Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **FtpDeleteServerCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **FtpServerStart** function.

Remarks

The structure that is created by this function may be used as server credentials when accepting a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **FtpServerStart** function.

An application only needs to call this function to support secure connections using TLS. When a certificate is specified, it must have a private key associated with it. Attempting to use a certificate

which does not have a private key will result in an error during the startup process indicating that the server credentials are invalid.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Example

```
// Create the server credentials that identifies the certificate
// that will be used for secure connections
LPSECURITYCREDENTIALS lpSecCred = NULL;

FtpCreateServerCredentials(SECURITY_PROTOCOL_DEFAULT,
                           0,
                           NULL,
                           NULL,
                           lpszCertStore,
                           lpszCertName,
                           NULL,
                           &lpSecCred);

// Start the server
hServer = FtpServerStart(lpszLocalHost,
                         FTP_PORT_DEFAULT,
                         FTP_SERVER_LOCALUSER | FTP_SERVER_UNIXMODE |
FTP_SERVER_SECURE,
                         &ftpConfig,
                         lpEventHandler,
                         0,
                         lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpDeleteServerCredentials Function

```
VOID WINAPI FtpDeleteServerCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **FtpDeleteServerCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer value will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)
    FtpDeleteServerCredentials(&lpSecCred);
```

Remarks

This function can be used to release the memory allocated for the credentials after the server has been started.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpDeleteVirtualUser Function

```
BOOL WINAPI FtpDeleteVirtualUser(
   HSERVER hServer,
   UINT nHostId,
   LPCTSTR lpszUserName
);
```

Remove a virtual user from the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host. This parameter is reserved for future use and must always have a value of zero.

lpszUserName

A null-terminated string which specifies the user that will be removed. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

This function removes a virtual user that was created by a previous call to the **FtpAddVirtualUser** function. This function will not match partial usernames and wildcard characters cannot be used to delete multiple users. Usernames are not case sensitive. You cannot use this function to delete the "anonymous" user.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpDisconnectClient Function

```
BOOL WINAPI FtpDisconnectClient(
    HSERVER hServer,
    UINT nClientId
);
```

Close the control connection for the specified client and release the resources allocated for the session

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpDisconnectClient** function will close the control channel, disconnecting the client from the server and terminating the client session thread. Resources that we allocated for the client, such as memory and open handles, will be released back to the operating system. If the client was in the process of transferring a file, the transfer will be aborted. This performs the same operation as if the client sent the QUIT command to the server.

This function sends an internal control message that notifies the server that this session should be terminated. When the session thread is signaled that it should terminate, it will abort any active file transfers and begin to release the resources allocated for that session. To ensure that the client session terminates gracefully, there may be a brief period of time where the session thread is still active after this function has returned.

After this function returns, the application should never use the same client ID with another function. Client IDs are unique to the session over the lifetime of the server, and are not reused.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpEnableClientAccess Function

```
BOOL WINAPI FtpEnableClientAccess(
    HSERVER hServer,
    UINT nClientId,
    DWORD dwUserAccess,
    BOOL bEnable
);
```

Enable or disable access rights for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies an access right to enable or disable. For a list of user access rights that can be granted to the client, see User Access Constants.

bEnable

An integer value which specifies if permission should be granted or revoked for the specified access right. If this value is non-zero, permission is granted to the client to perform the action specified by the *dwUserAccess* parameter. If this value is zero, that permission is revoked.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **FtpEnableClientAccess** function is used to enable or disable access to specific functionality by the client. The function can only change a single access right and cannot be used to enable or disable multiple access rights in a single function call. To change multiple user access rights for the client, use the **FtpSetClientAccess** function.

This function cannot be used to change the access rights for a restricted or anonymous user. Those rights are granted when the client session is authenticated and will persist until the client disconnects from the server. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpEnableCommand Function

```
BOOL WINAPI FtpEnableCommand(
   HSERVER hServer,
   LPCTSTR lpszCommand,
   BOOL bEnable
);
```

Enable or disable a specific server command

Parameters

hServer

The server handle.

lpszCommand

A null-terminated string that specifies the name of the command to be enabled or disabled. The command name is not case-sensitive, but the value must otherwise match the exact name. Partial matches are not recognized by this function. This parameter cannot be NULL.

bEnable

An integer value which specifies if the command should be enabled or disabled. If the value is non-zero, the command is enabled. If the value is zero, the command will be disabled.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the command is not recognized, the function will return zero. If the function fails, the **FtpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **FtpEnableCommand** function is used to enable or disable access to a specific command on the server. When a command is disabled, it will also disable any corresponding feature related to that command. For example, if the MDTM command is disabled and a client issues the FEAT command to request a list of supported features, the command will no longer be listed. This function is typically used to enable or disable certain commands for compatibility with older client software. The **FtpIsCommandEnabled** function can be used to determine if a command is enabled or not.

The command name provided to this function must match the commands defined in RFC 959 or related protocol standards. It is important to distinguish between commands recognized by an FTP server and the commands that client programs may use. For example, the standard Windows FTP command line program provides commands such as GET and PUT to download and upload files. However, those are not the actual commands sent to a server. Instead, the corresponding server commands issued by a client application would bet RETR (retrieve) and STOR (store). Refer to File Transfer Protocol Commands for a complete list of server commands.

Some commands cannot be disabled because they are required to perform essential server functions. For example, the USER and PASS commands are required to perform client authentication and therefore cannot be disabled. If you attempt to disable a required command, this function will return zero and the last error code will be set to ST_ERROR_COMMAND_REQUIRED. Because this function affects all clients connected to the server, it should not be used to limit access to certain commands for specific clients. Instead, either assign the client the appropriate permissions using the **FtpAuthenticateClient** function, or use an event handler to filter the commands.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpEnumServerClients Function

```
INT WINAPI FtpEnumServerClients(
    HSERVER hServer,
    DWORD dwReserved
    UINT *lpClients,
    INT nMaxClients
);
```

Return a list of active client sessions established with the specified server.

Parameters

hServer

Handle to the server socket.

dwReserved

An unsigned integer value that is reserved for future use. This parameter should always be zero.

lpClients

Pointer to an array of unsigned integers which will contain client IDs that uniquely identifies each client when the function returns. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client IDs to be returned in the ***lpClients*** array. If the ***lpClients*** parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetServerError**.

Remarks

If the ***nMaxClients*** parameter is less than the number of active client connections, the function will fail and the last error code will be set to the error ST_ERROR_BUFFER_TOO_SMALL. To dynamically determine the number of active connections, call the function with the ***lpClients*** parameter with a value of NULL, and the ***nMaxClients*** parameter with a value of zero.

Example

```
INT nClients = FtpEnumServerClients(hServer, 0, NULL, 0);

if (nClients > 0)
{
    UINT *lpClients = NULL;

    // Allocate memory for an array of client IDs
    lpClients = (UINT *)LocalAlloc(LPTR, nClients * sizeof(UINT));

    if (lpClients == NULL)
    {
        // Virtual memory has been exhausted
        return;
    }
```

```
    nClients = FtpEnumServerClients(hServer, 0, lpClients, nClients);

    if (nClients == FTP_ERROR)
    {
        // Unable to obtain list of connected clients
        return;
    }

    for (INT nIndex = 0; nIndex < nClients; nIndex++)
    {
        TCHAR szUserName[FTP_MAXUSERNAME];

        if (FtpGetClientUserName(hServer, lpClients[nIndex], szUserName,
FTP_MAXUSERNAME))
        {
            // Perform some action with the client user name
        }
    }

    // Free the memory allocated for the client IDs
    LocalFree((HLOCAL)lpClients);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpGetActiveClient Function

```
UINT WINAPI FtpGetActiveClient(
    HSERVER hServer
);
```

Return the client ID for the active client session associated with the current thread.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the unique ID associated with the client session for the current thread. If the server handle is invalid or there is no client session active on the current thread, the return value is zero.

Remarks

The **FtpGetActiveClient** function is used to obtain the client ID associated with the current thread. This means this function will only return a client ID if it is called within an event handler or a function called by an event handler. If this function is called by a function that is not executing within the context of an event handler it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpGetClientAccess Function

```
BOOL WINAPI FtpGetClientAccess(
   HSERVER hServer,
   UINT nClientId,
   LPDWORD lpdwUserAccess
);
```

Return the access rights that have been granted to the client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwUserAccess

A pointer to an unsigned integer which specifies one or more access rights for the client session. For a list of user access rights that can be granted to the client, see User Access Constants. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **FtpGetClientAccess** function is used to obtain all of the access rights that are currently granted to an authenticated client session. The **FtpEnableClientAccess** function can be used to enable or disable specific permissions, and the **FtpSetClientAccess** function can change multiple access rights at once.

Example

```
DWORD dwUserAccess = 0;

// Check if the client is a restricted user

if (FtpGetClientAccess(hServer, nClientId, &dwUserAccess))
{
    if (dwUserAccess & FTP_ACCESS_RESTRICTED)
    {
        _tprintf(_T("Client %u authenticated as a restricted user\n"), nClientId);
        return;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpGetClientAddress Function

```
INT WINAPI FtpGetClientAddress(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

Return the IP address of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszAddress

A null-terminated string buffer that will contain the client IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetClientCredentials Function

```
BOOL WINAPI FtpGetClientCredentials(
   HSERVER hServer,
   UINT nClientId,
   LPFTPCLIENTCREDENTIALS lpCredentials
);
```

Return the user credentials for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpCredentials

A pointer to an **FTPCLIENTCREDENTIALS** structure that will contain information about the user when the function returns. This parameter cannot be NULL.

Return Value

If the user credentials for the client session are available, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has not requested authentication, this function will return zero.

Remarks

The **FtpGetClientCredentials** function is used to obtain the username and password that was provided by the client when it requested authentication. Typically this function is used in an event handler to validate the credentials provided by the client. If the credentials are considered valid, the event handler would then call the **FtpAuthenticateClient** function to specify that the session has been authenticated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpAuthenticateClient, FTPCLIENTCREDENTIALS

FtpGetClientDirectory Function

```
INT WINAPI FtpGetClientDirectory(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszDirectory,
   INT nMaxLength
);
```

Returns the current working directory for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A null-terminated string buffer that will contain the current working directory for the specified client session, terminated with a null character. This buffer should be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be larger than zero or the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

This function returns the full path to the current working directory for the specified client session. For example, if the server root directory is C:\ProgramData\MyServer and the current working directory for the client is /Research/Documents, this function will return C:\ProgramData\MyServer\Research\Documents as the current working directory for the client session.

It is important to note that the current working directory for client sessions is virtual, and does not reflect the current working directory for the server process. To change the current working directory for a client, use the **FtpChangeClientDirectory** function.

This function should only be used with client sessions that have been authenticated. Unauthenticated clients are not assigned a current working directory and this function will return zero, with the last error code set to ST_ERROR_AUTHENTICATION_REQUIRED.

To convert a full path to the virtual path for a specific client session, use the **FtpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetClientFileType Function

```
BOOL WINAPI FtpGetClientFileType(
    HSERVER hServer,
    UINT nClientId,
    UINT *lpnFileType
);
```

Return the current file type used for transfers by the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpnFileType

A pointer to an unsigned integer value that will contain the current file type used by the client for data transfers. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetClientFileType** function will return the current file type that has been specified by the client sending the TYPE command to the server. The file type determines if there is any conversion performed on the data that is being exchanged between the client and server. The following file types are supported:

Value	Description
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those clients which use a different end-of-line character sequence, the text file has been converted to the local format which uses the carriage return (CR) and linefeed (LF) characters.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type has been performed on the file. This is the default file type for most data files and executable programs. If the client specified this file type when appending to a text file, the file will contain the end-of-line sequences used by its native operating system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpSetClientFileType

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetClientHomeDirectory Function

```
INT WINAPI FtpGetClientHomeDirectory(
    HSERVER hServer,
    UINT nClientId,
    LPTSTR lpszDirectory,
    INT nMaxLength
);
```

Returns the home directory for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A null-terminated string buffer that will contain the home directory for the specified client session, terminated with a null character. This buffer should be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be larger than zero or the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

This function returns the full path to the home working directory assigned to the specified client session. This will be the same path to the home directory specified when the **FtpAuthenticateClient** function was used to authenticate the client session. If a home directory was not explicitly assigned when the client was authenticated, then this function returns the default home directory that was created for the client, or the server root directory if the FTP_SERVER_MULTIUSER option was not specified when the server was started.

This function should only be used with client sessions that have been authenticated. Unauthenticated clients are not assigned a home directory and this function will return zero, with the last error code set to ST_ERROR_AUTHENTICATION_REQUIRED.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetClientIdentity Function

```
INT WINAPI FtpGetClientIdentity(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszIdentity,
   INT nMaxLength
);
```

Return the identity of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszIdentity

A null-terminated string buffer that will contain the identity of the client when the function returns, terminated with a null character. This parameter cannot be NULL. It is recommended that this buffer be at least 32 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero. If the client did not identify itself, this function will return zero.

Remarks

The **FtpGetClientIdentity** function returns the string that the client used to identify itself to the server. The client may use either the CLNT or CSID command to identify itself. Although the CLNT command is considered to be deprecated, it is supported for backwards compatibility with older clients. The identity string does not have any standard format and is used for informational purposes only and does not affect the operation of the server in any way. Not all clients identify themselves, in which case this function will return zero and the ***lpszIdentity*** string buffer will be set to an empty string.

If the client does identify itself, it typically uses the name of the client application that was used to establish the connection. The application may choose to assign an identity to a client session for its own internal purposes using the **FtpSetClientIdentity** function, regardless of whether the client identifies itself.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetClientIdleTime Function

```
UINT WINAPI FtpGetClientIdleTime(
    HSERVER hServer,
    UINT nClientId,
    UINT *lpnElapsed
);
```

Return the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpnElapsed

A pointer to an unsigned integer value that will contain the number of seconds the client session has been idle. This parameter may be NULL if this information is not required.

Return Value

If the function succeeds, the return value is client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetClientIdleTime** function will return the number of seconds that the client may remain idle before being automatically disconnected by the server. The idle time of a client session is based on the last time a command was issued to the server or when a file data transfer completed. The server will never disconnect a client that is in the process of uploading or downloading a file, regardless of the idle timeout period.

The default idle timeout period for a client is 900 seconds (15 minutes), however the server can be configured to use a different value and individual clients can request the timeout period be changed by sending the IDLE command to the server. For a client to be able to change its own timeout period, it must be granted the FTP_ACCESS_IDLE permission. The minimum timeout period for a client is 60 seconds, the maximum is 7200 seconds (2 hours). An application can change the timeout period for a specific client session using the **FtpSetClientIdleTime** function.

It is important to note that the idle timeout period only affects authenticated clients. Unauthenticated clients use a different internal timer that limits the amount of time they can remain connected to the server before successfully authenticating with a valid username and password. By default, the authentication timeout period is 60 seconds and is set when the server is started; it cannot be changed for an individual client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpGetClientLocalPath Function

```
INT WINAPI FtpGetClientLocalPath(
   HSERVER hServer,
   UINT nClientId,
   LPCTSTR lpszVirtualPath,
   LPTSTR lpszLocalPath,
   INT nMaxLength,
);
```

Return the full local path for a virtual filename or directory on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszVirtualPath

A null-terminated string that specifies an virtual path on the server. This parameter cannot be NULL.

lpszLocalPath

A null-terminated string buffer that will contain the full local path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

The **FtpGetClientLocalPath** function takes a virtual path and returns the full path to the specified file or directory on the local system. The virtual path may be absolute or relative to the current working directory for the client session. This function will recognize a tilde at the beginning of the path to specify the client home directory.

To obtain the virtual path for a local file or directory, use the **FtpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetClientVirtualPath

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetClientServer Function

```
HSERVER WINAPI FtpGetClientServer(
    UINT nClientId
);
```

The **FtpGetClientServer** function returns a handle to the server that created the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session. If the function fails, the return value is INVALID_SERVER. To get extended error information, call the **FtpGetServerError** function.

Remarks

The **FtpGetClientServer** function returns the handle to the server that created the client session and is typically used within a notification message handler. If the server is in the process of shutting down, or the client session thread is terminating, this function will fail and return INVALID_SERVER indicating that the session ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h.
Import Library: csftsv12.lib

FtpGetClientThreadId Function

```
DWORD WINAPI FtpGetClientThreadId(
    HSERVER hServer,
    UINT nClientId
);
```

Returns the thread ID associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is a thread ID. If the function fails, the return value is zero. To get extended error information, call the **FtpGetServerError** function.

Remarks

The **FtpGetClientThreadId** function returns a thread ID that can be used to identify the thread that is managing the client session. The thread ID can be used with other Windows API functions such as **OpenThread**. Exercise caution when using thread-related functions, interfering with the normal operation of the thread can have unexpected results. You should never use this function to obtain a thread handle and then call the **TerminateThread** function to terminate a client session. This will prevent the thread from releasing the resources that were allocated for the session and can leave the server in an unstable state. To terminate a client session, use the **FtpDisconnectClient** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpGetClientUserName Function

```
INT WINAPI FtpGetClientUserName(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszUserName,
   INT nMaxLength
);
```

Return the user name associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszUserName

A null-terminated string buffer that will contain the user name associated with the client session. This buffer must be large enough to store the complete user name, including the terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value larger than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetClientUserName** function returns the user name associated with an authenticated client session. If the client has not authenticated itself by sending the USER and PASS commands, this function will return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpAuthenticateClient, FtpGetClientAccess, FtpGetClientHomeDirectory

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetClientVirtualPath Function

```
INT WINAPI FtpGetClientVirtualPath(
   HSERVER hServer,
   UINT nClientId,
   LPCTSTR lpszLocalPath,
   LPTSTR lpszVirtualPath,
   INT nMaxLength,
);
```

Return the virtual path for a local file on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszLocalPath

A null-terminated string that specifies an absolute path on the local system. This parameter cannot be NULL.

lpszVirtualPath

A null-terminated string buffer that will contain the virtual path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

A virtual path for the client is either relative to the server root directory, or the client home directory if the client was authenticated as a restricted user. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the ***lpszLocalPath*** parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this function would return the virtual path to that directory as "/Documents/Research".

If the client session was authenticated as a restricted user, then the virtual path is always relative to the client home directory instead of the server root directory. This is because restricted users are isolated to their own home directory and any subdirectories. For example, if restricted user "John" has a home directory of "C:\ProgramData\MyServer\Users\John" and the ***lpszLocalPath*** parameter was specified as "C:\ProgramData\MyServer\Users\John\Accounting\Projections.pdf" this function would return the virtual path as "/Accounting/Projections.pdf".

If the *lpszLocalPath* parameter specifies a file or directory outside of the server root directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_FILE_NAME. This function can only be used with authenticated clients. If the *nClientId* parameter specifies a client session that has not been authenticated, this function will return zero and the last error code will be ST_ERROR_AUTHENTICATION_REQUIRED.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetCommandFile Function

```
INT WINAPI FtpGetCommandFile(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszFileName,
   INT nMaxLength
);
```

Get the full path to the local file name or directory specified by the client

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A null-terminated string buffer that will contain the full path to a file name or directory specified by the client when it issued a command. The string buffer will be null-terminated and must be large enough to store the complete file path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. It is recommended that the buffer be at least MAX_PATH characters in size. If the maximum length specified is smaller than the actual length of the full path, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **FtpGetServerError** function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that the command issued by the client accepts a file name as an argument, but the client did not specify one.

Remarks

The **FtpGetCommandFile** function is used to obtain the full path to a local file name or directory specified by the client as an argument to a standard FTP command. For example, if the client sends the RETR command to the server, this function will return the complete path to the local file that the client wants to download. This function will only work with those standard commands that perform some action on a file or directory.

This function should always be used to obtain the file name for a command that performs a file or directory operation. The **FtpGetCommandParam** function will return the actual command parameter, but the file name will typically be relative to the user home directory or server root directory, and cannot be passed directly to a Windows API function. The **FtpGetCommandFile** function normalizes the path provided by the client and ensures that it specifies a file or directory name in the correct location.

To change the file or directory name that is the target of the current command, use the **FtpSetCommandFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetClientDirectory, FtpGetClientHomeDirectory, FtpGetCommandLine, FtpGetCommandParam, FtpSetCommandFile

FtpGetCommandLine Function

```
INT WINAPI FtpGetCommandLine(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszCmdLine,
   INT nMaxLength
);
```

Return the complete command line issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCmdLine

A null-terminated string buffer that will contain the command, including all arguments. The string buffer will be null-terminated and must be large enough to store the complete command line. If this parameter is NULL, the function will return the length of the command line.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. The internal limit on the maximum length of a command is 1024 characters. If the maximum length specified is smaller than the actual length of the complete command, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **FtpGetServerError** function can be used to retrieve the last error code. If the last error code has a value of zero then no command has been issued by the client.

Remarks

The **FtpGetCommandLine** function is used to obtain the command that was issued by the client, and is commonly used inside FTP_CLIENT_COMMAND and FTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively. When the function returns, the string buffer provided by the caller will contain the complete command, including all command parameters. Any extraneous whitespace will be removed, however quoted parameters will be retained as-is.

To obtain a specific parameter to a command, use the **FtpGetCommandParam** function. The **FtpGetCommandParamCount** function will return the number of command parameters that were provided by the client. If the command sent by the client is used to perform an action on a file or directory, the **FtpGetCommandFile** function should be called to obtain the full path to the specified file rather than using the value of the command parameter.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetCommandName Function

```
INT WINAPI FtpGetCommandName
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszCommand,
   INT nMaxLength
);
```

Return the name of the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCommand

A null-terminated string buffer that will contain the command name. The string buffer will be null-terminated and must be large enough to store the complete command name. If this parameter is NULL, the function will only return the length of the current command in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the ***lpszCommand*** parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **FtpGetServerError** function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that no command has been issued by the client.

Remarks

The **FtpGetCommandName** function is used to obtain the name of the last command that was issued by the client. The command name returned by this function will always be capitalized, regardless of how it was sent by the client. This function is typically used inside FTP_CLIENT_COMMAND and FTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively.

The **FtpGetCommandParam** function can be used to return the value of individual command parameters specified by the client. The **FtpGetComandLine** function can be used to obtain the complete command line issued by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetCommandParam Function

```
INT WINAPI FtpGetCommandParam
   HSERVER hServer,
   UINT nClientId,
   INT nParam,
   LPTSTR lpszParam,
   INT nMaxLength
);
```

Return the value of the specified command parameter from the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nParam

An integer value which specifies the command parameter. A value of zero specifies the command itself, while values greater than zero specify a particular parameter. This function will fail if this value is less than zero or greater than the number of parameters available.

lpszParam

A null-terminated string buffer that will contain the command parameter. The string buffer will be null-terminated and must be large enough to store the complete parameter value. If this parameter is NULL, the function will only return the length of the specified parameter in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. The internal limit on the maximum length of a command is 1024 characters. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the ***lpszParam*** parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **FtpGetServerError** function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that no command has been issued by the client.

Remarks

The **FtpGetCommandParam** function is used to obtain a specific parameter for the last command that was issued by the client. If the parameter was surrounded in quotes, those quotes will be included in the value returned by this function. This function is typically used inside FTP_CLIENT_COMMAND and FTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively.

The **FtpGetCommandParamCount** function will return the number of command parameters that were provided by the client. If the command sent by the client is used to perform an action on a file or directory, the **FtpGetCommandFile** function should be called to obtain the full path to the specified file rather than using the value of the command parameter. To obtain the complete command line,

use the **FtpGetCommandLine** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetCommandParamCount Function

```
INT WINAPI FtpGetCommandParamCount
    HSERVER hServer,
    UINT nClientId
);
```

Return the number of command parameters for the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

An integer value which specifies the number of parameters that were specified in the last command issued by the client. If the command did not include any parameters, this function will return zero. If the client has not issued a command, or the client session ID is invalid, this function will return -1.

Remarks

The **FtpGetCommandParamCount** function is used to determine the number of parameters specified in the last client command, and the maximum value that may be passed as the parameter index to the **FtpGetCommandParam** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpGetCommandResult Function

```
INT WINAPI FtpGetCommandResult(
    HSERVER hServer,
    UINT nClientId,
    LPTSTR lpszResult,
    INT nMaxLength
);
```

Return the result code and description for the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszResult

A null-terminated string buffer that will contain the description of the result code. The string buffer will be null-terminated up to the maximum number of characters specified by the caller. This parameter can be NULL if this information is not required.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. If the ***lpszResult*** parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the result code for the last command issued by the client. A return value of zero indicates that the command has not completed and there is no result code available.

Remarks

The **FtpGetCommandResult** function is used to determine the result of the last command that was issued by the client and is typically called in the FTP_CLIENT_RESULT event handler. This function should only be called after a command has been processed or the **FtpSendResponse** function has been called.

The result code is a three-digit integer value that indicates the success or failure of a command. Whenever a client sends a command to the server, the server must respond with this numeric code, and optionally a text message that further describes the result. The text message may be a single line, or it may span multiple lines, with each line of text terminated by a carriage return and linefeed. Result codes are generally broken down into the following categories:

Result Code	Description
100-199	Result codes in this range indicate that the requested action is being initiated, and the client should expect another reply from the server before proceeding. This is normally used with file transfers, indicating to the client that the data transfer has started.
200-299	Result codes in this range indicate that the server has successfully completed the requested action. One exception is the 202 result code which indicates that the command is not implemented, but the client should not consider this to be an error condition.

300-399	Result codes in this range indicate that the requested action cannot complete until additional information is provided to the server. This is normally used with commands that require a specific sequence to complete. For example, the server will send the 331 result code in response to the USER command, which tells the client that it must send the PASS command to complete the authentication process.
400-499	Result codes in this range indicate that the requested action did not take place, but the error condition is temporary and may be attempted again. This error response is usually the result of a failed authentication attempt or a file transfer that could not complete.
500-599	Result codes in this range indicate that the requested action did not take place and the failure is permanent. The client should not attempt to send the command again. This error response is usually the result of an invalid command name, a syntax error or the client not having the appropriate access rights to a resource.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetCommandUsage Function

```
UINT WINAPI FtpGetCommandUsage(
   HSERVER hServer,
   LPCTSTR lpszCommand
);
```

Return the number of times a specific command has been issued by all clients.

Parameters

hServer

The server handle.

lpszCommand

A null-terminated string that specifies a command name. The name is not case-sensitive, but must match a valid server command exactly. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is the number of times the command has been issued by all clients since the server was started. If the server handle or command name is invalid, or the command has never been issued, the return value will be zero.

Remarks

The command name provided to this function must match the commands defined in RFC 959 or related protocol standards. It is important to distinguish between commands recognized by an FTP server and the commands that client programs may use. For example, the standard Windows FTP command line program provides commands such as GET and PUT to download and upload files. However, those are not the actual commands sent to a server. Instead, the corresponding server commands issued by a client application would bet RETR (retrieve) and STOR (store). Refer to File Transfer Protocol Commands for a complete list of server commands.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetProgramExitCode Function

```
BOOL WINAPI FtpGetProgramExitCode(
    HSERVER hServer,
    UINT nClientId,
    LPDWORD lpdwExitCode
);
```

Return the exit code of the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwExitCode

A pointer to an unsigned integer that will contain the program exit code when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpGetProgramExitCode** function returns the exit code of a registered program that was executed by the client using the SITE EXEC command. By convention, most programs return an exit code in the range of 0-255, with an exit code of zero indicating success. The exit code is commonly used by custom programs to communicate status information back to the server application.

Permission to use the SITE EXEC is not granted to authenticated users by default, and is limited to only those programs which are explicitly registered with the server. Exercise caution when allowing a client to execute a program on the server because this can expose the server to significant security risks. The programs that are registered for use with the SITE EXEC command should be thoroughly tested before being deployed on the server and should only be console programs that write to standard output.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpGetProgramName, FtpGetProgramOutput, FtpRegisterProgram

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetProgramName Function

```
INT WINAPI FtpGetProgramName(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszProgramName,
   INT nMaxLength
);
```

Return the name of the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszProgramName

A null-terminated string buffer that will contain the name of the last program executed by the client. This parameter cannot be NULL and should be at least 32 characters in size.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value greater than zero.

Return Value

If the function succeeds, the return value is the length of the command name. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, this function will return zero.

Remarks

The **FtpGetProgramName** function returns the name of the last program that was executed by the client using the SITE EXEC command. The name that is returned is the alias assigned to the program, not the full path to the executable file. The server application would typically use this function in an event handler when processing the FTP_CLIENT_EXECUTE event to determine which program has been executed on behalf of the client. The **FtpGetProgramExitCode** function will return the program's exit code and the **FtpGetProgramOutput** function can be used to obtain a copy of the output generated by the program.

Permission to use the SITE EXEC is not granted to authenticated users by default, and is limited to only those programs which are explicitly registered with the server. Exercise caution when allowing a client to execute a program on the server because this can expose the server to significant security risks. The programs that are registered for use with the SITE EXEC command should be thoroughly tested before being deployed on the server and should only be console programs that write to standard output.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetProgramOutput Function

```
DWORD WINAPI FtpGetProgramOutput(
    HSERVER hServer,
    UINT nClientId,
    LPBYTE lpBuffer,
    DWORD dwBufferSize
);
```

Return a copy of the standard output from the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A buffer that will contain the output from the last program executed by the client. If this parameter is NULL, the function will return the number of bytes of data that was output by the program. Note that this output is not null-terminated.

dwBufferSize

The maximum number of bytes that can be copied into the buffer. If the ***lpBuffer*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of bytes copied into the specified buffer. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **FtpGetProgramOutput** function is used to obtain a copy of the output generated by the program executed using the SITE EXEC command. To determine the number of bytes of output available to read, call this function with the ***lpBuffer*** parameter as NULL and the ***dwBufferSize*** parameter with a value of zero. The return value will be the number of bytes of data that was output by the program. It should be noted that for Unicode builds, the buffer is a byte array, not an array of characters, and will not be null-terminated.

This function returns the raw output from the command which may contain escape sequences, control characters and embedded nulls. When the application processes the output returned by this function, it should never coerce the buffer pointer to an LPTSTR value because there is no guarantee that the data will be null-terminated. To obtain the output from the command as a string, use the **FtpGetProgramText** function.

Example

```
LPBYTE lpBuffer = NULL;  // The output buffer
DWORD cbBuffer = 0;      // Number of bytes in the output buffer

// Determine the number of bytes in the output buffer
cbBuffer = FtpGetProgramOutput(hServer, nClientId, NULL, 0);
```

```
if (cbBuffer > 0)
{
    // Allocate memory for the buffer
    lpBuffer = (LPBYTE)LocalAlloc(LPTR, cbBuffer + 1);

    // Copy the program output to the buffer
    if (lpBuffer != NULL)
        cbBuffer = FtpGetProgramOutput(hServer, nClientId, lpBuffer, cbBuffer + 1);
}

// Free the memory allocated for the buffer when finished
if (lpBuffer != NULL)
{
    LocalFree((HLOCAL)lpBuffer);
    lpBuffer = NULL;
    cbBuffer = 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpGetProgramExitCode, FtpGetProgramName, FtpGetProgramText, FtpRegisterProgram

FtpGetProgramText Function

```
INT WINAPI FtpGetProgramText(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

Return a copy of the standard output from the last program in a string buffer.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszBuffer

A buffer that will contain the output from the last program executed by the client as a string. If this parameter is NULL, the function will return the number of bytes of characters that was output by the program, not including a terminating null character.

nMaxLength

The maximum number of bytes that can be copied into the buffer. If the ***lpszBuffer*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the specified string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **FtpGetProgramText** function is used to obtain a copy of the output generated by the program executed using the SITE EXEC command. To determine the number of characters of output available to read, call this function with the ***lpszBuffer*** parameter as NULL and the ***nMaxLength*** parameter with a value of zero. The return value will be the number of characters that were output by the program. If the application dynamically allocates the string buffer, make sure that it allocates an extra character for the terminating null character.

This function will only return textual output from the command and any non-printable control characters and the escape character will be replaced with a space. To obtain the unfiltered output from the last command that was executed, use the **FtpGetProgramOutput** function.

Example

```
LPTSTR lpszBuffer = NULL;  // The output buffer
INT cchBuffer = 0;         // Number of bytes in the output buffer

// Determine the number of bytes in the output buffer
cchBuffer = FtpGetProgramText(hServer, nClientId, NULL, 0);

if (cchBuffer > 0)
```

```
{
    // Allocate memory for the string buffer
    lpszBuffer = (LPTSTR)LocalAlloc(LPTR, (cchBuffer + 1) * sizeof(TCHAR));

    // Copy the program output to the buffer
    if (lpszBuffer != NULL)
        cchBuffer = FtpGetProgramText(hServer, nClientId, lpszBuffer, cchBuffer +
1);
}

// Free the memory allocated for the buffer when finished
if (lpszBuffer != NULL)
{
    LocalFree((HLOCAL)lpszBuffer);
    lpszBuffer = NULL;
    cchBuffer = 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetRenamedFile Function

```
INT WINAPI FtpGetRenamedFile(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszFileName,
   INT nMaxLength
);
```

Return the original name of a file being renamed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A null-terminated string buffer that will contain the full path of the last file or directory that was renamed. It is recommended that this buffer be at least MAX_PATH characters in size. The value of this parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null characters. This parameter must have a value larger than zero.

Return Value

If the function succeeds, the return value is the length of the file or directory path, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not renamed a file or directory, this function will return zero.

Remarks

When a client wishes to rename a file or directory, it must send two commands in sequence to the server. The first command is RNFR (rename from) which specifies the original name of the file or directory to be renamed. The second command is RNTO (rename to) and must be sent immediately after the RNFR command and specifies the new name for the file or directory. The **FtpGetRenamedFile** function will return the full path of the local file or directory that was specified by the RNFR command. Typically this function is used by an event handler that processes the FTP_CLIENT_COMMAND event to determine the original path name.

This function is only guaranteed to return a meaningful value when called within the context of the FTP_CLIENT_COMMAND event. Calling this function outside of the event handler will return the path of the last renamed file, but there is no way to determine at what point the client issued the command to rename a file or directory. To obtain the new file or directory name, the **FtpGetCommandFile** function should be called from within the event handler.

The RNFR and RNTO commands can also be used to move a file or directory to a new location. For example, they could be used to move a file from one directory to another. An application should never make the assumption that the paths of the original and new file will be the same.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetServerAddress Function

```
INT WINAPI FtpGetServerAddress(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

Return the IP address of the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszAddress

A null-terminated string buffer that will contain the server IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

This function will return the IP address assigned to the specified server as a printable string. If the ***nClientId*** parameter has a value of zero, this function will return the IP address assigned to the local system. If the FTP_SERVER_NATROUTER option was specified when the server was started, this function will return the external IP address assigned to the system. If the ***nClientId*** parameter specifies a valid client session, this function will return the IP address that the client used to establish the connection with the server. To determine the IP address assigned to the client, use the **FtpGetClientAddress** function.

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetServerDirectory Function

```
INT WINAPI FtpGetServerDirectory(
   HSERVER hServer,
   LPTSTR lpszDirectory,
   INT nMaxLength
);
```

Return the full path to the root directory assigned to the specified server.

Parameters

hServer

The server handle.

lpszDirectory

A null-terminated string buffer that will contain the server root directory, terminated with a null character. It is recommended that this buffer be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **FtpGetServerDirectory** function will return the full path to the root directory assigned to the server instance. The root directory may be specified as part of the server configuration, or if no directory is specified by the application, a temporary root directory will be created and this function can be used to obtain the full path to the directory. When the application specifies a root directory, it may use environment variables such as %AppData% in the path. This function will return the fully resolved path name, with all environment variables expanded.

There is no corresponding function to change the server root directory after the server has started. To change the root directory, you must stop the server using the **FtpServerStop** function and then start another instance of the server with a configuration that specifies the new directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetServerAddress, FtpGetServerIdentity, FtpGetServerName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetServerError Function

```
DWORD WINAPI FtpGetServerError(
    HSERVER hServer,
    LPTSTR lpszError,
    INT nMaxLength
);
```

Return the last server error code and a description of the error.

Parameters

hServer

The server handle.

lpszError

A null-terminated string buffer that will contain a description of the error. If the error description is not needed, this parameter may be NULL.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the error string buffer, including the terminating null character. If the ***lpszError*** parameter is NULL, this value should be zero.

Return Value

An unsigned integer value that specifies the last error that occurred. A value of zero indicates that there was no error.

Remarks

Error codes are unsigned 32-bit values which are private to each server. You should call the **FtpGetServerError** function immediately when a function's return value indicates that an error has occurred. That is because some functions clear the last error code when they succeed.

If the ***hServer*** parameter is specified with a value of INVALID_SERVER, this function will return the last error that occurred for the current thread. This value should only be used when the function does not have access to a valid server handle, such as when the **FtpServerStart** function fails.

It is important to note that the error codes returned by this function are different than the command result codes that are defined in RFC 959, the standard protocol specification for FTP. This function is used to determine reason that an API function has failed, and should not be used to determine if a command issued by the client was successful. The **FtpSendResponse** function is used to send result codes to the client, and the **FtpGetCommandResult** function can be used to determine the result of the last command sent by the client.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or FTP_ERROR. Those functions which clear the last error code when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

Unicode: Implemented as Unicode and ANSI versions

FtpGetServerIdentity Function

```
INT WINAPI FtpGetServerIdentity(
   HSERVER hServer,
   LPTSTR lpszIdentity,
   INT nMaxLength
);
```

Return the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A null-terminated string buffer that will contain the identity of the server when the function returns, terminated with a null character. This parameter cannot be NULL. It is recommended that this buffer be at least 32 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **FtpGetServerIdentity** function returns the identity string that was specified as part of the server configuration. It is used for informational purposes only and does not affect the operation of the server. Typically the string specifies the name of the application and a version number, and is displayed whenever a client establishes its initial connection to the server. The **FtpSetServerIdentity** function can be used to change the identity string associated with the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetServerLogFile Function

```
BOOL WINAPI FtpGetServerLogFile(
   HSERVER hServer,
   UINT *lpnLogFormat,
   UINT *lpnLogLevel,
   LPTSTR lpszFileName,
   INT nMaxLength
);
```

Return the current log file format and the full path to the file.

Parameters

hServer

The server handle.

lpnLogFormat

A pointer to an integer value that will contain the log file format being used when the function returns. If this information is not needed, this parameter may be NULL. The following formats are supported:

Value	Description
FTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
FTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
FTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

lpnLogLevel

A pointer to an integer value that will contain the level of detail the server uses when generating the log file. The minimum value is 1 and the maximum value is 10. If this information is not needed, this parameter may be NULL.

lpszFileName

A null-terminated string buffer that will contain the full path to the log file. This parameter may be NULL if this information is not required.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the file name string, including the terminating null character. If the ***lpszFileName*** parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the current log file format. Refer to the **FTPSERVERCONFIG** structure definition for a list of supported log file formats. If the server handle is invalid or logging has not been enabled, this function will return a value of zero.

Remarks

If the server is configured with logging enabled, but a log file name is not explicitly provided, then the server will automatically generate one. This function can be used to get the full path to the current log file along with the format that is being used to record client session data. Normally the log file is held open by the server thread while it is active, however you can call the **FtpRenameServerLogFile** function to explicitly rename or delete the log file.

To change the name of the log file, the log file format or level of detail, use the **FtpSetServerLogFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetServerMemoryUsage Function

```
BOOL WINAPI FtpGetServerMemoryUsage(
   HSERVER hServer,
   ULARGE_INTEGER *lpMemUsage
);
```

Return the amount of memory allocated for the server and all client sessions.

Parameters

hServer

The server handle.

lpMemUsage

A pointer to a ULARGE_INTEGER variable which will specify how much memory has been allocated by the server. This parameter will be initialized to a value of zero by the function and updated with the total number of bytes allocated by the server and all active client sessions when it returns.

Return Value

If the function succeeds, the return value is non-zero and the memory usage value will be updated. If the server handle is invalid, or the server cannot be locked, the return value is zero. Call the **FtpGetServerError** function to determine the cause of the failure.

Remarks

This function returns the amount of memory allocated by the server and all active client sessions. It enumerates all of memory allocations made by the server process and client session threads and returns the total number of bytes allocated for the server process. This value reflects the amount of memory explicitly allocated by this library and does not reflect the total working set size of the process, or memory allocated by any other libraries. To determine the working set size for the process, refer to the Win32 **GetProcessWorkingSetSize** and **GetProcessMemoryInfo** functions.

This function forces the server into a locked state, and all client sessions will block until the function returns. Because this function enumerates all heaps allocated for the server process, it can be an expensive operation, particularly when there are a large number of active clients connected to the server. Frequent use of this function can significantly degrade the performance of the server. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by the function remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpGetServerName Function

```
INT WINAPI FtpGetServerName(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszHostName,
   INT nMaxLength
);
```

Return the host name assigned to the specified server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A null-terminated string buffer that will contain the server host name, terminated with a null character. It is recommended that this buffer be at least 64 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will return the host name assigned to the specified server. If the ***nClientId*** parameter has a value of zero, the function will return the default host name that was specified as part of the server configuration. If no host name was explicitly assigned to the server, then it will return the local system name. If the ***nClientId*** parameter specifies a client session, then it this function will return the host name that the client used to establish the connection. If the client sends the HOST command to the server, this function will return the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetServerPriority Function

```
INT WINAPI FtpGetServerPriority(
    HSERVER hServer
);
```

Return the current priority assigned to the specified server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the priority for the specified server. If the function fails, the return value is FTP_PRIORITY_INVALID. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpGetServerPriority** function can be used to determine the current priority assigned to the server. It will return one of the following values:

Value	Description
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
FTP_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h.
Import Library: csftsv12.lib

FtpGetServerStackSize Function

```
DWORD WINAPI FtpGetServerStackSize(
     SOCKET hServer
);
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpGetServerStackSize** function returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h.
Import Library: csftsv12.lib

FtpGetServerTransferInfo Function

```
BOOL WINAPI FtpGetServerTransferInfo(
   HSERVER hServer,
   UINT nClientId,
   LPFTPSERVERTRANSFER lpTransferInfo
);
```

Return information about the file transfer that was performed by the server for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpTransferInfo

A pointer to an **FTPSERVERTRANSFER** structure that will contain information about the last file transfer. This parameter cannot be NULL, and the ***dwSize*** member of the structure must be initialized to specify the structure size prior to calling this function.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function should only be called after the client has issued the APPE, RETR, STOR or STOU commands to initiate a file transfer, otherwise the return value will be zero.

Remarks

The **FtpGetServerTransferInfo** function is used to obtain information about the last file transfer that was performed by the server for the specified client. This function is typically called within an event handler to determine how many bytes of data were transferred, the type of file and the full path to the file on the local system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetServerUuid Function

```
INT WINAPI FtpGetServerUuid(
   HSERVER hServer,
   UUID *lpUuid
);
```

Return the UUID assigned to the specified server.

Parameters

hServer

The server handle.

lpUuid

A pointer to a UUID structure that will contain the server UUID when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle is invalid or the pointer to the UUID structure is NULL, the function will return a value of zero.

Remarks

The **FtpGetServerUuid** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain a printable string version of the UUID, use the **FtpGetServerUuidString** function.

There is no corresponding function to change the UUID assigned to an active server. The server UUID is assigned when the server is started, and it must be a unique value that is maintained throughout the lifetime of the server. To change the UUID associated with the server, the server must be stopped using the **FtpServerStop** function and another instance of the server started with the new UUID.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpGetServerUuidString Function

```
INT WINAPI FtpGetServerUuidString(
    HSERVER hServer,
    LPTSTR lpszHostUuid,
    INT nMaxLength
);
```

Return the UUID assigned to the server as a printable string.

Parameters

hServer

The server handle.

lpszHostUuid

A null-terminated string buffer that will contain the server UUID, terminated with a null character. It is recommended that this buffer be at least 40 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the buffer is not large enough to store the complete UUID string, the function will return a value of zero.

Remarks

The **FtpGetServerUuidString** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain the numeric UUID value, use the **FtpGetServerUuid** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpIsClientAnonymous Function

```
BOOL WINAPI FtpIsClientAnonymous(
    HSERVER hServer,
    UINT nClientId
);
```

Determine if the specified client has authenticated as an anonymous user.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the client session has been authenticated, this function will return a non-zero value, otherwise it will return zero. If the server handle and client ID are valid, and the client session has been authenticated, this function will clear the last error code.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpIsClientAuthenticated Function

```
BOOL WINAPI FtpIsClientAuthenticated(
    HSERVER hServer,
    UINT nClientId
);
```

Determine if the specified client session has been authenticated.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the client session has been authenticated, this function will return a non-zero value, otherwise it will return zero. If the server handle and client ID are valid, this function will clear the last error code.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpIsCommandEnabled Function

```
BOOL WINAPI FtpIsCommandEnabled(
   HSERVER hServer,
   LPCTSTR lpszCommand
);
```

Determine if a specific server command has been enabled or disabled.

Parameters

hServer

The server handle.

lpszCommand

A null-terminated string that specifies the name of the command. The command name is not case-sensitive, but the value must otherwise match the exact command name. Partial matches are not recognized by this function. This parameter cannot be NULL.

Return Value

If the command is enabled, this function will return a non-zero value. If the command is disabled, the server handle is invalid or the command name does not match a supported command, this function will return zero.

Remarks

The **FtpIsCommandEnabled** function is used to determine whether a specific command is enabled. Typically this function is used in an event handler to make sure the command issued by a client is recognized by the server and enabled for use. Commands can be enabled and disabled using the **FtpEnableCommand** function.

This function does not account for the permissions granted to a specific client session. Clients are assigned access rights when they are authenticated using the **FtpAuthenticateClient** function, and certain commands can be limited by the permissions granted to the client. For example, even though the STOR command is enabled, a client must have the FTP_ACCESS_WRITE permission to use the command to upload a file to the server. For a list of access rights, see User Access Constants.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpRegisterProgram Function

```
BOOL WINAPI FtpRegisterProgram(
   HSERVER hServer,
   UINT nHostId,
   LPCTSTR lpszCommandName,
   LPCTSTR lpszProgramFile,
   LPCTSTR lpszParameters,
   LPCTSTR lpszDirectory
);
```

Register a program for use with the SITE EXEC command.

Parameters

hServer

The server handle.

nHostId

An unsigned integer that identifies the virtual host associated with the program. This value should always be zero.

lpszCommandName

A null-terminated string which specifies the name of the site specific command. This is the name that is passed to the SITE EXEC command and does not need to match the actual name of the executable file on the local system. The maximum length of the command name is 32 characters. This parameter cannot be NULL.

lpszProgramFile

A null-terminated string that specifies the full path to the executable program. This parameter cannot be NULL.

lpszParameters

A null-terminated string that specifies additional parameters for the program. If the program does not require any command line parameters, this value may be NULL or point to an empty string.

lpszDirectory

A null-terminated string that specifies the current working directory for the program. If this parameter is NULL or points to an empty string, the server will use the current working directory of the client that issues the SITE EXEC command.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpRegisterProgram** function registers an executable program for use with the SITE EXEC command. Because this can present a significant security risk to the server, clients are not given permission to use this command by default. A client must be explicitly granted permission to use SITE EXEC by including FTP_ACCESS_EXECUTE as one of the permissions when authenticating the client session with the **FtpAuthenticateClient** function or creating a virtual user using the **FtpAddVirtualUser** function.

To give the server complete control over what programs can be executed using SITE EXEC, the

program must be registered with the server and referenced by an alias specified by the *lpszCommandName* parameter. The maximum length of a program name is 31 characters and it must be at least 3 characters in length. The name must only consist of alphanumeric characters and the first character of the program name cannot be numeric. The program name is not case-sensitive, however convention is to use upper-case characters. If a program name is specified that already has been registered, it will be updated with the new information provided by this function.

The *lpszProgramFile* string specifies file name of the program that will be executed. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple command names that reference the same executable file. The only requirement is that the command names be unique. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the `C:\Program Files` folder.

It is important to note that the program specified by *lpszProgramFile* must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The *lpszParameters* string is used to define optional command line parameters that will be included with the command. This string can contain placeholders that are replaced by additional parameters specified by the client when it sends the SITE EXEC command. First replacement parameter is %1, the second is %2 and so on.

The executable program that is registered using this function must be a console application that writes to standard output. Programs that write directly to a console, or programs written to use a Windows user interface are not supported and will yield unpredictable results. In most cases, those programs that do not use standard input and output will be forcibly terminated by the server. If the program attempts to read from standard input, it will immediately encounter an end-of-file condition. Programs executed by the SITE EXEC command have no input; it is similar to a program that has its input redirected from the NUL: device. If the program must process a file on the server, the local file name should be passed as a command line parameter.

The output from the program will be redirected back to the client control channel. The output should be textual, with each line of text terminated by a carriage return and linefeed (CRLF). Programs that write binary data to standard output, particular data with embedded nulls, will yield unpredictable results and are not supported. To ensure that the program output conforms to the protocol standard, any non-printable characters will be replaced with a space and each line of output will be prefixed by a single space. The server application can obtain a copy of the output from the last command by calling the **FtpGetProgramOutput** function.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpRenameServerLogFile Function

```
BOOL WINAPI FtpRenameServerLogFile(
    HSERVER hServer,
    LPCTSTR lpszFileName
);
```

Rename or delete the current log file being updated by the server.

Parameters

hServer

The server handle.

lpszFileName

A null-terminated string that specifies the file name the current log file should be renamed to. If this parameter is NULL or an empty string, the current log file will be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero. If logging is not currently enabled for the server, this function will return zero.

Remarks

The **FtpRenameServerLogFile** function is used to rename or delete the current log file. Note that this does not change the current log file name or disable logging by the server. It only changes the file name of the current log file, or removes the log file if the ***lpszFileName*** parameter is NULL. This can be useful if you want your server to perform log file rotation, archiving the current log file. By renaming the current log file, the server will automatically create a new log file with original file name.

This function must be used to rename or delete the current log file while logging is active because the server holds an open handle on the file. The application should not use the **FtpGetServerLogFile** function to obtain the log file name and then use the **MoveFileEx** or **DeleteFile** functions with that file.

To disable logging, use the **FtpSetServerLogFile** function and specify the logging format as FTP_LOGFILE_NONE.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpSendResponse Function

```
BOOL WINAPI FtpSendResponse(
   HSERVER hServer,
   UINT nClientId,
   UINT nResultCode,
   LPCTSTR lpszMessage
);
```

Send a result code and message to the client in response to a command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nResultCode

An unsigned integer value which specifies the result code.

lpszMessage

A null-terminated string which specifies a message to be sent to the client. If this parameter is NULL or points to an empty string, a default message associated with the result code will be used.

Return Value

If the result code and message text was sent to the client, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the result code is invalid, this function will return zero.

Remarks

The **FtpSendResponse** function is used to respond to a command issued by the client. Command responses are normally handled by the server as a normal part of processing a command and this function is only used if the application has implemented custom commands or wishes to modify the standard responses sent by the server. The message may be a maximum of 2048 characters and may include embedded carriage-return and linefeed characters. If no message is specified, then a default message will be sent based on the result code.

Result codes must be three digits (in the range of 100 through 999) and although this function will support the use of non-standard result codes, it is recommended that the client application use the standard codes defined in RFC 959 whenever possible. The use of non-standard result codes may cause problems with FTP clients that expect specific result codes in response to a particular command. For more information, refer to the **FtpGetCommandResult** function.

This function should only be called once in response to a command sent by the client. If a result code has already been sent in response to a command and this function is called, it will fail and return a value of zero. This is necessary because sending multiple result codes in response to a single command may cause unpredictable behavior by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpServerAsyncNotify Function

```
BOOL WINAPI FtpServerAsyncNotify(
    HSERVER hServer,
    HWND hWnd,
    UINT uMsg
);
```

Enable or disable asynchronous notification of changes in server status.

Parameters

hServer

The server handle.

hWnd

A handle to the window whose window procedure will receive the notification message.

uMsg

The user-defined message that will be sent to the notification window.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **FtpGetServerError** function.

Remarks

The **FtpServerAsyncNotify** function is used by an application to enable or disable asynchronous notifications. The message window is typically the main UI window and these notifications are used signal to the application that it should update the user interface. If the ***hWnd*** parameter is not NULL, it must specify a valid window handle and the user-defined message must have a value of **WM_USER** or higher. The application cannot specify a notification message that is reserved by the operating system. The pseudo-handle **HWND_BROADCAST** cannot be specified as the notification window. If the ***hWnd*** parameter is NULL, notifications for the specified server will be disabled.

When asynchronous notifications are enabled for a server, the server will post the user-defined message to the window whenever there is a change in status or after a client has connected or disconnected from the server. The ***wParam*** message parameter will contain the notification message and the ***lParam*** message parameter will contain the handle to the server or the client ID. The following notification messages are defined:

Value	Description
FTP_NOTIFY_STARTUP	This notification is sent when the server has started and is preparing to accept client connections. This notification is only sent once, and only if asynchronous notifications are enabled immediately after the **FtpServerStart** function is called. This message will not be sent once the server has begun accepting client connections or when notification messages are disabled and then subsequently re-enabled at a later time. The ***lParam*** message parameter will specify the handle to the server.
FTP_NOTIFY_LISTEN	This notification is sent when the server is listening for client connections. This notification message may be sent to the

	application multiple times over the lifetime of the server. If the server was suspended, this notification will be sent after the application calls the **FtpServerResume** function to resume accepting client connections. The *lParam* message parameter will specify the handle to the server.
FTP_NOTIFY_SUSPEND	This notification is sent when the server suspends accepting new connections because the application has called the **FtpServerSuspend** function. This notification message may be sent to the application multiple times over the lifetime of the server. The *lParam* message parameter will specify the handle to the server.
FTP_NOTIFY_RESTART	This notification is sent when the server is restarted using the **FtpServerRestart** function. Note that the server socket handle provided by the *lParam* message parameter will specify the new socket handle of the restarted server instance, not the original socket handle. The *lParam* message parameter will specify the handle to the server.
FTP_NOTIFY_CONNECT	This notification is sent when the server accepts a client connection and the thread that manages the client session has begun processing network events for that client. This message notification will not be sent if the client connection is rejected by the server. The *lParam* message parameter will specify the unique ID of the client that connected to the server.
FTP_NOTIFY_DISCONNECT	This notification is sent when the client disconnects from the server and the client socket has been closed. This notification message may not occur for each client session that is forced to terminate as the result of the server being stopped using the **FtpServerStop** function. The *lParam* message parameter will specify the unique ID of the client that disconnected from the server.
FTP_NOTIFY_SHUTDOWN	This notification is sent when the server thread is in the process of terminating. At the time the application processes this notification message, the server handle in *lParam* will reference the defunct server and cannot be used with other server functions. The *lParam* message parameter will specify the handle to the server.

If asynchronous notifications are enabled, you should never use those notifications as a replacement for an event handler. When an event occurs, the callback function that handles the event is invoked in the context of the thread that manages the client session. The application should exchange data with the client within that event handler and not in response to a notification message. These notification messages should only be used to update the application UI in response to changes in the status of the server.

The FTP_NOTIFY_CONNECT and FTP_NOTIFY_DISCONNECT notifications are different from the other server notifications because the *lParam* message parameter does not specify the server handle, but rather the unique client ID associated with the session that connected to or disconnected from the server. Use the **FtpGetClientServer** function to obtain a handle to the server that created the client

session. Note that at the time the application processes the FTP_NOTIFY_DISCONNECT notification message, the client session will have already terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h.
Import Library: csftsv12.lib

See Also

FtpGetClientServer, FtpServerStart

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpServerDisableTrace Function

```
BOOL WINAPI FtpServerDisableTrace();
```

Disable the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpServerEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpServerEnableTrace Function

```
BOOL WINAPI FtpServerEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

Enable the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the process level and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpServerInitialize Function

```
BOOL WINAPI FtpServerInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **FtpServerInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**. All other functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **FtpServerInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **FtpServerUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **FtpServerInitialize** or **FtpServerUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpServerProc Function

```
VOID CALLBACK FtpServerProc(
   HSERVER hServer,
   UINT nClientId,
   UINT nEventId,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **FtpServerProc** function is an application-defined callback function that processes events generated by the server process.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client that has issued a request to the server.

nEventId

An unsigned integer which specifies which event occurred. For a list of events, see Server Event Constants.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero. The **FtpGetServerError** function can be used to obtain additional information about the error code.

dwParam

A user-defined integer value which was specified when the server was started. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

Return Value

None.

