host
0x80042749	ST_ERROR_NOT_CONNECTED	No connection established with remote host
0x8004274A	ST_ERROR_CONNECTION_SHUTDOWN	Unable to send or receive data after connection shutdown
0x8004274C	ST_ERROR_OPERATION_TIMEOUT	The specified operation has timed out
0x8004274D	ST_ERROR_CONNECTION_REFUSED	The connection has been refused by the remote host
0x80042750	ST_ERROR_HOST_UNAVAILABLE	The specified host is unavailable
0x80042751	ST_ERROR_HOST_UNREACHABLE	Remote host is unreachable
0x80042753	ST_ERROR_TOO_MANY_PROCESSES	Too many processes are using the networking subsystem
0x8004276B	ST_ERROR_NETWORK_NOT_READY	Network subsystem is not ready for communication
0x8004276C	ST_ERROR_INVALID_VERSION	This version of the operating system is not supported
0x8004276D	ST_ERROR_NETWORK_NOT_INITIALIZED	The networking subsystem has not been initialized
0x80042775	ST_ERROR_REMOTE_SHUTDOWN	The remote host has initiated a graceful shutdown sequence

0x80042AF9	ST_ERROR_INVALID_HOSTNAME	The specified hostname is invalid or could not be resolved
0x80042AFA	ST_ERROR_HOSTNAME_NOT_FOUND	The specified hostname could not be found
0x80042AFB	ST_ERROR_HOSTNAME_REFUSED	Unable to resolve hostname, request refused
0x80042AFC	ST_ERROR_HOSTNAME_NOT_RESOLVED	Unable to resolve hostname, no address for specified host
0x80042EE1	ST_ERROR_INVALID_LICENSE	The license for this product is invalid
0x80042EE2	ST_ERROR_PRODUCT_NOT_LICENSED	This product is not licensed to perform this operation
0x80042EE3	ST_ERROR_NOT_IMPLEMENTED	This function has not been implemented on this platform
0x80042EE4	ST_ERROR_UNKNOWN_LOCALHOST	Unable to determine local host name
0x80042EE5	ST_ERROR_INVALID_HOSTADDRESS	Invalid host address specified
0x80042EE6	ST_ERROR_INVALID_SERVICE_PORT	Invalid service port number specified
0x80042EE7	ST_ERROR_INVALID_SERVICE_NAME	Invalid or unknown service name specified
0x80042EE8	ST_ERROR_INVALID_EVENTID	Invalid event identifier specified
0x80042EE9	ST_ERROR_OPERATION_NOT_BLOCKING	No blocking operation in progress on this socket
0x80042F45	ST_ERROR_SECURITY_NOT_INITIALIZED	Unable to initialize security interface for this process
0x80042F46	ST_ERROR_SECURITY_CONTEXT	Unable to establish security context for this session
0x80042F47	ST_ERROR_SECURITY_CREDENTIALS	Unable to open client certificate store or establish client credentials
0x80042F48	ST_ERROR_SECURITY_CERTIFICATE	Unable to validate the certificate chain for this session
0x80042F49	ST_ERROR_SECURITY_DECRYPTION	Unable to decrypt data stream
0x80042F4A	ST_ERROR_SECURITY_ENCRYPTION	Unable to encrypt data stream
0x80043031	ST_ERROR_MAXIMUM_CONNECTIONS	The maximum number of client connections exceeded
0x80043032	ST_ERROR_THREAD_CREATION_FAILED	Unable to create a new thread for the current process
0x80043033	ST_ERROR_INVALID_THREAD_HANDLE	The specified thread handle is no longer valid
0x80043034	ST_ERROR_THREAD_TERMINATED	The specified thread has been terminated
0x80043035	ST_ERROR_THREAD_DEADLOCK	The operation would result in the current thread becoming deadlocked
0x80043036	ST_ERROR_INVALID_CLIENT_MONIKER	The specified moniker is not associated with any client session
0x80043037	ST_ERROR_CLIENT_MONIKER_EXISTS	The specified moniker has been assigned to another client session

0x80043038	ST_ERROR_SERVER_INACTIVE	The specified server is not listening for client connections
0x80043039	ST_ERROR_SERVER_SUSPENDED	The specified server is suspended and not accepting client connections