Remarks

The FTP_CLIENT_COMMAND event can be used to filter commands issued by the client. If the command performs an operation on a file or directory, the **FtpGetCommandFile** function can be used to obtain the file name on the server that the client specified. It is possible for the application to change the file name using the **FtpSetCommandFile** function to direct the server to use a different file than the one specified by the client. If the file name is changed and the event handler returns a value of zero, the server will perform the default action for the command using the new file name.

The FTP_CLIENT_TIMEOUT event will only occur for authenticated client sessions. The server has a second, internal timer that is maintained for unauthenticated sessions that requires the client to successfully authenticate itself within a fixed period of time. If a client does not authenticate within the allowed time period, the server will automatically close the control channel. For more information, refer to the documentation for the *nAuthTime* member of the **FTPSERVERCONFIG** structure.

The callback function will be called in the context of the thread that is currently managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the

results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within an event handler. Controls should only be modified by the same UI thread that created their window. To change the user interface in response to a server event, use the **FtpServerAsyncNotify** function to enable asynchronous notifications and update the UI in response to the notification message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpServerRestart Function

```
HSERVER WINAPI FtpServerRestart(
    HSERVER hServer
);
```

Restart the server, terminating all active client sessions.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the new handle for the specified server. If the function fails, the return value is INVALID_SERVER. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerRestart** function will restart the specified server, terminating all active client sessions. The server handle that is returned by the function is the handle for the new server instance, and the old handle value is no longer valid. If the function is unable to restart the server for any reason, the server thread is terminated. The server retains all of the configuration parameters from the previous instance, however the statistical information (such as the number of clients, files transferred, etc.) will be reset.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **FtpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpServerResume Function

```
BOOL WINAPI FtpServerResume(
    HSERVER hServer
);
```

Resume accepting client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerResume** function instructs the server to resume accepting new client connections after the **FtpServerSuspend** function has been called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpServerRestart, FtpServerStart, FtpServerStop, FtpServerSuspend, FtpServerThrottle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpServerStart Function

```
HSERVER WINAPI FtpServerStart(
   LPCTSTR lpszLocalHost,
   UINT nLocalPort,
   DWORD dwOptions,
   LPFTPSERVERCONFIG lpServerConfig,
   FTPSERVPROC lpServerProc,
   DWORD_PTR dwServerParam,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **FtpServerStart** function begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the callback function specified by the caller.

Parameters

lpszLocalHost

A null-terminated string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is NULL or an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

nLocalPort

The port number the server should use to listen for client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit TLS. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

dwOptions

An unsigned integer value that specifies the options used when creating an instance of the server. For a list of options, see Server Option Constants.

lpServerConfig

A pointer to an **FTPSERVERCONFIG** structure that specifies the configuration options for the server. If this parameter is NULL, then default configuration parameters will be used that starts the server in a restrictive mode.

lpServerProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **FtpServerProc** callback function. If this parameter is NULL, a default internal handler is used to process client commands.

dwServerParam

A user-defined integer value that is passed to the callback function. If the *lpServerProc* parameter is NULL, this value should be zero. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

lpCredentials

Pointer to a **SECURITYCREDENTIALS** structure. If this parameter is NULL, the default security credentials for the server host name will be used. If security is enabled for the server, it is

recommended that you provide a pointer to this structure with specific information about the server certificate that should be used. If the security options are not specified in the server configuration, this parameter is ignored.

Return Value

If the function succeeds, the return value is a handle to a server session. If the function fails, the return value is INVALID_SERVER. To get extended error information, call **FtpGetServerError**.

Remarks

In most cases, the *lpszLocalHost* parameter should be a NULL pointer or an empty string. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The handle returned by this function references the listening socket that was created when the server was started. The service is managed in another thread, and all interaction with the server and active client connections are performed inside the event handler. To disconnect all active connections, close the listening socket and terminate the server thread, call the **FtpServerStop** function.

The host UUID that is defined as part of the server configuration should be generated using the **uuidgen** utility that is included with the Windows SDK. You should not use the UUID that is provided in the example code, it is for demonstration purposes only. If no host UUID is specified in the server configuration, an ephemeral UUID will be generated automatically when the server is started.

If the server is started with security enabled, the *lpCredentials* parameter should be used to provide the server certificate information in a **SECURITYCREDENTIALS** structure. If the pointer is NULL, this function will search for a certificate that matches the hostname provided as part of the server configuration. This requires that the server certificate be installed in the personal certificate store of the current process user, and it must have a private key associated with it. To use a certificate with a different name, or one that is stored in a PFX file, a **SECURITYCREDENTIALS** structure must be defined and passed to this function.

Example

```
HSERVER hServer;
FTPSERVERCONFIG ftpConfig;

// Initialize the server configuration
ZeroMemory(&ftpConfig, sizeof(FTPSERVERCONFIG));
ftpConfig.dwSize = sizeof(ftpConfig);
ftpConfig.nMaxClients = 20;
ftpConfig.nMaxGuests = 5;
ftpConfig.nLogFormat = FTP_LOGFILE_EXTENDED;
ftpConfig.nAuthTime = 30;
```

```
ftpConfig.nIdleTime = 120;
ftpConfig.lpszIdentity = _T("MyProgram");
ftpConfig.lpszHostName = _T("server.company.com");
ftpConfig.lpszHostUuid = _T("10000000-1000-1000-1000-100000000000");
ftpConfig.lpszDirectory = _T("%ProgramData%\\MyProgram\\Files");
ftpConfig.lpszLogFile = _T("%ProgramData%\\MyProgram\\Server.log");

// Start the server
hServer = FtpServerStart(lpszLocalHost,
                         FTP_PORT_DEFAULT,
                         FTP_SERVER_LOCALUSER | FTP_SERVER_UNIXMODE,
                         &ftpConfig,
                         lpEventHandler,
                         0,
                         NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpServerStop Function

```
BOOL WINAPI FtpServerStop(
   HSERVER hServer
);
```

Stop the server, terminating all active client sessions and releasing the resources that were allocated for the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **FtpServerStop** function instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the server handle to be opaque and never depend on it being a specific value.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **FtpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpServerSuspend Function

```
BOOL WINAPI FtpServerSuspend(
    HSERVER hServer
);
```

Suspend the server and reject new client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerSuspend** function instructs the server to suspend accepting new client connections. Any incoming client connections will be rejected with an error message indicating that the server is currently unavailable. To resume accepting client connections, call the **FtpServerResume** function. Suspending the server will have no effect on clients that have already established a connection with the server.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **FtpServerThrottle** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpServerRestart, FtpServerResume, FtpServerStart, FtpServerStop, FtpServerThrottle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpServerThrottle Function

```
BOOL WINAPI FtpServerThrottle(
   HSERVER hServer,
   UINT nMaxClients,
   UINT nMaxClientsPerAddress,
   UINT nMaxGuests,
   DWORD dwConnectionRate
);
```

The **FtpServerThrottle** function limits the number of active client connections, connections per address and connection rate.

Parameters

hServer

Handle to the server.

nMaxClients

An integer value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections. A value of -1 specifies that the maximum number of clients should not be changed.

nMaxClientsPerAddress

An integer value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is a limit of four client connections per address. A value of -1 specifies that the maximum number of clients should not be changed.

nMaxGuests

An integer value which specifies the maximum number of guest users that may login to the server. A value of zero disables guest logins and requires that all clients authenticate with a valid username and password. A value of -1 specifies that the maximum number of guest users should not be changed.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate. A value of -1 specifies that the connection rate should not be changed.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpServerThrottle** function is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client

sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **FtpServerStart** function is called with the maximum number of clients set to 100, and then **FtpServerThrottle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

It is recommended that you always specify conservative connection limits for your server application based on expected usage. Allowing an unlimited number of client connections can potentially expose the system to denial-of-service attacks and should never be done for servers that are accessible over the Internet.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpServerUninitialize Function

```
VOID WINAPI FtpServerUninitialize();
```

The **FtpServerUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **FtpServerInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **FtpServerUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **FtpServerUninitialize** for every successful call to **FtpServerInitialize** made by a process. Operations for all threads in the server are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpServerInitialize, FtpServerStart, FtpServerStop

FtpSetClientAccess Function

```
BOOL WINAPI FtpSetClientAccess(
    HSERVER hServer,
    UINT nClientId,
    DWORD dwUserAccess
);
```

Change the access rights associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see User Access Constants.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **FtpSetClientAccess** function can change the access rights for an authenticated client session. This function can only be used after the **FtpAuthenticateClient** function has been used to grant the initial set of access rights to the client. The **FtpEnableClientAccess** function can be used to grant or revoke a specific permission for the client session.

The *dwUserAccess* parameter has a value of FTP_ACCESS_DEFAULT, then default permissions will be granted to the client session. A normal client cannot be changed to a restricted or anonymous client using this function. If the FTP_ACCESS_RESTRICTED or FTP_ACCESS_ANONYMOUS access flags are specified, this function will fail.

This function cannot be used to change the access rights for a restricted or anonymous user. Those rights are granted when the client session is authenticated and will persist until the client disconnects from the server. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

Example

```
DWORD dwUserAccess = 0;

// Allow the client to execute programs using SITE EXEC
if (FtpGetClientAccess(hServer, nClientId, &dwUserAccess))
{
    if (! (dwUserAccess & FTP_ACCESS_ANONYMOUS))
        FtpSetClientAccess(hServer, nClientId, dwUserAccess | FTP_ACCESS_EXECUTE);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpSetClientFileType Function

```
BOOL WINAPI FtpSetClientFileType(
    HSERVER hServer,
    UINT nClientId,
    UINT nFileType
);
```

Change the current file type used for transfers by the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nFileType

Specifies the type of file that will be uploaded or downloaded. This parameter determines whether subsequent file transfers require any data conversion and may be one of the following values.

Value	Description
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those clients which use a different end-of-line character sequence, the text file has been converted to the local format which uses the carriage return (CR) and linefeed (LF) characters.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type has been performed on the file. This is the default file type for most data files and executable programs. If the client specified this file type when appending to a text file, the file will contain the end-of-line sequences used by its native operating system.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpSetClientFileType** function will change the default file type that is used for subsequent transfers by the client. If the file type is set to FILE_TYPE_ASCII then the server will automatically convert any end-of-line character sequences to match the format used by the local system. For example, if the client is connecting from a UNIX based system, the server will convert a single linefeed character to a carriage return (CR) and linefeed (LF) sequence. If the file type is set to FILE_TYPE_IMAGE, then no conversion is performed.

This function can be used to override the file type specified by filtering the TYPE command issued by the client. For example, it could be used to force file transfers to use a specific type based on the file extension, regardless of the type specified by the client. To determine the current file type set by the client, use the **FtpGetClientFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpGetClientFileType

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpSetClientIdentity Function

```
BOOL WINAPI FtpSetClientIdentity(
    HSERVER hServer,
    UINT nClientId,
    LPCTSTR lpszIdentity
);
```

Change the identity of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszIdentity

A null-terminated string that identifies the client. If this parameter is NULL or specifies an empty string, the current identity for the client is cleared. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the server handle or client ID is invalid, the function will return a value of zero.

Remarks

The **FtpSetClientIdentity** function associates a string value with the client that can be used to identify the session. The identity string does not have any standard format and is used for informational purposes only. Typically it is used to identify the client application that was used to establish the connection. Changing the client identity has no effect on the operation of the server. To obtain the identity string currently associated with the client, use the **FtpGetClientIdentity** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetClientIdentity, FtpGetServerIdentity, FtpSetServerIdentity

FtpSetClientIdleTime Function

```
UINT WINAPI FtpSetClientIdleTime(
    HSERVER hServer,
    UINT nClientId,
    UINT nTimeout
);
```

Change the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nTimeout

An unsigned integer value that specifies the number of seconds that the client may remain idle. If this value is zero, the default idle timeout period for the server will be used.

Return Value

If the function succeeds, the return value is the previous client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpSetClientIdleTime** function is will change the number of seconds that the client may remain idle before being automatically disconnected by the server. The minimum timeout period for a client is 60 seconds, the maximum is 7200 seconds (2 hours). The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed.

If the value INFINITE is specified as the timeout period, the client activity timer will be refreshed, extending the idle timeout period for the session. This is typically done inside an event handler to prevent the client from being disconnected due to inactivity.

To obtain the current idle timeout period for a client, along with the amount of time the client has been idle, use the **FtpGetClientIdleTime** function.

This timeout period only affects authenticated clients. Unauthenticated clients use a different internal timer that limits the amount of time they can remain connected to the server and that value cannot be changed for individual client sessions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

See Also

FtpGetClientIdleTime

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpSetCommandFile Function

```
BOOL WINAPI FtpSetCommandFile(
   HSERVER hServer,
   UINT nClientId,
   LPCTSTR lpszFileName
);
```

Change the name of the local file or directory that is the target of the current command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A null-terminated string that specifies the new file name. This parameter may be NULL to specify that the original file or directory name should be used.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **FtpSetCommandFile** function is used by the application to change the target file or directory name for the current command from within an FTP_EVENT_COMMAND event handler. This can be used to effectively redirect the client to use a different file than the one that was actually requested. For example, if the client issues the RETR command to download a file from the server, this function can be used to redirect the command to use a different file name. To obtain the full path to the file or directory that is the target of the current command, use the **FtpGetCommandFile** function.

The *lpszFileName* parameter specifies the path to the new file or directory name. If the path is absolute, then it will be used as-is . If the path is relative, it will be relative to the current working directory for the client session. The full path to this file is not limited to the server root directory or its subdirectory, it can specify a file anywhere on the local system. If this parameter is a NULL pointer, or points to an empty string, then the server will revert to using the actual file or directory name specified by the command. This enables the application to effectively undo a previous call to this function to change the target file name.

Typically this function would be used to redirect a client to a file or directory that it may not normally have access to. Exercise caution when using this function to provide access to data that is stored outside of the server root directory. Incorrect use of this function could expose the server to security risks or cause unpredictable behavior by client applications.

This function should only be called within the context of the FTP_EVENT_COMMAND event, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_COMMAND. To obtain the name of the current command issued by the client, use the **FtpGetCommandName** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpSetServerAddress Function

```
BOOL WINAPI FtpSetServerAddress(
   HSERVER hServer,
   LPCTSTR lpszAddress
);
```

Change the IP address that the server will use with passive data connections.

Parameters

hServer

The server handle.

lpszAddress

A null-terminated string that specifies the IP address that the server should use for passive mode data transfers. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle or the IP address is invalid the function will return a value of zero.

Remarks

The **FtpSetServerAddress** function changes the IP address that the server will use when a client transfers a file using a passive mode data connection. In passive mode, the server will create a second passive (listening) socket that will accept an incoming connection from the client. The server sends the IP address and port number allocated for that socket to the client, and the client establishes the data connection to the server using that address. The IP address that the server sends to the client is normally the same as the IP address that the client used to establish the control connection, however if the server is located behind a router that performs Network Address Translation (NAT), the IP address reported to the client may not be usable.

This function enables your application to set the external IP address for the server to a specific value, rather than the server attempting to automatically discover its own external address. If you wish to set the external address for the server manually, call the **FtpServerStart** function without the FTP_SERVER_EXTERNAL option and then call this function to set the external IP address to the desired value.

This function will not change the IP address the server is using to listen for client connections. The only way to change the listening IP address is to stop and restart the server using the new address. This function only changes the IP address that is reported to clients when a passive data connection is used. Incorrect use of this function can prevent the client from establishing a data connection to the server. The address must be in the same address family as the local address that the server was started with. For example, if the server was started using an IPv4 address, the IP address passed to this function cannot be an IPv6 address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetServerAddress, FtpGetServerName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpSetServerError Function

```
VOID WINAPI FtpSetServerError(
    HSERVER hServer,
    DWORD dwError
);
```

Set the last error code for the specified server session.

Parameters

hServer

The server handle.

dwError

An unsigned integer that specifies an error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each server session. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or FTP_ERROR.

If the ***hServer*** parameter is specified as INVALID_SERVER, this function will set the last error code for the current thread, but will not change the error code associated with any server session. This should only be done if the application does not have access to a valid server handle.

If the ***dwError*** parameter is specified with a value of zero, this effectively clears the error code for the last function that failed. Those functions which clear the last error code when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **FtpGetServerError** function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

FtpSetServerIdentity Function

```
BOOL WINAPI FtpSetServerIdentity(
   HSERVER hServer,
   LPCTSTR lpszIdentity
);
```

Change the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A null-terminated string that identifies the server. If this parameter is NULL or specifies an empty string, the current identity for the server is reset to a default value. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **FtpSetClientIdentity** function changes a string value used by the server to identify itself to clients. The identity string does not have any standard format and is used for informational purposes only. Typically it consists of the application name and a version number. Changing the server identity has no effect on the operation of the server. To obtain the identity string currently associated with the server, use the **FtpGetServerIdentity** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpSetServerLogFile Function

```
BOOL WINAPI FtpSetServerLogFile(
   HSERVER hServer,
   UINT nLogFormat,
   UINT nLogLevel,
   LPCTSTR lpszFileName
);
```

Change the current log format, level of detail and file name.

Parameters

hServer

The server handle.

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Value	Description
FTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
FTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
FTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

nLogLevel

An integer value that specifies the level of detail that should generated in the log file. The minimum value is 1 and the maximum value is 10. If this parameter is zero, it is the same as specifying a log file format of FTP_LOGFILE_NONE and will disable logging by the server.

lpszFileName

A null-terminated string that specifies the name of the log file that should be created or appended to. If the server was configured with logging enabled and this parameter is NULL or an empty string, the current log file name will not be changed. If the log file does not exist, it will be created. If it does exist, the contents of the log file will be appended to.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero.

Remarks

The **FtpSetServerLogFile** function can be used to change the current log file name, the format of the log file or the level of detail recorded in the log file. In some situations it may be desirable to delete the current log file contents when changing the format or ensure that a new log file is created. To do this, combine the ***nLogFormat*** parameter with the constant FTP_LOGFILE_DELETE.

The higher the value of the ***nLogLevel*** parameter, the greater the level of detail that is recorded by the server. A log level of 1 instructs the server to only record file transfers, while a level of 10 instructs the server to record all commands processed by the server. Because a higher level of logging detail can negatively impact the performance of the server, it is recommended that you do not exceed a level of 5 for most applications. A log level of 10 should only be used for debugging purposes.

Example

```
UINT nLogFormat = FTP_LOGFILE_NONE;
UINT nLogLevel = 0;
UINT nNewLevel = 5;
BOOL bChanged = FALSE;

// Change the level of detail for the current log file if logging
// has been enabled and the current level is a lower value

if (FtpGetServerLogFile(hServer, &nLogFormat, &nLogLevel, NULL, 0))
{
    if (nLogFormat != FTP_LOGFILE_NONE && nLogLevel < nNewLevel)
        bChanged = FtpSetServerLogFile(hServer, nLogFormat, nNewLevel, NULL);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetServerLogFile, FtpRenameServerLogFile

FtpSetServerName Function

```
BOOL WINAPI FtpSetServerName(
   HSERVER hServer,
   UINT nClientId,
   LPCTSTR lpszHostName
);
```

Change the host name assigned to the specified server or client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A null-terminated string that specifies the new host name assigned to the server or client session. If this value is NULL or points to an empty string, the current host name will be changed to use the default host name.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will change the host name assigned to the specified client session. If the ***nClientId*** parameter has a value of zero, the function will change default host name that was assigned to the server as part of the server configuration. If the ***nClientId*** parameter specifies a valid client session and the ***lpszHostName*** parameter is NULL, the host name associated with the client session will be changed to the current host name assigned to the server.

When a client connects to the server, it can specify the host name that it used to establish the connection by sending the HOST command. This is typically used with virtual hosting, where one server may accept client connections for multiple domains. The **FtpGetServerName** function will return the host name specified by the client, and **FtpSetServerName** can be used by the application to either explicitly assign a different host name to the client session, or override the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetServerAddress, FtpGetServerName

FtpSetServerPriority Function

```
INT WINAPI FtpSetServerPriority(
    HSERVER hServer,
    INT nPriority
);
```

Change the priority assigned to the specified server.

Parameters

hServer

The server handle.

nPriority

An integer value which specifies the new priority for the server. It may be one of the following values:

Value	Description
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
FTP_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority assigned to the server. If the function fails, the return value is FTP_PRIORITY_INVALID. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpSetServerPriority** function can be used to change the current priority assigned to the specified server. Client connections that are accepted after this function is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h.
Import Library: csftsv12.lib

FtpSetServerStackSize Function

```
BOOL WINAPI FtpSetServerStackSize(
    SOCKET hServer,
    DWORD dwStackSize
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetServerError**.

Remarks

The **FtpSetServerStackSize** function changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change the stack size unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib

File Transfer Protocol Server Data Structures

- FTPCLIENTCREDENTIALS
- FTPSERVERCONFIG
- FTPSERVERTRANSFER
- SECURITYCREDENTIALS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FTPCLIENTCREDENTIALS

The **FTPCLIENTCREDENTIALS** structure defines the credentials used to authenticate a specific user.

```
typedef struct _FTPCLIENTCREDENTIALS
{
    DWORD dwSize;
    DWORD dwFlags;
    TCHAR szHostName[FTP_MAXHOSTNAME];
    TCHAR szUserName[FTP_MAXUSERNAME];
    TCHAR szPassword[FTP_MAXPASSWORD];
} FTPCLIENTCREDENTIALS, *LPFTPCLIENTCREDENTIALS;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value reserved for future use. This member will always be initialized to a value of zero.

szHostName

A null-terminated string that specifies the server host name.

szUserName

A null-terminated string that specifies the user name.

szPassword

A null-terminated string that specifies the user password.

Remarks

When an instance of this structure is passed to the **FtpGetClientCredentials** function, this member must be initialized to the size of the structure and all other members must be initialized with a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

FTPSERVERCONFIG

The **FTPSERVERCONFIG** structure provides the configuration information used to create an instance of an FTP server.

```
typedef struct _FTPSERVERCONFIG
{
    DWORD   dwSize;
    UINT    nMaxClients;
    UINT    nMaxClientsPerAddress;
    UINT    nMaxGuests;
    UINT    nLogFormat;
    UINT    nLogLevel;
    UINT    nMinPort;
    UINT    nMaxPort;
    UINT    nAuthFail;
    UINT    nAuthTime;
    UINT    nIdleTime;
    UINT    nExecTime;
    LPCTSTR lpszIdentity;
    LPCTSTR lpszHostUuid;
    LPCTSTR lpszHostName;
    LPCTSTR lpszRootPath;
    LPCTSTR lpszTempPath;
    LPCTSTR lpszLogFile;
} FTPSERVERCONFIG, *LPFTPSERVERCONFIG;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

nMaxClients

An integer value that specifies the maximum number of active client connections that will be accepted by the server. If the maximum number of clients is reached, any further connections are rejected by the server until one or more clients close their connection to the server or are disconnected. A value of zero specifies the default configuration value of 100 connections should be used.

nMaxClientsPerAddress

An integer value that specifies the maximum number of active client connections per IP address that will be accepted by the server. If the maximum number of clients from the same IP address is reached, any further connections are rejected until one of the clients closes its connection to the server. A value of zero specifies the default configuration value of 4 connections per address should be used.

nMaxGuests

An integer value that specifies the maximum number of anonymous client connections. If the server does not permit anonymous connections, this value is ignored. It is recommended that this value always be less than the value of the ***nMaxClients*** member. A value of zero specifies that the default configuration limit of 20 anonymous connections should be used.

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Value	Description
FTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
FTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
FTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

nLogLevel

An integer value that specifies the level of detail that should generated in the log file. The minimum value is 1 and the maximum value is 10. If the ***nLogFormat*** member specifies a valid log file format and this value is zero, a default level of detail will be selected based on the format. The common log file format generally contains less information by default, only logging the data transfers between the client and server. The W3C extended log file format defaults to a higher level of detail that includes additional information about the client session. The higher the level of detail, the larger the log file will be.

nMinPort

An integer value that specifies the minimum range of port numbers that will be used with passive data connections. A value of zero specifies that the default value of 30000 should be used. The minimum value of this member is 5000 and the maximum value is 65535. If the value is non-zero, it must be less than the value of the ***nMaxPort*** structure member.

nMaxPort

An integer value that specifies the maximum range of port numbers that will be used with passive data connections. A value of zero specifies the default value of 65535 should be used. The minimum value of this member is 5000 and the maximum value is 65535. If the value is non-zero, it must be greater than the value of the ***nMinPort*** structure member.

nAuthFail

An integer value that specifies the maximum number of user authentication attempts that are permitted until the server terminates the client connection. A value of zero specifies that the default configuration limit of 3 authentication attempts per login should be allowed. The maximum number of authentication attempts is 10.

nAuthTime

An integer value that specifies the maximum number of user authentication attempts that are permitted until the server terminates the client connection. A value of zero specifies the default value of 60 seconds. If the value is non-zero, the minimum value is 20 seconds and the maximum value is 300 seconds (5 minutes). This value is used to ensure that a client has successfully authenticated itself within a limited period of time. This prevents a potential denial-of-service attack against the server where clients establish connections and hold them open without authentication. In conjunction with the ***nAuthFail*** member, this also limits the ability of a client to attempt to probe the server for valid username and password combinations.

nIdleTime

An integer value that specifies the maximum number of seconds that a client session may be idle before the server closes the control connection to the client. A value of zero specifies the default

value of 900 seconds (15 minutes). If the value is non-zero, the minimum value is 60 seconds and the maximum value is 7200 seconds (2 hours). This value is used to initialize the default idle timeout period for each client session. A client may request that the server change the idle timeout period for its session by sending the SITE IDLE command. The server determines if a client is idle based on the time the last command was issued and whether or not a file transfer is in progress.

nExecTime

An unsigned integer value that specifies the maximum number of seconds that an external program is permitted to run on the server. External programs are registered using the **FtpRegisterProgram** function, and are executed by the client sending the SITE EXEC command to the server. If this value is zero, the default timeout period of 5 seconds will be used. The minimum execution time is 1 second and the maximum time limit is 30 seconds.

lpszIdentity

A null-terminated string that identifies the server. It is used for informational purposes only and has no effect on the operation of the server. If this member is not initialized to a value, then a default identity will be used. The server identity is provided when a client establishes the initial connection and when the client sends the STAT or CSID commands. If this member is defined, it is recommended that you only use printable ASCII characters.

lpszHostUuid

A null-terminated string that specifies a Universally Unique Identifier (UUID) that is used to uniquely identify the server. This value can be used when storing information about the server, and should be generated using a utility such as **uuidgen** which is included with Visual Studio. This structure member may be initialized to an empty string, in which case a temporary UUID will be randomly generated.

lpszHostName

A null-terminated string that specifies the fully-qualified host name for the server. If this structure member is initialized with an empty string, the local host name assigned to the Windows system will be used. This value does not need to correspond to the actual host name associated with the server's IP address. This value is used for informational purposes only and has no effect on the operation of the server.

lpszRootPath

A null-terminated string that specifies the path to the root directory for the server. If this structure member is initialized with an empty string, the current working directory for the process will be used as the root directory. It is recommended that you provide a full path to an existing directory and do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszTempPath

A null-terminated string that specifies the path to the temporary directory for the server. If this structure member is initialized with an empty string, the current temporary directory for the process will be used. The temporary directory cannot be the same as the root directory, and it is strongly recommended that you do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszLogFile

A null-terminated string that specifies the name of the server log file to create, if a logging format has been specified. If logging is enabled and this member is an empty string, then a default log file name will be created. If the file name does not include a path, then the file is created in the server log directory. If the file name includes a path, the log file will be created using that specific name. If the server is in multi-user mode, then the default location for log files will be the Logs subdirectory

in the server root directory. If the server is not in multi-user mode, the default location for log files will be the temporary directory for the server process.

Remarks

When an instance of this structure is passed to the **FtpServerStart** function, the *dwSize* member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the configuration is invalid.

The *nMaxClients* member limits the total number of client connections and the *nMaxGuests* member limits the total number of guest connections. The server will notify the client if either number of connections has been exceeded and will automatically close the connection. However, one difference is that a new client that exceeds the maximum number of connections will not generate any events; a client that exceeds the maximum number of guest connections will generate events. The reason for the difference is that the check for the number of active clients is made immediately after the client connects to the server, prior to session context being created for that client. The check for the number of anonymous clients is made later, after the client has sent the USER and PASS commands to the server. For more control over how the server accepts client connections, use the **FtpServerThrottle** function.

If the server is running on a system that is behind a firewall that restricts the range of port numbers for inbound connections, the *nMinPort* and *nMaxPort* members can be used to limit the ports which the server will use to listen for passive data connections from clients. By default, the server will use data port numbers that range from 30000 to 65535, which is typical for many firewall configurations. If you provide your own port range, the minimum number of ports available must be at least 1000. Specifying a port range that is too small will cause the **FtpServerStart** function to fail with an error indicating that the server configuration is invalid.

When specifying the root directory for the server configuration, it is important to consider that a client's access to files on the system will be limited to these directories and any subdirectories. If a root directory is not specified, then one will be created using the current working directory for the process. The root directory path may include environment variables surrounded by % symbols and these will be expanded.

If you have configured the server to permit clients to upload files, you must ensure that your application has permission to create files in the directory that you specify. A recommended location for the server root directory would be a subdirectory of the %ALLUSERSPROFILE% directory. Using the environment variable ensures that your server will work correctly on different versions of Windows. If the root directory does not exist at the time that the server is started, it will be created.

For servers that are publicly accessible, or where you want files to be a accessible across multiple server sessions, you should always populate the *szHostUuid* member with a valid UUID string, and the *szDirectory* member should specify an absolute path to an existing directory.

If the FTP_SERVER_MULTIUSER option is specified, the server will start in multi-user mode, with each user assigned to their own home directory based on their username. This option will cause the server to create a directory structure in the root directory that includes three subdirectories: Public, Users and Logs. The Public directory is the home directory for anonymous users, and they are isolated to that directory. The Users directory is where the user home directories are created. The Logs directory is where log files are created by default. If this option is not specified, then no subdirectories are created and all users will share the server root directory by default.

If the FTP_SERVER_LOCALUSER option is specified, the server will never attempt to authenticate the local Administrator or Guest accounts. This is done to prevent clients from attempting to probe for the administrator account password. However, the application can override this behavior by implementing

a handler for the FTP_CLIENT_LOGIN event.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

FTPSERVERTRANSFER

The **FTPSERVERTRANSFER** structure provides information about the last file transfer performed by a client.

```
typedef struct _FTPSERVERTRANSFER
{
    DWORD          dwSize;
    DWORD          dwReserved;
    DWORD          dwFileAccess;
    DWORD          dwTimeElapsed;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szFileName[MAX_PATH];
} FTPSERVERTRANSFER, *LPFTPSERVERTRANSFER;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

dwFileAccess

An unsigned integer value that specifies the how the local file was accessed. It can be one of the following values:

Value	Description
FTP_FILE_READ	The file was opened for reading. This mode indicates that the client issued the RETR command to download the contents of a file from the server to the client system. The ***szFileName*** member specifies the name of the local file on the server that was downloaded by the client.
FTP_FILE_WRITE	The file was opened for writing. This mode indicates that the client issued the STOR or STOU command to upload the contents of a file from the client system to server. The ***szFileName*** member specifies the name of the local file on the server that was created by the client. If a file already existed with the name name, it was replaced.
FTP_FILE_APPEND	The file was opened for writing. This mode indicates the client issued the APPE command to upload the contents of a file from the client system and append the data to a file on the server. If the file did not exist, then it was created. The ***szFileName*** member specifies the name of the local file that was appended to or created by the client.

dwTimeElapsed

The amount of time that it took for the file transfer to complete in milliseconds.

This value is limited to the resolution of the system timer, which is typically in the range of 10 to 16 milliseconds. This value may be zero if the transfer occurred over a local network or on the same host using a loopback address.

uiBytesCopied

A 64-bit integer value that specifies the total number of bytes copied during the file transfer. This value is represented by a ULARGE_INTEGER union which provides support for those programming languages that do not have intrinsic support for 64-bit integers. For more information, refer to the Windows SDK documentation. The application should not make the assumption that this is the actual size of the file. If the client specified a restart offset using the REST command, this value would only represent the number of bytes transferred from that byte offset, not the total file size.

szFileName

A null-terminated string value that will contain the full path to the local file that was transferred. The ***dwFileAccess*** member determines whether the file name represents a file that was downloaded by the client, or uploaded from the client and stored on the server.

Remarks

When an instance of this structure is passed to the **FtpGetServerTransferInfo** function, the ***dwSize*** member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the parameter is invalid. All other members should be initialized to a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify the security protocol and server certificate when accepting a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Hypertext Transfer Protocol Client Library

Transfer files between the local system and a web server, execute scripts and perform remote file management functions.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSHTPV12.DLL
Version	12.0.3024.1286
LibID	E5D90316-2B5F-4E36-BD24-F58F1B47C3BF
Import Library	CSHTPV12.LIB
Dependencies	None
Standards	RFC 1945, RFC 2616, RFC 7230, RFC 7540

Overview

The Hypertext Transfer Protocol (HTTP) is a lightweight, stateless application protocol that is used to access resources on web servers, as well as send data to those servers for processing. The library provides direct, low-level access to the server and the commands that are used to retrieve resources (i.e.: documents, images, etc.). The library also provides a simple interface for downloading resources to the local host, similar to how the HTTP library can be used to download files.

In a typical session, you would use the class to establish a connection, send a request (to download a resource, post data for processing, etc.), read the data returned by the server and then disconnect. It is the responsibility of the client to process the data returned by the server, depending on the type of resource that was requested.

This library supports HTTP versions 1.0, 1.1, 2.0 and 3.0. Secure connections use TLS 1.2 or later and supports the use of client certificates if required. There are several functions designed to make it easy to submit JSON and XML requests and include custom headers which may be required by REST APIs. The library also supports standard authentication methods and the use of OAuth bearer tokens.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum

required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Hypertext Transfer Protocol Functions

Function	Description
HttpAddFormField	Add the form field and its value to the specified form.
HttpAddFormFile	Add the contents of the file to the specified form.
HttpAddQueuedFile	Add a new file to the queue to be uploaded or downloaded.
HttpAddQueuedFileEx	Add a new file to the queue with additional transfer options.
HttpAddRequestHeaders	Add one or more request headers for the current client session.
HttpAsyncConnect	Establish an asynchronous connection to the specified server.
HttpAsyncGetData	Copy the contents of a resource on the server to a local buffer.
HttpAsyncGetFile	Copy a file from the server to the local system.
HttpAsyncGetFileEx	Copy a file from the server to the local system, use with files larger than 4 GiB.
HttpAsyncPostData	Post data from a local buffer to a script executed on the server.
HttpAsyncPostJson	Post JSON formatted data to a script executed on the server.
HttpAsyncPostXml	Post XML formatted data to a script executed on the server.
HttpAsyncProxyConnect	Establish an asynchronous connection to a proxy server.
HttpAsyncPutData	Create a file on the server using the contents of a local buffer.
HttpAsyncPutFile	Copy a file from the local system to the server.
HttpAsyncPutFileEx	Copy a file from the local system to the server, use with files larger than 4 GiB.
HttpAsyncSubmitForm	Submit the specified form to the server for processing.
HttpAttachThread	Attach the specified client handle to another thread.
HttpAuthenticate	Specify authentication information for restricted resources.
HttpCancel	Cancel the current blocking operation.
HttpCancelQueuedFile	Cancel the queued file transfer.
HttpClearForm	Remove all defined fields from the specified form.
HttpClearHeaders	Resets the current request and response headers to their default values.
HttpClearQueue	Remove all files from the current transfer queue.
HttpCloseFile	Close the file opened on the server.
HttpCommand	Send a command to the server.
HttpConnect	Connect to the specified server.
HttpConnectUrl	Establish a client connection using the specified URL.
HttpCreateFile	Create or replace a file on the server.
HttpCreateForm	Create a new form and return the form handle.
HttpCreateQueue	Create a new file transfer queue.
HttpCreateSecurityCredentials	Create a new security credentials structure.

HttpDeleteFile	Remove a file from the server.
HttpDeleteFormField	Delete the form field and its value from the specified form.
HttpDeleteHeaders	Delete all of the response or request headers for the current session.
HttpDeleteQueue	Delete a previously created file transfer queue.
HttpDeleteSecurityCredentials	Delete a previously created security credentials structure.
HttpDestroyForm	Destroy the specified form and free the memory allocated for it.
HttpDisableEvents	Disable asynchronous event notification.
HttpDisableTrace	Disable logging of network function calls.
HttpDisconnect	Disconnect from the current server.
HttpDownloadFile	Download a file from the server to the local system.
HttpEnableCompression	Enable or disable support for data compression.
HttpEnableEvents	Enable asynchronous event notification.
HttpEnableTrace	Enable logging of network function calls to a file.
HttpEnumQueuedFiles	Return a list of files in the transfer queue.
HttpEnumTasks	Return a list of asynchronous tasks.
HttpEventProc	Callback function that processes events generated by the client.
HttpFindQueuedFile	Find a file in the transfer queue which matches the search criteria.
HttpFreezeEvents	Suspend asynchronous event processing.
HttpGetBearerToken	Return the current OAuth 2.0 bearer token for the client session.
HttpGetContentLength	Return the size of the current resource in bytes.
HttpGetContentType	Return the content type for the current resource.
HttpGetCookie	Return information about the specified cookie.
HttpGetData	Copy the specified resource to a local buffer.
HttpGetDefaultUserAgent	Return the default user agent string included with requests.
HttpGetDefaultZoneId	Return the default security zone for downloaded files.
HttpGetEncodingType	Determines which content encoding option is enabled.
HttpGetErrorString	Return a description for the specified error code.
HttpGetFile	Copy a file from the server to the local system.
HttpGetFileEx	Copy a file from the server to the local system, use with large files over 4 GiB.
HttpGetFilePathUrl	Return a normalized URL for the specified file on the server.
HttpGetFileSize	Return the size of a file on the server.
HttpGetFileSizeEx	Return the size of a file on the server, supports large files over 4 GiB.
HttpGetFileTime	Return the date and time a file on the server was last modified.
HttpGetFileZoneInfo	Return file zone identifier information for the specified local file.
HttpGetFirstCookie	Return the first cookie set by the server.

HttpGetFirstHeader	Return the name and value of the first request or response header field.
HttpGetFirstQueuedFile	Return information about the first file in the transfer queue.
HttpGetFormProperties	Return the properties of the specified form.
HttpGetLastError	Return the last error code.
HttpGetNextCookie	Return the next cookie set by the server.
HttpGetNextHeader	Return the name and value of the next request or response header field.
HttpGetNextQueuedFile	Return information about the next file in the transfer queue.
HttpGetOption	Return the enabled/disabled state of a specified option.
HttpGetPriority	Return the current priority for file transfers.
HttpGetQueueClient	Return the handle to the current client session.
HttpGetQueuedFile	Return information about a file queued for transfer.
HttpGetQueueStatus	Return the status of the current file transfer queue.
HttpGetQueueThread	Return a value which uniquely identifies the queue manager thread.
HttpGetRedirectUrl	Return the URL for a redirected resource.
HttpGetResourceUrl	Return the URL for the current request.
HttpGetRequestHeader	Return the value of the specified request header field.
HttpGetResponseHeader	Return the value of the specified response header field.
HttpGetResultCode	Return the result code from the previous command.
HttpGetResultString	Return the result string from the previous command.
HttpGetSecurityInformation	Return security information about the current client connection.
HttpGetSecurityZoneId	Returns the security zone identifier for the specified resource.
HttpGetStatus	Return the current client status.
HttpGetTaskError	Return the last error code for the specified asynchronous task.
HttpGetTaskId	Return the unique task identifier associated with the specified client session.
HttpGetText	Return the contents of a text resource to a string buffer.
HttpGetTextEx	Return the contents of a text resource with additional conversion options.
HttpGetThreadQueue	Return the handle to a queue associated with the specified thread.
HttpGetTimeout	Return the number of seconds until an operation times out.
HttpGetTransferStatus	Return data transfer statistics.
HttpInitialize	Initialize the library and validate the specified runtime license key.
HttpIsBlocking	Determine if the client is blocked, waiting for information.
HttpIsConnected	Determine if the client is connected to the server.
HttpIsReadable	Determine if data can be read from the server.
HttpIsWritable	Determine if data can be written to the server.
HttpNormalizePath	Normalize the specified resource returning a canonical path.

HttpNormalizeUrl	Normalize the specified URL returning a canonical path.
HttpOpenFile	Open a file on the server for reading.
HttpPatchData	Submits JSON or XML patch data to the server and returns the response .
HttpPostData	Submit data to the server using the POST command and returns the response.
HttpPostFile	Submit the contents of a local file to the server.
HttpPostJson	Submit JSON structured data to the server and returns the response.
HttpPostText	Submit plain text data to the server and returns the response.
HttpPostTextEx	Submit plain text data to the server with additional conversion options.
HttpPostXml	Submit XML structured data to the server and returns the response.
HttpProxyConnect	Establish a connection with the specified proxy server.
HttpPutData	Create a file on the server using the contents of a local buffer.
HttpPutDataEx	Submit data to the server using the PUT command and returns the response.
HttpPutFile	Copy a file from the local system to the server.
HttpPutFileEx	Copy a file from the local system to the server, use with large files over 4 GiB.
HttpPutText	Create a text file on the server from the contents of a string buffer.
HttpPutTextEx	Submit text to the server using the PUT command and returns the response.
HttpRead	Read data from the server.
HttpRegisterEvent	Register an event callback function.
HttpRemoveQueuedFile	Remove a file from the transfer queue.
HttpResetQueue	Reset the internal state of file transfers in the specified queue.
HttpResumeQueue	Resume the transfer of files after queue processing has been paused.
HttpSetBearerToken	Set the value of the OAuth 2.0 bearer token for the client session.
HttpSetContentType	Set the content type for the next request.
HttpSetCookie	Set the value of the specified cookie.
HttpSetDefaultUserAgent	Set the default user agent string included with requests.
HttpSetDefaultZoneId	Set the default security zone for downloaded files.
HttpSetEncodingType	Specifies the type of encoding to be applied to data submitted to the server.
HttpSetFileZoneInfo	Set or remove the zone indentifier associated with the specified file.
HttpSetFormProperties	Modify the properties of the specified form.
HttpSetLastError	Set the last error code.
HttpSetOption	Enable or disable the specified option.
HttpSetPriority	Set the priority for file transfers.
HttpSetRequestHeader	Set the value of a request header field.
HttpSetTimeout	Set the number of seconds until an operation times out.
HttpStartQueue	Begin transferring the files in the specified queue.

HttpStopQueue	Stop transferring the files in the specified queue.
HttpSubmitForm	Submit the specified form to the server for processing.
HttpSubmitRequest	Submit a request to the server and return the response.
HttpSuspendQueue	Pause the transfer of files in the specified queue.
HttpTaskAbort	Abort the specified asynchronous task.
HttpTaskDone	Determine if an asynchronous task has completed.
HttpTaskResume	Resume execution of an asynchronous task.
HttpTaskSuspend	Suspend execution of an asynchronous task.
HttpTaskWait	Wait for an asynchronous task to complete.
HttpUninitialize	Terminate use of the library by the application.
HttpUploadFile	Upload a file from the local system to the server.
HttpValidateHostName	Validate the specified host name and return the resolved IP address.
HttpValidateUrl	Check the contents of a string to ensure it represents a valid URL.
HttpVerifyFile	Compare the size of a local file against a file stored on the server.
HttpWaitForQueue	Wait for the transfer of all queued files to complete.
HttpWrite	Write data to the server.

HttpAddFormField Function

```
INT WINAPI HttpAddFormField(
   HFORM hForm,
   LPCTSTR lpszFieldName,
   LPVOID lpFieldData,
   DWORD cbFieldData,
   DWORD dwReserved
);
```

The **HttpAddFormField** function adds a new field to the specified form.

Parameters

hForm

Handle to the virtual form.

lpszFieldName

A null-terminated string which specifies the name of the field to add to the form. If this parameter is NULL or points to an empty string, then a default field name will be assigned.

lpFieldData

The form field data. Typically this will either by a pointer to an array of bytes or a string which specifies the value for the form field. If no data is to be associated with the form field, then this argument may be NULL.

cbFieldData

An unsigned integer value which specifies the number of bytes of data in the form field. If this value is -1 then it is assumed that the ***lpFieldData*** parameter is a pointer to a null-terminated string. If ***lpFieldData*** is NULL, this value must be zero.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpAddFormField** function is used to add a field and its associated value to a form created using the **HttpCreateForm** function. If the field name has already been added to the form, the previous value is deleted and replaced by the new value.

If the Unicode version of this function is called and the ***cbFieldData*** parameter is -1, the ***lpFieldData*** parameter must point to a wide string terminated with a null character. The string will be automatically converted to UTF-8 when the form data is submitted to the server.

Example

```
HFORM hForm = INVALID_FORM;
HGLOBAL hgblResult = (HGLOBAL)NULL;
DWORD cbResult = 0;
INT nResult = 0;

hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);
```

```
if (hForm == INVALID_FORM)
    return;

HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);

nResult = HttpSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);
HttpDestroyForm(hForm);

if (hgblResult != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer points to data returned by the server after the form
    // data was submitted

    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAddFormFile Function

```
INT WINAPI HttpAddFormFile(
   HFORM hForm,
   LPCTSTR lpszFieldName,
   LPCTSTR lpszFileName,
   DWORD dwReserved
);
```

The **HttpAddFormFile** function adds the contents of a file to the specified form.

Parameters

hForm

Handle to the virtual form.

lpszFieldName

A null-terminated string which specifies the name of the field to add to the form. If this parameter is NULL or points to an empty string, then a default field name will be assigned.

lpszFileName

A null-terminated string which specifies the name of the file. The contents of the file will be added to the form data that is submitted to the server.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAddQueuedFile Function

```
DWORD WINAPI HttpAddQueuedFile(
   HQUEUE hQueue,
   DWORD dwQueueMode,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   UINT nTimeout
);
```

The **HttpAddQueuedFile** function adds a new file to the queue with additional transfer options.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An integer value which specifies if the file should be downloaded from the server or uploaded to the server. This parameter must be one of the following options and cannot have a value of zero.

Constant	Description
HTTP_QUEUE_DOWNLOAD	The file should be queued for downloading from the server to the local system.
HTTP_QUEUE_UPLOAD	The file should be queued for uploading from the local system to the server.

lpszLocalFile

A null-terminated string which specifies the name of the local file to be queued for transfer. This parameter cannot be NULL or point to an empty string. If the file is being queued for an upload, the file must exist on the local system or the function will fail. If the file is being downloaded, it will be created or replaced on the local system.

lpszRemoteFile

A null-terminated string which specifies the URL to the location of the file on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator and can be any of the options used with the **HttpConnect** function. If this value is zero, the default options for the queue will be used. The most common options are:

Value	Description
HTTP_OPTION_DEFAULT	Default options should be used for the queued transfer. All standard headers will be included with the request and redirected resources will return an error, allowing the application to determine if it should request the resource from the new location or inform the user the resource location has changed.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle

	resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control panel.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.

nTimeout

The number of seconds to wait for a response from the server before failing the file transfer. If this value is zero, the default timeout period for the queue will be used.

Return Value

If the function succeeds, the return value is a unique identifier which corresponds to the queued file. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function will add a file to the current transfer queue. If successful, the value returned is a unique integer which identifies that file in the queue. To obtain information about the queued file, you can call the **HttpGetQueuedFile** function and provide this return value as the ***dwFileId*** parameter. To remove a file from the queue, use the **HttpRemoveQueuedFile** function.

Files can only be added to the queue when in an idle or paused state. If you attempt to add a file to the queue while the queue manager is transferring files, the function will fail. To determine the current state of the queue, call the **HttpGetQueueStatus** function

There are no fixed limits to the number of files which can be queued for transfer. To release the memory allocated for the queue, call the **HttpClearQueue** function. To determine the current status of the queue, including how many file transfers have been queued and how many are pending completion, call the **HttpGetQueueStatus** function.

If the local file path includes environment variables enclosed in percentage (%) symbols, those values will be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

This function will not immediately begin the process of uploading or downloading the file. It will only add the transfer request to the current queue. The file transfers are managed by a background worker thread which is created when the **HttpStartQueue** function is called.

The **HttpAddQueuedFileEx** function is an extended version of this function with additional parameters to specify a hostname, port number, user name and password. Because most file uploads require authentication, using the extended function may be preferred to composing a URL which includes the account credentials.

Example

```
// Create a new queue
HQUEUE hQueue = HttpCreateQueue(INFINITE, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = HttpAddQueuedFile(
                     hQueue,
                     lpszLocalFile,
                     lpszRemoteFile,
                     HTTP_OPTION_DEFAULT,
                     HTTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case HTTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case HTTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (HttpStartQueue(hQueue, HTTP_QUEUE_ALL, 0, NULL, 0))
{
    HttpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    HttpStopQueue(hQueue);
}

// Remove all files from the queue
HttpDeleteQueue(hQueue);
```

Requirements

HttpAddQueuedFileEx Function

```
DWORD WINAPI HttpAddQueuedFileEx(
    HQUEUE hQueue,
    DWORD dwQueueMode,
    LPCTSTR lpszHostName,
    UINT nHostPort,
    UINT nAuthType,
    LPCTSTR lpszUserName,
    LPCTSTR lpszPassword,
    LPCTSTR lpszLocalFile,
    LPCTSTR lpszRemoteFile,
    DWORD dwOptions,
    UINT nTimeout,
    LPVOID lpvReserved
);
```

The **HttpAddQueuedFileEx** function adds a new file to the queue with additional transfer options.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An integer value which specifies if the file should be downloaded from the server or uploaded to the server. This parameter must be one of the following options and cannot have a value of zero.

Constant	Description
HTTP_QUEUE_DOWNLOAD	The file should be queued for downloading from the server to the local system.
HTTP_QUEUE_UPLOAD	The file should be queued for uploading from the local system to the server.

lpszHostName

The name of the server to establish a connection with. This may be a fully-qualified domain name or an IP address. If this parameter is NULL or points to an empty string, the ***lpszRemoteFile*** parameter must specify a complete URL which identifies the server as well as the path to the remote file.

nHostPort

The port number which should be used when establishing the connection. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443. If this parameter is zero and a URL is specified with the ***lpszRemoteFile*** parameter, the port number included in the URL will be used as the default value.

nAuthType

An unsigned integer value which specifies the method to be used when authenticating the client. The following values are supported:

Value	Description
HTTP_AUTH_NONE	No client authentication should be performed. The ***lpszUserName***

	and ***lpszPassword*** parameters are ignored and current authentication settings are cleared.
HTTP_AUTH_BASIC	The **Basic** authentication scheme should be used. This option is supported by all servers that support at least version 1.0 of the protocol. The user credentials are not encrypted and Basic authentication should not be used over standard (non-secure) connections. Most web services which use Basic authentication require the connection to be secure.
HTTP_AUTH_BEARER	The **Bearer** authentication scheme should be used. This authentication method does not require a user name and the ***lpszPassword*** parameter must specify the OAuth 2.0 bearer token issued by the service provider. If the access token has expired, the request will fail with an authorization error.

lpszUserName

A null-terminated string which specifies the user name to be used to authenticate the connection. If this parameter is NULL or an empty string, no client credentials are provided. If the authentication type is HTTP_AUTH_BEARER, this parameter is ignored.

lpszPassword

A null-terminated string which specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified. If the authentication type is HTTP_AUTH_BEARER, this value must be the bearer token issued by the service provider.

lpszLocalFile

A null-terminated string which specifies the name of the local file to be queued for transfer. This parameter cannot be NULL or point to an empty string. If the file is being queued for an upload, the file must exist on the local system or the function will fail. If the file is being downloaded, it will be created or replaced on the local system.

lpszRemoteFile

A null-terminated string which specifies the name of the file on the server. If the file is being downloaded, the file must exist on the server or the transfer will fail. If the file is being uploaded, the file will be created or replaced on the server. This parameter may specify a complete URL. Note that any values you specify as arguments to this function will override the values specified in the URL. If you want to use a URL as the remote file name, the ***lpszHostName*** parameter should be NULL and the ***nHostPort*** parameter should be zero.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator and can be any of the options used with the **HttpConnect** function. If this value is zero, the default options for the queue will be used. The most common options are:

Value	Description
HTTP_OPTION_DEFAULT	Default options should be used for the queued transfer. All standard headers will be included with the request and redirected resources will return an error, allowing the application to determine if it should request the resource from the new location or inform the user the resource location has changed.

HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control panel.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.

nTimeout

The number of seconds to wait for a response from the server before failing the file transfer. If this value is zero, the default timeout period for the queue will be used.

lpvReserved

A reserved parameter which should always be NULL.

Return Value

If the function succeeds, the return value is a unique identifier which corresponds to the queued file. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function will add a file to the current transfer queue. If successful, the value returned is a unique integer which identifies that file in the queue. To obtain information about the queued file, you can call the **HttpGetQueuedFile** function and provide this return value as the ***dwFileId*** parameter. To remove a file from the queue, use the **HttpRemoveQueuedFile** function.

Files can only be added to the queue when in an idle or paused state. If you attempt to add a file to the queue while the queue manager is transferring files, the function will fail. To determine the current state of the queue, call the **HttpGetQueueStatus** function

There are no fixed limits to the number of files which can be queued for transfer. To release the memory allocated for the queue, call the **HttpClearQueue** function. To determine the current status of the queue, including how many file transfers have been queued and how many are pending completion, call the **HttpGetQueueStatus** function.

If the local file path includes environment variables enclosed in percentage (%) symbols, those values will be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

This function will not immediately begin the process of uploading or downloading the file. It will only add the transfer request to the current queue. The file transfers are managed by a background worker thread which is created when the **HttpStartQueue** function is called.

Example

```
// Create a new queue
HQUEUE hQueue = HttpCreateQueue(INFINITE, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = HttpAddQueuedFileEx(
                    hQueue,
                    HTTP_QUEUE_DOWNLOAD,
                    lpszHostName,
                    HTTP_PORT_DEFAULT,
                    HTTP_AUTH_DEFAULT,
                    lpszUserName,
                    lpszPassword,
                    lpszLocalFile,
                    lpszRemoteFile,
                    HTTP_OPTION_DEFAULT,
                    HTTP_TIMEOUT,
                    NULL);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case HTTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case HTTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (HttpStartQueue(hQueue, HTTP_QUEUE_ALL, 0, NULL, 0))
{
    HttpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    HttpStopQueue(hQueue);
}
```

```
// Remove all files from the queue
HttpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAddRequestHeaders Function

```
BOOL WINAPI HttpAddRequestHeaders(
   HCLIENT hClient,
   LPCTSTR lpszHeaderList
);
```

The **HttpAddRequestHeaders** function adds one or more request headers for the current client session.

Parameters

hClient

Handle to the client session.

lpszHeaderList

A null-terminated string which specifies one or more header values which should be set for the current client session. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpAddRequestHeaders** function enables your application to set one or more header values by providing a list of name/value pairs separated by a colon. Multiple header values may be provided by separating them with a newline character. This function is similar to calling the **HttpSetRequestHeader** function for each value. When the list of header values is parsed, extraneous whitespace is ignored; however, if the header list contains invalid text (for example, a missing colon separating a header name from its value) the function will fail and an error will be returned.

Exercise caution when providing a header list created directly from user input, such as a list of values input using a textbox control. Any header values which have been previously set by your application can be overridden by this function and may yield unpredictable results. If the service you are using requires a custom authorization header, such as an API token or other user credentials, allowing users to directly modify request header values this way can present a security risk.

Example

```
// Define a list of header values which should be included with the
// request submitted to the server
LPCTSTR lpszHeaderList = _T("X-API-Token: 99d2fe39-0246-4efa-98e0-4d775579fa5d\n")
\
                         _T("X-API-UserId: someuser@domain.tld\n") \
                         _T("X-API-Version: 1.1\n")

if (!HttpAddRequestHeaders(hClient, lpszHeaderList))
{
    // Unable to add the headers for this client session
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: cshtpv12.lib

HttpAsyncConnect Function

```
HCLIENT WINAPI HttpAsyncConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   DWORD dwVersion,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg

);
```

The **HttpAsyncConnect** function is used to establish a connection with the specified server

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **HttpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

The name of the server to connect to. This may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically

	handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. This option will always establish a secure connection with the server. The value of the ***dwVersion*** parameter will be ignored when this option is used.
HTTP_OPTION_HTTP3	This option specifies the client should attempt a HTTP/3 (QUIC) connection with the server. If a connection cannot be established using HTTP/3 the client will attempt a connection using an earlier version of the protocol. You should only use this option if you know the server supports the QUIC protocol, otherwise requests will be delayed as a result of the fallback to attempting a HTTP/2 connection. The value of the ***dwVersion*** parameter will be ignored when this option is used.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.

HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the client will default to using TLS 1.2 or later. If HTTP_PORT_DEFAULT is specified as the remote port, this option will automatically change the port number to use HTTP_PORT_SECURE instead.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1. Although this option may permit connections with servers which do not support current standards, avoid using it unless absolutely necessary. Some servers may reject the connection if the client offers to use TLS 1.0, even when TLS 1.2 or later is also supported.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create a version value and the following values are defined:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this session. This is the same as specifying HTTP_VERSION_11 and is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_09	The client should use the original one-line protocol which

	includes no version number and no request header block. This version has been deprecated and should only be used with legacy servers which do not support the protocol standard. This version of the protocol does not support virtual hosts and is not supported by most modern web services.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.
HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.
HTTP_VERSION_30	The client should use the HTTP/3 protocol standard defined in RFC 9114. This protocol version is similar to earlier versions of the protocol in terms the request methods and server responses, but the underlying transport mechanism is significantly different. Instead of using TCP, this version of the protocol uses multiplexed UDP connections designed to reduce the overhead of TCP while maintaining reliability. If the client or server does not support HTTP/3, the client will automatically attempt to use an earlier version of the protocol.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
HTTP_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event occurs when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

Most applications should use HTTP_VERSION_DEFAULT as the value for the ***dwVersion*** parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support the features required for a secure HTTP/2 connection.

If the HTTP_OPTION_KEEPALIVE option is specified and the server does not support persistent connections, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is automatically enabled when using HTTP/2.

Under some circumstances, a server may forcibly close or abort a connection if the request fails. For example, this can happen when a malformed request is submitted to the server or a server-side error occurs. When this happens, the application will need to disconnect from the server and establish a new connection, even if the keep-alive option has been specified.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return INVALID_CLIENT.

You should only attempt to use HTTP/3 if you know the server supports that version of the protocol. If the server does not support HTTP/3, the client will wait for the timeout period to elapse to determine the server is not responding to the HTTP/3 request and will then attempt to use HTTP/2. If you specify HTTP/3 as the protocol version and you are experiencing long delays for requests the complete, the most likely reason is the server does not support the QUIC protocol and every request is falling back to use HTTP/2 instead. The minimum required platform for HTTP/3 support is Windows 11 21H2 and later builds or Windows Server 2022 or later.

The handle returned by this function is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

To cancel asynchronous notification and return the client to a blocking mode, use the **HttpDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpAsyncGetData Function

```
UINT WINAPI HttpAsyncGetData(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Copies the contents of a resource on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource on the server that will be transferred to the local system.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the **HttpEnableCompression**

	function.
HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncGetData** function is used to download the contents of a server resource into a local buffer. This function is similar to the **HttpGetData** function, however it retrieves the contents of the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being copied to the local system.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, such as with the example listed below, then you must ensure that your code does not return from the function while the data is being downloaded. In the example, this is achieved by calling the **HttpTaskWait** function. You can also perform other operation and poll the status of the task by calling the **HttpTaskDone** function. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the ***lpvBuffer*** and ***lpdwLength*** parameters on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

The ***lpvBuffer*** parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the file or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the ***lpdwLength*** parameter must be initialized to the maximum number of bytes that

can be copied into the buffer. If specifies the address of a global memory handle, then *lpdwLength* must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hgblBuffer = NULL;
DWORD dwLength = 0;
UINT nTaskId;

// Copy the data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter

nTaskId = HttpAsyncGetData(hClient,
                           lpszResource,
                           &hgblBuffer,
                           &dwLength,
                           HTTP_TRANSFER_DEFAULT,
                           NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    HttpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // contents of the file data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAsyncGetFile Function

```
UINT WINAPI HttpAsyncGetFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   DWORD dwOffset,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Downloads the specified file from the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be transferred to the local system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the **HttpEnableCompression** function. This option is ignored if the ***dwOffset*** parameter is non-zero.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically

used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncGetFile** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **HttpGetFile** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Example

```
UINT nTaskId;

// Begin a file transfer in the background
```

```
nTaskId = HttpAsyncGetFile(hClient,
                           lpszLocalFile,
                           lpszRemoteFile,
                           HTTP_TRANSFER_DEFAULT,
                           0, NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    HttpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);
}
```

Requirements

HttpAsyncGetFileEx Function

```
UINT WINAPI HttpAsyncGetFileEx(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   ULARGE_INTEGER uiOffset,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is copied to the local system exactly as it is stored on the server.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the **HttpEnableCompression** function. This option is ignored if the ***dwOffset*** parameter is non-zero.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies

that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncGetFileEx** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **HttpGetFileEx** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

HttpAsyncPostData Function

```
UINT WINAPI HttpAsyncPostData(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPVOID lpvBuffer,
   DWORD cbBuffer,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Post data from a local buffer to a script executed on the server.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource that the data will be posted to on the server. Typically this is the name of a script that will be executed. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

The data that will be provided to the script. This parameter may be NULL if the script does not require any additional data from the client.

cbBuffer

The number of bytes to copy from the buffer. If this ***lpvBuffer*** parameter is NULL, this value should be zero.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is

	automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.
HTTP_POST_MULTIPART	The contents of the buffer being sent to the server consists of multipart form data and will be sent as-is without any encoding.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPostData** function is used to submit data to a script that executes on the server and then copy the output from that script into a local buffer. This function is similar to the **HttpPostData** function, however it submits the data using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent and the response from the server is being returned to the caller.

Because this function works asynchronously, it is important that the memory allocated for the *lpvBuffer* and *lpvResult* parameters will not be released before the asynchronous task completes. If you provide pointers to memory that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

If you wish to submit XML formatted data to the server, it is recommended that you use the **HttpAsyncPostXml** function instead.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;
UINT nTaskId;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nTaskId = HttpAsyncPostData(hClient,
                            lpszResource,
                            lpParameters,
                            cbParameters,
                            &hgblBuffer,
                            &cbBuffer,
                            HTTP_POST_CONVERT,
                            NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAsyncPostJson Function

```
UINT WINAPI HttpAsyncPostJson(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCTSTR lpszJsonData,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Submit JSON formatted data to the server and return the response to the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource name that the JSON data will be submitted to. Typically this is the name of a script on the server.

lpszJsonData

A null-terminated string that specifies the JSON data that will be submitted to the server.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPostJson** function is used to submit JSON formatted data to a script that executes on the server and then copy the output from that script into a local buffer. It automatically sets the correct content type and encoding required for submitting JSON data to a server, however it does not parse the JSON data itself to ensure that it is well-formed. Your application is responsible for ensuring that the JSON data that is being submitted to the server is formatted correctly. This function is similar to the **HttpPostJson** function, however it submits the data using a background worker thread and does not block the current working thread.

Because this function works asynchronously, it is important that the memory allocated for the *lpszJsonData* and *lpvResult* parameters will not be released before the asynchronous task completes. If you provide pointers to memory that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;
UINT nTaskId;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nTaskId = HttpAsyncPostJson(hClient,
                            lpszResource,
                            lpszJsonData,
                            &hgblBuffer,
                            &cbBuffer,
                            HTTP_POST_CONVERT,
                            NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

HttpAsyncPostXml Function

```
UINT WINAPI HttpAsyncPostXml(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCTSTR lpszXmlData,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Submit XML formatted data to the server and return the response to the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource name that the XML data will be submitted to. Typically this is the name of a script on the server.

lpszXmlData

A null-terminated string that specifies the XML data that will be submitted to the server.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPostXml** function is used to submit XML formatted data to a script that executes on the server and then copy the output from that script into a local buffer. It automatically sets the correct content type and encoding required for submitting XML data to a server, however it does not parse the XML data itself to ensure that it is well-formed. Your application is responsible for ensuring that the XML data that is being submitted to the server is formatted correctly. This function is similar to the **HttpPostXml** function, however it submits the data using a background worker thread and does not block the current working thread.

Because this function works asynchronously, it is important that the memory allocated for the *lpszXmlData* and *lpvResult* parameters will not be released before the asynchronous task completes. If you provide pointers to memory that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;
UINT nTaskId;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nTaskId = HttpAsyncPostXml(hClient,
                           lpszResource,
                           lpszXmlData,
                           &hgblBuffer,
                           &cbBuffer,
                           HTTP_POST_CONVERT,
                           NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAsyncProxyConnect Function

```
HCLIENT WINAPI HttpAsyncProxyConnect(
   UINT nProxyType,
   LPCTSTR lpszProxyHost,
   UINT nProxyPort,
   LPCTSTR lpszProxyUser,
   LPCTSTR lpszProxyPassword,
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   DWORD dwVersion,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **HttpAsyncProxyConnect** function is used to establish a connection through a proxy server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **HttpProxyConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

nProxyType

An unsigned integer which specifies the type of proxy that the client is connecting to. The supported proxy server types are as follows:

Value	Description
HTTP_PROXY_NONE	A direct connection will be established with the server. When this value is specified the proxy parameters are ignored.
HTTP_PROXY_STANDARD	A standard connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard connections.
HTTP_PROXY_SECURE	A secure connection is established through the specified proxy server. This proxy type should be used with secure connections and the HTTP_OPTION_SECURE option should also be set via the *dwOptions* parameter.
HTTP_PROXY_WINDOWS	The configuration options for the current system should be used. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. These settings are the same proxy server settings configured in Windows.

lpszProxyHost

A null-terminated string which specifies the proxy server host name or IP address. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

nProxyPort

The port number that the proxy server is listening for connections on. A value of zero specifies that the default port number 80 should be used. Note that in most cases, a proxy server is not configured to use the default port. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

lpszProxyUser

A null-terminated string which specifies the user name that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpszProxyPassword

A null-terminated string which specifies the password that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpszRemoteHost

A null-terminated string which specifies the name of the server to connect to through the proxy server. This may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection

	and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. This option will always establish a secure connection with the server. The value of the ***dwVersion*** parameter will be ignored when this option is used.
HTTP_OPTION_HTTP3	This option specifies the client should attempt a HTTP/3 (QUIC) connection with the server. If a connection cannot be established using HTTP/3 the client will attempt a connection using an earlier version of the protocol. You should only use this option if you know the server supports the QUIC protocol, otherwise requests will be delayed as a result of the fallback to attempting a HTTP/2 connection. The value of the ***dwVersion*** parameter will be ignored when this option is used.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the proxy server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS

	protocol and the client will default to using TLS 1.2 or later. If HTTP_PORT_DEFAULT is specified as the remote port, this option will automatically change the port number to use HTTP_PORT_SECURE instead.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1. Although this option may permit connections with servers which do not support current standards, avoid using it unless absolutely necessary. Some servers may reject the connection if the client offers to use TLS 1.0, even when TLS 1.2 or later is also supported.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create a version value and the following values are defined:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this session. This is the same as specifying HTTP_VERSION_11 and is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_09	The client should use the original one-line protocol which includes no version number and no request header block. This version has been deprecated and should only be used with legacy servers which do not support the protocol standard.

	This version of the protocol does not support virtual hosts and is not supported by most modern web services.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.
HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.
HTTP_VERSION_30	The client should use the HTTP/3 protocol standard defined in RFC 9114. This protocol version is similar to earlier versions of the protocol in terms the request methods and server responses, but the underlying transport mechanism is significantly different. Instead of using TCP, this version of the protocol uses multiplexed UDP connections designed to reduce the overhead of TCP while maintaining reliability. If the client or server does not support HTTP/3, the client will automatically attempt to use an earlier version of the protocol.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

If the HTTP_PROXY_WINDOWS proxy type is specified, then the proxy configuration for the local system is used. If no proxy server has been defined, then the proxy-related parameters will be ignored

and the function will establish a connection directly to the server.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
HTTP_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event occurs when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

Most applications should use HTTP_VERSION_DEFAULT as the value for the ***dwVersion*** parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support

the features required for a secure HTTP/2 connection.

If the HTTP_OPTION_KEEPALIVE option is specified and the server does not support persistent connections, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is automatically enabled when using HTTP/2.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return INVALID_CLIENT.

You should only attempt to use HTTP/3 if you know the server supports that version of the protocol. If the server does not support HTTP/3, the client will wait for the timeout period to elapse to determine the server is not responding to the HTTP/3 request and will then attempt to use HTTP/2. If you specify HTTP/3 as the protocol version and you are experiencing long delays for requests the complete, the most likely reason is the server does not support the QUIC protocol and every request is falling back to use HTTP/2 instead. The minimum required platform for HTTP/3 support is Windows 11 21H2 and later builds or Windows Server 2022 or later.

The handle returned by this function is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

To cancel asynchronous notification and return the client to a blocking mode, use the **HttpDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpAsyncPutData Function

```
UINT WINAPI HttpAsyncPutData(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPVOID lpvBuffer,
   DWORD dwLength,
   DWORD dwReserved,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Copies the contents of the specified buffer to a file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A null-terminated string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

lpvBuffer

The data that will be copied to the server and stored in the specified file.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPutData** function is used to upload the contents of a local buffer to the server. This function is similar to the **HttpPutData** function, however it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent to the server.

Because this function works asynchronously, it is important that the memory allocated for the buffer is

not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, ensure that your code does not return from the function while the data is being uploaded. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the transfer has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the ***lpvBuffer*** parameter on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

If the ***lpvBuffer*** parameter is pointing to a Unicode string, it is important to note that the value of the ***dwLength*** parameter should specify the number of bytes, not the number of characters. When using UTF-16, each character is two bytes long and therefore the length of the buffer is effectively double the length of the string. Because Unicode strings can contain null characters, you must also set the current file type to FILE_TYPE_IMAGE prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAsyncPutFile Function

```
UINT WINAPI HttpAsyncPutFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   DWORD dwOffset,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Uploads the specified file from the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error

information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPutFile** function is used to upload the contents of a local file to the server. This function is similar to the **HttpPutFile** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpAsyncGetData, HttpAsyncGetFile, HttpAsyncPutData, HttpEventProc, HttpPutFile, HttpTaskDone, HttpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpAsyncPutFileEx Function

```
UINT WINAPI HttpAsyncPutFileEx(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   ULARGE_INTEGER uiOffset,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Uploads the specified file from the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique

asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncPutFileEx** function is used to upload the contents of a local file to the server. This function is similar to the **HttpPutFileEx** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the HTTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **HttpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **HttpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **HttpTaskWait** function. To stop a background file transfer that is in progress, call the **HttpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpAsyncSubmitForm Function

```
UINT WINAPI HttpAsyncSubmitForm(
   HCLIENT hClient,
   HFORM hForm,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Submit the specified form to the server for processing and return the response to the caller.

Parameters

hClient

Handle to the client session.

hForm

Handle to the virtual form which contains the data to be submitted to the server.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the lpvBuffer parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_SUBMIT_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_SUBMIT_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **HttpAsyncSubmitForm** function is used to submit form data to a script that executes on the server and then copy the output from that script into a local buffer. This function is similar to the **HttpSubmitForm** function, however it submits the data using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent and the response from the server is being returned to the caller.

Because this function works asynchronously, it is important that the memory allocated for the *lpvResult* parameter will not be released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, ensure that your code does not return from the function until the background task completes. This can be achieved by calling the **HttpTaskWait** function or periodically calling the **HttpTaskDone** function to determine if the operation has completed. If you wish to return from the calling function immediately, then you must dynamically allocate the buffer on the heap and free that memory after the task has completed and the data is no longer needed.

Do not call the **HttpDestroyForm** function to release the memory allocated for the virtual form until the background task completes. Doing so may result in unpredictable behavior and could cause your application to terminate abnormally.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the HTTP_EVENT_CONNECT event after the connection has been established, and the HTTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated.

The *lpvResult* parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the server response or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the *lpcbResult* parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then *lpcbResult* must be initialized to a value of zero. See the example code below.

Example

```
HFORM hForm = INVALID_FORM;
HGLOBAL hgblResult = (HGLOBAL)NULL;
DWORD cbResult = 0;
INT nResult = 0;
UINT nTaskId;

hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);

if (hForm == INVALID_FORM)
    return;
```

```
HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);

nTaskId = HttpAsyncSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the task to complete
    HttpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);

    // Get a pointer to the data returned by the server
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer now points to data returned by the server after
    // the form data was submitted

    // Release the memory allocated for the buffer
    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}

// Release the memory allocated for the virtual form
HttpDestroyForm(hForm);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAttachThread Function

```
DWORD WINAPI HttpAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **HttpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **HttpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **HttpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **HttpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **HttpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpAuthenticate Function

```
INT WINAPI HttpAuthenticate(
   HCLIENT hClient,
   UINT nAuthType,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

Parameters

hClient

Handle to the client session.

nAuthType

An unsigned integer value which specifies the method to be used when authenticating the client. The following values are supported:

Value	Description
HTTP_AUTH_NONE	No client authentication should be performed. The ***lpszUserName*** and ***lpszPassword*** parameters are ignored and current authentication settings are cleared.
HTTP_AUTH_BASIC	The **Basic** authentication scheme should be used. This option is supported by all servers that support at least version 1.0 of the protocol. The user credentials are not encrypted and Basic authentication should not be used over standard (non-secure) connections. Most web services which use Basic authentication require the connection to be secure.
HTTP_AUTH_BEARER	The **Bearer** authentication scheme should be used. This authentication method does not require a user name and the ***lpszPassword*** parameter must specify the OAuth 2.0 bearer token issued by the service provider. If the access token has expired, the request will fail with an authorization error. This function will not automatically refresh an expired token.

lpszUserName

A null-terminated string which specifies the user name used to authenticate the client session. This parameter may be NULL or an empty string if a user name is not required for the specified authentication type. If the authentication type is HTTP_AUTH_BEARER, this parameter is ignored.

lpszPassword

A null-terminated string that specifies the password used to authenticate the client session. If the authentication type is HTTP_AUTH_BEARER, this value must be the bearer token issued by the service provider.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function will set the **`Authorization`** request header for the client session using the credentials

provided by the caller. This function will always override any custom **Authorization** header value that may have been previously set using the **HttpSetRequestHeader** function.

If both the *lpszUserName* and *lpszPassword* parameters are NULL pointers or specify zero-length strings, the current authentication type will always be set to HTTP_AUTH_NONE regardless of the value of the *nAuthType* parameter. This effectively clears the current user credentials for the client session.

If the web service requires OAuth 2.0 authentication, it is recommended you use the **HttpSetBearerToken** function to specify the access token.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)
Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpCancel Function

```
INT WINAPI HttpCancel(
   HCLIENT hClient
);
```

The **HttpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When the **HttpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpCancelQueuedFile Function

```
BOOL WINAPI HttpCancelQueuedFile(
    HQUEUE hQueue,
    DWORD dwFileId
);
```

The **HttpCancelQueuedFile** function cancels the queued file transfer.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. If this value is zero, the function will cancel the current file transfer in progress. If queue transfers have been suspended, this parameter cannot be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

When this function is called, the queued file transfer may not immediately stop. An internal flag is set which causes the file transfer to exit with an error and the queue manager will begin processing the next file in the queue. If the queue is in an idle state, this function will fail.

It is permitted to call **HttpCancelQueuedFile** from within a queue event handler to cancel the current file transfer. In this case, the *dwFileId* parameter should be zero. If you specify a file which has not been transferred, it will be flagged as canceled and skipped by the queue manager when processing the queue. If you specify a file which has already been processed, this function will fail.

A canceled file transfer is also considered a failed transfer. When you call **HttpGetQueueStatus** after a queued file transfer is canceled, the *dwFailedFiles* member of the HTTPQUEUESTATUS structure will be incremented to reflect this change. You can determine the status of an individual file transfer by calling the **HttpGetQueuedFile** function and checking the value of the *dwQueueFlags* member of the HTTPQUEUEDFILE structure.

The **HttpResetQueue** function can be used to reset the state of previously canceled transfers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpClearForm Function

```
INT WINAPI HttpClearForm(
    HFORM hForm
);
```

The **HttpClearForm** function clears the specified form, removing all fields.

Parameters

hForm

Handle to the virtual form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpClearHeaders Function

```
INT WINAPI HttpClearHeaders(
    HCLIENT hClient
);
```

The **HttpClearHeaders** function resets the current request and response headers to their default values.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, it will return HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpClearHeaders** function removes all custom header values for the current client session and clears the response headers for the previous request. This function is useful when using persistent connections and you want to ensure that any custom header values from the previous request will not be included with subsequent requests made during the same session. Because this function clears all of the request headers for the client session, this means it will also remove any cookies which have been set using the **HttpSetCookie** function.

This function will clear any authentication credentials or tokens specified for the current client session. If the next request you make requires authentication, you must provide those credentials again using the **HttpAuthenticate** or **HttpSetBearerToken** function.

It is not necessary to use this function if the **HTTP_OPTION_KEEPALIVE** option was not specified when the connection was established. The headers for the previous request are automatically cleared when a new connection is established.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpClearQueue Function

```
BOOL WINAPI HttpClearQueue(
    HQUEUE hQueue
);
```

The **HttpClearQueue** function removes all files from the queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function can only be called when the queue is in an idle state. An error will be returned if the function is called while the queue manager is paused or actively transferring files in the queue. To determine the current state of the queue, call the **HttpGetQueueStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpCloseFile Function

```
INT WINAPI HttpCloseFile(
   HCLIENT hClient
);
```

The **HttpCloseFile** function flushes the internal client buffers and closes the previously opened file on the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

If the file is opened for writing, all buffered data is written to the server before the file is closed. This may cause the client to block until all of the data can be written. The client application should not perform any other action until the function returns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpCommand, HttpGetData, HttpGetFile, HttpOpenFile, HttpPutData, HttpPutFile

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpCommand Function

```
INT WINAPI HttpCommand(
   HCLIENT hClient,
   LPCTSTR lpszCommand,
   LPCTSTR lpszResource,
   LPBYTE lpParameter,
   DWORD cbParameter,
   DWORD dwReserved
);
```

The **HttpCommand** function sends a command to the server and returns the result code back to the caller. This function is typically used for extended commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

A null-terminated string which specifies the command to be executed by the server. The following table lists the standard commands recognized by most HTTP servers. Other commands may also be used, such as those extensions used by WebDAV to edit and manage files on a server.

Command	Description
GET	Return the contents of the specified resource. This command is recognized by all servers.
HEAD	Return only header information for the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
POST	Post data to the specified resource. This command is recognized by servers that support at least version 1.0 of the protocol.
PUT	Create or replace the specified resource on the server. This command is recognized by servers that support at least version 1.0 of the protocol. Not all servers support this command.
DELETE	Delete the specified resource from the server. This command is recognized by servers that support at least version 1.1 of the protocol. Not all servers support this command.

lpszResource

A null-terminated string which specifies the resource to be used with the command. This can be the name of a file, an executable script or any other valid resource name recognized by the server. Resource names must be absolute and include the complete path to the resource.

lpParameter

A pointer to a byte array which contains data that is to be passed to the command as one or more parameters. Typically this is used to pass additional information to a script that executes on the server. The data is encoded according to the encoding type specified for the client session. If the resource does not require any parameters, this value should be NULL.

cbParameter

Specifies the number of bytes stored in the parameter buffer. If the resource does not require any

parameters, this value should be zero.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the result code returned by the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Not all servers support all of the listed commands, and some commands may require specific changes to the server configuration. In particular, the PUT and DELETE commands typically require that configuration changes be made by the site administrator. All servers will support the use of the GET command, and all servers that support at least version 1.0 of the protocol will support the POST command.

If the *lpszResource* parameter specifies a path that contains reserved or restricted characters, such as a space, it will automatically be URL encoded by the library.

It is permissible to include a query string in the resource name specified by the *lpszResource* parameter. Query strings begin with a question mark, and then are followed by one or more name/value pairs separated by an equal sign. For example, the following resource includes a query string:

/cgi-bin/test.cgi?field1=value1&field2=value2

In this case, the query string is "?field1=value1&field2=value2". If the query string contains reserved or restricted characters, such as spaces, then it will be automatically URL encoded prior to being sent to the server. If additional resource data is specified in the *lpParameter* argument along with a query string in the resource name, the action taken by the library depends on the command being sent. If the command is a POST or PUT command, then query string is included with command request to the server and the parameter data is sent separately. For example, if the POST command was used, the script running on the server would see that both query data and form data has been provided to it. However, if any other command is specified, the parameter data is simply appended to the query string.

The *lpParameter* argument is used to pass additional information to the server when a resource is requested. This is most commonly used to provide information to scripts, similar to how arguments are used when executing a program from the command line. Unless the POST command is being executed, the data in the buffer will automatically be encoded using the current encoding mechanism specified for the client. By default, the data is URL encoded, which means that any spaces and non-printable characters are converted to printable characters before submitted to the server. The type of encoding that is performed can be set by calling the **HttpSetEncodingType** function. Although the default encoding is appropriate for most applications, those that submit XML formatted data may need to change the encoding type.

Only one request may be in progress at one time for each client session. Use the **HttpCloseFile** function to terminate the request after all of the data has been read from the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

Unicode: Implemented as Unicode and ANSI versions

HttpConnect Function

```
HCLIENT WINAPI HttpConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   DWORD dwVersion,
   LPSECURITYCREDENTIALS lpCredentials
);
```

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration

	can be changed in the system settings or control panel.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. This option will always establish a secure connection with the server. The value of the ***dwVersion*** parameter will be ignored when this option is used.
HTTP_OPTION_HTTP3	This option specifies the client should attempt a HTTP/3 (QUIC) connection with the server. If a connection cannot be established using HTTP/3 the client will attempt a connection using an earlier version of the protocol. You should only use this option if you know the server supports the QUIC protocol, otherwise requests will be delayed as a result of the fallback to attempting a HTTP/2 connection. The value of the ***dwVersion*** parameter will be ignored when this option is used.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the client will default to using TLS 1.2 or

	later. If HTTP_PORT_DEFAULT is specified as the remote port, this option will automatically change the port number to use HTTP_PORT_SECURE instead.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1. Although this option may permit connections with servers which do not support current standards, avoid using it unless absolutely necessary. Some servers may reject the connection if the client offers to use TLS 1.0, even when TLS 1.2 or later is also supported.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create a version value, or the following values can be used:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this session. This is the same as specifying HTTP_VERSION_11 and is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_09	The client should use the original one-line protocol which includes no version number and no request header block. This version has been deprecated and should only be used with legacy servers which do not support the protocol standard. This version of the protocol does not support virtual hosts and

	is not supported by most modern web services.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.
HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.
HTTP_VERSION_30	The client should use the HTTP/3 protocol standard defined in RFC 9114. This protocol version is similar to earlier versions of the protocol in terms the request methods and server responses, but the underlying transport mechanism is significantly different. Instead of using TCP, this version of the protocol uses multiplexed UDP connections designed to reduce the overhead of TCP while maintaining reliability. If the client or server does not support HTTP/3, the client will automatically attempt to use an earlier version of the protocol.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

Most applications should use HTTP_VERSION_DEFAULT as the value for the ***dwVersion*** parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support

the features required for a secure HTTP/2 connection.

If the HTTP_OPTION_KEEPALIVE option is specified and the server does not support persistent connections, the client will automatically attempt to reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is automatically enabled when using HTTP/2.

Using the HTTP_OPTION_NOUSERAGENT option to prevent sending a User-Agent header does not make requests anonymous. Servers may still identify clients based on IP address information, authentication credentials, request patterns or other HTTP headers included with the request.

Under some circumstances, a server may forcibly close or abort a connection if the request fails. For example, this can happen when a malformed request is submitted to the server or a server-side error occurs. When this happens, the application will need to disconnect from the server and establish a new connection, even if the keep-alive option has been specified.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return INVALID_CLIENT.

You should only attempt to use HTTP/3 if you know the server supports that version of the protocol. If the server does not support HTTP/3, the client will wait for the timeout period to elapse to determine the server is not responding to the HTTP/3 request and will then attempt to use HTTP/2. If you specify HTTP/3 as the protocol version and you are experiencing long delays for requests the complete, the most likely reason is the server does not support the QUIC protocol and every request is falling back to use HTTP/2 instead. The minimum required platform for HTTP/3 support is Windows 11 21H2 and later builds or Windows Server 2022 or later.

The handle returned by this function is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpConnectUrl Function

```
HCLIENT WINAPI HttpConnectUrl(
    LPCTSTR lpszUrl,
    UINT nTimeout,
    DWORD dwOptions
);
```

The **HttpConnectUrl** function establishes a connection with the specified server using a URL.

Parameters

lpszUrl

A null-terminated string which specifies the URL for the server. The URL must follow the conventions for the Hypertext Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control panel.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the

	content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. This option will always establish a secure connection with the server. If this option is not specified, the connection will use HTTP/1.1 as the default protocol version.
HTTP_OPTION_HTTP3	This option specifies the client should attempt a HTTP/3 (QUIC) connection with the server. If a connection cannot be established using HTTP/3 the client will attempt a connection using an earlier version of the protocol. You should only use this option if you know the server supports the QUIC protocol, otherwise requests will be delayed as a result of the fallback to attempting a HTTP/2 connection.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the client will default to using TLS 1.2 or later. If HTTP_PORT_DEFAULT is specified as the remote port, this option will automatically change the port number to use HTTP_PORT_SECURE instead.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use

	of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1. Although this option may permit connections with servers which do not support current standards, avoid using it unless absolutely necessary. Some servers may reject the connection if the client offers to use TLS 1.0, even when TLS 1.2 or later is also supported.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpConnectUrl** function uses an HTTP URL to establish a connection with a server. The URL must be in the following format:

```
[http|https]://[username : password] @] hostname [:port] / [path / ...]
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified. The **HttpValidateUrl** function can be used to verify that a URL is valid prior to calling this function.

The **HttpConnectUrl** function is designed to provide a simpler, more convenient interface to establishing a connection with a server. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to use the lower-level connection functions. If you only need to upload or download a file using a URL, then refer to the **HttpUploadFile** and **HttpDownloadFile** functions.

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **HttpConnectUrl** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

Most applications should use HTTP_VERSION_DEFAULT as the value for the ***dwVersion*** parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support the features required for a secure HTTP/2 connection.

If the HTTP_OPTION_KEEPALIVE option is specified and the server does not support persistent connections, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is automatically enabled when using HTTP/2.

Using the HTTP_OPTION_NOUSERAGENT option to prevent sending a User-Agent header does not make requests anonymous. Servers may still identify clients based on IP address information, authentication credentials, request patterns or other HTTP headers included with the request.

If your application specifies the HTTP_OPTION_HTTP2 option, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of Windows do not support the features required for a secure HTTP/2 connection. If the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return INVALID_CLIENT.

You should only attempt to use HTTP/3 if you know the server supports that version of the protocol. If the server does not support HTTP/3, the client will wait for the timeout period to elapse to determine the server is not responding to the HTTP/3 request and will then attempt to use HTTP/2. If you specify HTTP/3 as the protocol version and you are experiencing long delays for requests the complete, the most likely reason is the server does not support the QUIC protocol and every request is falling back to use HTTP/2 instead. The minimum required platform for HTTP/3 support is Windows 11 21H2 and later builds or Windows Server 2022 or later.

The handle returned by this function is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
HCLIENT hClient;
LPCTSTR lpszUrl = _T("https://www.example.com/");

// Connect to the site specified by the URL
hClient = HttpConnectUrl(lpszUrl, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hClient == INVALID_CLIENT)
```

```
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION | MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpCreateFile Function

```
INT WINAPI HttpCreateFile(
   HCLIENT hClient,
   LPCTSTR lpszRemoteFile,
   DWORD dwLength,
   DWORD dwOffset
);
```

The **HttpCreateFile** function creates the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

Points to a string that specifies the name of the file being created on the server. The client must have the appropriate access rights to create the file or an error will be returned.

dwLength

Specifies the length of the file that will be created on the server. This value must be greater than zero.

dwOffset

Specifies a byte offset in the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to create the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpCreateFile** function uses the PUT command to create the file. The server must support this command and the user must have the appropriate permission to create the specified file. If this function is successful, the client should then use the **HttpWrite** function to send the contents of the file to the server. Once all of the data has been written, the **HttpCloseFile** function should be called to close the file and complete the operation. Note that this function is typically only accepted by servers that support version 1.1 of the protocol or later.

When using **HttpWrite** to send the contents of the file to the server, it is recommended that the data be written in logical blocks that are no larger than 8,192 bytes in size. Attempting to write very large amounts of data in a single call can either cause the thread to block or, in the case of an asynchronous connection, return an error if the internal buffers cannot accommodate all of the data. To send the entire contents of a file in a single function call, use the **HttpPutData** function instead of calling **HttpCreateFile**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpCreateFileEx Function

```
INT WINAPI HttpCreateFileEx(
   HCLIENT hClient,
   LPCTSTR lpszRemoteFile,
   ULARGE_INTEGER uiLength,
   ULARGE_INTEGER uiOffset
);
```

The **HttpCreateFileEx** function creates the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

Points to a string that specifies the name of the file being created on the server. The client must have the appropriate access rights to create the file or an error will be returned.

uiLength

Specifies the length of the file that will be created on the server. This value must be greater than zero.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to create the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpCreateFileEx** function uses the PUT command to create the file. The server must support this command and the user must have the appropriate permission to create the specified file. If this function is successful, the client should then use the **HttpWrite** function to send the contents of the file to the server. Once all of the data has been written, the **HttpCloseFile** function should be called to close the file and complete the operation. Note that this function is typically only accepted by servers that support version 1.1 of the protocol or later.

When using **HttpWrite** to send the contents of the file to the server, it is recommended that the data be written in logical blocks that are no larger than 8,192 bytes in size. Attempting to write very large amounts of data in a single call can either cause the thread to block or, in the case of an asynchronous connection, return an error if the internal buffers cannot accommodate all of the data. To send the entire contents of a file in a single function call, use the **HttpPutData** function instead of calling **HttpCreateFileEx**.

HttpCreateForm Function

```
HFORM WINAPI HttpCreateForm(
   LPCTSTR lpszAction,
   UINT nFormMethod,
   UINT nFormType,
   DWORD dwReserved
);
```

The **HttpCreateForm** function creates a new form and returns a handle for use with the other form-related functions.

Parameters

lpszAction

A null-terminated string which specifies the name of the resource that the form data will be submitted to. Typically this is the name of a script that is executed on the server.

nFormMethod

An unsigned integer value which specifies how the form data will be submitted to the server. This parameter may be one of the following values:

Value	Description
HTTP_METHOD_DEFAULT	The form data should be submitted using the default method, using the GET command.
HTTP_METHOD_GET	The form data should be submitted using the GET command. This method should be used when the amount of form data is relatively small. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used instead.
HTTP_METHOD_POST	The form data should be submitted using the POST command. This is the preferred method of submitting larger amounts of form data. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used.

nFormType

An unsigned integer value which specifies the type of form and how the data will be encoded when it is submitted to the server. This parameter may be one of the following values:

Value	Description
HTTP_FORM_DEFAULT	The form data should be submitted using the default encoding method.
HTTP_FORM_ENCODED	The form data should be submitted as URL encoded values. This is typically used when the GET method is used to submit the data to the server.
HTTP_FORM_MULTIPART	The form data should be submitted as multipart form data. This is typically used when the POST method is used to submit a file to the server. Note that the script must understand how to process multipart form data if this form type is specified.

dwReserved

A reserved parameter. This value must be zero.

Return Value

If the function succeeds, the return value is a handle to the virtual form. If the function fails, the return value is INVALID_FORM. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpCreateForm** function is used to create a new form that will be populated with values and then submitted to the server for processing. When the form is no longer needed, it should be destroyed using the **HttpDestroyForm** function.

Example

```
HFORM hForm = INVALID_FORM;
HGLOBAL hgblResult = (HGLOBAL)NULL;
DWORD cbResult = 0;
INT nResult = 0;

hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);

if (hForm == INVALID_FORM)
    return;

HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);

nResult = HttpSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);
HttpDestroyForm(hForm);

if (hgblResult != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer points to data returned by the server after the form
    // data was submitted

    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpCreateQueue Function

```
HQUEUE WINAPI HttpCreateQueue(
    UINT nMaxFiles,
    UINT nTimeout,
    DWORD dwOptions
);
```

The **HttpCreateQueue** function creates new file transfer queue.

Parameters

nMaxFiles

An unsigned integer which specifies the maximum number of files which can be added to the queue. The constant INFINITE can be used to specify that there is no fixed limit to the number of files in the queue.

nTimeout

An unsigned integer which specifies the default timeout for all queued file transfers. If this value is zero, a reasonable default timeout period will be used. This timeout period is used when a file is added to the queue without providing a timeout period for that specific file transfer. If a timeout period is specified for a particular file, it will override this value.

dwOptions

An unsigned integer value which specifies one or more default options for all queued files. This parameter is constructed by using a bitwise operator and can be any of the options used with the **HttpConnect** function. If transfer options are specified for a particular file, it will override this value. The most common options are:

Value	Description
HTTP_OPTION_DEFAULT	Default options should be used for queued file transfers. All standard headers will be included with the request and redirected resources will return an error, allowing the application to determine if it should request the resource from the new location or inform the user the resource location has changed.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control panel.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect

	using an earlier version of the protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.

Return Value

If the function succeeds, the return value is a handle to the queue which can be used with subsequent function calls. If the function fails, the return value is INVALID_QUEUE. To get extended error information, call **HttpGetLastError**.

Remarks

If the *nMaxFiles* parameter is INFINITE, memory will be dynamically allocated on the process heap with no limit to the number of files which can be queued. If there is a logic error which causes the application to recursively add files to the queue, or repeatedly queue the same file, this can result in virtual memory being exhausted for the process. You can avoid this by specifying a reasonable maximum queue size, which will cause the **HttpAddQueuedFile** function to fail if that limit is exceeded.

The memory allocated for the queue will be released when the **HttpDeleteQueue** function is called.

Example

```
// Create a new queue
HQUEUE hQueue = HttpCreateQueue(INFINITE, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = HttpAddQueuedFile(
                     hQueue,
                     lpszLocalFile,
                     lpszRemoteFile,
                     HTTP_OPTION_DEFAULT,
                     HTTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case HTTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case HTTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
```

```
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
            }
        }
    }

    // Start the queued file transfers and wait for it to complete
    if (HttpStartQueue(hQueue, HTTP_QUEUE_ALL, 0, NULL, 0))
    {
        HttpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
        HttpStopQueue(hQueue);
    }

    // Remove all files from the queue
    HttpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpCreateSecurityCredentials Function

```
BOOL WINAPI HttpCreateSecurityCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **HttpCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **HttpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **HttpGetLastError** function.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **HttpConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
HttpCreateSecurityCredentials(SECURITY_PROTOCOL_DEFAULT,
                              0,
                              NULL,
                              NULL,
                              lpszCertStore,
                              lpszCertName,
                              NULL,
                              &lpSecCred);

hClient = HttpConnect(lpszHostName,
                      HTTP_PORT_SECURE,
                      HTTP_TIMEOUT,
                      HTTP_OPTION_SECURE | HTTP_OPTION_KEEPALIVE,
                      HTTP_VERSION_11,
                      lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpConnect, HttpDeleteSecurityCredentials, HttpGetSecurityInformation, HttpProxyConnect, SECURITYCREDENTIALS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpDeleteFile Function

```
INT WINAPI HttpDeleteFile(
   HCLIENT hClient,
   LPCTSTR lpszFileName
);
```

The **HttpDeleteFile** function deletes the specified file from the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to delete. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function uses the DELETE command to delete the specified file from the server. The server must be configured to support this command, and client must have the appropriate permission to delete the file, or an error will be returned.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpDeleteFormField Function

```
INT WINAPI HttpDeleteFormField(
   HFORM hForm,
   LPCTSTR lpszFieldName
);
```

The **HttpDeleteFormField** function deletes the specified field from the form.

Parameters

hForm

Handle to the virtual form.

lpszFieldName

Points to a string that specifies the name of the field to delete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpDeleteHeaders Function

```
BOOL WINAPI HttpDeleteHeaders(
    HCLIENT hClient,
    UINT nHeaderType
);
```

Delete all of the response or request headers for the current session.

Parameters

hClient

Handle to the client session.

nHeaderType

Specifies the type of header to delete. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Delete all of the request headers that have been set for the next request sent to the server. This will clear all of the header values that were set using the **HttpSetRequestHeader** function.
HTTP_HEADERS_RESPONSE	Delete all of the headers that were set in response to the previous request. A call to the **HttpGetResponseHeader** function to obtain a specific header value will fail after this function returns.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpDeleteHeaders** function will release the memory allocated for the request or response headers for the current session. This function is typically used to clear all of the current request headers so that the application may create a new set of headers when a persistent connection is being used. The memory allocated for the request and response headers is normally released when the session handle is closed by calling the **HttpDisconnect** function.

Whenever a request for a resource is sent to the server, the response headers from the previous request are automatically cleared. It is not necessary for an application to call the **HttpDeleteHeaders** function to delete the response headers prior to each request.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpDeleteQueue Function

```
BOOL WINAPI HttpDeleteQueue(
    HQUEUE hQueue
);
```

The **HttpDeleteQueue** function deletes the specified file transfer queue, releasing all memory allocated for the queued files.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function can only be called when the queue is in an idle state. If the queue manager is in the process of uploading or downloading files, the function will fail and return a value of zero. You can determine the current state of the queue by calling the **HttpGetQueueStatus** function. It is not necessary to explicitly clear the queue prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpDeleteSecurityCredentials Function

```
VOID WINAPI HttpDeleteSecurityCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **HttpDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)
    HttpDeleteSecurityCredentials(&lpSecCred);

HttpUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpCreateSecurityCredentials, HttpUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpDestroyForm Function

```
INT WINAPI HttpDestroyForm(
    HFORM hForm
);
```

The **HttpDestroyForm** function destroys the specified form, releasing the memory allocated for it.

Parameters

hForm

Handle to the form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpDisableEvents Function

```
INT WINAPI HttpDisableEvents(
    HCLIENT hClient
);
```

The **HttpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpEnableEvents, HttpFreezeEvents, HttpRegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpDisableTrace Function

```
BOOL WINAPI HttpDisableTrace();
```

The **HttpDisableTrace** function disables the logging of network function calls.

Parameters

None.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpDisconnect Function

```
INT WINAPI HttpDisconnect(
   HCLIENT hClient
);
```

The **HttpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpDownloadFile Function

```
BOOL WINAPI HttpDownloadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   UINT nTimeout
   DWORD dwOptions
   LPHTTPTRANSFERSTATUS lpStatus
   HTTPEVENTPROC lpEventProc
   DWORD_PTR dwParam
);
```

The **HttpDownloadFile** function downloads the specified file from the server to the local system.

Parameters

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.

HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

lpStatus

A pointer to an HTTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpDownloadFile** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then download the file to the local system. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @] hostname [:port] / [path / ...]
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return a value of zero.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **HttpDownloadFile** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpGetFile** to download the file.

Example

```
HTTPTRANSFERSTATUS httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile = _T("http://www.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = HttpDownloadFile(lpszLocalFile,
                           lpszRemoteFile,
                           HTTP_OPTION_DEFAULT,
                           &httpStatus,
                           NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpDownloadFileEx Function

```
BOOL WINAPI HttpDownloadFileEx(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   UINT nTimeout
   DWORD dwOptions
   LPHTTPTRANSFERSTATUSEX lpStatus
   HTTPEVENTPROC lpEventProc
   DWORD_PTR dwParam
);
```

The **HttpDownloadFileEx** function downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.

HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

lpStatus

A pointer to an HTTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpDownloadFileEx** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then download the file to the local system. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @] hostname [:port] / [path / ...]
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return a value of zero.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **HttpDownloadFileEx** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpGetFile** to download the file.

Example

```
HTTPTRANSFERSTATUSEX httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile = _T("http://www.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = HttpDownloadFileEx(lpszLocalFile,
                             lpszRemoteFile,
                             HTTP_OPTION_DEFAULT,
                             &httpStatus,
                             NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpEnableCompression Function

```
INT WINAPI HttpEnableCompression(
    HCLIENT hClient,
    BOOL bEnable
);
```

The **HttpEnableCompression** function enables or disables support for data compression.

Parameters

hClient

Handle to the client session.

bEnable

A boolean value which specifies if data compression should be enabled or disabled. A non-zero value enables compression, while a value of zero will disable compression.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpEnableCompression** function is used to indicate to the server whether or not it is acceptable to compress the data that is returned to the client. If compression is enabled, the client will advertise that it will accept compressed data by setting the **Accept-Encoding** request header. The server will decide whether a resource being requested can be compressed. If the data is compressed, the library will automatically expand the data before returning it to the caller.

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. Disabling compression informs the server that the client is not willing to accept compressed data; this is the default.

If the **HttpSetRequestHeader** function is used to explicitly set the **Accept-Encoding** header to request compressed data and compression is not enabled, the library will not attempt to automatically expand the data returned by the server. In this case, the raw compressed data will be returned to the caller and the application is responsible for processing it. This behavior is by design to maintain backwards compatibility with previous versions of the library that did not have internal support for compression.

To determine if the server compressed the data returned to the client, use the **HttpGetResponseHeader** function to get the value of the **Content-Encoding** header. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

Enabling compression is only meaningful when downloading files from a server that supports file compression. It has no effect on file uploads.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpEnableEvents Function

```
INT WINAPI HttpEnableEvents(
    HCLIENT hClient,
    HWND hEventWnd,
    UINT uEventMsg
);
```

The **HtpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **HttpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER. If the ***hEventWnd*** parameter is NULL, this value must be specified as WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
HTTP_EVENT_CONNECT	The connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.

HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving data from the server. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event occurs when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

As noted, some events are only generated when the client is asynchronous mode. These events depend on the Windows Sockets asynchronous notification mechanism.

If event notification is disabled by specifying a NULL window handle, there may still be outstanding events in the message queue that must be processed. Since event handling has been disabled, these events should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpEnableTrace Function

```
BOOL WINAPI HttpEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **HttpEnableTrace** function enables the logging of Windows Sockets function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

When logging is enabled for HTTP/2 and HTTP/3 client sessions, it is normal to see HTTP/1.1 in the

request and server response. They are binary protocols and the request and response header blocks emulate a standard HTTP/1.1 text response for backwards compatibility. Applications running on the server should work in the same way regardless of which protocol version is selected, however it is possible to check the server environment to determine which version of HTTP was used with the request.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpEnumQueuedFiles Function

```
LONG WINAPI HttpEnumQueuedFiles(
   HQUEUE hQueue,
   LPCTSTR lpszFileMask,
   DWORD dwQueueMode,
   DWORD dwExcludeFiles,
   LPDWORD lpFileList,
   LONG nMaxFiles
);
```

The **HttpEnumQueuedFiles** function returns a list of files in the current transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpszFileMask

A null-terminated string which specifies a file name which can include wildcards. Only those files which match this value will be enumerated. The character '?' will match against any single character, and '*' will match any number of characters. If this parameter is NULL or points to an empty string, all eligible files in the queue will be matched.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. Only those files which match the queue mode will be enumerated. This is a bitmask which may be one or more of the following values:

Constant	Description
HTTP_QUEUE_ALL	Match the file name to all files in the queue.
HTTP_QUEUE_DOWNLOAD	Match file names which are queued for download.
HTTP_QUEUE_UPLOAD	Match file names which are queued for upload.
HTTP_QUEUE_LOCAL	Match against the local file name instead of the remote file name.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the enumeration. If this value is zero, no files will be excluded; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_QUEUE_FLAG_NONE	No files should be excluded.
HTTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
HTTP_QUEUE_FLAG_FAILED	Exclude files which where not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.

HTTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the **HttpCancelQueuedFile** function has been called and a queued file is in the process of being uploaded or downloaded.

lpFileList

A pointer to an array of unsigned integer values which will contain the unique file identifiers for each matching file in the queue. This parameter must specify an array large enough to store all of the file identifiers, otherwise the function will fail with a ST_ERROR_BUFFER_TOO_SMALL error. If this parameter is NULL, the function will return the number of matching files.

nMaxFiles

An integer value which specifies the maximum number of file identifiers which can be copied into the *lpFileList* array. If the *lpFileList* parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of matching files. If the queue is empty or there are no matching files, this function will return zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function populates an array of unique file identifiers which can be used to obtain information about the files in the current queue. The values returned in the *lpFileList* array can be used in conjunction with the **HttpGetQueuedFile** function. This provides an alternative to using the **HttpGetFirstQueuedFile** and **HttpGetNextQueuedFile** functions.

The application should not make any assumptions about the value of the file identifiers returned by this function. They should be considered opaque values which are only guaranteed to uniquely identify a file in the transfer queue. In particular, there is no guarantee that the file identifiers will be sequential and they should not be used as index values into an array.

Example

```
// Get the total number of files in the queue
LONG nFiles = HttpEnumQueuedFiles(hQueue, NULL, HTTP_QUEUE_ALL,
HTTP_QUEUE_FLAG_NONE, NULL, 0)

// Display information about the queued files
if (nFiles > 0)
{
    DWORD *pdwFileList = new DWORD[nFiles];

    nFiles = HttpEnumQueuedFiles(hQueue, NULL, HTTP_QUEUE_ALL,
HTTP_QUEUE_FLAG_NONE, pdwFileList, nFiles);

    for (LONG nIndex = 0; nIndex < nFiles; nIndex++)
    {
        HTTPQUEUEDFILE queuedFile;

        if (HttpGetQueuedFile(hQueue, pdwFileList[nIndex], &queuedFile) == FALSE)
            break;

        switch (queuedFile.dwMode)
        {
```

```
        case HTTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        queuedFile.dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case HTTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        queuedFile.dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
        }
    }

    delete pdwFileList;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpEnumTasks Function

```
INT WINAPI HttpEnumTasks(
   UINT *lpTasks,
   INT nMaxTasks,
   DWORD dwOptions
);
```

Return a list of active, suspended or finished asynchronous tasks.

Parameters

lpTasks

A pointer to an array of unsigned integer values that will contain unique task identifiers when the function returns. If this parameter is NULL, the function will return the number of tasks.

nMaxTasks

An integer value that specifies the maximum number of task identifiers that may be copied into the ***lpTasks*** array. If the ***lpTasks*** parameter is NULL, this value must be zero.

dwOptions

An unsigned integer that specifies the type of asynchronous tasks that may be returned by this function. It may be a combination of the following values:

Value	Description
HTTP_TASK_DEFAULT	The list of asynchronous task IDs should include both active and suspended tasks. This option is the same as specifying both the HTTP_TASK_ACTIVE and HTTP_TASK_SUSPENDED options.
HTTP_TASK_ACTIVE	The list of asynchronous task IDs should include those tasks which are currently active. An active task represents a background connection to a server that is in the process of performing the requested action, such as uploading or downloading a file.
HTTP_TASK_SUSPENDED	The list of asynchronous task IDs should include those tasks which have been suspended. A suspended task represents a background connection that has been established, but the worker thread is not scheduled for execution.
HTTP_TASK_FINISHED	The list of asynchronous task IDs should include those tasks which have completed recently.

Return Value

If the function is successful, the return value is the number of task identifiers copied into the provided array. If there are no tasks which match the requested criteria, the return value is zero. A return value of HTTP_ERROR indicates an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpEnumTasks** function can be used to obtain a list of numeric identifiers that represent the asynchronous tasks that have been started or those that have completed. These task IDs are used by other functions to reference the background worker thread that has been created and obtain status

information for the task. For example, the **HttpTaskDone** function can be used to determine if a particular task has completed, and the **HttpTaskWait** function can be used to wait for a task to complete and return an error status code if the background operation failed.

There is an internal limit of 128 asynchronous tasks per process that may be active at any one time. When a task completes, the status information about that task is maintained for period of time after the task has completed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpEventProc Function

```
VOID CALLBACK HttpEventProc(
   HCLIENT hClient,
   UINT nEvent,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **HttpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **HttpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **HttpRegisterEvent** function. This callback function is also used by asynchronous tasks to notify the application when the task has started and completed. The **HttpEventProc** function is a placeholder for the application-defined function name.

If the callback function is invoked by an asynchronous task, it will execute in the context of the worker thread that is managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function for an asynchronous task. Controls should only be modified by the same UI thread that created their window. One common approach to resolve this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpFindQueuedFile Function

```
DWORD WINAPI HttpFindQueuedFile(
    HQUEUE hQueue,
    LPCTSTR lpszFileName,
    DWORD dwQueueMode,
    DWORD dwExcludeFiles
);
```

The **HttpFindQueuedFile** function finds a file in the transfer queue which matches the search criteria.

Parameters

hQueue

A handle to a file transfer queue.

lpszFileName

A null-terminated string which specifies the name of the file to search for. The string may contain the wildcard character '?' to match against any single character, and '*' will match any number of characters. This parameter cannot be NULL or point to an empty string.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. This is a bitmask which may be one or more of the following values:

Constant	Description
HTTP_QUEUE_ALL	Match the file name to all files in the queue.
HTTP_QUEUE_DOWNLOAD	Match file names which are queued for download.
HTTP_QUEUE_UPLOAD	Match file names which are queued for upload.
HTTP_QUEUE_LOCAL	Match against the local file name instead of the remote file name.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the search. If this value is zero, no files will be excluded from the search; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_QUEUE_FLAG_NONE	No files should be excluded from the search.
HTTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
HTTP_QUEUE_FLAG_FAILED	Exclude files which where not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.
HTTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the

	HttpCancelQueuedFile function has been called and a queued file is in the process of being uploaded or downloaded.

Return Value

If the function succeeds, the return value is a unique identifier for the file. To obtain information about the file, call the **HttpGetQueuedFile** function. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns a unique file identifier for the first file which matches the specified file name in the queue. If the *lpszFileName* parameter includes wildcard characters, this function will return the first file in the queue which matches the name. File name matches are not case-sensitive, even when matching against remote file names on servers which use case-sensitive naming, such as UNIX based servers.

To perform more complex searches based on the file name, or to find multiple files, you can use the **HttpGetFirstQueuedFile** and **HttpGetNextQueuedFile** functions to iterate through all queued files.

Example

```
// Find a local file in the download queue
DWORD dwFileId = HttpFindQueuedFile(
                    hQueue,
                    lpszFileName,
                    HTTP_QUEUE_DOWNLOAD | HTTP_QUEUE_LOCAL,
                    HTTP_QUEUE_FLAG_NONE);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case HTTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case HTTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpFreezeEvents Function

```
INT WINAPI HttpFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **HttpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpGetBearerToken Function

```
INT WINAPI HttpGetBearerToken(
   HCLIENT hClient,
   LPTSTR lpszBearerToken,
   INT nMaxLength
);
```

The **HttpGetBearerToken** function returns the OAuth 2.0 bearer token used to authenticate the client session with a web service.

Parameters

hClient

Handle to the client session.

lpszBearerToken

A null-terminated string buffer which will contain the bearer token when the function returns. The string will be null-terminated and the buffer must be large enough to accommodate the entire bearer token or the function will fail. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that may be copied into the string buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the length of the bearer token string. A return value of zero indicates that no bearer token has been specified. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns the bearer token which was previously set by a call to **HttpSetBearerToken**. Bearer tokens can be very long strings and do not contain any human readable information. For Google services, these tokens are usually about 180 characters in length. For Microsoft services, their bearer tokens are typically 1,200 characters in length. It is recommended that you provide a buffer size of at least 2,000 characters.

Your application should not store the bearer tokens provided by a web service. These tokens are short-lived and typically only valid for about an hour. If the token has expired, the authorization to access the resource will fail and it must be refreshed. The refresh tokens used to acquire a new bearer token should be stored and they are typically valid for a period of months.

Requirements

HttpGetContentLength Function

```
BOOL WINAPI HttpGetContentLength(
    HCLIENT hClient,
    LPDWORD lpdwLength
);
```

The **HttpGetContentLength** function returns the size of the current resource in bytes.

Parameters

hClient

Handle to the client session.

lpdwLength

A pointer to a unsigned integer which will contain the content length for the current resource. This value will be initialized to zero and updated with the length when the function returns.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

When this function is called after a GET or POST request has completed, the ***lpdwLength*** parameter will contain the total number of bytes returned by the server. If this function is called while a request is being processed (for example, from within an event handler), it will return the value of the Content-Length response header provided by the server. If it's possible the server will return more than 4GiB of data to the client, the **HttpGetContentLengthEx** function should be used. That version of the function accepts an unsigned 64-bit integer and will prevent the content length from being truncated to a 32-bit value.

Most servers will only include a Content-Length header in the response for static resources like documents or image files. For other types of resources where the response payload is generated dynamically, such as server-side scripts, servers typically use "chunked" output and there is no Content-Length header. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. In this case, the content length can only be determined after the request has completed.

This function should only be used after a request has completed and will not return a value for dynamic resources as they are being retrieved from the server. To obtain the current number of bytes copied from within an event handler, use the **HttpGetTransferStatus** function.

If the content type for the current resource is textual, the content length reported by the server may be different than what is stored on the local system due to different end-of-line character conventions. For example, on Windows the end of a line of text is indicated by a carriage-return and linefeed pair, while on Linux the end-of-line is indicated by a single linefeed. Depending on the options specified when the request is made, text returned by the server may be normalized for the Windows platform.

This function does not use the HEAD command to request the size of a document on the server. It will only return the content length of a resource which has already been requested, typically after using functions such as **HttpGetText** or **HttpPostXml**. To ask the server for the size of document without downloading the contents of that document, use the **HttpGetFileSize** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpGetContentLengthEx Function

```
BOOL WINAPI HttpGetContentLengthEx(
   HCLIENT hClient,
   ULARGE_INTEGER *lpLength
);
```

The **HttpGetContentLengthEx** function returns the size of the current resource in bytes.

Parameters

hClient

Handle to the client session.

lpLength

A pointer to a ULARGE_INTEGER union which will contain the content length for the current resource. This value will be initialized to zero and updated with the length when the function returns.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

When this function is called after a GET or POST request has completed, the ***lpLength*** parameter will contain the total number of bytes returned by the server. If this function is called while a request is being processed (for example, from within an event handler), it will return the value of the Content-Length response header provided by the server. This version of the function accepts an unsigned 64-bit integer as the ***lpLength*** parameter and is intended to support very large documents which exceed 4GiB.

Most servers will only include a Content-Length header in the response for static resources like documents or image files. For other types of resources where the response payload is generated dynamically, such as server-side scripts, servers typically use "chunked" output and there is no Content-Length header. In this case, the content length can only be determined after the request has completed.

This function should only be used after a request has completed and will not return a value for dynamic resources as they are being retrieved from the server. To obtain the current number of bytes copied from within an event handler, use the **HttpGetTransferStatusEx** function.

If the content type for the current resource is textual, the content length reported by the server may be different than what is stored on the local system due to different end-of-line character conventions. For example, on Windows the end of a line of text is indicated by a carriage-return and linefeed pair, while on Linux the end-of-line is indicated by a single linefeed. Depending on the options specified when the request is made, text returned by the server may be normalized for the Windows platform.

This function does not use the HEAD command to request the size of a document on the server. It will only return the content length of a resource which has already been requested, typically after using functions such as **HttpGetText** or **HttpPostXml**. To ask the server for the size of document without downloading the contents of that document, use the **HttpGetFileSizeEx** function.

HttpGetContentType Function

```
INT WINAPI HttpGetContentType(
   HCLIENT hClient,
   LPTSTR lpszContentType,
   INT nMaxLength
);
```

The **HttpGetContentType** function returns the content type for the current resource.

Parameters

hClient

Handle to the client session.

lpszContentType

A buffer which will contain the MIME content type of the resource returned by the web server. The buffer must be large enough to contain the entire content type string including the terminating null character. This parameter is optional and may be NULL if the information is not required.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the buffer. If the ***lpszContentType*** parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the value indicates the type of resource returned by the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Value	Description
HTTP_CONTENT_UNKNOWN	The content type for the resource could not be determined. This can occur if the content type returned by the server does not match a known value, such as an experimental or non-standard content type.
HTTP_CONTENT_BINARY	Application specific binary data which doesn't explicitly fall into any of the other standard MIME types. The most common type for binary data is application/octet-stream which can represent any type of data. Other examples are application/pdf and application/zip.
HTTP_CONTENT_TEXT	Textual data which can include plain text, HTML documents, XML, comma-separated value (CSV) data or any other human readable text formats. Examples are text/plain and text/html.
HTTP_CONTENT_AUDIO	Audio data which can include MEPG audio and Windows Media formats. Examples are audio/mpeg, audio/mp4 and audio/x-ms-wma.
HTTP_CONTENT_IMAGE	Image data which can include GIF, JPEG and PNG image formats. Examples are image/gif and image/jpeg.
HTTP_CONTENT_MESSAGE	A content type which specifies the response includes other messages, typically email messages in a standard MIME format. This content type is not commonly used with web

	services.
HTTP_CONTENT_MULTIPART	A content type which includes multiple types of data in a single response. The payload will typically be encoded text and the contents will need to be decoded to extract any binary data included in the message.
HTTP_CONTENT_VIDEO	Video data which can include MP4 movies or Window Media format video. Examples are video/mp4 and video/x-ms-wmv.
HTTP_CONTENT_FONT	Font data which can include TrueType and OpenType fonts. Examples are font/tff and font/otf.
HTTP_CONTENT_MODEL	Model data for 3D objects and scenes, such as those used with the Virtual Reality Modeling Language (VRML). Examples are model/3mf and model/vrml.

Remarks

This function does not examine the contents of the payload returned by the server and only returns a value based on the Content-Type response header. If the web server does not recognize the data format of the resource it is returning, it should identify it as **application/octet-stream** and the content type would be returned as HTTP_CONTENT_BINARY. However, some servers incorrectly return unrecognized formats as **text/plain**, causing the payload to be identified as human-readable text rather than binary data.

Some servers will return a content type of **text/plain** for JSON responses and others will use the IANA standard type of **application/json**. To ensure consistency with these two content types, this function will always return MIME_CONTENT_TEXT for JSON responses.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpGetCookie Function

```
BOOL WINAPI HttpGetCookie(
   HCLIENT hClient,
   LPCTSTR lpszCookieName,
   LPTSTR lpszCookieValue,
   INT nCookieValue,
   LPTSTR lpszCookiePath,
   INT nCookiePath,
   LPTSTR lpszCookieDomain,
   INT nCookieDomain,
   LPSYSTEMTIME lpCookieExpires,
   LPDWORD lpdwCookieFlags
);
```

The **HttpGetCookie** function returns information about a cookie set by the server.

Parameters

hClient

Handle to the client session.

lpszCookieName

A null-terminated string which specifies the name of the cookie to return information about.

lpszCookieValue

A null-terminated string buffer that will contain the value of the cookie. If this information is not required, a NULL pointer may be specified.

nCookieValue

The maximum number of characters that may be copied into the buffer specified by the *lpszCookieValue* parameter, including the terminating null character.

lpszCookiePath

A null-terminated string buffer that will contain the cookie path. If this information is not required, a NULL pointer may be specified.

nCookiePath

The maximum number of characters that may be copied into the buffer specified by the *lpszCookiePath* parameter, including the terminating null character.

lpszCookieDomain

A null-terminated string buffer that will contain the cookie domain. If this information is not required, a NULL pointer may be specified.

nCookieDomain

The maximum number of characters that may be copied into the buffer specified by the *lpszCookieDomain* parameter, including the terminating null character.

lpCookieExpires

A pointer to a SYSTEMTIME structure which specifies the date and time that the cookie expires. If this information is not required, a NULL pointer may be specified.

lpdwCookieFlags

One or more bit flags which specify status information about the cookie. A value of zero indicates that there are no special status flags for the cookie. This parameter may be NULL if the information

is not required. The following values are currently defined:

Value	Description
HTTP_COOKIE_SECURE	This flag specifies that the cookie should only be provided to the server if the connection is secure.
HTTP_COOKIE_SESSION	This flag specifies that the cookie should only be used for the current application session and should not be stored permanently on the local system.

Return Value

If the function succeeds, the return value is non-zero. If the specified cookie does not exist or function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The Hypertext Transfer Protocol uses special tokens called "cookies" to maintain persistent state information between requests for a resource. These cookies are exchanged between the client and server by setting specific header fields. When a server wants the client to use a cookie, it will include a header field named Set-Cookie in the response header when the client requests a resource. The client can then take this cookie and store it, either temporarily in memory or permanently in a file on the local system. The next time that the client requests a resource from that server, it can send the cookie back to the server by setting the Cookie header field. The **HttpGetCookie** function searches for a cookie set by the server in the Set-Cookie header field. The **HttpSetCookie** function creates or modifies the Cookie header field for the next resource requested by the client.

There are two general types of cookies that are used by servers. Session cookies exist only for the duration of the client session; they are stored in memory and not saved in any kind of permanent storage. When the client application terminates, session cookies are deleted and no longer used. Persistent cookies are stored on the local system and are used by the client until their expiration time. It is the responsibility of the client application to store persistent cookies; applications may use a flat text file, a database or any other storage method available.

In addition to the cookie name and value, the server may return additional information about the cookie which the client should use to determine if it should send the cookie back to the server:

The ***cookie path*** specifies a path for the resources where the cookie should be used. For example, a path of "/" indicates that the cookie should be provided for all resources requested from the server. A path of "/data" would mean that the cookie should be included if the resource is found in the /data folder or a sub-folder, such as /data/projections.asp. However, the cookie would not be provided if the resource /info/status.asp was requested, since it is not in the /data path.

The ***cookie domain*** specifies the domain for which the cookie should be used. Matches are made by comparing the name of the server against the domain name specified in the cookie. If the domain is example.com, then any server in the example.com domain would match; for example, both shipping.example.com and orders.example.com would match the domain value. However, if the cookie domain was orders.example.com, then the cookie would only be sent if the resource was requested from orders.example.com, not if the resource was located on shipping.example.com or www.example.com.

The ***cookie expiration*** specifies the date and time that the cookie should be deleted and no longer sent when a resource is requested from the server. This is only valid for persistent cookies, since session cookies are automatically deleted when the client application

terminates. The time is always expressed as Coordinated Universal Time.

The ***cookie flags*** provide additional information about the cookie. In some cases, a cookie should only be submitted to the server if the resource is requested using a secure connection. In this case, the bit flag HTTP_COOKIE_SECURE will be set.

It is the responsibility of the client application to determine if a cookie meets the criteria required to be submitted to the server. If the application wishes to send the cookie, it can use the **HttpSetCookie** function and specify the cookie name and value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

HttpGetData Function

```
INT WINAPI HttpGetData(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions
);
```

The **HttpGetData** function requests a resource from the server and copies the data to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to

	accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the **HttpEnableCompression** function.
HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetData** function is used to retrieve a resource from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated and the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvBuffer*** parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the ***lpdwLength*** parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the GET request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

When encountering a server error during a request, the **HttpGetData** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. Additionally, servers may provide further details about the failure, such as XML or JSON formatted data containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the HTTP_TRANSFER_ERRORDATA option. When this option is enabled, the behavior of **HttpGetData** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the buffer provided by the caller.

If compression has been enabled and the server returns compressed data, it will be automatically expanded before being returned to the caller. This will result in a difference between the value returned in the ***lpdwLength*** parameter, which contains the actual number of bytes copied into the buffer, and the values reported by **HttpGetTransferStatus**. For example, if the server returns 5,000 bytes of compressed data that expands into 15,000 bytes, this function will return 15,000 as the number of bytes copied into the buffer. However, the **HttpGetTransferStatus** function will return the

content length as the original 5,000 bytes of compressed data. For this reason, you should always use the value returned in the *lpdwLength* parameter to determine the amount of data that has been copied into the buffer.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Store the response in a block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = HttpGetData(hClient,
                      lpszResource,
                      &hgblBuffer,
                      &cbBuffer,
                      HTTP_TRANSFER_DEFAULT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

HttpGetDefaultUserAgent Function

```
INT WINAPI HttpGetDefaultUserAgent(
    LPTSTR lpszUserAgent,
    INT nMaxLength
);
```

The **HttpGetDefaultUserAgent** function returns the default user agent string which is included with all requests.

Parameters

lpszUserAgent

A buffer which will contain the default user agent string when the function returns. The buffer must be large enough to contain the entire user agent string including the terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When you submit a request to the server, a header named `User-Agent` is automatically defined which identifies your application. It typically uses a format where you have a product name and version number separated by a slash. There can be multiple products listed in the user agent string, with additional optional information enclosed in parenthesis.

A server uses the user agent to determine what type of client has issued the request, including what operating system and browser version was used. The **HttpGetDefaultUserAgent** function returns a copy of that default value. The value of the user agent string depends on which version of Windows the client is running on and whether the process is 32-bit or 64-bit. For example, a 64-bit application will typically return a value like this:

```
Mozilla/5.0 (Windows NT 10.0; Win64; x64) Chrome/134.0.0.0
Safari/537.36 SocketTools/12.0
```

Some web services check the value of the user agent string to determine if a compatible client is being used to issue the request. The default value is designed to emulate a common browser, but some services may require you change the user agent to use a specific value or include certain product names and versions.

You can change the value of the user agent string in one of two ways. You can use **HttpSetRequestHeader** to set the `User-Agent` header to a specific value for a client session, or you can use **HttpSetDefaultUserAgent** to set the default user agent string for all requests. If you use **HttpSetRequestHeader** to change the user agent string for a client session, it will always override the default value.

To prevent any user agent string from being included with a request, include the HTTP_OPTION_NOUSERAGENT option when connecting to the server or use **HttpSetOption** to

enable that option after a connection has been established.

Using the HTTP_OPTION_NOUSERAGENT option to prevent sending a User-Agent header does not make requests anonymous. Servers may still identify clients based on IP address information, authentication credentials, request patterns or other HTTP headers included with the request.

HttpGetDefaultZoneId Function

```
BOOL WINAPI HttpGetDefaultZoneId(
    HCLIENT hClient,
    LPDWORD lpdwZoneId
);
```

The **HttpGetDefaultZoneId** function returns the default security zone for downloaded files.

Parameters

hClient

Handle to the client session.

lpdwZoneId

A pointer to an unsigned integer which is updated with the default zone ID for the client session. It may be one of the following values:

Value	Description
SECURITY_ZONE_NONE	The file does not have a zone identifier associated with it.
SECURITY_ZONE_LOCAL	The file is considered to be part of the local computer zone.
SECURITY_ZONE_INTRANET	The file originates from the local intranet zone, such as an internal corporate network.
SECURITY_ZONE_TRUSTED	The file originates from a site in the **Trusted Sites** zone.
SECURITY_ZONE_INTERNET	The file was downloaded from the Internet and is treated with caution by Windows.
SECURITY_ZONE_RESTRICTED	The file originates from a site in the **Restricted Sites** zone, which is used for untrusted content.

Return Value

If the function succeeds, the return value is non-zero and *lpdwZoneId* will be updated with the default zone identifier. If no default zone has been explicitly set, the function will still return success, and the variable *lpdwZoneId* points to will be set to `SECURITY_ZONE_NONE`. If the function fails, it returns zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetDefaultZoneId** function returns the zone identifier which was previously set using the **HttpSetDefaultZoneId** function. If no default zone has been specified for the client session, the default behavior is to not set a security zone for the file. This maintains backwards compatibility with previous versions of the library which would not create the security zone metadata for local files.

This function is typically used to confirm the currently configured zone before downloading a file, or to verify whether the default behavior has been overridden. The default zone ID is specific to the client session and does not affect other sessions or system-wide settings.

To get the security zone identifier for a local file, use the **HttpGetFileZoneInfo** function. To change or remove the security zone information for a file, use the **HttpSetFileZoneInfo** function.

For more detailed information about the zone identifiers, refer to the **HttpSetDefaultZoneId** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpGetEncodingType Function

```
INT WINAPI HttpGetEncodingType(
    HCLIENT hClient
);
```

The **HttpGetEncodingType** function determines which content-encoding option is enabled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is one of the following values:

Value	Description
HTTP_ENCODING_NONE	No encoding will be applied to the content of a request and no default content type will be specified. This encoding type should be used with REST APIs and other services which expect XML or JSON request payloads.
HTTP_ENCODING_URL	Non-printable and extended ASCII characters will be encoded so they can be safely used with URLs and form data. Encoded characters will be represented by a percent symbol prefix, followed by a two digit hexadecimal value which represents the ASCII character code. This encoding is typically used with web services which process HTML form data.
HTTP_ENCODING_XML	This encoding is identical to URL encoding, except spaces are not encoded. It is used with legacy web services which expect form data in an XML format and cannot process encoded whitespace. This encoding should not be specified for services which use REST APIs.

If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The default encoding type is HTTP_ENCODING_URL which is used for submitting data to services which expect HTML form data using the **HttpPostData** or **HttpSubmitForm** functions.

When submitting a JSON or XML request to a service using a REST API, your application should use HTTP_ENCODING_NONE and set the appropriate content type for the request payload. The HTTP_ENCODING_XML encoding type should only be used if the server expects URL encoded form data. The **HttpPostJson** and **HttpPostXml** functions will automatically set the correct encoding and content type for those requests.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpGetErrorString Function

```
INT WINAPI HttpGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **HttpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **HttpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFile Function

```
INT WINAPI HttpGetFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   DWORD dwOffset
);
```

The **HttpGetFile** function transfers the specified file on the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local system.

lpszRemoteFile

A null-terminated string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the **HttpEnableCompression** function. This option is ignored if the ***dwOffset*** parameter is non-zero.

HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

dwOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to download the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. To determine if the server compressed the data returned to the client, use the **HttpGetResponseHeader** function to get the value of the **Content-Encoding** header after this function returns. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

To download large files that are over 4GB, use the **HttpGetFileEx** function.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
LPCTSTR lpszLocalFile = _T("index.html");
LPCTSTR lpszRemoteFile = _T("http://sockettools.com/");

if (HttpGetFile(hClient, lpszLocalFile, lpszRemoteFile) == HTTP_ERROR)
{
    dwError = HttpGetLastError();
    _tprintf(stderr, "Unable to download %s, error 0x%lx\n", lpszRemoteFile,
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetFileEx Function

```
INT WINAPI HttpGetFileEx(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   ULARGE_INTEGER uiOffset
);
```

The **HttpGetFileEx** function transfers the specified file on the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the resource on the server. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	The default transfer mode. The resource data is downloaded to the local system exactly as it is stored on the server. If you are requesting a text-based resource, the data may use a different end-of-line character sequence. For example, the end-of-line character may be a single linefeed character instead of a carriage return and linefeed pair.
HTTP_TRANSFER_CONVERT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences.
HTTP_TRANSFER_COMPRESS	This option informs the server that the client is willing to accept compressed data. If the server supports compression for the specified resource, then the data will be automatically expanded before being returned to the caller. This option is selected by default if compression has been enabled using the **HttpEnableCompression** function. This option is ignored if the ***uiOffset*** parameter is

	non-zero.
HTTP_TRANSFER_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to download the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Enabling compression does not guarantee that the data returned by the server will actually be compressed, it only informs the server that the client is willing to accept compressed data. Whether or not a particular resource is compressed depends on the server configuration, and the server may decide to only compress certain types of resources, such as text files. To determine if the server compressed the data returned to the client, use the **HttpGetResponseHeader** function to get the value of the **Content-Encoding** header after this function returns. If the header is defined, the value specifies the compression method used, otherwise the data was not compressed.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFilePathUrl Function

```
INT WINAPI HttpGetFilePathUrl(
   HCLIENT hClient,
   LPCTSTR lpszFilePath,
   LPTSTR lpszFileUrl,
   INT nMaxLength
);
```

The **HttpGetFilePathUrl** function returns a normalized URL for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFilePath

A null-terminated string which specifies the file path on the server. The path may be absolute or relative, and the path does not have to exist on the server. Although this may be any type of resource, this function is primarily intended for use with static content such as documents and images. This parameter cannot be NULL.

lpszFileUrl

A null-terminated string buffer that will contain the URL for the specified file. If this parameter is NULL, nothing will be copied but the function will return the length of the URL, not including the terminating null character.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer. This must include space for the terminating null character. If ***lpszFileUrl*** is NULL this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the ***lpszFileUrl*** buffer, not including the terminating null character. If a buffer is provided, it must be large enough to contain the entire URL or the function will fail. If the ***lpszFileUrl*** parameter is NULL, the function will return the length of the URL and nothing will be copied. If the function fails, it will return zero. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpGetFilePathUrl** function will return the URL associated with the specified file path. This can be useful if you wish to display or store URLs rather than relative paths to a file on the current server. For example, if you are connected to the server `example.com` on port 443 using a secure connection and you provide a file path such as `/documents/invoice.pdf` this function would return a URL which looks like `https://example.com/documents/invoice.pdf`. For security reasons, the resulting URL will never contain user credentials.

The file path in the URL will be normalized to remove extraneous directory traversals and path separators. It is not required for the file path to exist on the server at the time this function is called. For more information about path normalization, refer to the **HttpNormalizePath** function.

This function can also be used to obtain a URL which can be passed to the **HttpGetSercurityZoneId** function to determine which security zone should be assigned to the file when it is downloaded.

Example

The following example shows how **HttpGetFilePathUrl** could be used to obtain the origin URL for a file on the server and then use that in conjunction with the **HttpGetSecurityZoneId** function to update the security zone metadata for the file if the download is successful.

```
LPCTSTR lpszLocalFile = _T("\\Users\\Public\\Documents\\Document.pdf");
LPCTSTR lpszRemoteFile = _T("/files/document.pdf");

TCHAR szFileUrl[FTP_MAXURLPATHLEN] = { 0 };
DWORD dwZoneId = SECURITY_ZONE_NONE;

// Return a complete URL for the relative file path specified for the
// remote file on the server
if (HttpGetFilePathUrl(hClient, lpszRemoteFile, szFileUrl, FTP_MAXURLPATHLEN) < 1)
{
    _tprintf(_T("Unable to get URL for \"%s\"\n"), lpszRemoteFile);
    return;
}

// Check the security zone for the remote file URL
if (!HttpGetSecurityZoneId(szFileUrl, &dwZoneId))
{
    _tprintf(_T("Unable to determine a security zone for \"%s\"\n"), szFileUrl);
}

// Download the file from the server
INT nResult = HttpGetFile(hClient, lpszLocalFile, lpszRemoteFile,
HTTP_TRANSFER_DEFAULT, 0);

if (nResult != FTP_ERROR)
{
    // The download was successful; if a security zone was returned for
    // the file, then update it with the zone ID and origin URL
    if (dwZoneId != SECURITY_ZONE_NONE)
    {
        if (!HttpSetFileZoneInfo(lpszLocalFile, dwZoneId, szFileUrl))
        {
            _tprintf(_T("Unable to set the security zone for \"%s\"\n"),
lpszLocalFile);
            return;
        }
    }
}
else
{
    // The download failed
    _tprintf(_T("Unable to download \"%s\" to \"%s\"\n"), lpszRemoteFile,
lpszLocalFile);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFileSize Function

```
INT WINAPI HttpGetFileSize(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPDWORD lpdwFileSize
);
```

The **HttpGetFileSize** function returns the size of the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpdwFileSize

Points to an unsigned integer that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. If the file does not exist or the client does not have permission to access the file, this method will fail and the ***lpdwFileSize*** parameter will be set to zero.

The server may not return a file size for some resources. This is typically the case with scripts that generate dynamic content because the server has no way of determining the size of the output generated by the script without actually executing it. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. If the request to the server was successful and the file exists, but the server does not return a file size, the function will succeed but the file size returned to the caller will be zero.

When a request is made to the server for information about the file, the library will attempt to keep the connection alive, even if the HTTP_OPTION_KEEPALIVE option has not been specified for the session. This allows an application to request the file size and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the client handle will no longer be valid. If this happens, the ***lpdwFileSize*** parameter may still contain a valid value. If the library was able to determine the file size, but was not able to maintain the connection to the server, the returned file size will be greater than zero even if the function returns an error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFileSizeEx Function

```
INT WINAPI HttpGetFileSizeEx(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   ULARGE_INTEGER *lpFileSize
);
```

The **HttpGetFileSizeEx** function returns the size of the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileSize

Points to an unsigned 64-bit integer that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. If the file does not exist or the client does not have permission to access the file, this method will fail and the ***lpFileSize*** parameter will be set to zero.

The server may not return a file size for some resources. This is typically the case with scripts that generate dynamic content because the server has no way of determining the size of the output generated by the script without actually executing it. The server may also not provide a file size for HTML documents which use server side includes (SSI) because that content is also dynamically created by the server. If the request to the server was successful and the file exists, but the server does not return a file size, the function will succeed but the file size returned to the caller will be zero.

When a request is made to the server for information about the file, the library will attempt to keep the connection alive, even if the HTTP_OPTION_KEEPALIVE option has not been specified for the session. This allows an application to request the file size and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the client handle will no longer be valid. If this happens, the ***lpFileSize*** parameter may still contain a valid value. If the library was able to determine the file size, but was not able to maintain the connection to the server, the returned file size will be greater than zero even if the function returns an error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFileTime Function

```
INT WINAPI HttpGetFileTime(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPSYSTEMTIME lpFileTime,
   BOOL bLocalize
);
```

The **HttpGetFileTime** function returns the modification time for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileTime

Points to a SYSTEMTIME structure that will be set to the current modification time for the remote file.

bLocalize

A boolean flag which specifies if the file time is localized to the current timezone. If this value is non-zero, then the file time is adjusted to that the time is local to the current system. If this value is zero, the file time is returned in UTC time.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetFileTime** function can be used to determine the date and time that a file was last modified on the server. The time may either be localized to the current system, or it may be returned as UTC time.

This function uses the HEAD command to retrieve header information about the file without downloading the contents of the file itself. This requires that the server support at least version 1.0 of the protocol standard, or an error will be returned.

The server may not return a modification time for some resources. If the request to the server was successful and the file exists, but the server does not return a modification time, the function will succeed but all of the members of the SYSTEMTIME structure will be zero.

When a request is made to the server for information about the file, the library will attempt to keep the connection alive, even if the HTTP_OPTION_KEEPALIVE option has not been specified for the session. This allows an application to request the modification time and then download the file without having to write additional code to re-establish the connection. However, it is possible that the attempt to keep the connection open will fail. In that case, an error will be returned and the client handle will no longer be valid. If this happens, the SYSTEMTIME structure may still contain a valid value. If the library was able to determine the modification time, but was not able to maintain the connection to the server, the members of the SYSTEMTIME structure will specify a valid date and time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFileZoneInfo Function

```
BOOL WINAPI HttpGetFileZoneInfo(
   LPCTSTR lpszLocalFile,
   LPDWORD lpdwZoneId,
   LPTSTR lpszHostUrl,
   INT nMaxLength
);
```

The **HttpGetFileZoneInfo** function returns the security zone information for a local file.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of a local file. This parameter must specify a regular file which exists on the local system and the current process must have permission to access and read from the file. If the file path includes environment variables surrounded in percent (%) symbols, the variables will be expanded. This parameter cannot be NULL.

lpdwZoneId

A pointer to an unsigned integer which will contain the zone ID assigned to the file when the function returns. It may be one of the following values:

Value	Description
SECURITY_ZONE_NONE	The file does not have a zone identifier associated with it.
SECURITY_ZONE_LOCAL	The file is considered to be part of the local computer zone.
SECURITY_ZONE_INTRANET	The file originates from the local intranet zone, such as an internal corporate network.
SECURITY_ZONE_TRUSTED	The file originates from a site in the **Trusted Sites** zone.
SECURITY_ZONE_INTERNET	The file was downloaded from the Internet and is treated with caution by Windows.
SECURITY_ZONE_RESTRICTED	The file originates from a site in the **Restricted Sites** zone, which is used for untrusted content.

lpszHostUrl

An optional pointer to a string buffer which will contain the URL used to originally download the file. This information is not always available, in which case an empty string will be returned. If this information is not required, this parameter may be NULL and the ***nMaxLength*** parameter should be specified with a value of zero.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the ***lpszHostUrl*** string including the terminating null character. If the ***lpszHostUrl*** parameter is NULL, this value should be zero. If the buffer is not large enough to contain the entire URL, the string will be truncated. The maximum allowed URL length is 2,048 characters.

Return Value

If the function succeeds, the return value is non-zero. If the function fails or zone information is not available, the function returns zero. To get extended error information, call **HttpGetLastError**.

Remarks

When a file is downloaded from the Internet or other external sources, Windows may assign a zone identifier to the file using an alternate data stream named `Zone.Identifier`. This metadata helps determine how the system treats the file with respect to security, such as whether to prompt the user with a warning before opening it.

The **HttpGetFileZoneInfo** function retrieves the zone ID associated with the specified local file, allowing an application to determine the origin and trust level of that file. This can be useful when implementing additional security measures, auditing downloaded content, or providing user warnings about potentially untrusted files.

The file name specified by the *lpszLocalFile* parameter must not reference a network location. This includes UNC paths (such as `\\server\share\file.txt`) and drive letters that are mapped to network shares. Security zone metadata cannot be read from files on network volumes because the SMB protocol does not support alternate data streams.

In addition to the zone ID, this function can optionally return the source URL used to download the file. This information, if present, is extracted from the same alternate data stream. Not all files will include this URL, as it depends on the program or browser that downloaded the file and whether it preserved this metadata. This function will not return an error if the URL stored with the security zone information is not a valid HTTP URL. For example, it's possible for this function to return zone information with a FTP URL. You can use the **HttpValidateUrl** function to determine if the host URL is a valid HTTP URL.

Note that not all file systems support alternate data streams. For example, FAT32 volumes do not support them, and in such cases, zone information will not be available. Additionally, some applications may remove this metadata after download or strip it during file copy operations. The absence of zone information does not guarantee that a file is safe or originated locally.

If you wish to distinguish between a file which exists without any zone information, and an error condition where the file does not exist or could not be accessed, check the last error code. If this function returns zero and the **HttpGetLastError** function returns NO_ERROR, this indicates the file name is valid and it exists, but the `Zone.Identifier` alternate data stream does not exist.

For more detailed information about the security zone identifiers, refer to the **HttpSetDefaultZoneId** function. To change or remove the security zone metadata from a local file, use the **HttpSetFileZoneInfo** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFirstCookie Function

```
DWORD_PTR WINAPI HttpGetFirstCookie(
    HCLIENT hClient,
    LPTSTR lpszCookieName,
    LPINT lpnNameLen,
    LPTSTR lpszCookieValue,
    LPINT lpnValueLen
);
```

The **HttpGetFirstCookie** function returns the first cookie set by the server.

Parameters

hClient

Handle to the client session.

lpszCookieName

A null-terminated string buffer which will contain the name of the first cookie set by the server.

lpnNameLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie name string.

lpszCookieValue

A null-terminated string buffer which will contain the name of the first cookie value set by the server. If the cookie value is not required, this parameter may be NULL.

lpnValueLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie value string. If the *lpszCookieValue* parameter is NULL, this parameter should also be NULL.

Return Value

If the function succeeds, the return value is an opaque token which will be passed to the **HttpGetNextCookie** function to retrieve the next cookie. If there are no cookies or the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetFirstCookie** function is used to enumerate the cookies set by the server after a resource has been requested. The return value is an unsigned integer where the size depends on whether the application targets 32-bit or 64-bit platforms. This value should always be treated as an opaque integer which is only valid during the enumeration of the session cookies and should never be stored by the application.

To get information about a specific cookie, use the **HttpGetCookie** function.

Example

```
TCHAR szCookieName[MAXCOOKIENAME];
TCHAR szCookieValue[MAXCOOKIEVALUE];
INT nNameLen, nValueLen;
DWORD_PTR dwCookie;
```

```
// Initialize the nNameLen and nValueLen variables to
// the maximum number of characters that can be copied
// into the string buffers
nNameLen = MAXCOOKIENAME;
nValueLen = MAXCOOKIEVALUE;

// Get the first cookie set by the server
dwCookie = HttpGetFirstCookie(hClient,
                              szCookieName,
                              &nNameLen,
                              szCookieValue,
                              &nValueLen);

while (dwCookie != 0)
{
    // The szCookieName and szCookieValue strings contain the
    // the name and value for a cookie set by the server

    // Re-initialize the nNameLen and nValueLen variables
    // to the maximum length of the strings
    nNameLen = MAXCOOKIENAME;
    nValueLen = MAXCOOKIEVALUE;

    // Get the next cookie set by the server
    dwCookie = HttpGetNextCookie(hClient,
                                 dwCookie,
                                 szCookieName,
                                 &nNameLen,
                                 szCookieValue,
                                 &nValueLen);
};
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFirstHeader Function

```
BOOL WINAPI HttpGetFirstHeader(
    HCLIENT hClient,
    UINT nHeaderType,
    LPTSTR lpszHeader,
    LPINT lpcchHeader
    LPTSTR lpszValue,
    LPINT lpcchValue
);
```

The **HttpGetFirstHeader** function returns the name and value of the first request or response header.

Parameters

hClient

Handle to the client session.

nHeaderType

Specifies the type of header to return. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Return the first header set by the client before a resource has been requested. Request headers typically specify information that the server needs to complete the request, such as the name of the host that has the resource, or what types of resources are acceptable to the client.
HTTP_HEADERS_RESPONSE	Return the first header set by the server after a request has been submitted to the server. The response headers typically contain information about the resource, such as its size, the content type and the date it was last modified.

lpszHeader

A null-terminated string buffer that will contain the name of the header field when the function returns.

lpcchHeader

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header name string.

lpszValue

A null-terminated string buffer that will contain the name of the header value when the function returns.

lpcchValue

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header value string.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call

HttpGetLastError.

Remarks

Use this function together with **HttpGetNextHeader** to enumerate all request or response headers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFirstQueuedFile Function

```
DWORD WINAPI HttpGetFirstQueuedFile(
   HQUEUE hQueue,
   DWORD dwQueueMode,
   DWORD dwExcludeFiles,
   LPHTTPQUEUEDFILE lpFileInfo
);
```

The **HttpGetFirstQueuedFile** function returns information about the first file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. It may be one of the following values:

Constant	Description
HTTP_QUEUE_ALL	Return information about all files in the queue.
HTTP_QUEUE_DOWNLOAD	Return information for files which are queued for download.
HTTP_QUEUE_UPLOAD	Return information for files which are queued for upload.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the search. If this value is zero, no files will be excluded from the search; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_QUEUE_FLAG_NONE	No files should be excluded.
HTTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
HTTP_QUEUE_FLAG_FAILED	Exclude files which where not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.
HTTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the **HttpCancelQueuedFile** function has been called and a queued file is in the process of being uploaded or downloaded.

lpFileInfo

A pointer to a HTTPQUEUEDFILE structure which will contain information about the file. This

parameter cannot be NULL.

Return Value

If the function succeeds, the return value is an unsigned integer with a non-zero value which uniquely identifies the file in the queue. If there are no queued files which match the specified parameters, or the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns information about the first file in the current transfer queue. It is used in conjunction with the **HttpGetNextQueuedFile** function to obtain information about all queued files.

Example

```
// List all files in a file transfer queue
HTTPQUEUEDFILE queuedFile;
DWORD dwFileId;

dwFileId = HttpGetFirstQueuedFile(hQueue, HTTP_QUEUE_ALL, HTTP_QUEUE_FLAG_NONE,
&queuedFile);

while (dwFileId != 0)
{
    switch (queuedFile.dwQueueMode)
    {
    case HTTP_QUEUE_DOWNLOAD:
        _tprintf(_T("%u: download \"%s\" to \"%s\"\n"),
                 queuedFile.dwFileId,
                 queuedFile.szRemoteFile,
                 queuedFile.szLocalFile);
        break;

    case HTTP_QUEUE_UPLOAD:
        _tprintf(_T("%u: upload \"%s\" to \"%s\"\n"),
                 queuedFile.dwFileId,
                 queuedFile.szRemoteFile,
                 queuedFile.szLocalFile);
        break;
    }

    dwFileId = HttpGetNextQueuedFile(hQueue, &queuedFile);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetFormProperties Function

```
INT WINAPI HttpGetFormProperties(
   HFORM hForm,
   LPHTTPFORMPROPERTIES lpFormProp
);
```

The **HttpGetFormProperties** function returns information about the specified form.

Parameters

hForm

Handle to the virtual form.

lpFormProp

Points to a HTTPFORMPROPERTIES structure which will contain information about the specified form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpCreateForm, HttpSetFormProperties, HttpSubmitForm, HTTPFORMPROPERTIES

HttpGetLastError Function

```
DWORD WINAPI HttpGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **HttpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **HttpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **HttpSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or HTTP_ERROR. Those functions which call **HttpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpGetNextCookie Function

```
DWORD_PTR WINAPI HttpGetNextCookie(
   HCLIENT hClient,
   DWORD_PTR dwCookie,
   LPTSTR lpszCookieName,
   LPINT lpnNameLen,
   LPTSTR lpszCookieValue,
   LPINT lpnValueLen
);
```

The **HttpGetNextCookie** function returns the next cookie set by the server.

Parameters

hClient

Handle to the client session.

dwCookie

An unsigned integer value which specifies a cookie token returned by a previous call to either **HttpGetFirstCookie** or **HttpGetNextCookie**.

lpszCookieName

A null-terminated string buffer which will contain the name of the first cookie set by the server.

lpnNameLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie name string.

lpszCookieValue

A null-terminated string buffer which will contain the name of the first cookie value set by the server. If the cookie value is not required, this parameter may be NULL.

lpnValueLen

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the cookie value string. If the ***lpszCookieValue*** parameter is NULL, this parameter should also be NULL.

Return Value

If the function succeeds, the return value is an opaque token which will be passed to the **HttpGetNextCookie** function to retrieve the next cookie. If there are no more cookies or the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetNextCookie** function is used to enumerate the cookies set by the server after a resource has been requested. The return value is an unsigned integer where the size depends on whether the application targets 32-bit or 64-bit platforms. This value should always be treated as an opaque integer which is only valid during the enumeration of the session cookies and should never be stored by the application.

To get information about a specific cookie, use the **HttpGetCookie** function.

Example

```
TCHAR szCookieName[MAXCOOKIENAME];
TCHAR szCookieValue[MAXCOOKIEVALUE];
INT nNameLen, nValueLen;
DWORD_PTR dwCookie;

// Initialize the nNameLen and nValueLen variables to
// the maximum number of characters that can be copied
// into the string buffers
nNameLen = MAXCOOKIENAME;
nValueLen = MAXCOOKIEVALUE;

// Get the first cookie set by the server
dwCookie = HttpGetFirstCookie(hClient,
                              szCookieName,
                              &nNameLen,
                              szCookieValue,
                              &nValueLen);

while (dwCookie != 0)
{
    // The szCookieName and szCookieValue strings contain the
    // the name and value for a cookie set by the server

    // Re-initialize the nNameLen and nValueLen variables
    // to the maximum length of the strings
    nNameLen = MAXCOOKIENAME;
    nValueLen = MAXCOOKIEVALUE;

    // Get the next cookie set by the server
    dwCookie = HttpGetNextCookie(hClient,
                                 dwCookie,
                                 szCookieName,
                                 &nNameLen,
                                 szCookieValue,
                                 &nValueLen);
};
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetCookie, HttpGetFirstCookie, HttpGetResponseHeader, HttpSetCookie, HttpSetRequestHeader

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetNextHeader Function

```
BOOL WINAPI HttpGetNextHeader(
    HCLIENT hClient,
    UINT nHeaderType,
    LPTSTR lpszHeader,
    LPINT lpcchHeader,
    LPTSTR lpszValue,
    LPINT lpcchValue
);
```

The **HttpGetNextHeader** function returns the name and value of the next request or response header.

Parameters

hClient

Handle to the client session.

nHeaderType

Specifies the type of header to return. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Return the first header set by the client before a resource has been requested. Request headers typically specify information that the server needs to complete the request, such as the name of the host that has the resource, or what types of resources are acceptable to the client.
HTTP_HEADERS_RESPONSE	Return the first header set by the server after a request has been submitted to the server. The response headers typically contain information about the resource, such as its size, the content type and the date it was last modified.

lpszHeader

A null-terminated string buffer that will contain the name of the header field when the function returns.

lpcchHeader

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header name string.

lpszValue

A null-terminated string buffer that will contain the name of the header value when the function returns.

lpcchValue

A pointer to an integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. When the function returns, this value is updated to specify the actual length of the header value string.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client

handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

Use this function iteratively after **HttpGetFirstHeader** to enumerate all request or response headers.

Unlike the **HttpGetResponseHeader** function, which returns a single header name and value, the **HttpGetFirstHeader** and **HttpGetNextHeader** functions will return multiple headers that have the same common name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetNextQueuedFile Function

```
DWORD WINAPI HttpGetNextQueuedFile(
   HQUEUE hQueue,
   LPHTTPQUEUEDFILE lpFileInfo
);
```

The **HttpGetNextQueuedFile** function returns information about the next file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpFileInfo

A pointer to a HTTPQUEUEDFILE structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is an unsigned integer with a non-zero value which uniquely identifies the file in the queue. If there are no additional queued files which match the exclusion criteria specified with the call to **HttpGetFirstQueuedFile**, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns information about the next file in the current transfer queue after an initial call to **HttpGetFirstQueuedFile**. To obtain a list of all matching files in the queue, call this function repeatedly until it returns a value of zero. When information about the last file in the queue has been returned, the last error code will be set to `ST_ERROR_END_OF_QUEUE`.

Example

```
// List all files in a file transfer queue
HTTPQUEUEDFILE queuedFile;
DWORD dwFileId;

dwFileId = HttpGetFirstQueuedFile(hQueue, HTTP_QUEUE_ALL, HTTP_QUEUE_FLAG_NONE,
&queuedFile);

while (dwFileId != 0)
{
    switch (queuedFile.dwQueueMode)
    {
    case HTTP_QUEUE_DOWNLOAD:
        _tprintf(_T("%u: download \"%s\" to \"%s\"\n"),
                 queuedFile.dwFileId,
                 queuedFile.szRemoteFile,
                 queuedFile.szLocalFile);
        break;

    case HTTP_QUEUE_UPLOAD:
        _tprintf(_T("%u: upload \"%s\" to \"%s\"\n"),
                 queuedFile.dwFileId,
                 queuedFile.szRemoteFile,
                 queuedFile.szLocalFile);
        break;
```

```
    }

    dwFileId = HttpGetNextQueuedFile(hQueue, &queuedFile);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetOption Function

```
INT WINAPI HttpGetOption(
   HCLIENT hClient,
   DWORD dwOption,
   LPBOOL lpbEnabled
);
```

The **HttpGetOption** function determines whether a specified HTTP option is enabled.

Parameters

hClient

Handle to the client session.

dwOption

An unsigned integer which specifies the option that is to be checked. It may be one of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.
HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the

	connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

lpbEnabled

A pointer to an integer which will be set to a non-zero value when the function returns if the specified option has been enabled. If the option has not been enabled, a zero value will be returned in the variable.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**. Note that the value returned in the

lpbEnabled parameter is only valid if the function succeeds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpGetPriority Function

```
INT WINAPI HttpGetPriority(
   HCLIENT hClient
);
```

The **HttpGetPriority** function returns a value which specifies the priority of file transfers.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the current file transfer priority. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetPriority** function can be used to determine the current priority assigned to file transfers performed by the client. It may be one of the following values:

Value	Description
HTTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpGetQueueClient Function

```
HCLIENT WINAPI HttpGetQueueClient(
     HQUEUE hQueue
);
```

The **HttpGetQueueClient** function returns a handle to the current client session.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value a handle to a client session. If the function fails, it will return INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetQueueClient** function returns the handle to a client session which may be used with other functions, such as **HttpGetTransferStatus**. A valid handle will only be returned if the queue manager is currently uploading or downloading a file. If the queue is active but there are no file transfers in progress at the time this function is called, it will fail and set the last error code to `ST_ERROR_NO_QUEUED_TRANSFER`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

HttpGetQueuedFile Function

```
BOOL WINAPI HttpGetQueuedFile(
   HQUEUE hQueue,
   DWORD dwFileId,
   LPHTTPQUEUEDFILE lpFileInfo
);
```

The **HttpGetQueuedFile** function returns information about the specified file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. This value cannot be zero.

lpFileInfo

A pointer to a HTTPQUEUEDFILE structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the file identifier is not valid or the file has been removed from the queue, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The file identifier can be obtained by several different functions, including **HttpEnumQueuedFiles** and **HttpGetQueueStatus,** which provides information about the current file being processed in the queue. Do not make any assumptions about the value of the identifier. Although the value is guaranteed to be unique for the specified queue, it is not guaranteed that file identifiers will be assigned in sequential order.

Example

```
// Get the number of files in the queue
LONG nFiles = HttpEnumQueuedFiles(hQueue, NULL, 0)

// Display information about the queued files
if (nFiles > 0)
{
    DWORD *pdwFileList = new DWORD[nFiles];

    nFiles = HttpEnumQueuedFiles(hQueue, pdwFileList, nFiles);

    for (LONG nIndex = 0; nIndex < nFiles; nIndex++)
    {
        HTTPQUEUEDFILE queuedFile;

        if (HttpGetQueuedFile(hQueue, pdwFileList[nIndex], &queuedFile) == FALSE)
            break;

        switch (queuedFile.dwMode)
        {
        case HTTP_QUEUE_DOWNLOAD:
```

```
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        queuedFile.dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                 break;

        case HTTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        queuedFile.dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                 break;
        }
    }

    delete pdwFileList;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetQueueStatus Function

```
INT WINAPI HttpGetQueueStatus(
   HQUEUE hQueue,
   LPHTTPQUEUESTATUS lpQueueStatus
);
```

The **HttpGetQueuedFile** function returns information about the specified file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpQueueStatus

A pointer to a HTTPQUEUESTATUS structure which will contain information about the current state of the file transfer queue. If this parameter is NULL, the function will ignore the parameter and only return the current status of the queue.

Return Value

If the function succeeds, the return value is the current queue status. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**. The following status values may be returned:

Value	Description
HTTP_QUEUE_STATUS_IDLE	The file transfer queue is idle and no files are being uploaded or downloaded. This state is returned before **HttpStartQueue** has been called or after **HttpStopQueue** has been called. The queue will also automatically enter an idle state after the last file transfer has completed and the queue manager thread exits.
HTTP_QUEUE_STATUS_ACTIVE	The queue manager is active and files are currently being uploaded or downloaded.
HTTP_QUEUE_STATUS_PAUSED	The queue manager is active although file transfers are currently paused. The queue enters this state after the **HttpSuspendQueue** function is called and resumes file transfers after the **HttpResumeQueue** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpCancelQueuedFile, HttpResetQueue, HttpResumeQueue, HttpStartQueue, HttpSuspendQueue, HttpStopQueue

HttpGetQueueThread Function

```
DWORD WINAPI HttpGetQueueThread(
    HQUEUE hQueue
);
```

The **HttpGetQueueThread** function returns a value which uniquely identifies the queue manager thread.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero and specifies a unique identifier for the queue manager thread. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetQueueThread** function can be used to obtain a unique identifier for the queue manager thread which is responsible for performing the file transfers. If the function returns zero, this indicates that either the queue handle is no longer valid, or the queue is idle and no files are currently being processed. To obtain the handle to a queue associated with a particular thread, call the **HttpGetThreadQueue** function.

You should not store the thread ID or consider it a persistent value, even during the lifetime of the process. It is only valid while the queue manager is actively processing files in the queue. The thread ID value will change every time the **HttpStartQueue** function is called.

Never use the thread ID to obtain a handle to the thread and call Windows API functions such as **SuspendThread** or **TerminateThread**. This can result inconsistency within the internal state of the queue manager and may result in incomplete or corrupted file transfers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpGetRedirectUrl Function

```
INT WINAPI HttpGetRedirectUrl(
   HCLIENT hClient,
   LPTSTR lpszResource,
   INT nMaxLength
);
```

The **HttpGetRedirectUrl** function returns the URL for a redirected resource.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string buffer which will contain the URL of the redirected resource when the function returns. The string will be null-terminated and the buffer must be large enough to accommodate the entire URL or the function will fail. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that may be copied into the string buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the length of the URL. A return value of zero indicates that the request was not redirected. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns the complete URL for a request which has been redirected to a different resource. This is useful for applications which do not wish to use automatic redirection and instead prefer to handle the redirection by establishing a new connection by passing this value to the **HttpConnectUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpConnectUrl, HttpGetResourceUrl, HttpGetResponseHeader

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetRequestHeader Function

```
BOOL WINAPI HttpGetRequestHeader(
    HCLIENT hClient,
    LPCTSTR lpszHeader,
    LPTSTR lpszValue,
    INT nMaxLength
);
```

The **HttpGetRequestHeader** function returns the value of the specified request header field.

Parameters

hClient

Handle to the client session.

lpszHeader

A pointer to a null-terminated string which specifies the name of the header field. Header names may only contain ASCII letters, numbers and a restricted subset of punctuation characters. Header names cannot contain Unicode or ANSI multi-byte character sequences.

lpszValue

Pointer to a buffer which will contain the null-terminated string value of the specified header field.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

When a resource is requested from the server, it consists of two parts. The first part is the command issued to the server, along with the name of the resource and any optional encoded parameters. The second part consists of one or more header fields which can be used to provide additional information to the server. For example, here is what the command and header may look like for a simple request:

```
GET /test HTTP/1.0
Host: api.sockettools.com
Accept: text/*
```

The first line consists of the command, the resource and the protocol version. The subsequent lines are the header, which is similar to the headers used in email messages. The Host field specifies the name of the server the resource is being requested from, and the Accept field specifies the type of resources that are acceptable to the client; in this case, any type of text file.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetResourceUrl Function

```
INT WINAPI HttpGetResourceUrl(
   HCLIENT hClient,
   LPTSTR lpszResource,
   INT nMaxLength
);
```

The **HttpGetResourceUrl** function returns the URL for the current request.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string buffer which will contain the URL of the current resource when the function returns. The string will be null terminated and the buffer must be large enough to accommodate the entire URL or the function will fail. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that may be copied into the string buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the length of the URL. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function returns the URL for the current request which has been submitted to the server. This can be useful for applications which need to compose a URL for display or logging purposes, combining the connection information and resource path provided to functions such as **HttpGetData** or **HttpPostData**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetResponseHeader Function

```
BOOL WINAPI HttpGetResponseHeader(
    HCLIENT hClient,
    LPCTSTR lpszHeader,
    LPTSTR lpszValue,
    INT nMaxLength
);
```

The **HttpGetResponseHeader** function returns the value of the specified response header field.

Parameters

hClient

Handle to the client session.

lpszHeader

A pointer to a null-terminated string which specifies the name of the header field. Header names may only contain ASCII letters, numbers and a restricted subset of punctuation characters. Header names cannot contain Unicode or ANSI multi-byte character sequences.

lpszValue

Pointer to a buffer which will contain the null-terminated string value of the specified header field.

nMaxLength

Maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the header field does not exist or the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

When a resource is returned by the server, it consists of three parts. The first part consists of a single line that indicates the result of the request. The second part is one or more header fields which provides specific information about the resource, such as its size in bytes. The third part consists of the resource data itself, such as the HTML document or image data. For example, this is what the response to a request for a simple HTML document can look like:

```
HTTP/1.0 200 OK
Date: Mon, 5 Jan 2004 20:18:33 GMT
Content-Type: text/html
Last-Modified: Mon, 5 Jan 2004 19:34:19 GMT
Content-Length: 115

<html>
<head>
<title>Simple Document</title>
</head>
<body>
This is a simple HTML document.
<body>
</html>
```

The first line consists of the protocol version, a numeric response code and some text describing the

result. The subsequent lines are the header, which is similar to the headers used in email messages. For example, the Date field specifies the date the resource was requested, the Content-Type field specifies what type of resource was requested, and the Content-Length field specifies the size of the resource in bytes. The end of the header block is indicated by an empty line (two carriage-return/linefeed sequences), and is followed by the resource itself, in this case a simple HTML document.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetResultCode Function

```
INT WINAPI HttpGetResultCode(
    HCLIENT hClient
);
```

The **HttpGetResultCode** function reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpCommand, HttpGetResultString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetResultString Function

```
INT WINAPI HttpGetResultString(
    HCLIENT hClient,
    LPTSTR lpszResult,
    INT nMaxLength
);
```

The **HttpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

The buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **HttpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetSecurityInformation Function

```
BOOL WINAPI HttpGetSecurityInformation(
   HCLIENT hClient,
   LPSECURITYINFO lpSecurityInfo
);
```

The **HttpGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;

securityInfo.dwSize = sizeof(SECURITYINFO);
if (HttpGetSecurityInformation(hClient, &securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
```

```
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetSecurityZoneId Function

```
BOOL WINAPI HttpGetSecurityZoneId(
    LPCTSTR lpszResource,
    LPDWORD lpdwZoneId
);
```

The **HttpGetSecurityZoneId** function returns the security zone identifier for the specified resource.

Parameters

lpszResource

A null-terminated string which specifies the resource URL to check. This must be either a valid HTTP URL or a local file URL.

lpdwZoneId

A pointer to an unsigned integer which is updated with the zone ID for the specified resource. It may be one of the following values when the function returns:

Value	Description
SECURITY_ZONE_NONE	The security zone for this resource cannot be determined.
SECURITY_ZONE_LOCAL	The resource is considered to be part of the local computer zone.
SECURITY_ZONE_INTRANET	The resource originates from the local intranet zone, such as an internal corporate network.
SECURITY_ZONE_TRUSTED	The resource originates from a site in the **Trusted Sites** zone.
SECURITY_ZONE_INTERNET	The resource originates from the Internet and is treated with caution by Windows.
SECURITY_ZONE_RESTRICTED	The resource originates from a site in the **Restricted Sites** zone, which is used for untrusted content.

Return Value

If the function succeeds, the return value is non-zero and ***lpdwZoneId*** will be updated with the zone identifier. If the security zone could not be determined, ***lpdwZoneId*** will be set to `SECURITY_ZONE_NONE`. If the function fails, it returns zero and the error code can be retrieved by calling **HttpGetLastError**.

Remarks

This **HttpGetSecurityZoneId** function is used to determine how a resource should be handled in terms of local security policy before performing a file transfer or download. For example, you may want to determine whether a resource originates from the Internet or local intranet before deciding whether to attach zone metadata, prompt the user, or apply additional security restrictions. It can also be used to implement policy-based rules for accepting or rejecting downloads based on their origin.

The ***lpszResource*** parameter must use the `http://`, `https://` or `file://` schemes. This function will not accept URLs for other schemes such as `ftp://` or `sftp://`. While this function does not verify that the resource exists, it does require the URL to be syntatically valid. If the host name cannot be resolved to an IPv4 or IPv6 address, the function will fail. If the resource is a local file, it must be a

regular file and cannot be the name of a folder or device.

If the resource is specified using a `file://` URL that refers to a file on a network share (e.g.: `file://server/share/file.txt`), the function will attempt to access that file across the network. This may cause the application to block while Windows resolves the hostname and establishes a connection to the shared volume. If the network share is unavailable or slow to respond, the function may block until the connection succeeds or the attempt times out.

If this function returns FALSE, this indicates either the resource type is not supported or there was an internal failure when the Internet Security Manager attempted to map the resource URL to a security zone. In most default configurations, this function will return the zone `SECURITY_ZONE_INTERNET` for a valid URL unless the host has been explicitly added to the **Intranet Zone** or **Trusted Sites** list on the local system.

Security zones are used with Mark of the Web (MOTW) metadata which indicates if a file originated from an external source, such as the Internet or an untrusted network. When a file is downloaded using a web browser or other applications, it may add a `Zone.Identifier` alternate data stream to the file. This stream contains information such as `ZoneId=3`, which corresponds to the Internet Zone. Your application can use the **HttpGetFileZoneInfo** function to retrieve this information, which allows you to determine whether a file was downloaded from an external source and what zone Windows has associated with it. This metadata affects how files are handled by Windows security components such as Microsoft Defender, SmartScreen, Office Protected View, and script execution policies in Windows Explorer. If the file has no metadata, it is generally treated as coming from the Local Machine Zone (zone 0). If your application sets or clears this metadata using the **HttpSetFileZoneInfo** function, it can influence how other applications interpret the file's trust level.

It is important to note that this function is used to determine what security zone would be appropriate for a given resource, and it only performs syntactic checks and classification of the URL using the **IInternetSecurityManager** COM interface. The security zone this function returns is based on the current system and user policy, using zone assignments stored in the registry. Typically this information is managed using Windows settings or Internet options in the control panel. This function does not read the zone identifier metadata which has been assigned to a file.

For more detailed information about the zone identifiers, refer to the **HttpSetDefaultZoneId** function.

Example

```
LPCTSTR pszDownloadUrl = _T("https://example.com/pub/download/file.txt");
DWORD dwZoneId = SECURITY_ZONE_NONE;

if (HttpGetSecurityZoneId(pszDownloadUrl, &dwZoneId))
{
    // dwZoneId now contains SECURITY_ZONE_INTERNET
    _tprintf(_T("The security zone is: %u\n"), dwZoneId);
}
else
{
    DWORD dwError = HttpGetLastError();
    // Handle the error
}
```

Requirements

HttpGetStatus Function

```
INT WINAPI HttpGetStatus(
   HCLIENT hClient
);
```

The **HttpGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
HTTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
HTTP_STATUS_CONNECT	The client is establishing a connection with the server.
HTTP_STATUS_READ	The client is reading data from the server.
HTTP_STATUS_WRITE	The client is writing data to the server.
HTTP_STATUS_DISCONNECT	The client is disconnecting from the server.
HTTP_STATUS_GETDATA	The client is downloading data from the server.
HTTP_STATUS_PUTDATA	The client is uploading data to the server.
HTTP_STATUS_POSTDATA	The client is posting data to a script on the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session. To obtain status information about a file transfer, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetTaskError Function

```
DWORD WINAPI HttpGetTaskError(
    UINT nTaskId
);
```

Return the last error code for the specified asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed successfully, this function returns a value of zero. A non-zero return value indicates an error has occurred.

Remarks

The **HttpGetTaskError** function returns the last error code associated with the specified asynchronous task. If the task completed successfully, the return value will be zero. If the task is still active, the function will return the error ST_ERROR_TASK_ACTIVE. If the task has been suspended, the function will return ST_ERROR_TASK_SUSPENDED. Any other value indicates that the task completed, but the operation has failed and the error code will specify the cause of the failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpTaskAbort, HttpTaskResume, HttpTaskSuspend, HttpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetTaskId Function

```
UINT WINAPI HttpGetTaskId(
   HCLIENT hClient
);
```

Return the asynchronous task identifier associated with the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the client handle is not associated with an asynchronous task, the function will return a value of zero.

Remarks

The **HttpGetTaskId** function will return the task ID that is associated with a client session. This is a unique unsigned integer value that references the worker thread that was created to manage the asynchronous client session. This function should only be called within an event handler that is invoked by a background task that has been started using a function such as **HttpAsyncGetFile**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpGetText Function

```
INT WINAPI HttpGetText(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **HttpGetText** function returns the contents of a text resource in a null-terminated string buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource that will be transferred to the local system. This may be the name of a file on the server, or it may specify the name of a script that will be executed and the output returned to the caller. This string may specify a valid URL for the current server that the client is connected to.

lpszBuffer

A null-terminated string buffer which will contain the contents of the text file when the function returns. This buffer should be large enough to store the contents of the file, including a terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. This value must be larger than zero. If this value is smaller than the actual size of the text file, the data returned will be truncated.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetText** function is used to retrieve the contents of a text resource and return it in a null-terminated string buffer. Because binary data can include embedded null characters which would truncate the string, this function should only be used with text files or script output that is known to be textual. For example, it is safe to use this function when a resource returns HTML or XML data, but should not be used if it returns an image or executable file.

This function has been included as a convenience for applications that need to retrieve relatively small amounts of textual data and manipulate the contents as a string. If the Unicode version of this function is called, the text is automatically converted to a Unicode string. If the maximum amount of data being returned is unknown or the amount of text is very large, it is recommended that you use the **HttpGetTextEx** or **HttpGetFile** functions.

If the ANSI version of this function is called, the text returned will always be UTF-8 encoded. If you need to return the text using a different code page, use the **HttpGetTextEx** function which will allow you to specify a different code page used for the conversion.

If you use the **HttpGetFileSize** function to determine how large the string buffer should be prior to

calling this function, it is important to be aware that the actual number of characters may differ based on the end-of-line conventions used by the host operating system. For example, if you call **HttpGetFileSize** to obtain the size of a text file on a UNIX system, the value will not be large enough to store the complete file because UNIX uses a single linefeed (LF) character to indicate the end-of-line, while a Windows system will use a carriage-return and linefeed (CRLF) pair. To accommodate this difference, you should always allocate extra memory for the string buffer to store the additional end-of-line characters.

HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
LPTSTR lpszBuffer = (LPTSTR)calloc(MAXFILESIZE, sizeof(TCHAR));

if (lpszBuffer == NULL)
    return;

nResult = HttpGetText(hClient, lpszRemoteFile, lpszBuffer, MAXFILESIZE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetThreadQueue Function

```
HQUEUE WINAPI HttpGetThreadQueue(
    DWORD dwThreadId
);
```

The **HttpGetThreadQueue** function returns a handle to the queue associated with the specified thread.

Parameters

dwThreadId

An unsigned integer value which specifies a unique identifier for the queue manager thread. If this value is zero, it will return the handle associated with the current thread.

Return Value

If the function succeeds, the return value is the handle to the queue. If the function fails, it will return INVAID_QUEUE. To get extended error information, call **HttpGetLastError**.

Remarks

All queued file transfers are handled by a queue manager which executes asynchronously in a background worker thread. This worker thread is created when the **HttpStartQueue** function is called and terminates when all files in the queue have been processed, or when the **HttpStopQueue** function is called. This function will return the queue handle associated with that worker thread.

The most common use of this function would be to obtain the handle for the queue from within a queue event handler. The application would pass in a value of zero as the thread ID and the function will return the handle to the queue which invoked the event notification.

If you call this function outside of an event handler and the ***dwThreadId*** parameter is zero, or if the queue is idle and not transferring files, this function will return INVALID_QUEUE. The thread ID is only valid while the queue manager is actively processing files in the queue.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpGetTimeout Function

```
INT WINAPI HttpGetTimeout(
   HCLIENT hClient
);
```

The **HttpGetTimeout** function returns the number of seconds the client will wait for a response from the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. Once the specified number of seconds has elapsed, the blocking method will fail and return to the caller. The timeout value affects both the requests submitted and the responses returned by the server. The initial timeout value is set when establishing a connection and the default timeout period is 20 seconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpGetTransferStatus Function

```
INT WINAPI HttpGetTransferStatus(
   HCLIENT hClient,
   LPHTTPTRANSFERSTATUS lpStatus
);
```

The **HttpGetTransferStatus** function returns information about the current data transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an HTTPTRANSFERSTATUS structure which contains information about the status of the current data transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetTransferStatus** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option HTTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the HTTPTRANSFERSTATUS structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

If you are uploading or downloading large files which exceed 4GB, you should use the **HttpGetTransferStatusEx** function which returns the size as a 64-bit value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

HttpGetTransferStatusEx Function

```
INT WINAPI HttpGetTransferStatusEx(
   HCLIENT hClient,
   LPHTTPTRANSFERSTATUSEX lpStatus
);
```

The **HttpGetTransferStatusEx** function returns information about the current data transfer in progress. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an HTTPTRANSFERSTATUSEX structure which contains information about the status of the current data transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpGetTransferStatusEx** function returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option HTTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values of the ***dwTimeElapsed*** and ***dwTimeEstimated*** members of the HTTPTRANSFERSTATUSEX structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

HttpInitialize Function

```
BOOL WINAPI HttpInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **HttpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **HttpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **HttpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **HttpInitialize** or **HttpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpIsBlocking Function

```
BOOL WINAPI HttpIsBlocking(
   HCLIENT hClient
);
```

The **HttpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **HttpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpCancel, HttpIsConnected, HttpIsReadable, HttpIsWritable, HttpRead, HttpWrite

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpIsConnected Function

```
BOOL WINAPI HttpIsConnected(
    HCLIENT hClient
);
```

The **HttpIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpIsBlocking, HttpIsReadable, HttpIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpIsReadable Function

```
BOOL WINAPI HttpIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **HttpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpIsWritable Function

```
BOOL WINAPI HttpIsWritable(
   HCLIENT hClient,
   INT nTimeout
);
```

The **HttpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpNormalizePath Function

```
INT WINAPI HttpNormalizePath(
   LPCTSTR lpszResource,
   LPTSTR lpszNormalized,
   INT nMaxLength
);
```

The **HttpNormalizePath** function normalizes a resource on the server returning a canonical path.

Parameters

lpszResource

A null-terminated string which specifies a resource on the server. This parameter cannot be NULL.

lpszNormalized

A null-terminated string buffer which will contain the normalized resource path when the function returns. The buffer must be large enough to contain the entire path including the terminating null character. If this parameter is NULL it will be ignored and the function will return the length of the normalized path without copying any characters.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer. If this value is zero, the ***lpszNormalized*** parameter is ignored and the function will return the length of the normalized path without copying any characters.

Return Value

This function returns the number of characters copied into the string buffer, not including the terminating null character. If the ***lpszNormalized*** parameter is NULL, it will return the length of the normalized path but will not copy any characters. If the function fails, it will return HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function will accept a resource path on the server and return a normalized version of that path. Normalization will remove extraneous path delimiters and collapse the path if there are references to parent directories. For example, if the resource path provided is:

```
/text/..//project//./files/filename.pdf
```

This function would return the following as the normalized path:

```
/project/files/filename.pdf
```

The extraneous path delimiters are removed (the double slashes) and the reference to the parent directory is collapsed to produce a simple, uniform path. This can be useful both for display purposes and to normalize input provided by a user. This function will accept an HTTP URL and return only the normalized resource path for the URL. If you need to normalize a complete URL, use the **HttpNormalizeUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpNormalizeUrl, HttpValidateHostName HttpValidateUrl

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpNormalizeUrl Function

```
INT WINAPI HttpNormalizeUrl(
   LPCTSTR lpszUrl,
   LPTSTR lpszNormalized,
   INT nMaxLength
);
```

The **HttpNormalizeUrl** function normalizes the resource path and returns a canonical URL.

Parameters

lpszUrl

A null-terminated string which specifies an HTTP URL. This parameter cannot be NULL.

lpszNormalized

A null-terminated string buffer which will contain the normalized URL when the function returns. The buffer must be large enough to contain the entire URL including the terminating null character. If this parameter is NULL it will be ignored and the function will return the length of the normalized URL without copying any characters.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer. If this value is zero, the ***lpszNormalized*** parameter is ignored and the function will return the length of the normalized URL without copying any characters.

Return Value

This function returns the number of characters copied into the string buffer, not including the terminating null character. If the ***lpszNormalized*** parameter is NULL, it will return the length of the normalized URL but will not copy any characters. If the function fails, it will return HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

This function will accept a standard HTTP or HTTPS URL and return a canonical version of that URL. Normalization will remove extraneous path delimiters and collapse the path if there are references to parent directories. If non-standard port numbers are included in the URL, they will be preserved. For example, if the follwing URL is provided to the function:

```
https://www.example.com:443/file/..//project/filename.pdf
```

It will return the following as the normalized URL:

```
https://www.example.com/project/filename.pdf
```

Because the port number specified in the original URL is the default port number for secure HTTP connections, it is removed. In addition, the path is collapsed and the extraneous path delimiters are removed.

This function is primarily intended to normalize URLs which may be entered by a user or read from a configuration file. It is not necessary to call this function prior to calling **HttpConnectUrl** because it will always be normalized internally prior to the connection being established. If you wish to check a URL to ensure it is valid and the server name can be resolved to an IP address, use the **HttpValidateUrl** function.

If you need to normalize a remote file path, use the **HttpNormalizePath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpOpenFile Function

```
INT WINAPI HttpOpenFile(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   DWORD dwOffset
);
```

The **HttpOpenFile** function opens the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to open.

dwOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Use the **HttpCloseFile** function to close the file on the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpOpenFileEx Function

```
INT WINAPI HttpOpenFileEx(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   ULARGE_INTEGER uiOffset
);
```

The **HttpOpenFileEx** function opens the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to open.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Use the **HttpCloseFile** function to close the file on the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPatchData Function

```
INT WINAPI HttpPatchData(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCTSTR lpszPatchData,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions
);
```

The **HttpPatchData** function submits patch data to the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource name that the patch data will be submitted to. Typically this is the name of a script on the server.

lpszPatchData

A null-terminated string that specifies the patch data that will be submitted to the server.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvResult*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_PATCH_DEFAULT	The default post mode. The contents of the buffer will be submitted without encoding. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_PATCH_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

HTTP_PATCH_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPatchData** function is used to submit XML or JSON formatted patch data to a service, and then returns a copy of the response from the server into a local buffer. This function will not perform any encoding and will not automatically define the type of patch data being submitted. Your application is responsible for specifying the content type for the patch data, and ensuring that the XML or JSON data that is being submitted to the server is formatted correctly.

This function sends a PATCH command to the server, which is similar to a POST or PUT request. It is used to make partial updates to a resource, rather than creating or replacing it entirely. The format of the patch data is specific to the service being used. If the resource being patched does not exist, the behavior is defined by the server. If enough information is provided, it may choose to create the resource just as if a PUT command was used, or it may return an error.

Your application should use the **HttpSetRequestHeader** function to define the Content-Type header prior to calling the **HttpPatchData** function. One of the most common formats used is the JSON Merge Patch which is defined in RFC 7396. The value for the Content-Type header for this patch format is "application/merge-patch+json". Refer to your service API documentation to determine what patch formats are acceptable, along with any additional header values that must be defined.

The function may be used in one of two ways, depending on the needs of the application. The first approach is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the ***lpvResult*** parameter will point to the buffer that was allocated by the client and the value that the ***lpcbResult*** parameter points to should be initialized to the size of that buffer.

The second approach is to have the ***lpvResult*** parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the ***lpcbResult*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the ***lpcbResult*** parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the PATCH request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

When encountering a server error during a request, the **HttpPatchData** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the PATCH request fails, servers may also provide further details about the failure, such as XML or JSON formatted data containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the HTTP_PATCH_ERRORDATA option. When this

option is enabled, the behavior of **HttpPatchData** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification can be enabled by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Store the script output into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_PATCH_CONVERT option is used

nResult = HttpPatchData(hClient,
                        lpszResource,
                        lpszPatchData,
                        &hgblBuffer,
                        &cbBuffer,
                        HTTP_PATCH_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpPostData Function

```
INT WINAPI HttpPostData(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCVOID lpvBuffer,
   DWORD cbBuffer,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions
);
```

The **HttpPostData** function submits the contents of the specified buffer to a script on the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource that the data will be posted to on the server. Typically this is the name of a script that will be executed. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

The data that will be provided to the script. This parameter may be NULL if the script does not require any additional data from the client.

cbBuffer

The number of bytes to copy from the buffer. If this ***lpvBuffer*** parameter is NULL, this value should be zero.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_POST_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character

	sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.
HTTP_POST_MULTIPART	The contents of the buffer being sent to the server consists of multipart form data and will be sent as-is without any encoding.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostData** function is used to submit data to a script that executes on the server and then copy the output from that script into a local buffer. If you are submitting XML or JSON formatted data to the server, it is recommended that you use the **HttpPostXml** or **HttpPostJson** functions instead to ensure that the correct content type and encoding is automatically selected.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpcbResult* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the POST request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

When encountering a server error during a request, the **HttpPostData** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the POST request fails, servers may also provide further details about the failure, such as XML or JSON formatted data containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the HTTP_POST_ERRORDATA option. When this option is enabled, the behavior of **HttpPostData** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call

HttpGetResultCode to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification can be enabled by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of the transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Store the response in block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nResult = HttpPostData(hClient,
                       lpszResource,
                       lpParameters,
                       cbParameters,
                       &hgblBuffer,
                       &cbBuffer,
                       HTTP_POST_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPostFile Function

```
INT WINAPI HttpPostFile(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPCTSTR lpszResource,
   LPCTSTR lpszFieldName,
   DWORD dwOptions,
   DWORD dwReserved
);
```

The **HttpPostFile** function posts the contents of the specified file to a script executed on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A null-terminated string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszResource

A null-terminated string that specifies the resource on the server that the file data will be posted to. Typically this is the name of a script that is responsible for processing and storing the file data.

lpszFieldName

A null-terminated string that corresponds to the form field name that the script expects. If this parameter is NULL or an empty string, a default field name of "File1" is used.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostFile** function is similar to the **HttpPutFile** function in that it can be used to upload the contents of a local file to a server. However, instead of using the PUT command, the POST command is used to send the file data to a script that is executed on the server. This method has the advantage of not requiring any special configuration settings on the server, however it does require that the script be able to process multipart/form-data as defined in RFC 2388.

To support uploading files from a form on a webpage, the FILE input type is used along with the

action that specifies the script that will accept the file data and process it. For example, the HTML code could look like this:

```
<form action="/cgi-bin/upload.cgi" method="post" enctype="multipart/form-
data">
<input type="file" name="datafile" size="20">
<input type="submit">
</form>
```

In this example, the script /cgi-bin/upload.cgi is responsible for processing the file data that is posted by the client, and the form field name "datafile" is used. The user can select a file, and when the Submit button is clicked, the file data is posted to the script. To simulate this using the **HttpPostFile** function, the *lpszFileName* parameter should be set to the name of the local file that will be posted to the server. The *lpszResource* parameter should be the name of the script, in this case "/cgi-bin/upload.cgi". The *lpszFieldName* parameter should be specified as the string "datafile" to match the name of the field used by the form.

Note that the **HttpPostFile** function always submits the file contents as multipart/form-data with the content type set to application/octet-stream. The script that accepts the posted data must be able to parse the multipart header block and correctly process 8-bit data. If the script assumes that the data will be posted using a specific encoding type such as base64 then the file data may not be accepted or may be corrupted by the script.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpPostJson Function

```
INT WINAPI HttpPostJson(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCTSTR lpszJsonData,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions
);
```

The **HttpPostJson** function submits JSON structured data to the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource name the JSON data will be submitted to. Typically this is the name of a REST API endpoint or script on the server.

lpszJsonData

A null-terminated string which specifies the JSON structured text to be submitted to the server. If the Unicode version of this function is called, the text will sent as a UTF-8 encoded string.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvResult*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. This option does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function

	will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostJson** function is used to submit JSON structured data to a REST API endpoint or script and then returns the output in a local buffer. This function automatically sets the correct content type and encoding required for submitting JSON data to a server, however it does not parse the JSON data itself to ensure it is well-formed. Your application is responsible for ensuring the JSON data being submitted to the server is formatted correctly.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpcbResult* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the POST request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "application/json" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

When encountering a server error during a request, the **HttpPostJson** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the POST request fails, servers may also provide further details about the failure, such as XML or JSON formatted text containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the HTTP_POST_ERRORDATA option. When this option is enabled, the behavior of **HttpPostJson** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the POST completes, a timeout occurs or the operation is canceled. To prevent the request from blocking the main application thread, create a background worker thread to submit the JSON payload. Connections established in different threads will not interfere with one another and will not cause the main thread to block while it waits for the

server to respond.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
DWORD cbBuffer = 0;

// Store the response in a block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter.

nResult = HttpPostJson(hClient,
                       lpszResource,
                       lpszJsonData,
                       &hgblBuffer,
                       &cbBuffer,
                       HTTP_POST_DEFAULT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPostText Function

```
INT WINAPI HttpPostText(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCTSTR lpszTextData,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions
);
```

The **HttpPostText** function submits plain text data to the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource name the text will be submitted to. Typically this is the name of a REST API endpoint or script on the server.

lpszTextData

A null-terminated string which specifies the text to be submitted to the server. If the Unicode version of this function is called, the text will sent as a UTF-8 encoded string.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvResult*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. This option does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function

	will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostText** function is used to submit plain text to a REST API endpoint or script and then returns the output in a local buffer. This function can be used to submit any kind of text payload to the server, and automatically sets a default content type without any encoding, ensuring the text is submitted exactly as specified. If the Unicode version of this function is called, the text will be converted to UTF-8 prior to being submitted to the server. The endpoint or script on the server side must be capable of processing UTF-8 encoded text correctly or you may experience unexpected results.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the generic "text/plain" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type. Your application should ensure any content type you specify is valid for the contents of the payload; the content type is not checked against the text you submit to the server.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpcbResult* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the POST request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

If you are using the Unicode version of this function, the data returned in the *lpvResult* buffer will always contain bytes and not wide (16-bit) characters. It will typically consist of UTF-8 encoded text; however, depending on the request, the server may return binary data. The value of the Content-Type header returned by the server as part of its response will indicate what type of data the payload contains. If you expect the server to return text, you can use the **MultiByteToWideChar** function to convert the response to a Unicode string, or you can use the **HttpPostTextEx** function, which can handle the text conversion for you.

When encountering a server error during a request, the **HttpPostText** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the POST request fails, servers may also provide further details about the failure, such as XML or JSON formatted text containing specific error codes or diagnostic

messages.

To capture this error information, you can utilize the HTTP_POST_ERRORDATA option. When this option is enabled, the behavior of **HttpPostText** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the POST completes, a timeout occurs or the operation is canceled. To prevent the request from blocking the main application thread, create a background worker thread to submit the text payload. Connections established in different threads will not interfere with one another and will not cause the main thread to block while it waits for the server to respond.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
DWORD cbBuffer = 0;

// Store the response in a block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the output from the
// script is textual, the HTTP_POST_CONVERT option is used

nResult = HttpPostText(hClient,
                       lpszResource,
                       lpszTextData,
                       &hgblBuffer,
                       &cbBuffer,
                       HTTP_POST_DEFAULT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPostTextEx Function

```
INT WINAPI HttpPostTextEx(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCTSTR lpszTextData,
   LPTSTR lpszResult,
   LPDWORD lpcchResult,
   UINT nCodePage,
   DWORD dwOptions
);
```

The **HttpPostTextEx** function submits plain text data to the server and returns the result in a string provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource name the text will be submitted to. Typically this is the name of a REST API endpoint or script on the server.

lpszTextData

A null-terminated string which specifies the text to be submitted to the server. If the Unicode version of this function is called, the text will sent as a UTF-8 encoded string.

lpszResult

A null-terminated string buffer which will contain the text response returned by the server. This parameter cannot be NULL.

lpcchResult

A pointer to an unsigned integer which should be initialized to the maximum number of characters that can be copied to the string specified by the ***lpszResult*** parameter. When the function returns, this value will be updated with the number of characters returned by the server, not including the terminating null character.

nCodePage

An unsigned integer that specifies the ANSI code page which should be used to convert the text returned by the server. A value of zero specifies the default system code page should be used with the conversion. In most cases, applications should use CP_UTF8 as the code page. See the remarks below for more information.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	If the resource being downloaded from the server is textual, the data is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. This option

	does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostTextEx** function is used to submit plain text to a REST API endpoint or script and then returns the output in string provided by the caller. This function can be used to submit any kind of text payload to the server, and automatically sets a default content type, ensuring the text is submitted exactly as specified. If the Unicode version of this function is called, the text will be converted to UTF-8 prior to being submitted to the server. The endpoint or script on the server side must be capable of processing UTF-8 encoded text correctly or you may experience unexpected results.

This function differs from the **HttpPostText** function because it expects the response from the server to contain only text and will automatically convert the response to Unicode using the code page specified by the *nCodePage* parameter. If the Unicode version of this function is called, the text returned by the server will be converted to UTF-16 text and returned as a null-terminated string. If the ANSI version of this function is called, the text returned by the server will be converted to UTF-8 text and returned in the string buffer. This function should never be used to submit a request when the response from the server may contain binary data.

In most cases, you should specify the *nCodePage* parameter as **CP_UTF8** because this is what most servers use as their default character set. If the server is returning text using a character set other than UTF-8, specifying a code page enables your application to automatically normalize that text to Unicode. It is important to note the text returned by this function will always be either UTF-16 or UTF-8 Unicode to ensure there is no data loss during the conversion process. If you have a specific need to return a localized ANSI string, use **HttpPostTextExW** and then convert the Unicode string with **WideCharToMultiByte** using **CP_ACP** as the code page. This can potentially result in data loss if the current ANSI code page cannot represent all of the Unicode text returned by the server.

The string buffer specified by *lpszResult* should be large enough to contain the entire response from the server, including the terminating null character. If the buffer is not large enough, the response returned by the server will be truncated. If you cannot estimate what the largest reasonable buffer size should be, it's recommended you use the **HttpPostText** function instead which can return an HGLOBAL handle rather than a fixed-length buffer.

It is important for your application to initialize the value of the *lpcchResult* parameter correctly. This parameter must be passed by reference and if not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the POST request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the generic "text/plain" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers

require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type. Your application should ensure any content type you specify is valid for the contents of the payload; the content type is not checked against the text you submit to the server.

When encountering a server error during a request, the **HttpPostText** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the POST request fails, servers may also provide further details about the failure, such as XML or JSON formatted text containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the HTTP_POST_ERRORDATA option. When this option is enabled, the behavior of **HttpPostText** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the POST completes, a timeout occurs or the operation is canceled. To prevent the request from blocking the main application thread, create a background worker thread to submit the text payload. Connections established in different threads will not interfere with one another and will not cause the main thread to block while it waits for the server to respond.

Example

```
TCHAR szResponse[MAXBUFSIZE];
DWORD cchResponse = MAXBUFSIZE;

// Submit the request to the server and return the response in a
// string buffer. End-of-line characters will be automatically
// converted to use Windows conventions. Note that cchResponse
// must be initialized with the maximum string length and will
// be updated to contain the actual string length when the function
// returns.

nResult = HttpPostTextEx(hClient,
                         lpszResource,
                         lpszTextData,
                         szResponse,
                         &cchResponse,
                         HTTP_POST_ERRORDATA);

if (nResult != HTTP_ERROR)
{
    // Because we have used the HTTP_POST_ERRORDATA option, the
    // function will not return an error if the server returns
    // a status code in the 400 or 500 range. In this case, the
    // the response will typically contain more information
    // about the cause of the failure.

    INT nCode = HttpGetResultCode(hClient);

    if (nCode >= 200 && nCode <= 299)
    {
        // The server has indicated the request was successful
```

```
    }
    else if (nCode >= 400)
    {
        // There was some problem with the request; check the
        // szResponse string for more information
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPostXml Function

```
INT WINAPI HttpPostXml(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCTSTR lpszXmlData,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions
);
```

The **HttpPostXml** function submits XML structured data to the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource name the XML data will be submitted to. Typically this is the name of a REST API endpoint or script on the server.

lpszXmlData

A null-terminated string which specifies the XML structured text to be submitted to the server. If the Unicode version of this function is called, the text will sent as a UTF-8 encoded string.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvResult*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the number of bytes of data returned by the server.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_POST_DEFAULT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. This option does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_POST_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function

	will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPostXml** function is used to submit XML structured data to a REST API endpoint or script and then returns the output in a local buffer. This function automatically sets the correct content type and encoding required for submitting XML data to a server, however it does not parse the XML data itself to ensure it is well-formed. Your application is responsible for ensuring the XML data being submitted to the server is formatted correctly.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the *lpvResult* parameter will point to the buffer that was allocated by the client and the value that the *lpcbResult* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvResult* parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the *lpcbResult* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the *lpcbResult* parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when issuing the POST request to the server, the variable passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "text/xml" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

When encountering a server error during a request, the **HttpPostXml** function normally returns HTTP_ERROR, and no data is copied into the caller-provided buffer. The last error code for the current thread is updated to reflect the general cause of the failure, allowing the application to handle this error condition appropriately. If the POST request fails, servers may also provide further details about the failure, such as XML or JSON formatted text containing specific error codes or diagnostic messages.

To capture this error information, you can utilize the HTTP_POST_ERRORDATA option. When this option is enabled, the behavior of **HttpPostXml** changes; it does not return HTTP_ERROR for server error statuses. Instead, any error data provided in the server's response, regardless of its format, is copied into the result buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the POST completes, a timeout occurs or the operation is canceled. To prevent the request from blocking the main application thread, create a background worker thread to submit the XML payload. Connections established in different threads will not interfere with one another and will not cause the main thread to block while it waits for the

server to respond.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
DWORD cbBuffer = 0;

// Store the response in a block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter.

nResult = HttpPostXml(hClient,
                      lpszResource,
                      lpszXmlData,
                      &hgblBuffer,
                      &cbBuffer,
                      HTTP_POST_ERRORDATA);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // output data from the script
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // Because we have used the HTTP_POST_ERRORDATA option, the
    // function will not return an error if the server returns
    // a status code in the 400 or 500 range. In this case, the
    // the response will typically contain more information
    // about the cause of the failure.

    INT nCode = HttpGetResultCode(hClient);

    if (nCode >= 200 && nCode <= 299)
    {
        // The server has indicated the request was successful
    }
    else if (nCode >= 400)
    {
        // There was some problem with the request; check the
        // contents of lpBuffer for more information
    }

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpProxyConnect Function

```
HCLIENT WINAPI HttpProxyConnect(
   UINT nProxyType,
   LPCTSTR lpszProxyHost,
   UINT nProxyPort,
   LPCTSTR lpszProxyUser,
   LPCTSTR lpszProxyPassword,
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   DWORD dwVersion,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **HttpProxyConnect** function is used to establish a connection through a proxy server.

Parameters

nProxyType

An unsigned integer which specifies the type of proxy that the client is connecting to. The supported proxy server types are as follows:

Value	Description
HTTP_PROXY_NONE	A direct connection will be established with the server. When this value is specified the proxy parameters are ignored.
HTTP_PROXY_STANDARD	A standard connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard connections.
HTTP_PROXY_SECURE	A secure connection is established through the specified proxy server. This proxy type should be used with secure connections and the HTTP_OPTION_SECURE option should also be set via the ***dwOptions*** parameter.
HTTP_PROXY_WINDOWS	The configuration options for the current system should be used. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. These settings are the same proxy server settings configured in Windows.

lpszProxyHost

A null-terminated string which specifies the proxy server host name or IP address. This argument is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

nProxyPort

The port number that the proxy server is listening for connections on. A value of zero specifies that the default port number 80 should be used. Note that in most cases, a proxy server is not configured to use the default port. This argument is ignored if the proxy type is set to

HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

lpszProxyUser

A null-terminated string which specifies the user name that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpszProxyPassword

A null-terminated string which specifies the password that will be used to authenticate the client session to the proxy server. If the server does not require user authentication, then a NULL pointer may be passed in this argument.

lpszRemoteHost

A null-terminated string which specifies the name of the server to connect to through the proxy server. This may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number 80 should be used. For standard connections, the default port number is 80. For secure connections, the default port number is 443.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.

HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. This option will always establish a secure connection with the server. The value of the ***dwVersion*** parameter will be ignored when this option is used.
HTTP_OPTION_HTTP3	This option specifies the client should attempt a HTTP/3 (QUIC) connection with the server. If a connection cannot be established using HTTP/3 the client will attempt a connection using an earlier version of the protocol. You should only use this option if you know the server supports the QUIC protocol, otherwise requests will be delayed as a result of the fallback to attempting a HTTP/2 connection. The value of the ***dwVersion*** parameter will be ignored when this option is used.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the client will default to using TLS 1.2 or later. If HTTP_PORT_DEFAULT is specified as the remote port, this option will automatically change the port number to use HTTP_PORT_SECURE instead.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that

	use RC4, MD5 and SHA1. Although this option may permit connections with servers which do not support current standards, avoid using it unless absolutely necessary. Some servers may reject the connection if the client offers to use TLS 1.0, even when TLS 1.2 or later is also supported.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

dwVersion

The requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. The HTTPVERSION macro can be used to create a version value and the following values are defined:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this session. This is the same as specifying HTTP_VERSION_11 and is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_09	The client should use the original one-line protocol which includes no version number and no request header block. This version has been deprecated and should only be used with legacy servers which do not support the protocol standard. This version of the protocol does not support virtual hosts and is not supported by most modern web services.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.

HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.
HTTP_VERSION_30	The client should use the HTTP/3 protocol standard defined in RFC 9114. This protocol version is similar to earlier versions of the protocol in terms the request methods and server responses, but the underlying transport mechanism is significantly different. Instead of using TCP, this version of the protocol uses multiplexed UDP connections designed to reduce the overhead of TCP while maintaining reliability. If the client or server does not support HTTP/3, the client will automatically attempt to use an earlier version of the protocol.

lpCredentials

Pointer to credentials structure SECURITYCREDENTIALS. This parameter is only used if the HTTP_OPTION_SECURE option is specified for the connection. This parameter may be NULL, in which case no client credentials will be provided to the server. If client credentials are required, the fields ***dwSize***, ***lpszCertStore***, and ***lpszCertName*** must be defined, while other fields may be left undefined. Set ***dwSize*** to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to the client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **HttpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **HttpProxyConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

If the HTTP_PROXY_WINDOWS proxy type is specified, then the proxy configuration for the local system is used. If no proxy server has been defined, then the proxy-related parameters will be ignored and the function will establish a connection directly to the server.

The username and password information is only used when connecting to a server which supports version 1.1 or later of the protocol.

Most applications should use HTTP_VERSION_DEFAULT as the value for the ***dwVersion*** parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2 or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support the features required for a secure HTTP/2 connection.

If the HTTP_OPTION_KEEPALIVE option is specified and the server does not support persistent connections, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers. This option is automatically enabled when using HTTP/2.

Using the HTTP_OPTION_NOUSERAGENT option to prevent sending a User-Agent header does not make requests anonymous. Servers may still identify clients based on IP address information, authentication credentials, request patterns or other HTTP headers included with the request.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the function will fail and return INVALID_CLIENT.

You should only attempt to use HTTP/3 if you know the server supports that version of the protocol. If the server does not support HTTP/3, the client will wait for the timeout period to elapse to determine the server is not responding to the HTTP/3 request and will then attempt to use HTTP/2. If you specify HTTP/3 as the protocol version and you are experiencing long delays for requests the complete, the most likely reason is the server does not support the QUIC protocol and every request is falling back to use HTTP/2 instead. The minimum required platform for HTTP/3 support is Windows 11 21H2 and later builds or Windows Server 2022 or later.

The handle returned by this function is initially attached to the thread that created it. From that point on, until it is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **HttpAttachThread** function.

Specifying the HTTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPutData Function

```
INT WINAPI HttpPutData(
   HCLIENT hClient,
   LPCTSTR lpszRemoteFile,
   LPCVOID lpvBuffer,
   DWORD dwLength,
   DWORD dwReserved
);
```

The **HttpPutData** function copies the contents of the specified buffer and stores it in a file on the server.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be created. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A buffer which will contain the data to be transferred from the client and stored in a file on the server.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutData** function is used to store the contents of the specified buffer in a file on the server. Not all servers permit files to be created using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** function prior to uploading the data.

This function is designed for uploading the contents of a buffer to be stored as a file on the server. If you need to use the PUT command to as part of a RESTful API where the PUT command is used to submit data to the server, use the **HttpPutDataEx** function. That function will return the success or failure responses back to the client.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPutDataEx Function

```
INT WINAPI HttpPutDataEx(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCVOID lpvBuffer,
   DWORD cbBuffer,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions
);
```

The **HttpPutDataEx** function submits the contents of the specified buffer to the server using the PUT command and returns the server's response to the command.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string which specifies the resource path on the server. This string may specify a valid URL for the current server that the client is connected to.

lpvBuffer

A buffer which will contain the data to be transferred from the client and submitted to the server. This parameter may not be NULL.

cbBuffer

The number of bytes to copy from the buffer. This value must be larger than zero.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvResult*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_PUT_DEFAULT	The default mode. The contents of the buffer are sent unmodified and the data returned by the server is copied to the result buffer exactly as it is returned from the server. This option should be used if the server is expected to return binary data in the response to the PUT request.
HTTP_PUT_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual

	carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_PUT_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutDataEx** function is used to submit data to the server using the PUT command. This is typically used with RESTful APIs and is similar in functionality to the POST command. However, the data that is submitted will be sent to the server as-is and will not be encoded.

The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the response from the server. In this case, the ***lpvResult*** parameter will point to the buffer allocated by the client and the value that the ***lpcbResult*** parameter points to should be initialized to the size of that buffer.

The second method is to have the ***lpvResult*** parameter point to a global memory handle which will reference the data when the function returns. In this case, the value that the ***lpcbResult*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

If the Unicode version of this function is called and the server returns a text response to the PUT request, it is the application's responsibility to convert the contents of the ***lpvResult*** buffer to UTF-16 text. If the server returns text, most likely it will use UTF-8 encoding.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "application/octet-stream" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

It is common for servers to return additional information about a failed request in their response to the client. If you need to process this information, use the HTTP_PUT_ERRORDATA option which causes the error message to be returned in the ***lpvResult*** buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a data transfer while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HGLOBAL hgblResponse = (HGLOBAL)NULL;
LPBYTE lpResponse = (LPBYTE)NULL;
DWORD cbResponse = 0;

// Store the response into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter. Since the response from
// the server is textual, the HTTP_PUT_CONVERT option is used

nResult = HttpPutDataEx(hClient,
                        lpszResource,
                        lpRequest,
                        cbRequest,
                        &hgblResponse,
                        &cbResponse,
                        HTTP_PUT_CONVERT);

if (nResult != HTTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // response from the server
    lpResponse = (LPBYTE)GlobalLock(hgblResponse);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblResponse);
    GlobalFree(hgblResponse);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPutFile Function

```
INT WINAPI HttpPutFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions
   DWORD dwOffset
);
```

The **HttpPutFile** function transfers the specified file on the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local system.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be created, overwritten or appended to. This string may specify a valid URL for the current server that the client is connected to.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

dwOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutFile** function is used to transfer a file from the local system to a server. Not all servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** function prior to uploading the file.

To upload large files that are over 4GB, use the **HttpPutFileEx** function.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically

fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpPutFileEx Function

```
INT WINAPI HttpPutFileEx(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions
   ULARGE_INTEGER uiOffset
);
```

The **HttpPutFileEx** function transfers the specified file on the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
HTTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.

uiOffset

Specifies a byte offset into the file. If this value is greater than zero, the server must support the ability to specify a byte range with the request to open the file, otherwise this function will fail.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutFileEx** function is used to transfer a file from the local system to a server. Not all servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** function prior to uploading the file.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be

enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPutText Function

```
INT WINAPI HttpPutText(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCTSTR lpszBuffer
);
```

The **HttpPutText** function creates a text file on the server using the contents of a string buffer.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string that specifies the resource on the server which will be created or overwritten. This string may specify a valid URL for the current server.

lpszBuffer

A null-terminated string that contains the text which will be submitted to the server .

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutText** function is used to create a text file on the server from the contents of a string. If the specified file already exists on the server, its contents will be overwritten. Not all servers permit files to be created using this method, and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the client authenticate itself using the **HttpAuthenticate** command prior to uploading the data.

If the Unicode version of this function is called, the string will be automatically converted to UTF-8 and then uploaded to the server. If you wish to upload UTF-16 Unicode or ANSI text to the server, you must use the **HttpPutData** function. This function should never be used to upload binary data.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpPutTextEx Function

```
INT WINAPI HttpPutTextEx(
   HCLIENT hClient,
   LPCTSTR lpszResource,
   LPCTSTR lpszBuffer,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions
);
```

The **HttpPutTextEx** function submits the contents of a string buffer to the server using the PUT command and returns the server's response to the command.

Parameters

hClient

Handle to the client session.

lpszResource

A null-terminated string which specifies the resource path on the server. This string may specify a valid URL for the current server.

lpszBuffer

A null-terminated string that contains the text that will be submitted to the server. This parameter cannot be NULL and may not specify an empty string.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvResult*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_PUT_DEFAULT	The default mode. automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the data being submitted to the server, only on the data returned by the server.
HTTP_PUT_ERRORDATA	This option causes the client to accept error data from the server if the request fails. If this option is specified, an error response from the server will not cause the function to fail. Instead, the response is returned to the client and the function will succeed.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpPutTextEx** function is used to submit the contents of a null-terminated string to the server using the PUT command. This is typically used with RESTful APIs and is similar in functionality to the POST command. However, the text that is submitted will not be encoded in the same way that the **HttpPostData** function submits data.

If the Unicode version of this function is called, the text will be converted to UTF-8 and then submitted to the server. If you wish to submit the contents of the string as UTF-16 Unicode text, or the payload contains binary data, you must use the **HttpPutDataEx** function. This function should never be used to upload binary data. If the server returns a text response and the Unicode version of this function is called, it is the application's responsibility to convert the contents of the *lpvResult* buffer to UTF-16 text. If the server returns text, most likely it will use UTF-8 encoding.

If the content type for the request has not been explicitly specified, it will be automatically updated by this function to use the "text/plain" content type. You can override the default content type for the request by calling the **HttpSetRequestHeader** function prior to calling this function. Most servers require you to explicitly specify what type of data is being submitted by the client and will reject requests which do not correctly identify the content type.

It is common for servers to return additional information about a failed request in their response to the client. If you need to process this information, use the HTTP_PUT_ERRORDATA option which causes the error message to be returned in the *lpvResult* buffer provided by the caller. If this option is used, your application should call **HttpGetResultCode** to obtain the HTTP status code returned by the server. This will enable you to determine if the operation was successful.

This function will cause the current thread to block until the data transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a data transfer while it is in progress, use the **HttpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpRead Function

```
INT WINAPI HttpRead(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **HttpRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

When **HttpRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpRegisterEvent Function

```
INT WINAPI HttpRegisterEvent(
   HCLIENT hClient,
   UINT nEventId,
   HTTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **HttpRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
HTTP_EVENT_CONNECT	The connection to the server has completed.
HTTP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
HTTP_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
HTTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
HTTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
HTTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
HTTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a

	transfer so that the client can update any user interface components such as a status control or progress bar.
HTTP_EVENT_REDIRECT	This event occurs when a the server indicates that the requested resource has been moved to a new location. The new resource location may be on the same server, or it may be located on another server. Check the value of the Location header field to determine where the resource has been moved to.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Remarks

The **HttpRegisterEvent** function associates a callback function with a specific event. The event handler is an **HttpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a file is being uploaded or downloaded. The HTTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one HTTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpRemoveQueuedFile Function

```
BOOL WINAPI HttpRemoveQueuedFile(
    HQUEUE hQueue,
    DWORD dwFileId
);
```

The **HttpRemoveQueuedFile** removes the specified file from the queue.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. This value cannot be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

Files can only be removed from the queue when in an idle or paused state. If you attempt to remove a file while the queue manager is in the process of uploading or download files, the function will fail.

The file identifier can be obtained by several different functions, including **HttpEnumQueuedFiles** and **HttpGetQueueStatus,** which provides information about the current file being processed in the queue. Do not make any assumptions about the value of the identifier. Although the value is guaranteed to be unique for the specified queue, it is not guaranteed that file identifiers will be assigned in sequential order.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpAddQueuedFile, HttpClearQueue, HttpEnumQueuedFiles, HttpGetQueuedFile, HttpGetQueueStatus, HttpSuspendQueue, HttpResetQueue

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpResetQueue Function

```
BOOL WINAPI HttpResetQueue(
    HQUEUE hQueue,
    DWORD dwOptions
);
```

The **HttpResetQueue** function resets the state of all file transfers in the current queue.

Parameters

hQueue

A handle to a file transfer queue.

dwOptions

An integer value which specifies which files should be reset in the queue. It may be one of the following values:

Value	Description
HTTP_QUEUE_RESET_ALL	All files in the queue should be reset to their initial state.
HTTP_QUEUE_RESET_COMPLETED	All files in the queue which have been successfully transferred will be reset to their initial state.
HTTP_QUEUE_RESET_FAILED	All files in the queue which were not transferred will be reset to their initial state.
HTTP_QUEUE_RESET_CANCELED	All files in the queue which were canceled will be reset to their initial state.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

When the **HttpStartQueue** function is called multiple times using the same queue handle, it will not attempt to transfer files which have already been successfully copied, and it will not attempt to re-transfer files if the previous transfer failed. This function resets queued files back to their initial state, prior to when the queue manager attempted to perform the transfer. The most common use would be to call the function with the HTTP_QUEUE_RESET_FAILED mode and then call **HttpStartQueue** to retry failed or canceled file transfers.

Because canceled file transfers are also considered failed transfers, specifying HTTP_QUEUE_RESET_FAILED will reset queued files which either encountered an error during the transfer or were explicitly canceled by calling the **HttpCancelQueuedFile** function. The HTTP_QUEUE_RESET_CANCELED option will only reset the state of queued file transfers which were canceled.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cshtpv12.lib

See Also

HttpCancelQueuedFile, HttpGetQueuedFile, HttpResumeQueue, HttpStartQueue, HttpStopQueue, HttpSuspendQueue

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpResumeQueue Function

```
BOOL WINAPI HttpResumeQueue(
    HQUEUE hQueue
);
```

The **HttpResumeQueue** function resumes transfers in the queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function signals the queue manager to resume processing files in the transfer queue after the **HttpSuspendQueue** function has been called. This function will fail if the queue is in an idle (stopped) state, and will be ignored if the queue manager is already transferring files. The **HttpGetQueueStatus** function can be called to obtain the current status of the queue.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpSetBearerToken Function

```
INT WINAPI HttpSetBearerToken(
   HCLIENT hClient,
   LPTSTR lpszBearerToken
);
```

The **HttpSetBearerToken** function sets the OAuth 2.0 bearer token used to authenticate the client session with a web service.

Parameters

hClient

Handle to the client session.

lpszBearerToken

A null-terminated string buffer which contains the bearer token used to authorize client requests. If this parameter is NULL or a zero-length string, the current bearer token will be cleared and no client authentication will be performed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

Using OAuth 2.0 requires you to understand the process of how to request the bearer (access) token. Obtaining a bearer token requires registering your application with the web service provider, getting a unique client ID associated with your application and then requesting the token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access the service.

Your application should not store a bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)
Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpAuthenticate, HttpGetBearerToken, HttpSetRequestHeader

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpSetContentType Function

```
BOOL WINAPI HttpSetContentType(
   HCLIENT hClient,
   LPCTSTR lpszContentType
);
```

The **HttpSetContentType** function sets the content type for the next request.

Parameters

hClient

Handle to the client session.

lpszContentType

A null-terminated string which contains the MIME content type of the data being submitted to the web server. If this parameter is NULL or an empty string, the current type will be cleared and the client will use a default type based on the request and content encoding.

Return Value

If the function succeeds, it will return a non-zero value. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

The content type string must use the standard IANA format which consists of a type and subtype separated by a forward slash. Some common content types are:

Content Type	Description
`text/plain`	The request payload is unstructured text in a human readable format. This content type serves a default for textual data which does not explicitly have another standard subtype.
`text/csv`	The request payload is in a comma-separated value (CSV) text format.
`application/octet-stream`	The request payload contains binary data. This content type serves a default for binary data which does not explicitly have another standard subtype.
`application/json`	The request payload is standard JSON formatted text. This is the default content type used when submitting JSON requests, however some services may expect the client to use the non-standard `text/x-json` type.
`application/xml`	The request payload is standard XML formatted text. This is the default content type used when submitting XML requests, however some servers may expect the client use the deprecated `text/xml` type. The standard content type for XML is defined in RFC 7303, however most services will recognize both types as valid.

If a content type is not explicitly specified with a request, an appropriate default content type will be automatically selected. For example, the **HttpPostJson** function will set the content type to **application/json** by default. This function can be used to override that default value.

This function will validate the content type, but does not validate the subtype. Unregistered subtypes should always be prefixed with "x-" which designates it as experimental. Some commonly used types also use this designation, such as **text/x-vcalendar** for the vCalendar format.

If your application needs to set the content type to a non-standard value for a proprietary API, use the **HttpSetRequestHeader** function to set the Content-Type header value. That function will not perform any validation on the header value. The contents of the payload will not be checked to ensure the content type is valid. It is the responsibility of the application to ensure the correct content type is used when submitting the request.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

HttpSetCookie Function

```
BOOL WINAPI HttpSetCookie(
   HCLIENT hClient,
   LPCTSTR lpszCookieName,
   LPCTSTR lpszCookieValue
);
```

The **HttpSetCookie** function sends the specified cookie to the server when a resource is requested.

Parameters

hClient

Handle to the client session.

lpszCookieName

Pointer to a string which specifies the name of the cookie that will be sent to the server when the next resource is requested.

lpszCookieValue

Pointer to a string which specifies the value of the cookie. To delete a cookie that has been previously set, this parameter should be NULL or point to an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetCookie** function submits the cookie name and value to the server when a resource is requested or data is posted to a script. For more information about cookies and how they are used, refer to the **HttpGetCookie** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpSetDefaultUserAgent Function

```
INT WINAPI HttpSetDefaultUserAgent(
    LPCTSTR lpszUserAgent
);
```

The **HttpSetDefaultUserAgent** function sets the default user agent string which is included with all requests.

Parameters

lpszUserAgent

A null-terminated string which specifies the new default user agent string. If this parameter is NULL or an empty string, the client will revert to using the default user agent string defined when the library was first initialized.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetDefaultUserAgent** function changes the default user agent string which is included with each request made by the client. This default value is global and changing it will change the default user agent for all client sessions in all threads created by the process.

The user agent string should use a format with the product name and version number separated by a slash. There can be multiple products listed in the user agent string separated by spaces, with additional optional information enclosed in parenthesis. For example, a valid user agent string for an application named "MyProgram" could look like this:

```
MyProgram/1.0 (Win32)
```

Some web services check the value of the user agent string to determine if a compatible client is being used to issue the request. The default value used by SocketTools is designed to emulate a common browser, but some services may require you change the user agent to use a specific value or include certain product names and versions.

To change the user agent string for a specific client session, use the **HttpSetRequestHeader** function to set a value for the `User-Agent` header. To get the current value of the default user agent string, use the **HttpGetDefaultUserAgent** function.

To prevent any user agent string from being included with a request, include the HTTP_OPTION_NOUSERAGENT option when connecting to the server or use **HttpSetOption** to enable that option after a connection has been established.

Using the HTTP_OPTION_NOUSERAGENT option to prevent sending a User-Agent header does not make requests anonymous. Servers may still identify clients based on IP address information, authentication credentials, request patterns or other HTTP headers included with the request.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpSetDefaultZoneId Function

```
BOOL WINAPI HttpSetDefaultZoneId(
    HCLIENT hClient,
    DWORD dwZoneId
);
```

The **HttpSetDefaultZoneId** function sets the default security zone for downloaded files.

Parameters

hClient

Handle to the client session.

dwZoneId

An unsigned integer which specifies the default security zone identifier. It may be one of the following values:

Value	Description
SECURITY_ZONE_NONE	The file does not have a zone identifier associated with it. This typically indicates that the file was created locally or has not been marked by Windows as originating from another zone. This is the default behavior if the application does not explicitly set a default security zone.
SECURITY_ZONE_LOCAL	The file is considered to be part of the **Local Machine** zone, which includes files stored on the user's local system or removable media. This zone has the least restrictive security settings, and files are typically allowed to run without prompting or limitation. ***This zone should not be assigned to downloaded files***, as doing so can bypass security mechanisms designed to protect against potentially harmful content. Only use this setting for files that are created locally by the application itself and are known to be safe. Misuse of this setting can result in a significant security risk, especially if the file contains scripts, executables, or other active content.
SECURITY_ZONE_INTRANET	The file originates from the **Local Intranet** zone, which includes content served from internal network resources, such as shared drives, file servers, and internal web applications. This zone typically has fewer security restrictions than the Internet zone but more than the Local Machine zone. It is commonly used in enterprise environments where network resources are managed and considered relatively safe. ***This zone should not be used for files downloaded from the public Internet***, as doing so may incorrectly signal that the file is trusted within the organization. Assign this zone only to files that are retrieved from authenticated internal sources or known secure locations on the local network.
SECURITY_ZONE_TRUSTED	The file is from a site or source explicitly added to the

	Trusted Sites zone in Internet Explorer or Windows security settings. This zone is intended for domains or locations that the user or system administrator considers to be safe, such as internal applications hosted on the public Internet or third-party services with a strong reputation for safety. Files marked with this zone typically bypass certain security checks, and applications may allow active content (such as scripts or macros) to run without prompting. Use caution when assigning this zone to downloaded files, as it may override protections that would otherwise apply to untrusted content.
SECURITY_ZONE_INTERNET	The file was downloaded from the **Internet** zone, which represents untrusted or unknown sources outside the local network. This is the standard zone identifier automatically applied by web browsers, email clients, and many applications when a file is downloaded from a public website or external server. Windows uses this zone to enforce security restrictions, such as prompting the user before executing scripts, blocking active content, or displaying a warning when the file is opened. This is typically the appropriate zone to assign for any file obtained over HTTP from an external site. Assigning this zone helps ensure that users are notified before opening potentially unsafe content, in accordance with Windows Attachment Manager and Group Policy settings.
SECURITY_ZONE_RESTRICTED	The file is associated with the **Restricted Sites** zone, which enforces the strictest security policies. This zone is used for content that is explicitly marked as untrusted or potentially harmful. Files tagged with this zone may be blocked from execution, prevent active content from running, or trigger warnings when accessed. Assigning this zone can be useful for sandboxing unverified downloads or limiting the risk from files obtained from questionable sources. However, it may also cause legitimate files to fail to open or operate with reduced functionality depending on system policy and application behavior.

Return Value

If the function succeeds, the return value is non-zero. If the function fails it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetDefaultZoneId** function sets the default security zone identifier that will be applied to all files downloaded during the client session. This setting controls how Windows treats downloaded files with respect to security prompts and content execution restrictions. Once the default zone ID is set, it will be automatically applied to all subsequent file downloads performed by the client session. This eliminates the need to manually set the security zone for each individual file, ensuring consistent zone tagging across the session.

When is specified, no alternate data stream is created. This

`SECURITY_ZONE_NONE` `Zone.Identifier`

causes the file to be treated as if it originated from the local system, and Windows will not apply zone-based security restrictions. This is the default behavior which maintains backwards compatibility with previous versions of the library that did not create the security zone metadata for files.

The zone ID metadata is interpreted by Windows components such as **Attachment Execution Services** and **SmartScreen** to determine whether the user should be warned when opening a file. In enterprise environments, Group Policy settings may alter how different zone IDs are handled, such as blocking scripts, macros, or unsigned executables. Developers should test zone assignment behavior in target environments when distributing files to end users.

Note that this function does not retroactively modify existing files. The default zone identifier is applied only at the time a file is downloaded using functions such as **HttpDownloadFile**.

If your application is distributed in a controlled environment, such as a corporate network with endpoint protection or user access controls, consult your organization's security policy before modifying default zone behavior. Improper zone tagging can impact file access, generate security prompts, or interfere with digital signature enforcement.

Be aware that some file operations (such as extracting from a ZIP archive, or copying files to non-NTFS volumes or across certain network shares) may strip the `Zone.Identifier` metadata. Developers should not rely solely on zone tagging as a persistent trust mechanism outside of the initial download context.

To get the security zone identifier for a local file, use the **HttpGetFileZoneInfo** function. To change or remove the security zone information for a file, use the **HttpSetFileZoneInfo** function.

Assigning `SECURITY_ZONE_LOCAL` as the default security zone identifier for downloaded files is strongly discouraged. This zone disables key Windows security features and can expose users to significant risk. This security zone should only be used with files that are generated locally by the application and are guaranteed to be safe. Never assign this zone to content obtained from the Internet or other untrusted sources.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HttpSetEncodingType Function

```
INT WINAPI HttpSetEncodingType(
    HCLIENT hClient
    INT nEncodingType
);
```

The **HttpSetEncodingType** function specifies the type of encoding to be applied to the content of a HTTP request.

Parameters

hClient

Handle to the client session.

nEncodingType

Specifies the content encoding type for the request. The following values are defined:

Value	Description
HTTP_ENCODING_NONE	No encoding will be applied to the content of a request and no default content type will be specified.
HTTP_ENCODING_URL	Non-printable and extended ASCII characters will be encoded so they can be safely used with URLs and form data. Encoded characters will be represented by a percent symbol prefix, followed by a two digit hexadecimal value which represents the ASCII character code. This encoding is typically used with web services which process HTML form data. If the content type has not been explicitly specified, it will default to **application/x-www-form-urlencoded**.
HTTP_ENCODING_XML	This encoding specifies the content being submitted to the server contains XML structured data. If the content type has not been defined, it will default to **application/xml**, which is the official MIME media type for XML text. Legacy services may expect **text/xml** as the content type.
HTTP_ENCODING_JSON	This encoding specifies the content being submitted to the server contains JSON structured data. If the content type has not been defined, it will default to **application/json**, which is the official MIME media type for JSON text. In rare cases, legacy services may expect **text/x-json** as the content type.
HTTP_ENCODING_UTF8	This encoding specifies the content is unstructured text which has been UTF-8 encoded. If the content type has not been defined, it will default to **text/plain; charset=utf-8** which is appropriate for any kind of general text payloads. If you use the Unicode version of the functions in this library, all text is normally submitted as UTF-8 encoded text.
HTTP_ENCODING_ANSI	This encoding specifies the content is unstructured text and may not be UTF-8 encoded if the ANSI version of the functions in this library are used. This encoding is not

	recommended unless there is a specific need to send text using a specific character set. If the content type has not been defined, it will default to **`plain/text`**.
HTTP_ENCODING_XMLURL	This encoding is identical to URL encoding, except spaces are not encoded. It is used with legacy web services which expect form data in an XML format and cannot process encoded whitespace. This encoding should not be specified for services which use REST APIs. If the content type has not been specified, it will default to **`application/x-www-form-urlencoded`**.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetEncodingType** function sets the type of encoding used when optional parameter data is submitted with a request for a resource. If you do not set the Content-Type request header prior to submitting the request, the default content type provided to the server will be determined by the encoding you choose. If you specify HTTP_ENCODING_NONE, no default content type will be provided. Because most services require a Content-Type header as part of a POST request, this can cause the server to reject the request. The **HttpSetContentType** function can be used to explicitly specify the content type for the request.

If the service you are connected with expects an XML formatted request, it is recommended you use the **HttpPostXml** function. If the service expects JSON formatted text, use the **HttpPostJson** function. These functions ensure the correct encoding and content type are always used. If the service expects some other kind of text payload, you can set the appropriate content type using the **HttpSetContentType** function and then use the **HttpPostText** function to submit the request.

If you are using the **HttpPostData** function to submit form data to the server, in most cases you should use HTTP_ENCODING_URL. If the form data contains XML text, you may need to use the HTTP_ENCODING_XMLURL encoding type. However, in most cases, this is not the appropriate encoding type for XML and should never be used when submitting XML to a REST API endpoint.

If you are submitting a payload which contains binary data, you would typically use HTTP_ENCODING_NONE and explicitly set the appropriate content type using the **HttpSetContentType** function. For example, if you're submitting a JPEG image to a REST endpoint, you should not use any encoding and set the Content-Type header to **`image/jpeg`**. If your application needs to set the content type to a non-standard value for a proprietary API, use the **HttpSetRequestHeader** function to set the Content-Type header value. That function will not perform any validation on the header value.

Requirements

HttpSetFileZoneInfo Function

```
BOOL WINAPI HttpSetFileZoneInfo(
   LPCTSTR lpszLocalFile,
   DWORD dwZoneId,
   LPCTSTR lpszHostUrl
);
```

The **HttpSetFileZoneInfo** function sets or clears the zone identifier information for a local file.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of a local file. This parameter must specify a regular file which exists on the local system and the current process must have permission to access and write to the file. If the file path includes environment variables surrounded in percent (%) symbols, the variables will be expanded. This parameter cannot be NULL.

dwZoneId

An unsigned integer which specifies the zone ID which should be assigned to the file. It may be one of the following values:

Value	Description
SECURITY_ZONE_NONE	The file does not have a zone identifier associated with it.
SECURITY_ZONE_LOCAL	The file is considered to be part of the local computer zone.
SECURITY_ZONE_INTRANET	The file originates from the local intranet zone, such as an internal corporate network.
SECURITY_ZONE_TRUSTED	The file originates from a site in the **Trusted Sites** zone.
SECURITY_ZONE_INTERNET	The file was downloaded from the Internet and is treated with caution by Windows.
SECURITY_ZONE_RESTRICTED	The file originates from a site in the **Restricted Sites** zone, which is used for untrusted content.

lpszHostUrl

An optional pointer to a string which specifies the URL used to originally download the file. If this information is not required the parameter may be a NULL pointer or an empty string. If an originating URL is provided, it must be a valid HTTP URL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetFileZoneInfo** function enables applications to set or remove the security zone identifier metadata associated with a local file. This information is stored in an alternate data stream named `:Zone.Identifier` and is used by Windows to determine the origin and trust level of a file, potentially prompting the user with a warning before the file is opened.

The file name specified by the *lpszLocalFile* parameter must not reference a network location. This

includes UNC paths (such as `\\server\share\file.txt`) and drive letters that are mapped to network shares. Security zone metadata cannot be applied to files on network volumes because the SMB protocol does not support alternate data streams. If a file with zone metadata is copied from a local NTFS drive to a network share, any associated streams like `Zone.Identifier` will be lost.

Specifying `SECURITY_ZONE_NONE` will remove any existing zone identifier stream from the file. This has the same effect as selecting the Unblock option in the file's properties dialog in Windows Explorer. Once the stream is removed, the file will be treated as though it originated from the local computer. Note that when the `Zone.Identifier` stream is deleted from a file to remove its security zone information, Windows Explorer may not immediately reflect this change. This is because Explorer caches certain file metadata, including zone information used to display the "This file came from another computer" warning in the file's Properties dialog.

When assigning a zone ID, it is important to ensure that the value accurately reflects the source of the file. For files that have been downloaded from the Internet, it is strongly recommended to use `SECURITY_ZONE_INTERNET`. This allows Windows and other software to enforce appropriate security measures, such as requiring user confirmation before executing or opening the file.

In most scenarios, zone identifiers should only be set for files that were downloaded from untrusted or external sources. Setting an overly permissive zone (such as `SECURITY_ZONE_LOCAL`) for files obtained from the Internet or other potentially unsafe locations can expose users to security risks and circumvent built-in protections.

If a URL is provided via the *lpszHostUrl* parameter, it will be included in the zone metadata and can be retrieved later using the **HttpGetFileZoneInfo** function. This provides additional context about the origin of the file and may aid in auditing or diagnostic tasks. The URL must be a syntactically valid HTTP address and should reflect the actual location from which the file was downloaded.

Not all file systems support alternate data streams. The function will fail if used on a volume (such as FAT32) that does not support this feature. Additionally, modifying zone information may fail if the file is in use, read-only, or if the current process does not have the required permissions. It is possible to disable the creation of security zone metadata through local policy settings. In this case, the function will fail and the last error code will be set to `ST_ERROR_POLICY_NO_ZONEINFO`.

For more detailed information about the security zone identifiers, refer to the **HttpSetDefaultZoneId** function.

Assigning `SECURITY_ZONE_LOCAL` as the security zone identifier for downloaded files is strongly discouraged. This zone disables key Windows security features and can expose users to significant risk. This security zone should only be used with files that are generated locally by the application and are guaranteed to be safe. Never assign this zone to content obtained from the Internet or other untrusted sources.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpSetFormProperties Function

```
INT WINAPI HttpSetFormProperties(
   HFORM hForm,
   LPHTTPFORMPROPERTIES lpFormProp
);
```

The **HttpSetFormProperties** function updates the properties of the specified form.

Parameters

hForm

Handle to the virtual form.

lpFormProp

Points to a HTTPFORMPROPERTIES structure which specifies the new properties for the form.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpSetLastError Function

```
VOID WINAPI HttpSetLastError(
   DWORD dwErrorCode
);
```

The **HttpSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or HTTP_ERROR. Those functions which call **HttpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **HttpGetLastError** function. The use of **HttpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpSetOption Function

```
INT WINAPI HttpSetOption(
   HCLIENT hClient,
   DWORD dwOption,
   BOOL bEnabled
);
```

The **HttpSetOption** function enables or disables the specified option.

Parameters

hClient

Handle to the client session.

dwOption

An unsigned integer which specifies one of the following options:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_KEEPALIVE	This instructs the server to maintain a persistent connection between requests. This can improve performance because it eliminates the need to establish a separate connection for each resource that is requested. If the server does not support the keep-alive option, the client will automatically reconnect when each resource is requested. Although it will not provide any performance benefits, this allows the option to be used with all servers.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_ERRORDATA	This option specifies the client should return the content of an error response from the server, rather than returning an error code. Note that this option will disable automatic resource redirection, and should not be used with HTTP_OPTION_REDIRECT.

HTTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

bEnabled

An integer value which determines if the option should be enabled or disabled. A non-zero value specifies that the option should be enabled, while a zero value specifies that the option should be disabled.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetOption** function can only enable or disable the options listed above. Other options are only available when the connection is initially established. For example, you cannot use this function to enable security options or switch to using HTTP/2 after the connection has been made.

If you use HTTP_OPTION_FREETHREAD to permit any thread to reference a client handle allocated in another thread, your application is responsible for ensuring it does not attempt to submit requests using the same handle on different threads at the same time. If two different threads attempt to perform an operation using the same handle, there is no guarantee as to which thread will complete the operation first.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpSetPriority Function

```
INT WINAPI HttpSetPriority(
   HCLIENT hClient,
   INT nPriority
);
```

The **HttpSetPriority** function specifies the priority for file transfers.

Parameters

hClient

Handle to the client session.

nPriority

An integer value which specifies the new priority for file transfers. It may be one of the following values:

Value	Description
HTTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Return Value

If the function succeeds, the return value is the previous file transfer priority. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetPriority** function can be used to control the processor usage, memory and network

bandwidth allocated for file transfers. The default priority balances resource utilization and transfer speed while ensuring that a single-threaded application remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of transfer speed. For example, if you create a worker thread to download a file in the background and want to ensure that it has a minimal impact on the process, the HTTP_PRIORITY_BACKGROUND value can be used.

Higher priority values increase the memory allocated for the transfers and increases processor utilization for the transfer. The HTTP_PRIORITY_CRITICAL priority maximizes transfer speed at the expense of system resources. It is not recommended that you increase the file transfer priority unless you understand the implications of doing so and have thoroughly tested your application.

If the file transfer is being performed in the main UI thread, increasing the priority may interfere with the normal processing of Windows messages and cause the application to appear to become non-responsive. It is also important to note that when the priority is set to HTTP_PRIORITY_CRITICAL, normal progress events will not be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpSetRequestHeader Function

```
BOOL WINAPI HttpSetRequestHeader(
    HCLIENT hClient,
    LPCTSTR lpszHeader,
    LPCTSTR lpszValue
);
```

The **HttpSetRequestHeader** function sets the value of the specified request header field.

Parameters

hClient

Handle to the client session.

lpszHeader

A pointer to a null-terminated string which specifies the name of the header field. Header names may only contain ASCII letters, numbers and a restricted subset of punctuation characters. Header names cannot contain Unicode or ANSI multi-byte character sequences.

lpszValue

A pointer to a null-terminated string which specifies the value of the HTTP header. Headers values cannot contain carriage-return or linefeed characters. If the value contains Unicode characters, they will be UTF-8 encoded. If this parameter or NULL or a zero-length string, the header field is deleted from the request headers.

Return Value

If the function succeeds, the return value is non-zero. If the client handle is invalid, the function returns a value of zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSetRequestHeader** function defines a header field and value that is submitted to the server when a resource is requested. If the header field has already been defined, it will be replaced by the new value. There are a number of header fields which are automatically created by the library, and others that are conditionally created depending on whether or not certain options are specified. The following header fields are automatically created by the library:

Header Field	Description
Accept	This header specifies the types of resources that are acceptable to the client. By default, all resource data types are accepted by the client.
Authorization	This header is automatically created if the client uses the HttpAuthenticate function to authenticate a client session.
Connection	This header determines if the connection is maintained after a resource has been requested, or if the connection should be immediately closed. The value of this header depends on whether the HTTP_OPTION_KEEPALIVE option has been specified.
Content-Length	This header defines the length of the data that is being posted to the server or the size of a file being uploaded to the server.
Content-Type	This header defines the content type for data posted to the server.

	This header is automatically created if required.
Host	This header specifies the name of the server that the client has connected to. This is automatically generated when any resource is requested.
Pragma	This header is used to control caching performed by the server. If the option HTTP_OPTION_NOCACHE has been specified, this header will automatically be defined with the value "no-cache".
Proxy-Authorization	This header is automatically created if a proxy connection has been established and a username and password is required to authenticate the client session.

Request headers are generated by functions that send resource requests. In some cases, header values are supplied by the requesting function only if the application has not previously defined the header. For others, the requesting function overrides what the application may have defined.

If you use this function to set the Authorization header to a custom value for this client session, you must not call the **HttpAuthenticate** function. The **HttpAuthenticate** function will always override any custom Authorization header value and replace it with the credentials token generated from the username and password provided. If your application was using this function to specify an OAuth 2.0 bearer token, it is recommended you use the **HttpSetBearerToken** function instead.

If you need to change the default content type for the next request, it is recommended you use the **HttpSetContentType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpSetTimeout Function

```
INT WINAPI HttpSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **HttpSetTimeout** function sets the number of seconds the client will wait for a response from the server.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete. If this value is zero, the default timeout period of 20 seconds will be used.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. Once the specified number of seconds has elapsed, the blocking method will fail and return to the caller. The timeout value affects both the requests submitted and the responses returned by the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpStartQueue Function

```
BOOL WINAPI HttpStartQueue(
  HQUEUE hQueue,
  DWORD dwQueueMode,
  DWORD dwReserved,
  HTTPEVENTPROC lpEventProc,
  DWORD_PTR dwParam
);
```

The **HttpStartQueue** function begins transferring files in the queue.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An unsigned integer which specifies which files in the queue should be transferred. It may be one of the following values:

Constant	Description
HTTP_QUEUE_ALL	All files in the queue should be transferred.
HTTP_QUEUE_DOWNLOAD	Transfer only those files which have been queued for download.
HTTP_QUEUE_UPLOAD	Transfer only those files which have been queued for upload.

dwReserved

An unsigned integer reserved for internal use. This parameter value should always be zero.

lpEventProc

Specifies the procedure-instance address of an application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, there will be no callback notifications.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

Queued file transfers are performed asynchronously using a background worker thread. If you provide the address to an event callback function, that function will always be invoked in the context of the queue manager thread. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself and you should avoid calling any functions which could cause the thread to block. For example, you should not attempt to establish other network

connections from within the event handler.

If your application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function. Controls should only be modified by the same UI thread that created their window. One common approach to address this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

To obtain the handle to the queue from within an event handler, call the **HttpGetThreadQueue** function with the ***dwThreadId*** parameter set to a value of zero. This will return the handle for the current queue management session which invoked the callback function.

If a callback function is provided, the HTTP_QUEUE_EVENT event notification will be invoked whenever the internal state of the queue has changed. The handle value passed to the callback function will be a handle to the queue, not to a client connection. The **HttpGetQueueStatus** function can be called within the event handler to obtain the current state of the queue. This will event will always occur when the queue manager begins processing files in the queue and after it has stopped. This event will also occur whenever the queue is suspended and then resumed.

The **HttpWaitForQueue** function can be used to wait for the queue manager to complete processing the transfer queue.

Example

```
// Create a new queue
HQUEUE hQueue = HttpCreateQueue(INFINITE, HTTP_TIMEOUT, HTTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = HttpAddQueuedFile(
                     hQueue,
                     lpszLocalFile,
                     lpszRemoteFile,
                     HTTP_OPTION_DEFAULT,
                     HTTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    HTTPQUEUEDFILE queuedFile;

    if (HttpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case HTTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case HTTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szLocalFile,
```

```
                        queuedFile.szRemoteFile);
                break;
            }
        }
    }

    // Start the queued file transfers and wait for it to complete
    if (HttpStartQueue(hQueue, HTTP_QUEUE_ALL, 0, NULL, 0))
    {
        HttpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
        HttpStopQueue(hQueue);
    }

    // Remove all files from the queue
    HttpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpStopQueue Function

```
BOOL WINAPI HttpStopQueue(
    HQUEUE hQueue
);
```

The **HttpStopQueue** function stops transferring queued files.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

When the **HttpStopQueue** function is called and there is a file transfer in progress, it will not immediately stop the upload or download of the file. Instead, the queue manager is signaled to stop processing additional files in the queue after the transfer has completed. To wait for the current transfer to complete, call the **HttpWaitForQueue** function.

It is permitted to call **HttpStopQueue** from within a queue event handler. In this case, the current file transfer will complete and the queue manager will terminate.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpSubmitForm Function

```
INT WINAPI HttpSubmitForm(
   HCLIENT hClient,
   HFORM hForm,
   LPVOID lpvResult,
   LPDWORD lpcbResult,
   DWORD dwOptions
);
```

The **HttpSubmitForm** function submits the contents of the specified form to a script on the server and returns the result in a buffer provided by the caller.

Parameters

hClient

Handle to the client session.

hForm

Handle to the virtual form which contains the data to be submitted to the server.

lpvResult

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpcbResult

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvResult*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_SUBMIT_DEFAULT	The default post mode. The contents of the buffer are encoded and sent as standard form data. The data returned by the server is copied to the result buffer exactly as it is returned from the server.
HTTP_SUBMIT_CONVERT	If the data being returned from the server is textual, it is automatically converted so that the end of line character sequence is compatible with the Windows platform. Individual carriage return or linefeed characters are converted to carriage return/linefeed character sequences. Note that this option does not have any effect on the form data being submitted to the server, only on the data returned by the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpSubmitForm** function is used to submit form data to a script that executes on the server and then copy the output from that script into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the resulting output of the script. In this case, the ***lpvResult*** parameter will point to the buffer that was allocated by the client and the value that the ***lpcbResult*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvResult*** parameter point to a global memory handle which will contain the data when the function returns. In this case, the value that the ***lpcbResult*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

This function will cause the current thread to block until the post completes, a timeout occurs or the operation is canceled. During the transfer, the HTTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **HttpEnableEvents**, or by registering a callback function using the **HttpRegisterEvent** function.

To determine the current status of a transaction while it is in progress, use the **HttpGetTransferStatus** function.

Example

```
HFORM hForm = INVALID_FORM;
HGLOBAL hgblResult = (HGLOBAL)NULL;
DWORD cbResult = 0;
INT nResult = 0;

hForm = HttpCreateForm(_T("/login.php"), HTTP_METHOD_POST, HTTP_FORM_ENCODED);

if (hForm == INVALID_FORM)
    return;

HttpAddFormField(hForm, _T("UserName"), lpszUserName, (DWORD)-1L, 0);
HttpAddFormField(hForm, _T("Password"), lpszPassword, (DWORD)-1L, 0);

nResult = HttpSubmitForm(hClient, hForm, &hgblResult, &cbResult, 0);
HttpDestroyForm(hForm);

if (hgblResult != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResult);

    // lpBuffer points to data returned by the server after the form
    // data was submitted

    GlobalUnlock(hgblResult);
    GlobalFree(hgblResult);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

Unicode: Implemented as Unicode and ANSI versions

HttpSubmitRequest Function

```
INT WINAPI HttpSubmitRequest(
   DWORD dwRequestType,
   LPCTSTR lpszResource,
   LPHTTPCONNECTION lpConnection,
   LPCVOID lpvRequest,
   DWORD dwRequestLength,
   LPVOID lpvResponse,
   LPDWORD lpdwResponseLength
);
```

The **HttpSubmitRequest** function provides a high-level interface for submitting requests to a web service.

Parameters

dwRequestType

An unsigned integer which specifies the type of request being submitted to the server. It may be one of the following values:

Value	Description
HTTP_METHOD_DEFAULT	Perform a default request action based on the value of parameters passed to this function. If there is no request payload, the action will default to HTTP_METHOD_GET, otherwise it will default to HTTP_METHOD_POST. It is generally recommended that you explicitly specify the request method; however, this default value can be useful if your application does not know if a payload will be included with the request at the time the function is called.
HTTP_METHOD_GET	Use the GET method when submitting the request to the server. If this action is used, the ***lpvRequest*** and ***dwRequestLength*** parameters will be ignored. The buffer specified by the ***lpvResponse*** parameter will contain the server's response to the request.
HTTP_METHOD_POST	Use the POST method when submitting the request to the server. The payload specified by the ***lpvRequest*** parameter will be included with the request and the buffer specified by the ***lpvResponse*** parameter will contain the server's response to the request.
HTTP_METHOD_PUT	Use the PUT method when submitting the request to the server. The payload specified by the ***lpvRequest*** parameter will be included with the request. This method is typically used with persistent storage on the server, such as uploading the contents of a file. If the ***lpvResponse*** parameter is not NULL, it will contain any response from the server after the operation has completed.

lpszResource

A null-terminated string which specifies the complete URL for the resource. Both standard and

secure connections are supported, and query parameters may be included with the URL. This parameter cannot be NULL and must specify an absolute (fully qualified) URI which begins with either http:// or https://.

lpConnection

A pointer to a **HTTPCONNECTION** structure which contains additional information about the client connection. This structure is required if your application must connect through a proxy server or when authentication is required to access a resource. This parameter can be NULL, in which case default values will be used when establishing the connection.

lpvRequest

A buffer which contains the payload data submitted to the server as part of the request. This parameter may point to a byte buffer or a null-terminated string. If there is no payload required for the request this parameter may be NULL. If the Unicode version of this function is called and the request buffer contains text, it will be automatically converted to UTF-8 prior to submitting the data to the server. If the ***dwRequestLength*** parameter is -1, the payload will always be processed as a null-terminated string and the function will fail if the buffer does not contain text characters.

dwRequestLength

An unsigned integer which specifies the size of the request payload. If the payload contains text, this should specify the number of characters in the buffer. If the payload contains binary data, this value should specify the number of bytes in the buffer. If the ***lpvRequest*** parameter points to a null-terminated string, this value can be -1 and the length of the payload will be determined automatically. If the Unicode version of this function is called and the length is -1, the request payload will be UTF-8 encoded prior to being submitted to the server.

lpvResponse

A buffer which will contain the data returned by the server, or a pointer to a global memory handle which will reference the data when the function returns. This parameter may be NULL if the response data is not required. If this parameter is NULL, the ***lpdwResponseLength*** parameter must also be NULL. If a response buffer is provided, the data will always be returned as a byte stream, even when the Unicode version of this function is called. If the server returns a text payload, it will typically be UTF-8 encoded and the application can convert the text to Unicode using the **MultiByteToWideChar** function.

lpdwResponseLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvResponse*** parameter. If the ***lpvResponse*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual number of bytes of data that was returned. If the ***lpvResponse*** parameter is not NULL, this parameter cannot be NULL.

Return Value

If the function succeeds, the return value is the server status code. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**. The application should always check the return value to determine if the request was successful. If the server returns a 4xx or 5xx status code, this indicates the request was not accepted and the response buffer will typically contain information about the cause of the failure.

Remarks

The **HttpSubmitRequest** function provides a single high-level interface for submitting requests to a web server and returning the server's response. This function is entirely self-contained and does not require a client session handle. The current thread will block until the function returns and will not

generate event notifications. If you need to download a large file from a web server and want progress updates, it is recommended you use the **HttpDownloadFile** function.

If the service you are using requires authentication, you will need to allocate a **HTTPCONNECTION** structure and set the appropriate member values to specify the authentication method and user credentials. This structure also allows you to provide additional information, such as additional request header values, a custom timeout period and additional connection options.

When the *lpvRequest* parameter is not NULL, the contents of the buffer will be examined to determine if it contains text or binary data. If the *dwRequestLength* parameter is -1, the *lpvRequest* parameter is always considered to be a pointer a null-terminated string, with the length calculated by counting the number of characters up to the terminating null character. If the request payload is text, the function will also attempt to determine if the payload looks like XML or JSON and will automatically set the appropriate content type. The application can explicitly provide a MIME content type by setting the *lpszContentType* member of the **HTTPCONNECTION** structure.

Example

```
// Submit an XML payload to the server and return the response in a global
// memory buffer allocated by the function
LPCTSTR lpszResource = _T("https://www.example.com/postxml");
LPCTSTR lpszRequest = _T("<?xml version=\"1.0\" encoding=\"utf-8\"?>\r\n") \
                      _T("<test>\r\n") \
                      _T("  <data param=\"A\">Value1</data>\r\n") \
                      _T("  <data param=\"B\">Value2</data>\r\n") \
                      _T("</test>\r\n");

// Provide additional connection information which includes user credentials
// and a custom header which includes an API token for the service; note that
// we need to initialize the dwSize member of the structure
HTTPCONNECTION httpConnection = { 0, };
httpConnection.dwSize = sizeof(httpConnection);
httpConnection.nAuthType = HTTP_AUTH_BASIC;
httpConnection.lpszUserName = _T("userid");
httpConnection.lpszPassword = _T("secret");
httpConnection.lpszContentType = _T("application/xml");
httpConnection.lpszHeaders = _T("X-API-Token: 99d2fe39-0246-4efa-98e0-
4d775579fa5d");

// Declare the global memory handle which will contain the server response
// and initialize the length to 0, which tells the API that a HGLOBAL handle
// is being used rather than a pointer to a pre-allocated buffer
HGLOBAL hgblResponse = NULL;
DWORD dwLength = 0;

INT nResult = HttpSubmitRequest(
    HTTP_METHOD_POST,
    lpszResource,
    &httpConnection,
    lpszRequest,
    (DWORD)-1,
    &hgblResponse,
    &dwLength);

if (nResult != HTTP_ERROR && hgblResponse != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblResponse);
```

```
    // The lpBuffer variable points to the data returned by the server and
    // the application is responsible for freeing the global memory handle

    GlobalUnlock(hgblResponse);
    GlobalFree(hgblResponse);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpSuspendQueue Function

```
BOOL WINAPI HttpSuspendQueue(
    HQUEUE hQueue
);
```

The **HttpSuspendQueue** function pauses all file transfers for the specified queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

If there is a file transfer in progress when this function is called, the transfer will complete normally. The queue manager will enter a suspended state after the transfer has completed and before it begins processing the next file in the queue.

It is permitted to call **HttpSuspendQueue** from within a queue event handler. In this case, the current file transfer will complete and the queue manager will stop processing additional files in the queue until it is resumed or stopped.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpCancelQueuedFile, HttpGetQueueStatus, HttpResetQueue, HttpResumeQueue, HttpStartQueue, HttpStopQueue

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpTaskAbort Function

```
BOOL WINAPI HttpTaskAbort(
   UINT nTaskId,
   DWORD dwMilliseconds
);
```

Abort the specified asynchronous task.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to abort.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskAbort** function signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the *dwMilliseconds* parameter has a value of zero, the function returns immediately after the background thread has been signaled. If the *dwMilliseconds* parameter is non-zero, the function will wait that amount of time for the background thread to terminate.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock. To abort a file transfer within an event handler, use the **HttpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpTaskDone, HttpTaskResume, HttpTaskSuspend, HttpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpTaskDone Function

```
BOOL WINAPI HttpTaskDone(
    UINT nTaskId
);
```

Determine if an asynchronous task has completed.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed, this function returns a non-zero value. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskDone** function is used to determine if the specified asynchronous task has completed. If you use this function to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this function rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **HttpGetTaskError** function will return the last error code associated with the task. A return value of zero indicates success, while a non-zero return value specifies an error code that indicates the cause of the failure. The last error code for the task can also be retrieved using the **HttpTaskWait** function, which causes the application to wait for the asynchronous task to complete.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpGetTaskError, HttpTaskAbort, HttpTaskResume, HttpTaskSuspend, HttpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpTaskResume Function

```
BOOL WINAPI HttpTaskResume(
    UINT nTaskId
);
```

Resume execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskResume** function resumes execution of the background worker thread that was previously suspended using the **HttpTaskSuspend** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpTaskAbort, HttpTaskDone, HttpTaskSuspend, HttpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpTaskSuspend Function

```
BOOL WINAPI HttpTaskSuspend(
    UINT nTaskId
);
```

Suspend execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskSuspend** function will suspend execution of the background worker thread associated with the task. Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **HttpTaskResume** function. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

HttpTaskAbort, HttpTaskDone, HttpTaskResume, HttpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpTaskWait Function

```
BOOL WINAPI HttpTaskWait(
   UINT nTaskId,
   DWORD dwMilliseconds,
   DWORD dwReserved,
   LPDWORD lpdwElapsed,
   LPDWORD lpdwError
);
```

Wait for an asynchronous task to complete.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to complete.

dwReserved

An unsigned integer reserved for future use. This value should always be zero.

lpdwElapsed

A pointer to an unsigned integer that will contain elapsed time in milliseconds when the function returns. If this information is not required, this parameter may be NULL.

lpdwError

A pointer to an unsigned integer that will contain the error code associated with the completed task. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **HttpGetLastError** function.

Remarks

The **HttpTaskWait** function waits for the specified task to complete. If the task is active and the ***dwMilliseconds*** parameter is non-zero, this function will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the ***dwMilliseconds*** parameter is zero, then this function will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this function is called, the function will return immediately without causing the current thread to block. If the ***lpdwElapsed*** parameter is not NULL, it will contain the number of milliseconds that it took for the task to complete. If the ***lpdwError*** parameter is not NULL, it will contain the last error code value that was set by the worker thread before it terminated. If this value is zero, that means that the background operation was successful and no error occurred. A non-zero value will indicate that the background operation has failed.

You should not call this function from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this function is blocked waiting for the background task to complete, and this can cause your application to appear non-

responsive to the end-user. If you have a GUI application and you need to periodically check to see if a task has completed, create a timer to periodically call the **HttpTaskDone** function. When it returns a non-zero value (indicating that the task has completed), you can safely call **HttpTaskWait** to obtain the elapsed time and last error code without blocking the current thread.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = HttpAsyncGetFile(hClient,
                           lpszLocalFile,
                           lpszRemoteFile,
                           HTTP_TRANSFER_DEFAULT,
                           0,
                           NULL,
                           0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    HttpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpUninitialize Function

```
VOID WINAPI HttpUninitialize();
```

The **HttpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **HttpInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **HttpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **HttpUninitialize** for every successful call to **HttpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpUploadFile Function

```
BOOL WINAPI HttpUploadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   UINT nTimeout
   DWORD dwOptions
   LPHTTPTRANSFERSTATUS lpStatus
   HTTPEVENTPROC lpEventProc
   DWORD_PTR dwParam
);
```

The **HttpUploadFile** function uploads the specified file from the local system to the server.

Parameters

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the Hypertext Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed using the system Control Panel.

HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller amounts of data over fast network connections.

lpStatus

A pointer to an HTTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpUploadFile** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then upload the file to the server. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @] hostname [:port] / [path / ...]
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

Not all web servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the URL specify a username and password to upload a file.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the method will fail and return a value of zero.

The ***lpStatus*** parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The ***lpEventProc*** parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The ***dwParam*** parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the ***this*** pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for ***lpEventProc*** and the ***dwParam*** parameter will be ignored.

The **HttpUploadFile** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpPutFile** to upload the file. If the server does not support the PUT command, you may be able to upload files using the **HttpPostFile** function. Refer to that function for more information.

Example

```
HTTPTRANSFERSTATUS httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile =
_T("https://update:secret@www.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = HttpUploadFile(lpszLocalFile,
                         lpszRemoteFile,
                         HTTP_OPTION_DEFAULT,
                         &httpStatus,
                         NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpUploadFileEx Function

```
BOOL WINAPI HttpUploadFileEx(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   UINT nTimeout
   DWORD dwOptions
   LPHTTPTRANSFERSTATUSEX lpStatus
   HTTPEVENTPROC lpEventProc
   DWORD_PTR dwParam
);
```

The **HttpUploadFileEx** function uploads the specified file from the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the Hypertext Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource. When connected to an HTTP 1.0 or earlier server, this directive may be ignored.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration

	can be changed using the system Control Panel.
HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol.
HTTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol. The client will default to using TLS 1.2 or later for secure connections.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
HTTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times

	for smaller amounts of data over fast network connections.

lpStatus

A pointer to an HTTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **HttpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpUploadFileEx** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session and then upload the file to the server. The URL must be complete, and specify either a standard or secure HTTP scheme:

```
[http|https]://[username : password] @] hostname [:port] / [path / ...]
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "http" scheme is used and the HTTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, the "https" scheme must be specified.

Not all web servers permit files to be uploaded and some may require that specific configuration changes be made to the server in order to support this functionality. Consult your server's technical reference documentation to see if it supports the PUT command, and if so, what must be done to enable it. It may be required that the URL specify a username and password to upload a file.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the method will fail and return a value of zero.

The ***lpStatus*** parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The ***lpEventProc*** parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **HttpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The ***dwParam*** parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the ***this*** pointer as the value, and then cast it back to an object pointer inside the

callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **HttpUploadFileEx** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a specific proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **HttpConnect** or **HttpProxyConnect** and then use **HttpPutFileEx** to upload the file. If the server does not support the PUT command, you may be able to upload files using the **HttpPostFile** function. Refer to that function for more information.

Example

```
HTTPTRANSFERSTATUSEX httpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile =
_T("http://update:secret@www.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = HttpUploadFileEx(lpszLocalFile,
                           lpszRemoteFile,
                           HTTP_OPTION_DEFAULT,
                           &httpStatus,
                           NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    HttpGetErrorString(HttpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpValidateHostName Function

```
BOOL WINAPI HttpValidateHostName(
   LPCTSTR lpszHostName,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **HttpValidateHostName** function determines if the specified host name is valid and returns its IP address.

Parameters

lpszHostName

A null-terminated string which specifies the host name. The function will fail If this parameter is NULL or an empty string.

lpszAddress

A null-terminated string buffer which will contain the IP address of the host. If specified, this string must be large enough to store the complete IP address, including the terminating null character. If this parameter is NULL or the ***nMaxLength*** parameter is zero, it will be ignored and the IP address will not be returned.

nMaxLength

An integer value that specifies the maximum number of characters which can be copied into the ***lpszAddress*** string buffer. The buffer must be large enough to store the complete address. Because this function can return either an IPv4 or IPv6 address, it is recommended the minimum length for the buffer to be 46 characters. If this parameter is zero, the ***lpszAddress*** parameter will be ignored.

Return Value

If the function succeeds, the host name is valid and the return value will be non-zero. If the function fails, the host name could not be resolved to an IP address and the return value will be zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpValidateHostName** function provides a convenient way to determine if a host name is valid by attempting to resolve the name into an IP address. If the Unicode version of this function is used, any non-ASCII characters in the host name will be automatically encoded into a compatible format and then resolved to an IP address. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended you use the Unicode version.

If the ***lpszHostName*** parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address.

If you wish to validate a complete HTTP URL instead of a host name, use the **HttpValidateUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpConnectUrl, HttpValidateUrl

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpValidateUrl Function

```
BOOL WINAPI HttpValidateUrl(
    LPCTSTR lpszUrl
);
```

The **HttpValidateUrl** function determines if a string represents a valid HTTP URL.

Parameters

lpszUrl

A null-terminated string that specifies the URL to validate.

Return Value

If the specified URL is valid and the host name can be resolved to an IP address, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpValidateUrl** function will check the value of a string to ensure that it represents a complete, valid URL using either a standard or secure HTTP scheme. This function will not establish a connection with the server to verify that it exists, it will only attempt to resolve the host name to an IP address. If the remote host is specified as an IP address, this function will check to make sure that the address is formatted correctly. Note that if you wish to specify an IPv6 address, you must enclose the address in brackets.

To establish a connection with a server using a URL, use the **HttpConnectUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpVerifyFile Function

```
BOOL WINAPI HttpVerifyFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwReserved
);
```

The **HttpVerifyFile** function attempts to verify that the size of a file on the local system is the same as the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the name of file on the local system.

lpszRemoteFile

A null-terminated string that specifies the name of the file on the server.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetLastError**.

Remarks

The **HttpVerifyFile** function will attempt to verify that the contents of the local and remote files are identical by comparing the size of the files. This function is provided for compatibility with the File Transfer Protocol API, and should not be considered a reliable method for comparing files. Web servers may not consistently return file size information for dynamically created content such as HTML pages which use server-side includes.

It is not recommended that you use this function with text files because of the different end-of-line conventions used by different operating systems. For example, a text file on a Windows system uses a carriage-return and linefeed pair to indicate the end of a line of text. However, on a UNIX system, a single linefeed is used to indicate the end of a line. This can cause the **HttpVerifyFile** function to indicate the files are not identical, even though the only difference is in the end-of-line characters that are used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpWaitForQueue Function

```
BOOL WINAPI HttpWaitForQueue(
   HQUEUE hQueue,
   DWORD dwMilliseconds,
   LPDWORD lpdwElapsed,
   LPDWORD lpdwError
);
```

The **HttpWaitForQueue** function waits for the specified queue to complete the file transfers.

Parameters

hQueue

A handle to a file transfer queue.

dwMilliseconds

An unsigned integer value which specifies the number of milliseconds to wait for the queue to complete processing. If this value is zero, the function will return immediately. If this value is INFINITE (0xFFFFFFFF), the function will block indefinitely until all files in the queue have been processed.

lpdwElapsed

A pointer to an unsigned integer which will contain the number of milliseconds the queue manager has been active when the function returns. If this information is not needed, this parameter can be NULL. If this parameter is not NULL, it will always be initialized to a value of zero.

lpdwError

A pointer to an unsigned integer which will contain the last error code set if a file transfer has failed or was canceled. If this information is not needed, this parameter can be NULL. If this parameter is not NULL, it will always be initialized to a value of zero.

Return Value

If the function succeeds, the return value is non-zero, which means the queue manager has completed transferring all queued files. If the function fails, or the timeout period elapses, it will return zero. To get extended error information, call **HttpGetLastError**.

Remarks

This function will cause the current thread to block until either the queue manager has completed processing all files in the queue, or until the specified number of milliseconds have elapsed. It is important to note that Windows messages will not be processed during this time. If you call this function within the main UI thread, it can potentially cause the application to become non-responsive. To determine the current state of the queue without blocking the current thread, call the **HttpGetQueueStatus** function.

If the *dwMilliseconds* parameter is non-zero and file transfers have not completed within the specified amount of time, the function will return zero and the last error code will be set to `ST_ERROR_OPERATION_TIMEOUT`.

If an event callback function has been specified when starting the queue, you should never call this function within the event handler. Attempting to do so can potentially create a situation which will cause the application to become non-responsive. The function will return zero if it determines it's being called within the context of the queue manager thread and will set the last error code to `ST_ERROR_THREAD_DEADLOCK`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

HttpWrite Function

```
INT WINAPI HttpWrite(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **HttpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for an asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

HTTPCONNECTION

The **HTTPCONNECTION** structure provides additional information used when submitting a request to the server.

```
typedef struct _HTTPCONNECTION
{
    DWORD   dwSize;
    DWORD   dwOptions;
    DWORD   dwVersion;
    UINT    nTimeout;
    UINT    nEncoding;
    UINT    nProxyType;
    UINT    nProxyPort;
    UINT    nAuthType;
    LPCTSTR lpszProxyServer;
    LPCTSTR lpszProxyUser;
    LPCTSTR lpszProxyPassword;
    LPCTSTR lpszUserAgent;
    LPCTSTR lpszUserName;
    LPCTSTR lpszPassword;
    LPCTSTR lpszContentType;
    LPCTSTR lpszHeaders;
    LPSECURITYCREDENTIALS lpCredentials;
} HTTPCONNECTION, *LPHTTPCONNECTION;
```

Members

dwSize

The size of this structure in bytes. If this member is not initialized to the correct value, the structure will be considered invalid.

dwOptions

A bitmask of supported options. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
HTTP_OPTION_NOCACHE	This instructs the server to not return a cached copy of the resource.
HTTP_OPTION_REDIRECT	This option specifies the client should automatically handle resource redirection. If the server indicates that the requested resource has moved to a new location, the client will close the current connection and request the resource from the new location. Note that it is possible that the redirected resource will be located on a different server.
HTTP_OPTION_PROXY	This option specifies the client should use the default proxy configuration for the local system. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. The local proxy configuration can be changed in the system settings or control

	panel.
HTTP_OPTION_NOUSERAGENT	This option specifies that the client should not include a User-Agent header with requests made during the session. The User-Agent header is typically used by servers to identify the client application, operating system and other platform information. This option may be used when the server does not require a User-Agent header.
HTTP_OPTION_HTTP2	This option specifies the client should attempt a HTTP/2 connection with the server. If a connection cannot be established using HTTP/2 the client will attempt to connect using an earlier version of the protocol. The value of the ***dwVersion*** member will be ignored when this option is used.
HTTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects secure connections.
HTTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server even if the request URL does not use the **https://** scheme. If this option is not specified, the type of connection depends on the URL scheme provided when submitting the request.
HTTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.

dwVersion

A value which specifies the requested protocol version used when sending requests to the server. The high word should specify the major version, and the low word should specify the minor version number. If this value is zero, the default protocol version will be used. The HTTPVERSION macro can be used to create a version value, or the following values can be used:

Value	Description
HTTP_VERSION_DEFAULT	The client should use the default protocol version for this

	session. This is the same as specifying HTTP_VERSION_11 and is recommended to ensure the broadest compatibility with most servers.
HTTP_VERSION_10	The client should use the HTTP/1.0 protocol standard originally defined in RFC 1945. This version of the protocol supports the use of request header blocks, however it does not support persistent connections or chunked data and has limited cache control mechanisms.
HTTP_VERSION_11	The client should use the HTTP/1.1 protocol standard defined in RFC 2616 and RFC 7230. This is the most widely used version of the protocol and is the default for client connections. It is recommended most applications use this version.
HTTP_VERSION_20	The client should use the HTTP/2 protocol standard defined in RFC 7540. This protocol version is a significant change from previous versions and can provide improved performance with header compression and optimizing how requests are serviced. If the client or server does not support HTTP/2, the client will automatically attempt to use an earlier version of the protocol.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the operation. If this value is zero, a default timeout period of 20 seconds will be used.

nEncoding

A value which specifies the content encoding type for the request. If the value is zero, no encoding will be used. The following values are defined:

Value	Description
HTTP_ENCODING_NONE	No encoding will be applied to the content of a request and no default content type will be specified. This encoding type should be used with REST APIs and other services which expect XML or JSON request payloads.
HTTP_ENCODING_URL	Non-printable and extended ASCII characters will be encoded so they can be safely used with URLs and form data. Encoded characters will be represented by a percent symbol prefix, followed by a two digit hexadecimal value which represents the ASCII character code. This encoding is typically used with web services which process HTML form data.
HTTP_ENCODING_XML	This encoding is identical to URL encoding, except spaces are not encoded. It is used with legacy web services which expect form data in an XML format and cannot process encoded whitespace. This encoding should not be specified for services which use REST APIs.

nProxyType

A value which specifies the type of proxy server the client is connecting to. A value of zero specifies no proxy server is being used and the client should establish a direct connection to the server. The following proxy server types are supported:

Value	Description
HTTP_PROXY_NONE	A direct connection will be established with the server. When this value is specified the proxy parameters are ignored.
HTTP_PROXY_STANDARD	A standard connection is established through the specified proxy server, and all resource requests will be specified using a complete URL. This proxy type should be used with standard connections.
HTTP_PROXY_SECURE	A secure connection is established through the specified proxy server. This proxy type should be used with secure connections and the HTTP_OPTION_SECURE option should also be set via the ***dwOptions*** parameter.
HTTP_PROXY_WINDOWS	The configuration options for the current system should be used. If the system is configured to use a proxy server, then the connection will be automatically established through that proxy; otherwise, a direct connection to the server is established. These settings are the same proxy server settings configured in Windows.

nProxyPort

A value which specifies the port the proxy server will use to accept connections. This value is ignored if the proxy type is set to HTTP_PROXY_NONE or HTTP_PROXY_WINDOWS and no proxy configuration has been specified for the local system.

nAuthType

A value which specifies the type of authentication used to establish the connection. If the value is zero, the client session will not be authenticated. The following values are defined:

Value	Description
HTTP_AUTH_NONE	No client authentication should be performed. The ***lpszUserName*** and ***lpszPassword*** members are ignored.
HTTP_AUTH_BASIC	The **Basic** authentication scheme should be used. This option is supported by all servers that support at least version 1.0 of the protocol. The user credentials are not encrypted and Basic authentication should not be used over standard (non-secure) connections. Most web services which use Basic authentication require the connection to be secure.
HTTP_AUTH_BEARER	The **Bearer** authentication scheme should be used. This authentication method does not require a user name and the ***lpszPassword*** member must specify the OAuth 2.0 bearer token issued by the service provider. If the access token has expired, the request will fail with an authorization error.

lpszProxyServer

A null-terminated string which identifies the proxy server which should be used to establish the connection. If this value is ignored if the ***nProxyType*** member is zero. If a proxy server type has been been specified, this value cannot be a NULL pointer or an empty string.

lpszProxyUser

A null-terminated string which specifies the user name used to authenticate the connection to the proxy server. If the proxy server does not require user authentication, this member can be a NULL pointer or an empty string. This member is ignored if the ***nProxyType*** member is zero.

lpszProxyPassword

A null-terminated string which specifies the password used to authenticate the connection to the proxy server. If the proxy server does not require user authentication, this member can be a NULL pointer or an empty string. This member is ignored if the ***nProxyType*** member is zero.

lpszUserAgent

A null-terminated string which identifies the application which is making a request to the server. If this value is NULL or an empty string, a default user agent string will be included with the request. To prevent a user agent from being included with the request, use the HTTP_OPTION_NOUSERAGENT option.

lpszUserName

A null-terminated string which specifies the user name used to authenticate the client session. This member may be NULL or an empty string if a user name is not required for the specified authentication type.

lpszPassword

A null-terminated string which specifies the password used to authenticate the client session. This member may be NULL or an empty string if a password is not required for the specified authentication type. If the authentication type is HTTP_AUTH_BEARER, this value must be the bearer token issued by the service provider.

lpszContentType

A null-terminated string which specifies the MIME content type for the request. If this member is NULL or specifies an empty string, the content type will be automatically determined based on the contents of the request payload. This value will only be used with PUT and POST methods.

lpszHeaders

A null-terminated string which specifies one or more additional header values which should be included with the request. The string must contain header name and value pairs separated by a colon, and multiple header values must be terminated with a carriage return/linefeed (CRLF) sequence after each value. The header values defined in this string will override any default values.

lpCredentials

A pointer to a **SECURITYCREDENTIALS** structure. This value is only used if the HTTP_OPTION_SECURE option is specified in the ***dwOptions*** member. This member may be NULL, in which case no client credentials will be provided to the server.

Remarks

This structure is used with the **HttpSubmitRequest** function to provide additional information used to establish a connection with the server. The ***dwSize*** member must be initialized to the actual size of the structure in bytes, and all other members should be initialized to a value of zero or NULL. If the structure is not initialized correctly, the function will fail and the last error code will be set to ST_ERROR_INVALID_PARAMETER.

Member values which are zero or NULL pointers will either be ignored or cause the function to use appropriate default values.

Applications should use HTTP_VERSION_DEFAULT as the value for the ***dwVersion*** parameter. This will default to an appropriate version for the Windows platform and ensures the broadest compatibility with most servers. If your application specifies HTTP_VERSION_20, a secure connection using TLS 1.2

or later will always be used. The minimum required platform for HTTP/2 support is Windows 10 (Build 1903) or Windows Server 2019. Earlier versions of the Schannel SSP do not support the features required for a secure HTTP/2 connection.

If your application requests a HTTP/2 connection and the server only accepts earlier versions of the protocol, the client will attempt to automatically downgrade the request to HTTP/1.1. If a connection using an earlier version of the protocol cannot be established, the connection attempt will fail.

If the server requires a secure connection with a client certificate, the **HttpCreateSecurityCredentials** function can be used to allocate a credentials structure which can be assigned to the ***lpCredentials*** member. Call **HttpDeleteSecurityCredentials** after the **HttpSubmitRequest** function has returned to ensure the memory allocated for the security credentials has been freed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

HTTPFORMPROPERTIES

This structure is used by the **HttpGetFormProperties** and **HttpSetFormProperties** function to return and modify the properties of the specified form.

```
typedef struct _HTTPFORMPROPERTIES
{
   UINT    nFormMethod;
   UINT    nFormType;
   LPCTSTR lpszFormAction;
   DWORD   dwReserved1;
   DWORD   dwReserved2;
} HTTPFORMPROPERTIES, *LPHTTPFORMPROPERTIES;
```

Members

nFormMethod

An unsigned integer value which specifies how the form data will be submitted to the server. It may be one of the following values:

Value	Description
HTTP_METHOD_GET	The form data should be submitted using the GET command. This method should be used when the amount of form data is relatively small. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used instead.
HTTP_METHOD_POST	The form data should be submitted using the POST command. This is the preferred method of submitting larger amounts of form data. If the total amount of form data exceeds 2048 bytes, it is recommended that the POST method be used.

nFormType

An unsigned integer value which specifies the type of form and how the data will be encoded when it is submitted to the server. It may be one of the following values:

Value	Description
HTTP_FORM_ENCODED	The form data should be submitted as URL encoded values. This is typically used when the GET method is used to submit the data to the server.
HTTP_FORM_MULTIPART	The form data should be submitted as multipart form data. This is typically used when the POST method is used to submit a file to the server. Note that the script must understand how to process multipart form data if this form type is specified.

lpszFormAction

A null-terminated string which specifies the name of the resource that the form data will be submitted to. Typically this is the name of a script that is executed on the server.

dwReserved1

A reserved structure member.

dwReserved2

A reserved structure member.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

HTTPQUEUEDFILE

This structure is used by the **HttpGetFirstQueuedFile**, **HttpGetNextQueuedFile** and **HttpGetQueuedFile** functions to return information about a file in the transfer queue.

```
typedef struct _HTTPQUEUEDFILE
{
    DWORD          dwFileId;
    DWORD          dwQueueMode;
    DWORD          dwQueueFlags;
    DWORD          dwTimeElapsed;
    DWORD          dwLastError;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szLocalFile[HTTP_MAXFILENAMELEN];
    TCHAR          szRemoteFile[HTTP_MAXURLPATHLEN];
} HTTPQUEUEDFILE, *LPHTTPQUEUEDFILE;
```

Members

dwFileId

An unsigned integer which specifies a unique identifier for the queued file. The application should not make any assumptions about the value of the file identifiers. They should be considered opaque values which are only guaranteed to uniquely identify a file in the transfer queue. In particular, there is no guarantee that the file identifiers will be sequential and they should not be used as index values into an array.

dwQueueMode

An unsigned integer value which specifies how the file was queued for transfer. It may be one of the following values:

Constant	Description
HTTP_QUEUE_DOWNLOAD	The file was queued for download.
HTTP_QUEUE_UPLOAD	The file was queued for upload.

dwQueueFlags

An unsigned integer which specifies one or more bit flags which provides information about the status of the file transfer. It may be one or more of the following values:

Constant	Description
HTTP_QUEUE_FLAG_NONE	The file is pending transfer in queue.
HTTP_QUEUE_FLAG_COMPLETED	The file has been transferred successfully. If this flag is set, no errors were encountered during the upload or download.
HTTP_QUEUE_FLAG_FAILED	The file transfer failed. If this flag is set, the *dwError* member of this structure will contain the error code associated with the failed transfer.
HTTP_QUEUE_FLAG_CANCELED	The file transfer was canceled. This flag is only set when the **HttpCancelQueuedFile** function has been called and a queued file is in the process of being uploaded or downloaded.

dwTimeElapsed

An unsigned integer which specifies the number of milliseconds required to complete the transfer. This value will be zero unless the file has been transferred successfully.

dwLastError

An unsigned integer which specifies the last error code for a failed transfer. If the file was transferred successfully, this value will be zero.

uiBytesCopied

A value which specifies the number of bytes which were copied during the file transfer. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

szLocalFile

A null-terminated string which specifies the full path to the local file being transferred.

szRemoteFile

A null-terminated string which specifies the complete URL to the remote file being transferred.

Remarks

It is possible that the ***szLocalFile*** and ***szRemoteFile*** structure members will be different than the values passed to the **HttpAddQueuedFile** function. Those values are normalized, with any relative paths converted to absolute paths. Internationalized domain names will be encoded and the URL paths will be collapsed, removing any extraneous path information. For example, if the remote file name is specified as `https://www.server.tld/folder1/../folder2/filename.txt` it would be normalized as `https://www.server.tld/folder2/filename.txt`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HTTPQUEUESTATUS

This structure is used by the **HttpGetQueueStatus** function to return information about the current status of the file transfer queue.

```
typedef struct _HTTPQUEUESTATUS
{
    DWORD dwStatus;
    DWORD dwThreadId;
    DWORD dwQueuedFiles;
    DWORD dwPendingFiles;
    DWORD dwCopiedFiles;
    DWORD dwFailedFiles;
    DWORD dwTimeElapsed;
    DWORD dwCurrentFile;
    DWORD dwLastError;
    ULARGE_INTEGER uiBytesCopied;
    ULARGE_INTEGER uiBytesTotal;
} HTTPQUEUESTATUS, *LPHTTPQUEUESTATUS;
```

Members

dwStatus

An unsigned integer which specifies the current status of the queue. It can be one of the following values:

Value	Description
HTTP_QUEUE_STATUS_IDLE	The file transfer queue is idle and no files are being uploaded or downloaded. This state is returned before **HttpStartQueue** has been called or after **HttpStopQueue** has been called. The queue will also automatically enter an idle state after the last file transfer has completed and the queue manager thread exits.
HTTP_QUEUE_STATUS_ACTIVE	Files in the queue are being uploaded or downloaded. The *dwCurrentFile* member of this structure identifies the file which is currently being transferred.
HTTP_QUEUE_STATUS_PAUSED	File transfers are currently paused. The queue enters this state after the **HttpSuspendQueue** function is called and resumes file transfers after the **HttpResumeQueue** function is called.

dwThreadId

An unsigned integer which specifies the thread ID for the queue manager which is performing the file transfers. All file transfers are performed asynchronously in a background worker thread. If this structure member is zero, the queue is idle and not performing file transfers. The application should not use the thread ID to obtain a handle to suspend or terminate the thread. This can potentially result in unexpected behavior or instability within the application.

dwQueuedFiles

An unsigned integer which specifies the total number of queued files. This value includes pending and completed file transfers.

dwPendingFiles

An unsigned integer which specifies the number of files which are queued to be transferred.

dwCopiedFiles

An unsigned integer which specifies the number of files which have been successfully transferred. This value reflects the total number of files which have the HTTP_QUEUE_FLAG_COMPLETED status.

dwFailedFiles

An unsigned integer which specifies the number of files which have failed to transfer or the file transfer has been canceled. This value reflects the total number of files which have the HTTP_QUEUE_FLAG_FAILED status.

dwTimeElapsed

An unsigned integer which specifies the total amount of time, in milliseconds, the queue manager has been active performing a file transfer. If the queue is idle, this value will reflect the total run time for the previously active queue. A value of zero indicates the queue was never active or the queue state has been reset with a call to **HttpResetQueue**.

dwCurrentFile

An unsigned integer which specifies the unique identifier for the current file being transferred. If no file transfer is in progress, this member will have a value of zero. If the value is non-zero, it can be passed to the **HttpGetQueuedFile** function to obtain information about the queued file.

dwLastError

An unsigned integer which specifies the last error code for a failed file transfer. If there have been no errors, this value will be zero.

uiBytesCopied

A value which specifies the number of bytes which were copied during the current or last transfer. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

uiBytesTotal

A value which specifies the total number of bytes which were copied during the current queue run. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HTTPTRANSFERSTATUS

This structure is used by the **HttpGetTransferStatus** function to return information about a data transfer in progress.

```
typedef struct _HTTPTRANSFERSTATUS
{
   DWORD   dwBytesTotal;
   DWORD   dwBytesCopied;
   DWORD   dwBytesPerSecond;
   DWORD   dwTimeElapsed;
   DWORD   dwTimeEstimated;
} HTTPTRANSFERSTATUS, *LPHTTPTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the data is being downloaded from the server to the local host, this is the size of the requested resource. If the data is being uploaded from the local host to the server, it is the size of the local file or memory buffer. If the size of the resource cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

Remarks

If the option HTTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values returned in the ***dwTimeElapsed*** and ***dwTimeEstimated*** members will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

HTTPTRANSFERSTATUSEX

This structure is used by the **HttpGetTransferStatusEx** function to return information about a data transfer in progress. This structure is designed for use with extended functions that support files larger than 4GB.

```
typedef struct _HTTPTRANSFERSTATUSEX
{
   ULARGE_INTEGER uiBytesTotal;
   ULARGE_INTEGER uiBytesCopied;
   DWORD          dwBytesPerSecond;
   DWORD          dwTimeElapsed;
   DWORD          dwTimeEstimated;
} HTTPTRANSFERSTATUSEX, *LPHTTPTRANSFERSTATUSEX;
```

Members

uiBytesTotal

The total number of bytes that will be transferred. If the data is being downloaded from the server to the local host, this is the size of the requested resource. If the data is being uploaded from the local host to the server, it is the size of the local file or memory buffer. If the size of the resource cannot be determined, this value will be zero.

uiBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

Remarks

If the option HTTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values returned in the ***dwTimeElapsed*** and ***dwTimeEstimated*** members will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small amounts of data over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Hypertext Transfer Protocol Server Library

Implements a server that enables the application to access documents using the Hypertext Transfer Protocol.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSHTSV12.DLL
Version	12.0.3024.1286
LibID	25AA25CC-886B-4CFD-8089-96B70CAC2169
Import Library	CSHTSV12.LIB
Dependencies	None
Standards	RFC 1945, RFC 2616, RFC 3875

Overview

This library provides an interface for implementing an embedded, lightweight server that can be used to provide access to documents and other resources using the Hypertext Transfer Protocol. The server can accept connections from any standard web browser, third-party applications or programs developed using the SocketTools HTTP client API.

The application specifies an initial server configuration and then responds to events that are generated when the client sends a request to the server. An application may implement only minimal handlers for most events, in which case the default actions are performed for most standard HTTP commands. However, an application may also use the event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

The server includes support for CGI scripting, virtual hosting, client authentication and the creation of virtual directories and files. The server also supports secure connections using TLS 1.2 and later versions. Secure connections require that a valid security certificate be installed on the system.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum

required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Hypertext Transfer Protocol Server Functions

Function	Description
HttpAddVirtualHost	Add a new virtual host to the server virtual host table
HttpAddVirtualHostAlias	Add an alternate host name for an existing virtual host
HttpAddVirtualPath	Add a new virtual path for the specified host
HttpAddVirtualUser	Add a new virtual user for the specified host
HttpAuthenticateClient	Authenticate the client and assign access rights for the session
HttpCheckVirtualPath	Determine if the client has permission to access the specified virtual path
HttpCreateServerCredentials	Create a new server security credentials structure
HttpDeleteAllClientHeaders	Delete all of the request or response headers for the specified client session
HttpDeleteClientHeader	Delete a request or response header for the specified client session
HttpDeleteServerCredentials	Delete a previously created security credentials structure
HttpDeleteVirtualHost	Delete a virtual host associated with the specified server
HttpDeleteVirtualPath	Delete a virtual path from the specified virtual host
HttpDeleteVirtualUser	Delete a virtual user from the specified virtual host
HttpDisconnectClient	Disconnect the specific client session, closing the control channel and aborting any file transfer
HttpEnableClientAccess	Enable or disable access rights for the specified client session
HttpEnableCommand	Enable or disable a specific server command
HttpEnumServerClients	Returns a list of active client sessions established with the specified server
HttpGetActiveClient	Return the client ID for the active client session associated with the current thread
HttpGetAllClientHeaders	Return all client request or response headers in a string buffer
HttpGetClientAccess	Return the access rights that have been granted to the client session
HttpGetClientAddress	Return the IP address of the specified client session
HttpGetClientCredentials	Return the credentials for the specified client session
HttpGetClientDirectory	Return the root document directory for a client session
HttpGetClientHeader	Return the value of a request or response header for the specified client session
HttpGetClientIdleTime	Return the idle timeout period for the specified client
HttpGetClientLocalPath	Return the full local path for the specified virtual path
HttpGetClientServer	Return the handle to the server that created the specified client session
HttpGetClientThreadId	Returns the thread ID associated with the specified client session
HttpGetClientUserName	Return the user name associated with the specified client session
HttpGetClientVariable	Return the value of a CGI environment variable for the specified client
HttpGetClientVirtualHost	Return the name of the virtual host the client used to establish the connection
HttpGetClientVirtualHostId	Return the virtual host ID associated with the specified client session
HttpGetClientVirtualPath	Return the virtual path for a local file on the server
HttpGetCommandFile	Return the full path to the local file name or directory specified by the client
HttpGetCommandLine	Return the complete command line issued by the client
HttpGetCommandName	Return the name of the command that was issued by the client

HttpGetCommandQuery	Return the query parameters included with the command
HttpGetCommandResource	Return the path for the resource requested by the client
HttpGetCommandResult	Return the result code and a description of the last command processed by the server
HttpGetCommandUrl	Return the complete URL of the resource requested by the client
HttpGetProgramExitCode	Return the exit code of the last program executed by the client
HttpGetProgramName	Return the name of the CGI program executed by the client
HttpGetProgramOutput	Return a copy of the standard output from a CGI program executed by the client
HttpGetProgramText	Return a copy of the standard output from a CGI program in a string buffer
HttpGetServerAddress	Return the IP address for the server
HttpGetServerDirectory	Return the full path to the root directory assigned to the specified server
HttpGetServerError	Return information about the last server error that occurred
HttpGetServerIdentity	Return the identity and version information for the specified server
HttpGetServerLogFile	Return the current log file format and full path for the file
HttpGetServerMemoryUsage	Return the amount of memory allocated for the server and all client sessions
HttpGetServerName	Return the host name assigned to the server or specified client session
HttpGetServerOptions	Return the configuration options for the specified server
HttpGetServerPriority	Return the current priority assigned to the specified server
HttpGetServerStackSize	Return the initial size of the stack allocated for threads created by the server
HttpGetServerTransferInfo	Return information about the current file transfer
HttpGetServerUuid	Return the UUID assigned to the specified server
HttpGetServerUuidString	Return the UUID assigned to the server as a printable string
HttpGetVirtualHostId	Return the virtual host ID associated with the specified hostname
HttpGetVirtualHostName	Return the hostname associated with the specified virtual host ID
HttpIsClientAuthenticated	Determine if the specified client session has been authenticated
HttpIsCommandEnabled	Determine if the specified command is currently enabled or disabled
HttpReceiveRequest	Receive the request that was sent by the client to the server
HttpRedirectRequest	Redirect the request from the client to another URL
HttpRegisterHandler	Register a CGI program for use and associate it with a file name extension
HttpRegisterProgram	Register a CGI program for use and associate it with a virtual path on the server
HttpRenameServerLogFile	Rename or delete the current log file being updated by the server
HttpRequireAuthentication	Send a response to the client indicating that authentication is required
HttpSendErrorResponse	Send a customized error response to the specified client
HttpSendResponse	Send a response from the server to the specified client
HttpSendResponseData	Send additional data to the client in response to a command
HttpServerAsyncNotify	Enable or disable asynchronous notification of changes in server status
HttpServerDisableTrace	Disable logging of network function calls
HttpServerEnableTrace	Enable logging of network function calls to a file
HttpServerInitialize	Initialize the library and validates the specified license key at runtime
HttpServerProc	Callback function used to process server events
HttpServerRestart	Restart the server, terminating all active client sessions

HttpServerResume	Resume accepting client connections on the specified server
HttpServerStart	Start the server and begin accepting client connections
HttpServerStop	Stop the server and terminate all active client connections
HttpServerSuspend	Suspend accepting client connections on the specified server
HttpServerThrottle	Limit the number of active client connections, connections per address and connection rate
HttpServerUninitialize	Terminate use of the library by the application
HttpSetClientAccess	Change the access rights associated with the specified client session
HttpSetClientHeader	Create or change the value of a request or response header for the client session
HttpSetClientIdleTime	Change the idle timeout period for the specified client session
HttpSetClientVariable	Create or change the value of a CGI environment variable for the specified client
HttpSetCommandFile	Change the name of the local file or directory that is the target of the current command
HttpSetServerError	Set the last error code for the specified server session
HttpSetServerIdentity	Change the identity and version information for the specified server
HttpSetServerLogFile	Change the current log format, level of detail and file name
HttpSetServerName	Change the hostname assigned to the specified server or client session
HttpSetServerPriority	Change the priority assigned to the specified server
HttpSetServerStackSize	Change the initial size of the stack allocated for threads created by the server.

HttpAddVirtualHost Function

```
UINT WINAPI HttpAddVirtualHost(
   HSERVER hServer,
   LPCTSTR lpszHostName,
   UINT nHostPort,
   LPCTSTR lpszDirectory
);
```

Add a new virtual host to the server virtual host table.

Parameters

hServer

The server handle.

lpszHostName

A null-terminated string which specifies the hostname that will be added to the virtual host table. This parameter must specify a valid hostname and cannot be a NULL pointer or a zero-length string.

nHostPort

An integer value which specifies the port number for the virtual host. This value must be zero or the same value as the original port number that the server was configured to use.

lpszDirectory

A null-terminated string which specifies the root document directory for the virtual host. If this parameter is NULL or a zero-length string, the virtual host will use the same root directory that was specified when the server was started. This parameter may contain environment variables enclosed in % symbols.

Return Value

If the function is successful, it will return a non-zero integer value that identifies the virtual host. If the function fails, it will return INVALID_VIRTUAL_HOST and the last error code will be updated to indicate the cause of the failure.

Remarks

Virtual hosting is a method for sharing multiple domain names on a single instance of a server. The client provides the server with the hostname that it has used to establish the connection, and that name is compared against a table of virtual hosts configured for the server. If the hostname matches a virtual host, the client will use the root directory and any virtual paths that have been assigned to that host.

When the server is first started, a default virtual host with an ID of zero is automatically created and is identified as VIRTUAL_HOST_DEFAULT. This virtual host uses the same hostname, port number and root directory that the server instance was created with. The application should treat all other host IDs as opaque values and never make assumptions about how they are allocated.

The *nHostPort* parameter should always be specified with a value of zero, or the same port number that the server was configured to use. Port-based virtual hosting is currently not supported and this parameter is included for future use.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpAddVirtualHostAlias, HttpAddVirtualPath, HttpAddVirtualUser, HttpDeleteVirtualHost

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpAddVirtualHostAlias Function

```
BOOL WINAPI HttpAddVirtualHostAlias(
    HSERVER hServer,
    UINT nHostId,
    LPCTSTR lpszHostAlias
);
```

Add an alternate host name for an existing virtual host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszHostAlias

A null-terminated string which specifies the alias for the virtual host. The alias must be a valid domain name that uniquely identifies the host. This parameter cannot be a NULL pointer or specify an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpAddVirtualHostAlias** function adds an alias for an existing virtual host. This enables a client to establish a connection using a number of different domain names which all reference the same virtual host. When the server responds to the client, it will identify itself with the primary domain name assigned to the virtual host rather than the alias provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpAddVirtualHost, HttpAddVirtualPath

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpAddVirtualPath Function

```
BOOL WINAPI HttpAddVirtualPath(
   HSERVER hServer,
   UINT nHostId,
   DWORD dwFileAccess,
   LPCTSTR lpszVirtualPath,
   LPCTSTR lpszLocalPath
);
```

Add a new virtual path for the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

dwFileAccess

An integer value which specifies the access clients will be given to the virtual path. For a list of file access permissions, see User and File Access Constants.

lpszVirtualPath

A null-terminated string which specifies the virtual path that will be created. This parameter cannot be a NULL pointer or an empty string. The maximum length of the virtual path is 1024 characters.

lpszLocalPath

A null-terminated string which specifies the local directory or file name that the virtual path will be mapped to. This path must exist and can be no longer than MAX_PATH characters. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpAddVirtualPath** function maps a virtual path name to a directory or file name on the local system. Virtual paths are assigned to specific hosts and if multiple virtual hosts are created for the server, each can have its own virtual paths which map to different files. To create a virtual path for the default server, the ***nHostId*** parameter should be specified as VIRTUAL_HOST_DEFAULT.

It is recommended that the ***lpszLocalPath*** parameter always specify the full path to the local file or directory. If the path is relative, it will be considered relative to the current working directory for the process and expanded to its full path name. The local path can include environment variables surrounded by % symbols. For example, if the value %ProgramData% is included in the path, it will be expanded to the full path for the common application data folder. The local path cannot specify a Windows system folder or the root directory of a mounted drive volume.

The local file or directory does not need to located in the document root directory for the server or virtual host. It can specify any valid local path that the server process has the appropriate permissions to access. You should exercise caution when creating virtual paths to files or directories outside of the

server root directory. If the ***lpszLocalPath*** parameter specifies a directory, clients will have access to that directory and all subdirectories using its virtual path.

If you wish to password protect the virtual file or directory, include the HTTP_ACCESS_PROTECTED flag in the file permissions. The default command handlers will recognize this flag and require that the client authenticate itself to grant access to the resource. If the server application implements a custom command handler, it is responsible for checking for the presence of this flag and perform the appropriate checks to ensure that the client session has been authenticated.

If the server was started in restricted mode, the client will be unable to access documents outside of the server root directory and its subdirectories. This restriction also applies to virtual paths that reference documents or other resources outside of the root directory. To allow a client to access a document outside of the server root directory, the **HttpSetClientAccess** function should be used to grant the client HTTP_ACCESS_READ permission.

The **HttpGetClientVirtualPath** function will return the virtual path that is associated with a local file or directory. The **HttpGetClientLocalPath** function will return the full path to a local file or directory that is mapped to a virtual path.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAddVirtualUser Function

```
BOOL WINAPI HttpAddVirtualUser(
   HSERVER hServer,
   UINT nHostId,
   DWORD dwUserAccess,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszDirectory
);
```

Add a new virtual user for the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

dwUserAccess

An integer value which specifies the access clients will be given when authenticated as this user. For a list of user access permissions, see User and File Access Constants.

lpszUserName

A null-terminated string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the function will fail with an error indicating the username is invalid. This parameter cannot be NULL and the name must be at least three characters in length. Usernames are not case sensitive.

lpszPassword

A null-terminated string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the function will fail with an error indicating the password is invalid. This parameter cannot be NULL and must be at least one character in length. Passwords are case sensitive.

lpszDirectory

A null-terminated string which specifies the local directory that is considered to be the virtual user's home directory. This path must exist and can be no longer than MAX_PATH characters. The maximum length of the local path is 260 characters. The directory cannot be located in a Windows system folder or the root directory of a mounted disk volume. If this parameter is NULL or an empty string, the server root directory will be assigned as the user home directory.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpAddVirtualUser** function adds a virtual user that is associated with the specified virtual host.

If a client attempts to access a protected document and provides credentials, the server will attempt to automatically authenticate the session by searching for virtual user with the same username and password. If a match is found, then the client session is assigned the same access permissions as the virtual user.

If the server is started with the HTTP_SERVER_MULTIUSER option, then documents in the virtual user's home directory can be accessed by specifying their username using a specially formatted request URL. For example, if a virtual user named "Thomas" is created, the documents in that user's home directory could be accessed as http://***servername***/~thomas/***document***.html

All files and subdirectories in the user's home directory are considered to be read-only. A client cannot create files in a user's home directory, even if they are authenticated as that user. In addition, CGI programs and scripts cannot be executed from a user's home directory.

If you wish to modify the information for a user, it is not necessary to delete the username first. If this function is called with a username that already exists, that record is replaced with the values passed to this function.

The virtual users created by this function exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this function for each user that is listed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpAuthenticateClient Function

```
BOOL WINAPI HttpAuthenticateClient(
    HSERVER hServer,
    UINT nClientId,
    DWORD dwUserAccess
);
```

Authenticate the client and assign access rights for the session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see User and File Access Constants.

Return Value

If the client session could be authenticated, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has already been authenticated, this function will return zero.

Remarks

The **HttpAuthenticateClient** function is used to authenticate a specific client session, typically in response to an HTTP_CLIENT_USERAUTH event that indicates a client has provided authentication credentials as part of the request for a document or other resource.

To enable the server to automatically authenticate a client session, use the **HttpAddVirtualUser** function to add one or more virtual users. The server will search the list of virtual users for a match to the credentials provided by the client and will set the appropriate permissions for the session without requiring a event handler to manually authenticate the session using this function.

If the server was started with the HTTP_SERVER_LOCALUSER option and the client session is not authenticated using this function, the server will attempt to authenticate the client session using the local Windows user database. Although this option can be convenient because it does not require the implementation of an event handler for the HTTP_CLIENT_USERAUTH event, it can be used by clients to attempt to discover valid usernames and passwords for the local system. It is recommended that you use the **HttpAddVirtualUser** function to create virtual users rather than using the local user database.

It is recommended that most applications specify HTTP_ACCESS_DEFAULT as the ***dwUserAccess*** value for a client session, since this allows the server automatically grant the appropriate access based on the server configuration options.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpCreateServerCredentials Function

```
BOOL WINAPI HttpCreateServerCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **HttpCreateServerCredentials** function creates a SECURITYCREDENTIALS structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This value should always be zero for connections using SSH. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **HttpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The structure that is created by this function may be used as server credentials when accepting a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **HttpServerStart** function.

An application only needs to call this function to support secure connections using TLS. When a certificate is specified, it must have a private key associated with it. Attempting to use a certificate which does not have a private key will result in an error during the startup process indicating that the server credentials are invalid.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify

the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Example

```
// Create the server credentials that identifies the certificate
// that will be used for secure connections
LPSECURITYCREDENTIALS lpSecCred = NULL;

HttpCreateServerCredentials(SECURITY_PROTOCOL_DEFAULT,
                            0,
                            NULL,
                            NULL,
                            lpszCertStore,
                            lpszCertName,
                            NULL,
                            &lpSecCred);

// Start the server
hServer = HttpServerStart(lpszLocalHost,
                          HTTP_PORT_SECURE,
                          HTTP_SERVER_SECURE,
                          &httpConfig,
                          lpEventHandler,
                          0,
                          lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpCheckVirtualPath Function

```
BOOL WINAPI HttpCheckVirtualPath(
   HSERVER hServer,
   UINT nClientId,
   LPCTSTR lpszVirtualPath,
   DWORD dwFileAccess
);
```

Determine if the client has permission to access the specified virtual path.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszVirtualPath

A null-terminated string which specifies the virtual path that should be checked. This path must be absolute and cannot be a NULL pointer or an empty string. The maximum length of the virtual path is 1024 characters.

dwFileAccess

An unsigned integer value which specifies the access permissions that should be checked. For a list of file access permissions, see User and File Access Constants.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the client ID does not specify a valid client, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpCheckVirtualPath** function is used to determine if the client has permission to access the virtual file or directory, based on the value of the ***dwFileAccess*** parameter. For example, if the ***dwFileAccess*** parameter has the value HTTP_ACCESS_WRITE, this function will check if the client has write permission for the file or directory. The function will return a non-zero value if the client does have the requested permission, or zero if it does not.

Applications that implement their own custom handlers for standard HTTP commands should use this function to ensure that the client has the appropriate permissions to access the requested resource. Failure to check the access permissions for the client can result in the client being able to access restricted documents and other resources. It is recommended that most applications use the default command handlers.

To obtain the path to the local file or directory that the virtual path is mapped to, use the **HttpGetClientLocalPath** function.

Example

```
TCHAR szPathName[1024];

// Get the current request URL path
INT cchPathName = HttpGetCommandResource(
```

```
                    hServer,
                    nClientId,
                    szPathName,
                    1024);

if (cchPathName == 0)
{
    HttpSendErrorResponse(hServer, nClientId, 500, NULL);
    return;
}

// Check if the client has write access to that resource
BOOL bAllowed = HttpCheckVirtualPath(
                    hServer,
                    nClientId,
                    szPathName,
                    HTTP_ACCESS_WRITE);

if (!bAllowed)
{
    HttpSendErrorResponse(hServer, nClientId, 403, NULL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpDeleteAllClientHeaders Function

```
BOOL WINAPI HttpDeleteAllClientHeaders(
    HSERVER hServer,
    UINT nClientId,
    UINT nHeaderType
);
```

Delete all of the request or response headers for the specified client session.

Parameters

hServer

The server handle.

nClientId

Delete all of the request or response headers for the specified client session.

nHeaderType

Specifies the type of headers to delete. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Delete all of the request headers that were provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Delete all of the response headers that were created by the server in response to a request made by the client. Response header values provide additional information to the client about the type of information that is being returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpDeleteAllClientHeaders** function is used to delete all of the request or response headers that were set as the result of the client issuing a request for a document or other resource. If this function is used to delete all of the response headers, the server will automatically generate a standard set of response headers when it returns the requested information to the client.

It is not necessary to call this function inside an HTTP_CLIENT_DISCONNECT event handler to delete the header values that were set during the client session. This is done automatically when the client disconnects from the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpDeleteClientHeader, HttpSetClientHeader

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpDeleteClientHeader Function

```
BOOL WINAPI HttpDeleteClientHeader(
    HSERVER hServer,
    UINT nClientId,
    UINT nHeaderType,
    LPCTSTR lpszHeaderName
);
```

Delete a request or response header for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header to delete. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Delete a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Delete a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A null-terminated string that specifies the name of the header that should be deleted. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpDeleteClientHeader** function will delete a request or response header for the specified client session. There are a number of required response headers that are always sent to a client and deleting the header using this function will cause the server to automatically generate a new default header value. You should not delete response header values unless you are certain of the impact that it would have on the normal operation of the client.

It is not necessary for you to delete a header value to change the value of an existing header. The **HttpSetClientHeader** function will replace an existing header value with a new value, or create a new header if the header name does not already exist.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpDeleteServerCredentials Function

```
VOID WINAPI HttpDeleteServerCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **HttpDeleteServerCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer value will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)
    HttpDeleteServerCredentials(&lpSecCred);
```

Remarks

This function can be used to release the memory allocated for the credentials after the server has been started.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpCreateServerCredentials, HttpServerStop

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpDeleteVirtualHost Function

```
BOOL WINAPI HttpDeleteVirtualHost(
    HSERVER hServer,
    UINT nHostId
);
```

Delete a virtual host associated with the specified server.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpDeleteVirtualHost** function removes a virtual host that was created by a previous call to the **HttpAddVirtualHost** function. All virtual paths and users associated with the specified host are no longer valid. It is not necessary to call this function to delete any of the virtual hosts prior to stopping the server. Part of the normal shutdown process is releasing the resources allocated for each virtual host that was added to the server.

This function cannot be used to delete the virtual host with an ID of zero, which is the default virtual host that is allocated when the server is started.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpAddVirtualHost, HttpAddVirtualPath, HttpAddVirtualUser HttpDeleteVirtualPath, HttpDeleteVirtualUser

HttpDeleteVirtualPath Function

```
BOOL WINAPI HttpDeleteVirtualPath(
   HSERVER hServer,
   UINT nHostId,
   LPCTSTR lpszVirtualPath
);
```

Remove a virtual path from the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszVirtualPath

A null-terminated string which specifies the virtual path that will be removed. This path must be absolute and cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

This function removes a virtual path that was created by a previous call to the **HttpAddVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpDeleteVirtualUser Function

```
BOOL WINAPI HttpDeleteVirtualUser(
    HSERVER hServer,
    UINT nHostId,
    LPCTSTR lpszUserName
);
```

Remove a virtual user from the specified host.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszUserName

A null-terminated string which specifies the user that will be removed. This parameter cannot be a NULL pointer or an empty string.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

This function removes a virtual user that was created by a previous call to the **HttpAddVirtualUser** function. This function will not match partial usernames and wildcard characters cannot be used to delete multiple users. Usernames are not case sensitive.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpDisconnectClient Function

```
BOOL WINAPI HttpDisconnectClient(
    HSERVER hServer,
    UINT nClientId
);
```

Close the control connection for the specified client and release the resources allocated for the session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpDisconnectClient** function will close the control channel, disconnecting the client from the server and terminating the client session thread. Resources that we allocated for the client, such as memory and open handles, will be released back to the operating system. If the client was in the process of transferring a file, the transfer will be aborted.

This function sends an internal control message that notifies the server that this session should be terminated. When the session thread is signaled that it should terminate, it will abort any active data transfers and begin to release the resources allocated for that session. To ensure that the client session terminates gracefully, there may be a brief period of time where the session thread is still active after this function has returned.

After this function returns, the application should never use the same client ID with another function. Client IDs are unique to the session over the lifetime of the server, and are not reused.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpEnableClientAccess Function

```
BOOL WINAPI HttpEnableClientAccess(
    HSERVER hServer,
    UINT nClientId,
    DWORD dwUserAccess,
    BOOL bEnable
);
```

Enable or disable access rights for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies an access right to enable or disable. For a list of user access rights that can be granted to the client, see User and File Access Constants.

bEnable

An integer value which specifies if permission should be granted or revoked for the specified access right. If this value is non-zero, permission is granted to the client to perform the action specified by the *dwUserAccess* parameter. If this value is zero, that permission is revoked.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpEnableClientAccess** function is used to enable or disable access to specific functionality by the client. The function can only change a single access right and cannot be used to enable or disable multiple access rights in a single function call. To change multiple user access rights for the client, use the **HttpSetClientAccess** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpEnableCommand Function

```
BOOL WINAPI HttpEnableCommand(
   HSERVER hServer,
   LPCTSTR lpszCommand,
   BOOL bEnable
);
```

Enable or disable a specific server command

Parameters

hServer

The server handle.

lpszCommand

A null-terminated string that specifies the name of the command to be enabled or disabled. The command name is not case-sensitive, but the value must otherwise match the exact name. Partial matches are not recognized by this function. This parameter cannot be NULL.

bEnable

An integer value which specifies if the command should be enabled or disabled. If the value is non-zero, the command is enabled. If the value is zero, the command will be disabled.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the command is not recognized, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpEnableCommand** function is used to enable or disable access to a specific command on the server. This function is typically used to enable or disable certain commands for security purposes. For example, the PUT command can be disabled, preventing any client from attempting to upload files directly to the server. The **HttpIsCommandEnabled** function can be used to determine if a command is enabled or not.

The command name provided to this function must match the commands defined in RFC 2616 or related protocol standards. Refer to Hypertext Transfer Protocol Commands for a complete list of server commands.

Some commands cannot be disabled because they are required to perform essential server functions. For example, the GET and HEAD commands cannot be disabled. If you attempt to disable a required command, this function will return zero and the last error code will be set to ST_ERROR_COMMAND_REQUIRED. Because this function affects all clients connected to the server, it should not be used to limit access to certain commands for specific clients. Instead, use an event handler to filter the commands.

The OPTIONS and TRACE commands are disabled by default for all server instances and must be explicitly enabled using the **EnableCommand** method if you wish permit clients to use them. It is not recommended that you enable these commands if your server is going to be publicly accessible over the Internet. If the server started with the option HTTP_SERVER_READONLY, commands that can be used to create or modify files on the server will be disabled by default.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpEnumServerClients Function

```
INT WINAPI HttpEnumServerClients(
    HSERVER hServer,
    DWORD dwReserved
    UINT *lpClients,
    INT nMaxClients
);
```

Return a list of active client sessions established with the specified server.

Parameters

hServer

Handle to the server socket.

dwReserved

An unsigned integer value that is reserved for future use. This parameter should always be zero.

lpClients

Pointer to an array of unsigned integers which will contain client IDs that uniquely identifies each client when the function returns. If this parameter is NULL, then the function will return the number of active client connections established with the server.

nMaxClients

Maximum number of client IDs to be returned in the ***lpClients*** array. If the ***lpClients*** parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is the number of active client connections to the server. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetServerError**.

Remarks

If the ***nMaxClients*** parameter is less than the number of active client connections, the function will fail and the last error code will be set to the error ST_ERROR_BUFFER_TOO_SMALL. To dynamically determine the number of active connections, call the function with the ***lpClients*** parameter with a value of NULL, and the ***nMaxClients*** parameter with a value of zero.

Example

```
INT nClients = HttpEnumServerClients(hServer, 0, NULL, 0);

if (nClients > 0)
{
    UINT *lpClients = NULL;

    // Allocate memory for an array of client IDs
    lpClients = (UINT *)LocalAlloc(LPTR, nClients * sizeof(UINT));

    if (lpClients == NULL)
    {
        // Virtual memory has been exhausted
        return;
    }
```

```
    nClients = HttpEnumServerClients(hServer, 0, lpClients, nClients);

    if (nClients == HTTP_ERROR)
    {
        // Unable to obtain list of connected clients
        return;
    }

    for (INT nIndex = 0; nIndex < nClients; nIndex++)
    {
        TCHAR szUserName[HTTP_MAXUSERNAME];

        if (HttpGetClientUserName(hServer, lpClients[nIndex], szUserName,
HTTP_MAXUSERNAME))
        {
            // Perform some action with the client user name
        }
    }

    // Free the memory allocated for the client IDs
    LocalFree((HLOCAL)lpClients);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpServerStart

HttpGetActiveClient Function

```
UINT WINAPI HttpGetActiveClient(
    HSERVER hServer
);
```

Return the client ID for the active client session associated with the current thread.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the unique ID associated with the client session for the current thread. If the server handle is invalid or there is no client session active on the current thread, the return value is zero.

Remarks

The **HttpGetActiveClient** function is used to obtain the client ID associated with the current thread. This means this function will only return a client ID if it is called within an event handler or a function called by an event handler. If this function is called by a function that is not executing within the context of an event handler it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpGetClientAccess Function

```
BOOL WINAPI HttpGetClientAccess(
   HSERVER hServer,
   UINT nClientId,
   LPDWORD lpdwUserAccess
);
```

Return the access rights that have been granted to the client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwUserAccess

A pointer to an unsigned integer which specifies one or more access rights for the client session. For a list of user access permissions that can be granted to the client, see User and File Access Constants. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **HttpGetClientAccess** function is used to obtain all of the access rights that are currently granted to the client session. The **HttpEnableClientAccess** function can be used to enable or disable specific permissions, and the **HttpSetClientAccess** function can change multiple access rights at once.

Example

```
DWORD dwUserAccess = 0;

// Check if the client has execute permission
if (HttpGetClientAccess(hServer, nClientId, &dwUserAccess))
{
    if (dwUserAccess & HTTP_ACCESS_EXECUTE)
    {
        _tprintf(_T("Client %u can execute programs and scripts\n"), nClientId);
        return;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpGetClientAddress Function

```
INT WINAPI HttpGetClientAddress(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

Return the IP address of the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszAddress

A null-terminated string buffer that will contain the client IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetClientCredentials Function

```
BOOL WINAPI HttpGetClientCredentials(
   HSERVER hServer,
   UINT nClientId,
   LPHTTPCLIENTCREDENTIALS lpCredentials
);
```

Return the user credentials for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpCredentials

A pointer to an **HTTPCLIENTCREDENTIALS** structure that will contain information about the user when the function returns. This parameter cannot be NULL.

Return Value

If the user credentials for the client session are available, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has not requested authentication, this function will return zero.

Remarks

The **HttpGetClientCredentials** function is used to obtain the username and password that was provided by the client when it requested authentication. Typically this function is used in an event handler to validate the credentials provided by the client. If the credentials are considered valid, the event handler would then call the **HttpAuthenticateClient** function to specify that the session has been authenticated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetClientDirectory Function

```
INT WINAPI HttpGetClientDirectory(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszDirectory,
   INT nMaxLength
);
```

Returns the root document directory for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A null-terminated string buffer that will contain the root directory for the specified client session, terminated with a null character. This buffer should be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be larger than zero or the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

This function returns the full path to the root document directory for the specified client session. If no virtual hosts have been configured, then this path will be the same as the root directory assigned to the server when it was started. If the server has been configured with multiple virtual hosts, this function will return the path to the root directory associated with the hostname provided by the client.

To convert a full path to the virtual path for a specific client session, use the **HttpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetClientHeader Function

```
INT WINAPI HttpGetClientHeader(
   HSERVER hServer,
   UINT nClientId,
   UINT nHeaderType,
   LPCTSTR lpszHeaderName,
   LPTSTR lpszHeaderValue,
   INT nMaxLength,
);
```

Return the value of a request or response header for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Return the value of a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Return the value of a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A null-terminated string that specifies the name of the header field. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszHeaderValue

A buffer that will contain the header value, terminated with a null character. To determine the length of the header value, this parameter can be NULL and the ***nMaxLength*** parameter should be specified with a value of zero.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the header value buffer, including the terminating null character. If the ***lpszHeaderValue*** parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the return value is the length of the header value, not including the terminating null character. If the server handle and client ID do not specify a valid client session, or there is no header that matches the given name, the function will return zero. If the ***lpszHeaderValue***

parameter is not NULL and the buffer is not large enough to store the complete header value, the function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpGetClientHeader** function will return the value of a request or response header for the specified client session. If the *lpszHeaderName* value matches an existing header field, its value will be copied to the string buffer provided by the caller.

Refer to Hypertext Transfer Protocol Headers for a list of common request and response headers that are used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetClientIdleTime Function

```
UINT WINAPI HttpGetClientIdleTime(
    HSERVER hServer,
    UINT nClientId,
    UINT *lpnElapsed
);
```

Return the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpnElapsed

A pointer to an unsigned integer value that will contain the number of seconds the client session has been idle. This parameter may be NULL if this information is not required.

Return Value

If the function succeeds, the return value is client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetClientIdleTime** function will return the number of seconds that the client may remain idle before being automatically disconnected by the server. The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed. The server will never disconnect a client that is in the process of sending or receiving data, regardless of the idle timeout period.

The default idle timeout period for a client session is 60 seconds, however the server can be configured to use a different value. The minimum timeout period for a client is 10 seconds, the maximum is 300 seconds (5 minutes). An application can change the timeout period for a specific client session using the **HttpSetClientIdleTime** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpSetClientIdleTime

HttpGetClientLocalPath Function

```
INT WINAPI HttpGetClientLocalPath(
   HSERVER hServer,
   UINT nClientId,
   LPCTSTR lpszVirtualPath,
   LPTSTR lpszLocalPath,
   INT nMaxLength,
);
```

Return the full local path for a virtual filename or directory on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszVirtualPath

A null-terminated string that specifies an virtual path on the server. This parameter cannot be NULL.

lpszLocalPath

A null-terminated string buffer that will contain the full local path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

The **HttpGetClientLocalPath** function takes a virtual path and returns the full path to the specified file or directory on the local system. The virtual path may be absolute or relative to the root directory for the client session.

To obtain the virtual path for a local file or directory, use the **HttpGetClientVirtualPath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetClientVirtualPath

HttpGetClientServer Function

```
HSERVER WINAPI HttpGetClientServer(
     UINT nClientId
);
```

The **HttpGetClientServer** function returns a handle to the server that created the specified client session.

Parameters

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is the handle to the server that created the client session. If the function fails, the return value is INVALID_SERVER. To get extended error information, call the **HttpGetServerError** function.

Remarks

The **HttpGetClientServer** function returns the handle to the server that created the client session and is typically used within a notification message handler. If the server is in the process of shutting down, or the client session thread is terminating, this function will fail and return INVALID_SERVER indicating that the session ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetClientThreadId Function

```
DWORD WINAPI HttpGetClientThreadId(
    HSERVER hServer,
    UINT nClientId
);
```

Returns the thread ID associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the function succeeds, the return value is a thread ID. If the function fails, the return value is zero. To get extended error information, call the **HttpGetServerError** function.

Remarks

The **HttpGetClientThreadId** function returns a thread ID that can be used to identify the thread that is managing the client session. The thread ID can be used with other Windows API functions such as **OpenThread**. Exercise caution when using thread-related functions, interfering with the normal operation of the thread can have unexpected results. You should never use this function to obtain a thread handle and then call the **TerminateThread** function to terminate a client session. This will prevent the thread from releasing the resources that were allocated for the session and can leave the server in an unstable state. To terminate a client session, use the **HttpDisconnectClient** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpGetClientUserName Function

```
INT WINAPI HttpGetClientUserName(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszUserName,
   INT nMaxLength
);
```

Return the user name associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszUserName

A null-terminated string buffer that will contain the user name associated with the client session. This buffer must be large enough to store the complete user name, including the terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value larger than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetClientUserName** function returns the user name associated with an authenticated client session. If the client has not authenticated itself, this function will return zero and the *lpszUserName* parameter will be set to an empty string.

The **HttpIsClientAuthenticated** function can be used to determine if the client has provided credentials as part of the request made to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetClientVariable Function

```
INT WINAPI HttpGetClientVariable(
    HSERVER hServer,
    UINT nClientId,
    LPCTSTR lpszName,
    LPTSTR lpszValue,
    INT nMaxLength,
);
```

Return the value of a CGI environment variable for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszName

A null-terminated string that specifies the name of the environment variable. Variable names are not case-sensitive and should not include the equal sign which acts as a delimiter that separates the variable name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszValue

A buffer that will contain the value of the environment variable, terminated with a null character. To determine the length of the header value, this parameter can be NULL and the ***nMaxLength*** parameter should be specified with a value of zero.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the value buffer, including the terminating null character. If the ***lpszValue*** parameter is NULL, this value must be zero.

Return Value

If the function succeeds, the return value is the length of the environment variable value, not including the terminating null character. If the server handle and client ID do not specify a valid client session, or there is no environment variable that matches the given name, the function will return zero. If the ***lpszValue*** parameter is not NULL and the buffer is not large enough to store the complete header value, the function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpGetClientVariable** function will return the value of an environment variable that has been defined for the client. Each client session inherits a copy of the process environment block, which is then modified to define various environment variables that are used with CGI programs and scripts. The **HttpSetClientVariable** function can be used to change existing environment variables or create new variables.

The standard CGI environment variables that are defined by the server are not created until the client request has been processed. This means that environment variables such as REMOTE_ADDR and SERVER_NAME will not be defined inside an HTTP_CLIENT_CONNECT event handler.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetClientVirtualHost Function

```
INT WINAPI HttpGetClientVirtualHost(
    HSERVER hServer,
    UINT nClientId,
    LPTSTR lpszHostName,
    INT nMaxLength
);
```

Return the name of the virtual host the client used to establish the connection.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszHostName

A null-terminated string buffer that will contain the virtual host name. The string buffer will be null-terminated and must be large enough to store the complete hostname. If this parameter is NULL, the function will only return the length of the current command in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the ***lpszHostName*** parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetClientVirtualHost** function is used to obtain the hostname that the client used to establish a connection with the server. This function is typically used within an event handler to determine the hostname associated with the request made by the client. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the virtual host has not been selected at that point. If the virtual hostname is not available at the time this function is called, the function will return zero and the last error code will be set to ST_ERROR_VIRTUAL_HOST_NOT_FOUND.

The **HttpGetClientVirtualHostId** function can be used to obtain the virtual host ID associated with the hostname.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetClientVirtualHostId Function

```
UINT WINAPI HttpGetClientVirtualHostId(
    HSERVER hServer,
    UINT nClientId
);
```

Return the virtual host ID associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

An unsigned integer value which specifies the virtual host ID. If the function fails, the return value will be INVALID_VIRTUAL_HOST and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetClientVirtualHostId** function is used to obtain the virtual host ID associated with the hostname the client used to establish a connection with the server. This function should not be called inside a HTTP_CLIENT_CONNECT event handler because the virtual host has not been selected at that point. If the virtual host ID is not available at the time this function is called, the function will return INVALID_VIRTUAL_HOST and the last error code will be set to ST_ERROR_VIRTUAL_HOST_NOT_FOUND.

The **HttpGetClientVirtualHost** function can be used to obtain the hostname that the client used to establish the connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpGetClientVirtualPath Function

```
INT WINAPI HttpGetClientVirtualPath(
   HSERVER hServer,
   UINT nClientId,
   LPCTSTR lpszLocalPath,
   LPTSTR lpszVirtualPath,
   INT nMaxLength,
);
```

Return the virtual path for a local file on the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszLocalPath

A null-terminated string that specifies an absolute path on the local system. This parameter cannot be NULL.

lpszVirtualPath

A null-terminated string buffer that will contain the virtual path, terminated with a null-character. This buffer should be at least MAX_PATH characters to accommodate the complete path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the string buffer is not large enough to contain the complete path, this function will return zero and the last error code will be set to ST_ERROR_BUFFER_TOO_SMALL.

Remarks

A virtual path for the client is relative to the root directory for the specified client session. These virtual paths are what the client will see as an absolute path on the server. For example, if the server was configured to use "C:\ProgramData\MyServer" as the root directory, and the ***lpszLocalPath*** parameter was specified as "C:\ProgramData\MyServer\Documents\Research", this function would return the virtual path to that directory as "/Documents/Research".

If the ***lpszLocalPath*** parameter specifies a file or directory outside of the server root directory, this function will return zero and the last error code will be set to ST_ERROR_INVALID_FILE_NAME. This function can only be used with authenticated clients. If the ***nClientId*** parameter specifies a client session that has not been authenticated, this function will return zero and the last error code will be ST_ERROR_AUTHENTICATION_REQUIRED.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetCommandFile Function

```
INT WINAPI HttpGetCommandFile(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszFileName,
   INT nMaxLength
);
```

Get the full path to a file name or directory specified by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A null-terminated string buffer that will contain the full path to a file name or directory specified by the client when it issued a command. The string buffer will be null-terminated and must be large enough to store the complete file path. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. It is recommended that the buffer be at least MAX_PATH characters in size. If the maximum length specified is smaller than the actual length of the full path, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetCommandFile** function is used to obtain the full path to a local file name or directory specified by the client as an argument to a standard HTTP command. For example, if the client sends the GET command to the server, this function will return the complete path to the local file that the client wants to retrieve. This function will only work with those standard commands that perform some action on a file or directory.

This function should always be used to obtain the file name for a command that performs a file or directory operation. It normalizes the path provided by the client and ensures that it specifies a file or directory name in the correct location. The **HttpGetCommandUrl** function can be used to obtain the URL that was provided by the client.

To map a virtual path to a file or directory on the local system, use the **HttpAddVirtualPath** function. To redirect a client to use a different URL to access the resource, use the **HttpRedirectRequest** function.

The **HttpSetCommandFile** function can be used to change the name of the local file or directory that is the target of the command, however using this function to redirect access to a resource can have unintended side-effects, particularly in the case where the URL provided by the client actually resolves to an executable CGI program that handles the request.

If the client has provided a URL that resolves to a CGI program that handles the request, this function behaves differently than if the URL is resolved to a local file or directory. If the client uses the GET or POST command that results in a program being executed to handle the request, this function will return the path to the server root directory along with any additional path information provided in the URL. In other words, the file name returned by this function will be the same as the PATH_TRANSLATED value passed to the CGI program.

This function should only be called after the client request has been received by the server, typically inside a HTTP_CLIENT_COMMAND or HTTP_CLIENT_EXECUTE event handler. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetCommandLine Function

```
INT WINAPI HttpGetCommandLine(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszCmdLine,
   INT nMaxLength
);
```

Return the complete command line issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCmdLine

A null-terminated string buffer that will contain the command, including all arguments. The string buffer will be null-terminated and must be large enough to store the complete command line. If this parameter is NULL, the function will return the length of the command line.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. The internal limit on the maximum length of a command is 1024 characters. If the maximum length specified is smaller than the actual length of the complete command, this function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code. If the last error code has a value of zero then no command has been issued by the client.

Remarks

The **HttpGetCommandLine** function is used to obtain the command that was issued by the client, and is commonly used inside HTTP_CLIENT_COMMAND and HTTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively. When the function returns, the string buffer provided by the caller will contain the complete command, including the resource path and requested HTTP version. Any extraneous whitespace will be removed, however all encoding will be preserved.

To obtain the complete URL associated with the request issued by the client, use the **HttpGetCommandUrl** function. If the command sent by the client is used to perform an action on a file or directory, the **HttpGetCommandFile** function should be called to obtain the full path to the local file rather than using the resource path.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetCommandFile, HttpGetCommandUrl

HttpGetCommandName Function

```
INT WINAPI HttpGetCommandName
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszCommand,
   INT nMaxLength
);
```

Return the name of the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCommand

A null-terminated string buffer that will contain the command name. The string buffer will be null-terminated and must be large enough to store the complete command name. If this parameter is NULL, the function will only return the length of the current command in characters, not including the terminating null character.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the maximum length specified is smaller than the actual length of the parameter, this function will fail. If the ***lpszCommand*** parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code. If the last error code is returned as a value of zero, this means that no command has been issued by the client.

Remarks

The **HttpGetCommandName** function is used to obtain the name of the last command that was issued by the client. The command name returned by this function will always be capitalized, regardless of how it was sent by the client. This function is typically used inside HTTP_CLIENT_COMMAND and HTTP_CLIENT_RESULT event handlers to pre-process and post-process client commands, respectively. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

The **HttpGetCommandUrl** function can be used to return the resource that was requested by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

Unicode: Implemented as Unicode and ANSI versions

HttpGetCommandQuery Function

```
INT WINAPI HttpGetCommandQuery(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszParameters,
   INT nMaxLength
);
```

Return the query parameters included with the command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszParameters

A null-terminated string buffer that will contain the query parameters when the function returns. The string buffer will be null terminated up to the maximum number of characters specified by the caller. If this parameter is NULL the function will return the length of the query string.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. If the ***lpszParameters*** parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code. If the client did not provide any query parameters, this function will return zero and the last error code will be zero.

Remarks

The **HttpGetCommandQuery** function is used to obtain a copy of the query parameters that were included in the request URL. If there were no query parameters, the string buffer will be empty and the return value will be zero. If the request did include query parameters, they will be returned to the caller in their original, encoded form.

This function should not be called within a HTTP_CLIENT_CONNECT event handler because the client request has not been processed at that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetCommandName, HttpGetCommandResource, HttpReceiveRequest

HttpGetCommandResource Function

```
INT WINAPI HttpGetCommandResource(
    HSERVER hServer,
    UINT nClientId,
    LPTSTR lpszResource,
    INT nMaxLength
);
```

Return the URL path for the resource requested by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszResource

A null-terminated string buffer that will contain the URL path provided by the client for the current command. The string buffer will be null terminated and must be large enough to store the complete path. If this parameter is NULL, the function will only return the length of the path.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the ***lpszResource*** parameter is NULL, this value should be zero. If this value is less than the length of the URL, the function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetCommandResource** function returns the URL path that the client provided to access the requested resource. The path will not include the URI scheme, user credentials or query parameters. The **HttpGetCommandFile** function can be used to determine the name of the local file on the server that will be accessed using this URL.

If you require the complete URL, not just the path to the resource, use the **HttpGetCommandUrl** function.

This function should only be called after the client request has been received by the server, typically inside a HTTP_CLIENT_COMMAND event handler. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetCommandResult Function

```
INT WINAPI HttpGetCommandResult(
    HSERVER hServer,
    UINT nClientId,
    LPTSTR lpszResult,
    INT nMaxLength
);
```

Return the result code and description for the last command issued by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszResult

A null-terminated string buffer that will contain the description of the result code. The string buffer will be null-terminated up to the maximum number of characters specified by the caller. This parameter can be NULL if this information is not required.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. If the ***lpszResult*** parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the result code for the last command issued by the client. A return value of zero indicates that the command has not completed and there is no result code available.

Remarks

The **HttpGetCommandResult** function is used to determine the result of the last command that was issued by the client and is typically called in the HTTP_CLIENT_RESULT event handler. This function should only be called after a command has been processed or the **HttpSendResponse** function has been called.

The result code is a three-digit integer value that indicates the success or failure of a command. Whenever a client sends a command to the server, the server must respond with this numeric code and a brief description of the result. Result codes are generally broken down into the following categories:

Result Code	Description
100-199	Result codes in this range are informational and only used with version 1.1 of the protocol. If the server returns a result code in this range, it means that it has received the request and that the client should proceed.
200-299	Result codes in this range indicate that the server has successfully completed the requested action. In most cases this means that the server has returned the requested data to the client, however if a 204 result code is sent, this indicates that the request has been processed but there is no data available.
300-399	Result codes in this range indicate that the requested resource has been moved to a

	new location. The most common result codes are 301 and 302. A value of 301 indicates that the location of the resource has changed permanently and all future requests should be sent to the new URL. A value of 302 indicates that the resource location has changed temporarily. The new location of the resource is sent to the client by setting the Location response header field.
400-499	Result codes in this range indicate an error with the request that was made by the client. These types of errors include invalid commands, requests that can only be issued by authenticated clients, or resources that cannot be accessed on the server. The most common result code in this range is the 404 code which indicates that the requested document could not be found.
500-599	Result codes in this range indicate a server error has occurred while processing a valid request. These types of errors are returned when a command has not been implemented, the execution of a CGI program or script has failed unexpectedly, or an internal server error has occurred.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetCommandUrl Function

```
INT WINAPI HttpGetCommandUrl(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszCmdUrl,
   INT nMaxLength
);
```

Return the complete URL of the resource requested by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszCmdUrl

A null-terminated string buffer that will contain the URL provided by the client for the current command. The string buffer will be null terminated and must be large enough to store the complete URL. If this parameter is NULL, the function will only return the length of the URL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the ***lpszCmdUrl*** parameter is NULL, this value should be zero. If this value is less than the length of the URL, the function will fail.

Return Value

An integer value which specifies the number of characters copied into the buffer, not including the terminating null character. If the function fails, the return value will be zero and the **HttpGetServerError** function can be used to retrieve the last error code.

Remarks

The **HttpGetCommandUrl** function returns the complete URL that the client provided to access the requested resource. The URL will include any query parameters that were specified by the client, but it will not include any user credentials. The **HttpGetCommandFile** function can be used to determine the name of the local file on the server that will be accessed using this URL.

If you only require the URL path, without the URI scheme or the query parameters, use the **HttpGetCommandResource** function.

This function should only be called after the client request has been received by the server, typically inside a HTTP_CLIENT_COMMAND event handler. It should not be called inside a HTTP_CLIENT_CONNECT event handler because the server has not processed the client request at that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetProgramExitCode Function

```
BOOL WINAPI HttpGetProgramExitCode(
    HSERVER hServer,
    UINT nClientId,
    LPDWORD lpdwExitCode
);
```

Return the exit code of the last program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpdwExitCode

A pointer to an unsigned integer that will contain the program exit code when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetProgramExitCode** function returns the exit code of a registered CGI program or script that was executed. By convention, most programs return an exit code in the range of 0-255, with an exit code of zero indicating success. The exit code is commonly used by programs to communicate status information back to the server application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpGetProgramOutput, HttpRegisterProgram

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetProgramName Function

```
INT WINAPI HttpGetProgramName(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszProgramName,
   INT nMaxLength
);
```

Return the name of the CGI program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszProgramName

A null-terminated string buffer that will contain the name of the CGI program executed by the client. This parameter cannot be NULL and should be at least MAX_PATH characters in size.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. This parameter must have a value greater than zero.

Return Value

If the function succeeds, the return value is the length of the executable file name. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed a CGI program this function will return zero and the last error code will be set to zero.

Remarks

The **HttpGetProgramName** function returns the local file name of the CGI program that was executed in response to a request from the client. This is the full path to the executable that was registered with the server using the **HttpRegisterProgram** function. If the client specified a regular document or directory, this function will return a value of zero, indicating that no CGI program has been executed to handle the request.

To obtain the resource URL that was provided by the client, use the **HttpGetCommandUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetProgramExitCode, HttpGetProgramOutput, HttpRegisterProgram

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetProgramOutput Function

```
DWORD WINAPI HttpGetProgramOutput(
    HSERVER hServer,
    UINT nClientId,
    LPBYTE lpBuffer,
    DWORD dwBufferSize
);
```

Return a copy of the standard output from a CGI program executed by the client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A buffer that will contain the output from the last program executed by the client. If this parameter is NULL, the function will return the number of bytes of data that was output by the program. Note that this output is not null-terminated.

dwBufferSize

The maximum number of bytes that can be copied into the buffer. If the ***lpBuffer*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of bytes copied into the specified buffer. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **HttpGetProgramOutput** function is used to obtain a copy of the output generated by a CGI program. To determine the number of bytes of output available to read, call this function with the ***lpBuffer*** parameter as NULL and the ***dwBufferSize*** parameter with a value of zero. The return value will be the number of bytes of data that was output by the program. It should be noted that for Unicode builds, the buffer is a byte array, not an array of characters, and will not be null terminated.

This function returns the raw output from the program which may contain a response header block, escape sequences, control characters and embedded nulls. When the application processes the output returned by this function, it should never coerce the buffer pointer to an LPTSTR value because there is no guarantee that the data will be null-terminated. To obtain the output from the program as a string, use the **HttpGetProgramText** function.

This function should only be used within an HTTP_CLIENT_EXECUTE event handler, which occurs after the program has terminated.

Example

```
LPBYTE lpBuffer = NULL;  // The output buffer
DWORD cbBuffer = 0;      // Number of bytes in the output buffer

// Determine the number of bytes in the output buffer
```

```
cbBuffer = HttpGetProgramOutput(hServer, nClientId, NULL, 0);

if (cbBuffer > 0)
{
    // Allocate memory for the buffer
    lpBuffer = (LPBYTE)LocalAlloc(LPTR, cbBuffer + 1);

    // Copy the program output to the buffer
    if (lpBuffer != NULL)
        cbBuffer = HttpGetProgramOutput(hServer, nClientId, lpBuffer, cbBuffer +
1);
}

// Free the memory allocated for the buffer when finished
if (lpBuffer != NULL)
{
    LocalFree((HLOCAL)lpBuffer);
    lpBuffer = NULL;
    cbBuffer = 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpGetProgramExitCode, HttpGetProgramText, HttpRegisterProgram

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetProgramText Function

```
INT WINAPI HttpGetProgramText(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

Return a copy of the standard output from a CGI program in a string buffer.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszBuffer

A buffer that will contain the output from the last program executed by the client as a string. If this parameter is NULL, the function will return the number of bytes of characters that was output by the program, not including a terminating null character.

nMaxLength

The maximum number of bytes that can be copied into the buffer. If the ***lpszBuffer*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the specified string buffer, not including the terminating null character. If the server handle and client ID do not specify a valid client session, the function will return zero. If the client has not executed any programs, the return value will be zero.

Remarks

The **HttpGetProgramText** function is used to obtain a copy of the output generated by a CGI program. To determine the number of characters of output available to read, call this function with the ***lpszBuffer*** parameter as NULL and the ***nMaxLength*** parameter with a value of zero. The return value will be the number of characters that were output by the program. If the application dynamically allocates the string buffer, make sure that it allocates an extra character for the terminating null character.

This function will only return textual output from the program and any non-printable control characters and the escape character will be replaced with a space. To obtain the unfiltered output from the program, use the **HttpGetProgramOutput** function. If the program outputs a response header block, this will be included in the string buffer.

This function should only be used within an HTTP_CLIENT_EXECUTE event handler, which occurs after the program has terminated.

Example

```
LPTSTR lpszBuffer = NULL;  // The output buffer
INT cchBuffer = 0;         // Number of bytes in the output buffer
```

```
// Determine the number of bytes in the output buffer
cchBuffer = HttpGetProgramText(hServer, nClientId, NULL, 0);

if (cchBuffer > 0)
{
    // Allocate memory for the string buffer
    lpszBuffer = (LPTSTR)LocalAlloc(LPTR, (cchBuffer + 1) * sizeof(TCHAR));

    // Copy the program output to the buffer
    if (lpszBuffer != NULL)
        cchBuffer = HttpGetProgramText(hServer, nClientId, lpszBuffer, cchBuffer +
1);
}

// Free the memory allocated for the buffer when finished
if (lpszBuffer != NULL)
{
    LocalFree((HLOCAL)lpszBuffer);
    lpszBuffer = NULL;
    cchBuffer = 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetServerAddress Function

```
INT WINAPI HttpGetServerAddress(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

Return the IP address of the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszAddress

A null-terminated string buffer that will contain the server IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete address, the function will return a value of zero.

Remarks

This function will return the IP address assigned to the specified server as a printable string. If the ***nClientId*** parameter has a value of zero, this function will return the IP address assigned to the local system. If the HTTP_SERVER_NATROUTER option was specified when the server was started, this function will return the external IP address assigned to the system. If the ***nClientId*** parameter specifies a valid client session, this function will return the IP address that the client used to establish the connection with the server. To determine the IP address assigned to the client, use the **HttpGetClientAddress** function.

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cshtsv12.lib

HttpGetServerDirectory Function

```
INT WINAPI HttpGetServerDirectory(
   HSERVER hServer,
   LPTSTR lpszDirectory,
   INT nMaxLength
);
```

Return the full path to the root directory assigned to the specified server.

Parameters

hServer

The server handle.

lpszDirectory

A null-terminated string buffer that will contain the server root directory, terminated with a null character. It is recommended that this buffer be at least MAX_PATH characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **HttpGetServerDirectory** function will return the full path to the root directory assigned to the server instance. The root directory may be specified as part of the server configuration, or if no directory is specified by the application, a temporary root directory will be created and this function can be used to obtain the full path to the directory. When the application specifies a root directory, it may use environment variables such as %AppData% in the path. This function will return the fully resolved path name, with all environment variables expanded.

There is no corresponding function to change the server root directory after the server has started. To change the root directory, you must stop the server using the **HttpServerStop** function and then start another instance of the server with a configuration that specifies the new directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetServerError Function

```
DWORD WINAPI HttpGetServerError(
    HSERVER hServer,
    LPTSTR lpszError,
    INT nMaxLength
);
```

Return the last server error code and a description of the error.

Parameters

hServer

The server handle.

lpszError

A null-terminated string buffer that will contain a description of the error. If the error description is not needed, this parameter may be NULL.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the error string buffer, including the terminating null character. If the ***lpszError*** parameter is NULL, this value should be zero.

Return Value

An unsigned integer value that specifies the last error that occurred. A value of zero indicates that there was no error.

Remarks

Error codes are unsigned 32-bit values which are private to each server. You should call the **HttpGetServerError** function immediately when a function's return value indicates that an error has occurred. That is because some functions clear the last error code when they succeed.

If the ***hServer*** parameter is specified with a value of INVALID_SERVER, this function will return the last error that occurred for the current thread. This value should only be used when the function does not have access to a valid server handle, such as when the **HttpServerStart** function fails.

It is important to note that the error codes returned by this method are different than the command result codes that are defined in RFC 2616, the standard protocol specification for HTTP. This function is used to determine reason that an API function has failed, and should not be used to determine if a command issued by the client was successful. The **HttpSendResponse** function is used to send responses to the client, and the **HttpGetCommandResult** function can be used to determine the result of the last command sent by the client.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or HTTP_ERROR. Those functions which clear the last error code when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetServerIdentity Function

```
INT WINAPI HttpGetServerIdentity(
   HSERVER hServer,
   LPTSTR lpszIdentity,
   INT nMaxLength
);
```

Return the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A null-terminated string buffer that will contain the identity of the server when the function returns, terminated with a null character. This parameter cannot be NULL. It is recommended that this buffer be at least 32 characters in length.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the server handle is invalid, or the buffer is not large enough to store the complete path, the function will return a value of zero.

Remarks

The **HttpGetServerIdentity** function returns the identity string that was specified as part of the server configuration. It is used for informational purposes only and does not affect the operation of the server. Typically the string specifies the name of the application and a version number. The **HttpSetServerIdentity** function can be used to change the identity string associated with the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetServerLogFile Function

```
BOOL WINAPI HttpGetServerLogFile(
   HSERVER hServer,
   UINT *lpnLogFormat,
   UINT *lpnLogLevel,
   LPTSTR lpszFileName,
   INT nMaxLength
);
```

Return the current log file format and the full path to the file.

Parameters

hServer

The server handle.

lpnLogFormat

A pointer to an integer value that will contain the log file format being used when the function returns. If this information is not needed, this parameter may be NULL. The following formats are supported:

Value	Description
HTTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
HTTP_LOGFILE_COMBINED	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

lpnLogLevel

A pointer to an integer value that will contain the level of detail the server uses when generating the log file. The minimum value is 1 and the maximum value is 10. If this information is not needed, this parameter may be NULL.

lpszFileName

A null-terminated string buffer that will contain the full path to the log file. This parameter may be NULL if this information is not required.

nMaxLength

An integer that specifies the maximum number of characters that can be copied into the file name string, including the terminating null character. If the ***lpszFileName*** parameter is NULL, this value should be zero.

Return Value

An integer value which specifies the current log file format. Refer to the **HTTPSERVERCONFIG** structure definition for a list of supported log file formats. If the server handle is invalid or logging has not been enabled, this function will return a value of zero.

Remarks

If the server is configured with logging enabled, but a log file name is not explicitly provided, then the server will automatically generate one. This function can be used to get the full path to the current log file along with the format that is being used to record client session data. Normally the log file is held open by the server thread while it is active, however you can call the **HttpRenameServerLogFile** function to explicitly rename or delete the log file.

To change the name of the log file, the log file format or level of detail, use the **HttpSetServerLogFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetServerMemoryUsage Function

```
BOOL WINAPI HttpGetServerMemoryUsage(
   HSERVER hServer,
   ULARGE_INTEGER *lpMemUsage
);
```

Return the amount of memory allocated for the server and all client sessions.

Parameters

hServer

The server handle.

lpMemUsage

A pointer to a ULARGE_INTEGER variable which will specify how much memory has been allocated by the server. This parameter will be initialized to a value of zero by the function and updated with the total number of bytes allocated by the server and all active client sessions when it returns.

Return Value

If the function succeeds, the return value is non-zero and the memory usage value will be updated. If the server handle is invalid, or the server cannot be locked, the return value is zero. Call the **HttpGetServerError** function to determine the cause of the failure.

Remarks

This function returns the amount of memory allocated by the server and all active client sessions. It enumerates all of memory allocations made by the server process and client session threads and returns the total number of bytes allocated for the server process. This value reflects the amount of memory explicitly allocated by this library and does not reflect the total working set size of the process, or memory allocated by any other libraries. To determine the working set size for the process, refer to the Win32 **GetProcessWorkingSetSize** and **GetProcessMemoryInfo** functions.

This function forces the server into a locked state, and all client sessions will block until the function returns. Because this function enumerates all heaps allocated for the server process, it can be an expensive operation, particularly when there are a large number of active clients connected to the server. Frequent use of this function can significantly degrade the performance of the server. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active client sessions. If the value returned by the function remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpGetServerName Function

```
INT WINAPI HttpGetServerName(
   HSERVER hServer,
   UINT nClientId,
   LPTSTR lpszHostName,
   INT nMaxLength
);
```

Return the host name assigned to the specified server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A null-terminated string buffer that will contain the server host name, terminated with a null character. It is recommended that this buffer be at least 64 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will return the host name assigned to the specified server. If the ***nClientId*** parameter has a value of zero, the function will return the default host name that was specified as part of the server configuration. If no host name was explicitly assigned to the server, then it will return the local system name. If the ***nClientId*** parameter specifies a client session, then it this function will return the host name that the client used to establish the connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetServerAddress

HttpGetServerOptions Function

```
BOOL WINAPI HttpGetServerOptions(
    HSERVER hServer,
    LPDWORD lpdwOptions
);
```

Return the configuration options for the specified server.

Parameters

hServer

The server handle.

lpdwOptions

A pointer to an unsigned integer that will contain the options that were specified when the server was started. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

This function will return the options that were specified when the server was started. For a list of server options see Server Option Constants.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpGetServerPriority Function

```
INT WINAPI HttpGetServerPriority(
    HSERVER hServer
);
```

Return the current priority assigned to the specified server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the priority for the specified server. If the function fails, the return value is HTTP_PRIORITY_INVALID. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpGetServerPriority** function can be used to determine the current priority assigned to the server. It will return one of the following values:

Value	Description
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
HTTP_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpServerStart, HttpSetServerPriority

HttpGetServerStackSize Function

```
DWORD WINAPI HttpGetServerStackSize(
     SOCKET hServer
);
```

Return the initial size of the stack allocated for threads created by the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the amount of memory that will be allocated for the stack in bytes. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpGetServerStackSize** function returns the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpGetServerTransferInfo Function

```
BOOL WINAPI HttpGetServerTransferInfo(
   HSERVER hServer,
   UINT nClientId,
   LPHTTPSERVERTRANSFER lpTransferInfo
);
```

Return information about the current file transfer.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpTransferInfo

A pointer to an **HTTPSERVERTRANSFER** structure that will contain information about the last file transfer. This parameter cannot be NULL, and the ***dwSize*** member of the structure must be initialized to specify the structure size prior to calling this function.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpGetServerTransferInfo** function is used to obtain information about the last file transfer that was performed by the server for the specified client. This function is typically called within an event handler to determine how many bytes of data were transferred, the type of file and the full path to the file on the local system.

This function will only return information about a file transfer using the GET or PUT commands, with any other command causing this function to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetServerUuid Function

```
INT WINAPI HttpGetServerUuid(
    HSERVER hServer,
    UUID *lpUuid
);
```

Return the UUID assigned to the specified server.

Parameters

hServer

The server handle.

lpUuid

A pointer to a UUID structure that will contain the server UUID when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle is invalid or the pointer to the UUID structure is NULL, the function will return a value of zero.

Remarks

The **HttpGetServerUuid** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain a printable string version of the UUID, use the **HttpGetServerUuidString** function.

There is no corresponding function to change the UUID assigned to an active server. The server UUID is assigned when the server is started, and it must be a unique value that is maintained throughout the lifetime of the server. To change the UUID associated with the server, the server must be stopped using the **HttpServerStop** function and another instance of the server started with the new UUID.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpGetServerUuidString, HTTPSERVERCONFIG

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetServerUuidString Function

```
INT WINAPI HttpGetServerUuidString(
    HSERVER hServer,
    LPTSTR lpszHostUuid,
    INT nMaxLength
);
```

Return the UUID assigned to the server as a printable string.

Parameters

hServer

The server handle.

lpszHostUuid

A null-terminated string buffer that will contain the server UUID, terminated with a null character. It is recommended that this buffer be at least 40 characters in length. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. This value must be greater than zero. If the buffer size is too small, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the buffer is not large enough to store the complete UUID string, the function will return a value of zero.

Remarks

The **HttpGetServerUuidString** function returns the Universally Unique Identifier (UUID) that has been assigned to the server. The UUID may either be generated by the application and assigned as part of the server configuration, or an ephemeral UUID may be automatically generated when the server is started. To obtain the numeric UUID value, use the **HttpGetServerUuid** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpGetVirtualHostId Function

```
UINT WINAPI HttpGetVirtualHostId(
   HSERVER hServer,
   LPCTSTR lpszHostName,
   UINT nHostPort
);
```

Return the virtual host ID associated with the specified hostname.

Parameters

hServer

The server handle.

lpszHostName

A string that specifies the virtual host name.

nHostPort

An integer value which specifies the port number for the virtual host. This value must be zero or the same value as the original port number that the server was configured to use.

Return Value

If the function succeeds, the return value is the host ID that uniquely identifies the virtual host. If the server handle is invalid, or there is no virtual host with the specified name, the function will return VIRTUAL_HOST_UNKNOWN. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **HttpGetVirtualHostId** function is used to obtain the unique virtual host ID that is associated with a specific hostname. This function will match both the primary virtual hostname added using the **HttpAddVirtualHost** function, as well as any aliases that were added using the **HttpAddVirtualHostAlias** function. To obtain the virtual host ID associated with the active client session, use the **HttpGetClientVirtualHostId** function.

The *nHostPort* parameter should always be specified with a value of zero, or the same port number that the server was configured to use. Port-based virtual hosting is currently not supported and this parameter is included for future use.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpAddVirtualHost, HttpAddVirtualHostAlias, HttpDeleteVirtualHost, HttpGetClientVirtualHostId, HttpGetVirtualHostName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpGetVirtualHostName Function

```
INT WINAPI HttpGetVirtualHostName(
    HSERVER hServer,
    UINT nHostId,
    LPTSTR lpszHostName,
    INT nMaxLength
);
```

Return the hostname associated with the specified virtual host ID.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host.

lpszHostName

A null-terminated string buffer that will contain the virtual host name, terminated with a null character. It is recommended that this buffer be at least 64 characters in length. If this parameter is NULL, the function will return the length of the virtual hostname.

nMaxLength

An integer value that specifies the maximum number of characters can be copied into the string buffer, including the terminating null character. If the ***lpszHostName*** parameter is NULL this value must be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If either the server handle or the host ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

The **HttpGetVirtualHostName** function returns the primary hostname associated with the specified virtual host ID. This is the same hostname that was specified when the virtual host was added to the server configuration using the **HttpAddVirtualHost** function. To obtain the hostname that was used by the active client session to connect to the server, use the **HttpGetClientVirtualHost** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpIsClientAuthenticated Function

```
BOOL WINAPI HttpIsClientAuthenticated(
    HSERVER hServer,
    UINT nClientId
);
```

Determine if the specified client session has been authenticated.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

Return Value

If the client session has been authenticated, this function will return a non-zero value, otherwise it will return zero. If the server handle and client ID are valid, this function will clear the last error code.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpAuthenticateClient, HttpGetClientCredentials, HttpRequireAuthentication

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpIsCommandEnabled Function

```
BOOL WINAPI HttpIsCommandEnabled(
    HSERVER hServer,
    LPCTSTR lpszCommand
);
```

Determine if a specific server command has been enabled or disabled.

Parameters

hServer

The server handle.

lpszCommand

A null-terminated string that specifies the name of the command. The command name is not case-sensitive, but the value must otherwise match the exact command name. Partial matches are not recognized by this function. This parameter cannot be NULL.

Return Value

If the command is enabled, this function will return a non-zero value. If the command is disabled, the server handle is invalid or the command name does not match a supported command, this function will return zero.

Remarks

The **HttpIsCommandEnabled** function is used to determine whether a specific command is enabled. Typically this function is used in an event handler to make sure the command issued by a client is recognized by the server and enabled for use. Commands can be enabled and disabled using the **HttpEnableCommand** function.

This function does not account for the permissions granted to a specific client session. Clients are assigned access rights when they are authenticated using the **HttpAuthenticateClient** function, and certain commands can be limited by the permissions granted to the client. For example, even if the PUT command is enabled, a client must have the HTTP_ACCESS_WRITE permission to use the command to upload a file to the server. For a list of access rights, see User Access Constants.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpReceiveRequest Function

```
BOOL WINAPI HttpReceiveRequest(
   HSERVER hServer,
   UINT nClientId,
   DWORD dwOptions,
   LPHTTPREQUEST lpRequest,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength
);
```

Receive the request that was sent by the client to the server.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwOptions

An unsigned integer which specifies how the client request data will be stored. It may be one of the following values:

Value	Description
HTTP_REQUEST_DEFAULT	If the ***lpdwLength*** parameter points to a integer with a non-zero value, the ***lpvBuffer*** parameter is considered to be a pointer to a block of memory that has been allocated to store the request data. This is the same as specifying the HTTP_REQUEST_MEMORY option. If the ***lpdwLength*** parameter points to an integer with a value of zero, the ***lpvBuffer*** parameter is considered to be a pointer to an HGLOBAL memory handle. This is the same as specifying the HTTP_REQUEST_HGLOBAL option.
HTTP_REQUEST_MEMORY	The ***lpvBuffer*** parameter is a pointer to a block of memory that has been allocated to store the request data. The maximum number of bytes of data that can stored is determined by the value of the integer that the ***lpdwLength*** parameter points to. When the function returns, that value will updated with with actual number of bytes copied into the buffer.
HTTP_REQUEST_STRING	The ***lpvBuffer*** parameter is a pointer to a string buffer that has been allocated to store the request data. The maximum number of bytes of data that can be copied is determined by the value of the integer that the ***lpdwLength*** parameter points to. When the function returns, that value will updated with with actual number of bytes copied into the buffer. If the Unicode version of this function is called, the request data will be converted to a null-terminated Unicode string.
HTTP_REQUEST_HGLOBAL	The ***lpvBuffer*** parameter is a pointer to an HGLOBAL memory

	handle. When the function returns, the handle will reference a block of memory that contains the request data submitted by the client. The *lpdwLength* parameter will contain the number of bytes copied to the buffer.
HTTP_REQUEST_FILE	The *lpvBuffer* parameter is a pointer to a string which specifies the name of a file that will contain the request data. If the file does not exist, it will be created. If it does exist, the contents will be replaced. This option is typically used in conjunction with the PUT command. If the *lpdwLength* parameter is not NULL, the value it points to will be updated with the actual number of bytes stored in the file.
HTTP_REQUEST_HANDLE	The *lpvBuffer* parameter is a handle to an open file. This option is typically used in conjunction with the POST or PUT commands. If the *lpdwLength* parameter is not NULL, the value it points to will be updated with the actual number of bytes written to the file. If this option is specified, the request data will be written from the current position in the file and will advance the file pointer by the number of bytes received from the client.

lpRequest

A pointer to a **HTTPREQUEST** structure which contains information about the request from the client. This parameter cannot be NULL. The structure that is passed to this function must have all members set to a value of zero except the *dwSize* member, which must be initialized to the size of the structure.

lpvBuffer

The buffer that will contain any request data that was submitted by the client. The *dwOptions* parameter determines if this pointer references a block of memory, a null-terminated string buffer, a global memory handle or a file name. If this parameter is NULL, any data submitted by the client will not be copied.

lpdwLength

A pointer to an unsigned integer that will contain the number of bytes of data submitted by the client when the function returns. If the *lpvBuffer* parameter specifies a memory or string buffer, this value must be initialized to the maximum size of the buffer before the function is called. If the *lpvBuffer* parameter points to a global memory handle, this value must be initialized to zero. If *lpvBuffer* is NULL or specifies a file name, this parameter may be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpReceiveRequest** function is called within a HTTP_CLIENT_COMMAND event handler to process the command issued by the client and return information about the request to the server application. It is only necessary for the application to call this function if it wants to implement its own custom handling for a command. It is recommended that most applications use the default command processing for standard commands such as GET and POST to ensure that the appropriate security checks are performed and the response conforms to the protocol standard.

This function may only be called once per command issued by the client and the data referenced in the **HTTPREQUEST** structure only remains valid while the client is connected to the server. You should never attempt to directly modify the data referenced by any of the structure members. If you wish to store or modify any of the string values returned in the structure, you should allocate a buffer large enough to store the contents of the string, including the terminating null character, and copy the string into that buffer.

If the HTTP_REQUEST_HGLOBAL option is used to return a copy of the request data in a global memory buffer, the HGLOBAL handle must be freed by the application when the data is no longer needed. Failure to free this handle will result in a memory leak.

If the HTTP_REQUEST_HANDLE option is used to write a copy of the request data to an open file, the handle must reference a disk file that was opened or created using the **CreateFile** function with GENERIC_WRITE access. It cannot be a handle to a device or named pipe. If the function succeeds, the file pointer is advanced by the number of bytes of request data submitted by the client. If the function fails, the file pointer is returned to its original position prior to the function being called.

Example

```
// Initialize the HTTPREQUEST structure
HTTPREQUEST httpRequest;
ZeroMemory(&httpRequest, sizeof(httpRequest));
httpRequest.dwSize = sizeof(httpRequest);

// Return the data in a global memory buffer
HGLOBAL hgblBuffer = NULL;
DWORD dwLength = 0;

bSuccess = HttpReceiveRequest(hServer,
                              nClientId,
                              HTTP_REQUEST_HGLOBAL,
                              &httpRequest,
                              &hgblBuffer,
                              &dwLength);

if (bSuccess && hgblBuffer != NULL)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    if (lpBuffer != NULL)
    {
        // Process dwLength bytes of data submitted by the client
    }

    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpRedirectRequest Function

```
BOOL WINAPI HttpRedirectRequest(
   HSERVER hServer,
   UINT nClientId,
   UINT nMethod,
   LPCTSTR lpszLocation
);
```

Redirect the request from the client to another URL.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nMethod

An integer value that specifies if the redirection is permanent or temporary. The following values may be used:

Value	Description
HTTP_REDIRECT_PERMANENT	This value is used for permanent redirection, indicating that the client should update any record of the link with the new URL specified by the ***lpszLocation*** parameter. This result is cacheable and when the client makes subsequent requests for the resource, it should always use the new URL.
HTTP_REDIRECT_TEMPORARY	This value is used for temporary redirection, indicating that the client should issue a request for the resource using the new URL specified by the ***lpszLocation*** parameter, but subsequent requests should continue to use the original URL.
HTTP_REDIRECT_OTHER	This value is used for temporary redirection, however it instructs the client that it should use the GET command to request the redirected resource. This option is typically used to redirect a client after it has used the POST command.

lpszLocation

A null-terminated string that specifies the new location for the requested resource. This value must be a complete URL, including the http:// or https:// scheme. This parameter cannot be NULL or point to zero-length string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRedirectRequest** function can be used within a HTTP_CLIENT_COMMAND event handler to redirect the client to a new location for the resource that it has requested. This redirection can be permanent or temporary, depending on whether the server expects the client to continue to use the original URL when requesting the resource.

If the HTTP_REDIRECT_TEMPORARY method is used, the actual status code that is returned to the client depends on the version of the protocol that is being used. If the client has issued the request using HTTP 1.0 then the server will return a 302 code to the client. If the client used HTTP 1.1, the server will return a 307 code to the client that indicates it should use the same command verb (GET, POST, etc.) when requesting the resource at the new location.

If the HTTP_REDIRECT_OTHER method is used, the status code that is returned to the client depends on which version of the protocol is being used. For clients who are using HTTP 1.0, the server will return a 302 code to the client just as with the HTTP_REDIRECT_TEMPORARY method. If the client is using HTTP 1.1, the server will return a 303 code to the client that indicates it should always use the GET command to request the new resource, regardless if a different command was originally used (POST, PUT, etc.)

This function provides a simplified interface for sending a redirection status code that also implicitly sets the Location response header to the value of the ***lpszLocation*** parameter. If the server application needs to send alternate redirection codes such as 305 (Use Proxy) then it should use the **HttpSendReponse** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpRegisterHandler Function

```
BOOL WINAPI HttpRegisterHandler(
   HSERVER hServer,
   UINT nHostId,
   LPCTSTR lpszExtension,
   LPCTSTR lpszProgramFile,
   LPCTSTR lpszParameters,
   LPCTSTR lpszDirectory
);
```

Register a CGI program for use and associate it with a file name extension.

Parameters

hServer

The server handle.

nHostId

An unsigned integer that identifies the virtual host associated with the program. The value VIRTUAL_HOST_DEFAULT should be used for the default host that is created when the server is first started.

lpszExtension

A null-terminated string which specifies the file name extension that is associated with the CGI program. This parameter cannot be NULL.

lpszProgramFile

A null-terminated string that specifies the full path to the executable program. This parameter cannot be NULL.

lpszParameters

A null-terminated string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the program does not require any command line parameters, this value may be NULL or point to an empty string.

lpszDirectory

A null-terminated string that specifies the current working directory for the program. If this parameter is NULL or points to an empty string, the server will use the root document directory for the virtual host.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRegisterHandler** function registers an executable CGI program and associates it with a file name extension. When the client issues a GET or POST command that specifies a file with that extension, the program will be executed and the output return to the client.

The *lpszProgramFile* string specifies file name of the CGI program. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the ability to directly access the executable file itself. It is permitted to have multiple file name extensions that reference the same program. The only requirement is that the extension be unique for the given

host. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the `C:\Program Files` folder.

It is important to note that the program specified by *lpszProgramFile* must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The *lpszParameters* string can specify additional command line parameters that should be passed to the CGI program as arguments. This string can also contain a placeholder named "%1" that will be replaced by the full path to the local script filename. If no placeholder is included in the parameters, or *lpszParameters* is a NULL pointer, the script file name will be passed to the program as its only argument.

The executable program that is registered using this program must be a console application that conforms to the CGI/1.1 specification defined in RFC 3875. Request data submitted by the client as part of a POST will be provided to the program as standard input. The output from the program must be written to standard output. The first lines of output from the program should be any response headers, followed by an empty line. Each line should be terminated with a carriage-return and linefeed (CRLF) sequence. If the CGI program outputs additional data to be processed by the client, it should provide Content-Type and Content-Length response headers.

The application can obtain a copy of the output from the command by calling the **HttpGetProgramOutput** function from within a HTTP_CLIENT_EXECUTE event handler.

When developing a CGI program, it is important to take into consideration the environment that it will be executing in. The program will be started as a child process of the server application, and will inherit the same privileges. This means that it will typically have access to the boot drive, the Windows folders and the system registry. CGI programs must ensure that all query parameters and request data submitted by the client have been validated.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

Example

```
// Register a handler for VBScript
HttpRegisterHandler(hServer,
                    VIRTUAL_HOST_DEFAULT,
                    _T("vbs"),
                    _T("%SystemRoot%\\System32\\cscript.exe"),
                    _T("/nologo /b \"%1\""),
                    NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpRegisterProgram Function

```
BOOL WINAPI HttpRegisterProgram(
   HSERVER hServer,
   UINT nHostId,
   LPCTSTR lpszVirtualPath,
   LPCTSTR lpszProgramFile,
   LPCTSTR lpszParameters,
   LPCTSTR lpszDirectory
);
```

Register a CGI program for use and associate it with a virtual path on the server.

Parameters

hServer

The server handle.

nHostId

An unsigned integer that identifies the virtual host associated with the program. The value VIRTUAL_HOST_DEFAULT should be used for the default host that is created when the server is first started.

lpszVirtualPath

A null-terminated string which specifies the virtual path to the CGI program. This must be an absolute path, but does not have to specify a pre-existing virtual path or map to the directory structure of the root document directory for the server. This parameter cannot be NULL. The maximum length of the virtual path is 1024 characters.

lpszProgramFile

A null-terminated string that specifies the full path to the executable program. This parameter cannot be NULL.

lpszParameters

A null-terminated string that specifies additional parameters for the program. This value will be passed to the program as command line arguments. If the program does not require any command line parameters, this value may be NULL or point to an empty string.

lpszDirectory

A null-terminated string that specifies the current working directory for the program. If this parameter is NULL or points to an empty string, the server will use the root document directory for the virtual host.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRegisterProgram** function registers an executable CGI program and associates it with a virtual path. When the client issues a GET or POST command specifying the virtual path associated with the program, the program will be executed and the output return to the client.

The *lpszProgramFile* string specifies file name of the CGI program. You should not install any executable programs in the server root directory or its subdirectories. A client should never have the

ability to directly access the executable file itself. It is permitted to have multiple virtual paths that reference the same executable file. The only requirement is that the virtual path be unique for the given host. The program name may contain environment variables surrounded by % symbols. For example, %ProgramFiles% would be expanded to the `C:\Program Files` folder.

It is important to note that the program specified by *lpszProgramFile* must be an executable file, not a script or batch file. If the program name does not contain a directory path, then the standard Windows pathing rules will be used when searching for an executable file that matches the given name. It is recommended that you always provide a full path to the executable file.

The *lpszParameters* string can specify additional command line parameters that should be passed to the CGI program as arguments. This string can also contain a placeholder named "%1" that will be replaced by the virtual path associated with the program. If *lpszParameters* is NULL or a zero-length string, then no additional parameters are passed to the program.

The executable program that is registered using this program must be a console application that conforms to the CGI/1.1 specification defined in RFC 3875. Request data submitted by the client as part of a POST will be provided to the program as standard input. The output from the program must be written to standard output. The first lines of output from the program should be any response headers, followed by an empty line. Each line should be terminated with a carriage-return and linefeed (CRLF) sequence. If the CGI program outputs additional data to be processed by the client, it should provide Content-Type and Content-Length response headers.

The application can obtain a copy of the output from the command by calling the **HttpGetProgramOutput** function from within a HTTP_CLIENT_EXECUTE event handler.

When developing a CGI program, it is important to take into consideration the environment that it will be executing in. The program will be started as a child process of the server application, and will inherit the same privileges. This means that it will typically have access to the boot drive, the Windows folders and the system registry. CGI programs must ensure that all query parameters and request data submitted by the client have been validated.

If the server is running on a system with User Account Control (UAC) enabled and does not have elevated privileges, do not register a program that requires elevated privileges or has a manifest that specifies the requestedExecutionLevel as requiring administrative privileges.

Example

```
HttpRegisterProgram(hServer,
                    VIRTUAL_HOST_DEFAULT,
                    HTTP_METHOD_DEFAULT,
                    _T("/order/invoice"),
                    _T("%ProgramData%\\MyServer\\Programs\\invoice.exe"),
                    NULL,
                    NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpRenameServerLogFile Function

```
BOOL WINAPI HttpRenameServerLogFile(
    HSERVER hServer,
    LPCTSTR lpszFileName
);
```

Rename or delete the current log file being updated by the server.

Parameters

hServer

The server handle.

lpszFileName

A null-terminated string that specifies the file name the current log file should be renamed to. If this parameter is NULL or an empty string, the current log file will be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero. If logging is not currently enabled for the server, this function will return zero.

Remarks

The **HttpRenameServerLogFile** function is used to rename or delete the current log file. Note that this does not change the current log file name or disable logging by the server. It only changes the file name of the current log file, or removes the log file if the ***lpszFileName*** parameter is NULL. This can be useful if you want your server to perform log file rotation, archiving the current log file. By renaming the current log file, the server will automatically create a new log file with original file name.

This function must be used to rename or delete the current log file while logging is active because the server holds an open handle on the file. The application should not use the **HttpGetServerLogFile** function to obtain the log file name and then use the **MoveFileEx** or **DeleteFile** functions with that file.

To disable logging, use the **HttpSetServerLogFile** function and specify the logging format as HTTP_LOGFILE_NONE.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetServerLogFile, HttpSetServerLogFile

HttpRequireAuthentication Function

```
BOOL WINAPI HttpRequireAuthentication(
    HSERVER hServer,
    UINT nClientId,
    UINT nAuthType,
    LPCTSTR lpszRealm
);
```

Send a response to the client indicating that authentication is required.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nAuthType

An integer value that corresponds to a result code, informing the client if the redirection is permanent or temporary. The following values may be used:

Value	Description
HTTP_AUTH_BASIC	This option specifies the Basic authentication scheme should be used. This option is supported by all clients that support at least version 1.0 of the protocol.

lpszRealm

A null-terminated string that is displayed by a web browser to indicate to the user which username and password they should use. If this parameter is NULL or an empty string, the domain name the client used to establish the connection will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpRequireAuthentication** function can be used within a HTTP_CLIENT_COMMAND event handler to indicate to the client that it must provide a username and password to access the requested resource. The client should respond by issuing another request that includes the required credentials. To determine if a client has included credentials with its request, use the **HttpIsClientAuthenticated** function. The **HttpGetClientCredentials** function will return the username and password that was provided by the client.

Some clients may require that the session be secure if authentication is requested or display warning messages to the user if the connection is not secure. It is recommended that you enable security using the HTTP_OPTION_SECURE option if your application will require clients to authenticate before accessing specific resources.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetClientCredentials, HttpIsClientAuthenticated, HttpSendResponse

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpSendErrorResponse Function

```
BOOL WINAPI HttpSendErrorResponse(
    HSERVER hServer,
    UINT nClientId,
    UINT nErrorCode,
    LPCTSTR lpszMessage
);
```

Send a customized error response to the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nErrorCode

An integer value that specifies the error code that should be sent to the client. This value should correspond to the error result codes defined for HTTP in RFC 2616, which are three-digit values in the range of 400 through 599. The function will fail if an invalid error code is specified.

lpszMessage

A null-terminated string that describes the error. If this parameter is NULL or specifies a zero-length string, a default message will be selected based on the error code.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSendErrorResponse** function sends a response to the client indicating that an error has occurred, providing a numeric error code and HTML formatted text which may be displayed to the user. The *lpszMessage* parameter should provide a brief description of the error that will be included in the output sent to the client. Note that the message should not contain any special formatting control characters or HTML markup.

This function provides a simplified interface for sending an error response to the client. In some cases, a browser may choose to display its own error message to the user in place of the generic HTML document generated by this function. If you want your application to send a customized HTML document for a specific type of error, you should use the **HttpSendResponse** function.

If you wish to redirect the client to use an alternate URL to access the requested resource, it is recommended that you use the **HttpRedirectRequest** function rather than sending an error response.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpRedirectRequest, HttpSendResponse

HttpSendResponse Function

```
BOOL WINAPI HttpSendResponse(
  HSERVER hServer,
  UINT nClientId,
  DWORD dwOptions,
  LPHTTPRESPONSE lpResponse,
  LPVOID lpvBuffer,
  DWORD dwLength
);
```

Send a response from the server to the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwOptions

An unsigned integer which specifies how the client request data will be copied. It may be one of the following values:

Value	Description
HTTP_RESPONSE_DEFAULT	The ***lpvBuffer*** parameter is a pointer to a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the ***dwLength*** parameter. This is the same as specifying the HTTP_RESPONSE_MEMORY option.
HTTP_RESPONSE_MEMORY	The ***lpvBuffer*** parameter is a pointer to a block of memory that contains the response data. The number of bytes of data that in the buffer is specified by the ***dwLength*** parameter. The data will be sent to the client as a stream of bytes. If the server application was compiled using Unicode, it is responsibility of the application to convert any Unicode text to either ANSI or UTF-8, depending on the resource that was requested by the client.
HTTP_RESPONSE_STRING	The ***lpvBuffer*** parameter is a pointer to a string buffer that contains the response data. The maximum number of bytes of data that will be sent to the client is determined by the ***dwLength*** parameter. If the value of the ***dwLength*** parameter exceeds the string length, the value will be ignored and the contents of the string will be sent up to the terminating null character. If the Unicode version of this function is called, the string will be converted to a byte array before being sent to the client.
HTTP_RESPONSE_HGLOBAL	The ***lpvBuffer*** parameter is an HGLOBAL memory handle which references a block of memory that contains the response data. The number of bytes of data that in the

	buffer is specified by the ***dwLength*** parameter. The data will be sent to the client as a stream of bytes. It is the responsibility of the application to free the global memory handle after it is no longer needed.
HTTP_RESPONSE_FILE	The ***lpvBuffer*** parameter is a pointer to a string which specifies the name of a file that contains the response data. If the file does not exist, or does not specify a regular file, this function will fail. The ***dwLength*** parameter is ignored. If the content type for the specified file is not explicitly defined in the response, the function will attempt to automatically determine the correct type based on the file name extension and/or the contents of the file.
HTTP_RESPONSE_HANDLE	The ***lpvBuffer*** parameter is a handle to an open file and the ***dwLength*** parameter specifies the number of bytes to be read from the file and send to the client. If this option is specified, the response data will be read from the current position in the file and will advance the file pointer by the number of bytes sent to the client.
HTTP_RESPONSE_DYNAMIC	The response data will be generated dynamically. This prevents the content length from being included in the response header, and forces the connection to close, regardless if the client has requested to keep the connection open. This option must be specified if the application wishes to use the **HttpSendResponseData** function to send additional data to the client.
HTTP_RESPONSE_NOCACHE	Informs the client that the data being returned by the server should not be cached. Typically this is used in conjunction with the HTTP_RESPONSE_DYNAMIC option when the data is being generated dynamically.

lpResponse

A pointer to a **HTTPRESPONSE** structure which contains additional information about the response to the client. The structure that is passed by reference to this function must have the ***dwSize*** member initialized to the size of the structure or the function will fail. This parameter may be NULL, in which case a default response of "200 OK" is sent to the client along with any data specified by the ***lpvBuffer*** parameter.

lpvBuffer

The buffer that will contain any response data that should be sent to the client. The ***dwOptions*** parameter determines if this pointer references a block of memory, a null-terminated string buffer, a global memory handle or a file name. This parameter may be NULL, in which case no data will be sent to the client. If this function is called in response to a HEAD command being sent by the client, this parameter is ignored.

dwLength

An unsigned integer that specifies the number of bytes of data to be sent to the client. If the ***lpvBuffer*** parameter is NULL, this value must be zero. If this function is called in response to a HEAD command being sent by the client, this parameter is ignored.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSendResponse** function is called within a HTTP_CLIENT_COMMAND event handler to respond to the request made by the client. This function may only be called once after a command has been received, and must be called after the **HttpReceiveRequest** function. It is only necessary for the application to call this function if it wants to implement its own custom handling for a command. It is recommended that most applications use the default command processing for standard commands such as GET and POST to ensure that the appropriate security checks are performed and the response conforms to the protocol standard.

If the HTTP_RESPONSE_HANDLE option is used to read a copy of the response data from an open file, the handle must reference a disk file that was opened using the **CreateFile** function with GENERIC_READ access. It cannot be a handle to a device or named pipe. If the ***dwLength*** parameter is larger than the total number of bytes available to be read from the current position in the file, the function will stop sending data to the client when it reaches the end-of-file. If the function succeeds, the file pointer is advanced by the number of bytes of response data sent to the client. If the function fails, the file pointer is returned to its original position prior to the function being called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpSendResponseData Function

```
INT WINAPI HttpSendResponseData(
   HSERVER hServer,
   UINT nClientId,
   LPBYTE lpBuffer,
   DWORD dwLength,
   LPDWORD lpdwResponse
);
```

Send additional data to the client in response to a command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpBuffer

A buffer that contains the response data that should be sent to the client. This parameter cannot be NULL and must point to a valid byte buffer. If the response contains non-ASCII text characters, it should be UTF-8 encoded.

dwLength

An unsigned integer that specifies the size of the response data sent to the client. This value must be greater than zero and should never exceed the number of bytes stored in the buffer specified by the *lpBuffer* parameter.

lpdwResponse

A pointer to an unsigned integer which will contain the total number of bytes successfully sent to the client in response to the request. This parameter may be NULL, in which case it is ignored.

Return Value

If the function succeeds, the return value is the number of bytes of data sent to the client. If the function fails, the return value is HTTP_ERROR. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSendResponseData** function is called within a HTTP_CLIENT_COMMAND event handler to send data to the client in response to a request. This function can only be used to send dynamically generated content after the **HttpSendResponse** function has been called. The HTTP_RESPONSE_DYNAMIC option must have been specified when responding to the client or this function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpServerAsyncNotify Function

```
BOOL WINAPI HttpServerAsyncNotify(
    HSERVER hServer,
    HWND hWnd,
    UINT uMsg
);
```

Enable or disable asynchronous notification of changes in server status.

Parameters

hServer

The server handle.

hWnd

A handle to the window whose window procedure will receive the notification message.

uMsg

The user-defined message that will be sent to the notification window.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **HttpGetServerError** function.

Remarks

The **HttpServerAsyncNotify** function is used by an application to enable or disable asynchronous notifications. The message window is typically the main UI window and these notifications are used signal to the application that it should update the user interface. If the *hWnd* parameter is not NULL, it must specify a valid window handle and the user-defined message must have a value of **WM_USER** or higher. The application cannot specify a notification message that is reserved by the operating system. The pseudo-handle **HWND_BROADCAST** cannot be specified as the notification window. If the *hWnd* parameter is NULL, notifications for the specified server will be disabled.

When asynchronous notifications are enabled for a server, the server will post the user-defined message to the window whenever there is a change in status or after a client has connected or disconnected from the server. The *wParam* message parameter will contain the notification message and the *lParam* message parameter will contain the handle to the server or the client ID. The following notification messages are defined:

Value	Description
HTTP_NOTIFY_STARTUP	This notification is sent when the server has started and is preparing to accept client connections. This notification is only sent once, and only if asynchronous notifications are enabled immediately after the **HttpServerStart** function is called. This message will not be sent once the server has begun accepting client connections or when notification messages are disabled and then subsequently re-enabled at a later time. The *lParam* message parameter will specify the handle to the server.
HTTP_NOTIFY_LISTEN	This notification is sent when the server is listening for client connections. This notification message may be sent to the

	application multiple times over the lifetime of the server. If the server was suspended, this notification will be sent after the application calls the **HttpServerResume** function to resume accepting client connections. The ***lParam*** message parameter will specify the handle to the server.
HTTP_NOTIFY_SUSPEND	This notification is sent when the server suspends accepting new connections because the application has called the **HttpServerSuspend** function. This notification message may be sent to the application multiple times over the lifetime of the server. The ***lParam*** message parameter will specify the handle to the server.
HTTP_NOTIFY_RESTART	This notification is sent when the server is restarted using the **HttpServerRestart** function. Note that the server socket handle provided by the ***lParam*** message parameter will specify the new socket handle of the restarted server instance, not the original socket handle. The ***lParam*** message parameter will specify the handle to the server.
HTTP_NOTIFY_CONNECT	This notification is sent when the server accepts a client connection and the thread that manages the client session has begun processing network events for that client. This message notification will not be sent if the client connection is rejected by the server. The ***lParam*** message parameter will specify the unique ID of the client that connected to the server.
HTTP_NOTIFY_DISCONNECT	This notification is sent when the client disconnects from the server and the client socket has been closed. This notification message may not occur for each client session that is forced to terminate as the result of the server being stopped using the **HttpServerStop** function. The ***lParam*** message parameter will specify the unique ID of the client that disconnected from the server.
HTTP_NOTIFY_SHUTDOWN	This notification is sent when the server thread is in the process of terminating. At the time the application processes this notification message, the server handle in ***lParam*** will reference the defunct server and cannot be used with other server functions. The ***lParam*** message parameter will specify the handle to the server.

If asynchronous notifications are enabled, you should never use those notifications as a replacement for an event handler. When an event occurs, the callback function that handles the event is invoked in the context of the thread that manages the client session. The application should exchange data with the client within that event handler and not in response to a notification message. These notification messages should only be used to update the application UI in response to changes in the status of the server.

The HTTP_NOTIFY_CONNECT and HTTP_NOTIFY_DISCONNECT notifications are different from the other server notifications because the ***lParam*** message parameter does not specify the server handle, but rather the unique client ID associated with the session that connected to or disconnected from the server. Use the **HttpGetClientServer** function to obtain a handle to the server that created the client

session. Note that at the time the application processes the HTTP_NOTIFY_DISCONNECT notification message, the client session will have already terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpGetClientServer, HttpServerStart

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerDisableTrace Function

```
BOOL WINAPI HttpServerDisableTrace();
```

Disable the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpServerEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerEnableTrace Function

```
BOOL WINAPI HttpServerEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

Enable the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string that specifies the name of the log file. If this parameter is NULL or points to an empty string, a log file is created in the temporary directory for the current user.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_DEFAULT	All function calls are written to the trace file. This is the default value.
TRACE_ERROR	Only those function calls which fail are recorded in the trace file.
TRACE_WARNING	Only those function calls which fail, or return values which indicate a warning, are recorded in the trace file.
TRACE_HEXDUMP	All functions calls are written to the trace file, plus all the data that is sent or received is displayed, in both ASCII and hexadecimal format.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call HttpGetServerError.

Remarks

When trace logging is enabled, the log file is opened, appended to and closed for each socket function call. Using the same file name, you can do the same in your application to add additional information to the file if needed. This can provide an application-level context for the entries made by the library. Make sure that the file is closed after the data has been written. If a file name is not specified by the caller, a file named **cstrace.log** will be created in the temporary directory for the current user.

The TRACE_HEXDUMP option can produce very large files, since all data that is being sent and received by the application is logged. To reduce the size of the file, you can enable and disable logging around limited sections of code that you wish to analyze.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerInitialize Function

```
BOOL WINAPI HttpServerInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **HttpServerInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**. All other functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **HttpServerInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **HttpServerUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **HttpServerInitialize** or **HttpServerUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpServerStart, HttpServerStop, HttpServerUninitialize

HttpServerProc Function

```
VOID CALLBACK HttpServerProc(
   HSERVER hServer,
   UINT nClientId,
   UINT nEventId,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **HttpServerProc** function is an application-defined callback function that processes events generated by the server process.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client that has issued a request to the server.

nEventId

An unsigned integer which specifies which event occurred. For a list of events, see Server Event Constants.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero. The **HttpGetServerError** function can be used to obtain additional information about the error code.

dwParam

A user-defined integer value which was specified when the server was started. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

Return Value

None.

Remarks

The HTTP_CLIENT_COMMAND event can be used to filter commands issued by the client. If the command performs an operation on a file or directory, the **HttpGetCommandFile** function can be used to obtain the file name on the server that the client specified. It is possible for the application to change the file name using the **HttpSetCommandFile** function to direct the server to use a different file than the one specified by the client. If the file name is changed and the event handler returns a value of zero, the server will perform the default action for the command using the new file name.

The callback function will be called in the context of the thread that is currently managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself.

If the application has a graphical user interface, you should never attempt to directly modify a UI control from within an event handler. Controls should only be modified by the same UI thread that created their window. To change the user interface in response to a server event, use the

HttpServerAsyncNotify function to enable asynchronous notifications and update the UI in response to the notification message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpServerAsyncNotify, HttpServerStart

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerRestart Function

```
HSERVER WINAPI HttpServerRestart(
    HSERVER hServer
);
```

Restart the server, terminating all active client sessions.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is the new handle for the specified server. If the function fails, the return value is INVALID_SERVER. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerRestart** function will restart the specified server, terminating all active client sessions. The server handle that is returned by the function is the handle for the new server instance, and the old handle value is no longer valid. If the function is unable to restart the server for any reason, the server thread is terminated. The server retains all of the configuration parameters from the previous instance, however the statistical information (such as the number of clients, files transferred, etc.) will be reset.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **HttpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpServerStart, HttpServerStop

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerResume Function

```
BOOL WINAPI HttpServerResume(
    HSERVER hServer
);
```

Resume accepting client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerResume** function instructs the server to resume accepting new client connections after the **HttpServerSuspend** function has been called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpServerRestart, HttpServerStart, HttpServerStop, HttpServerSuspend, HttpServerThrottle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerStart Function

```
HSERVER WINAPI HttpServerStart(
   LPCTSTR lpszLocalHost,
   UINT nLocalPort,
   DWORD dwOptions,
   LPHTTPSERVERCONFIG lpServerConfig,
   HTTPSERVPROC lpServerProc,
   DWORD_PTR dwServerParam,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **HttpServerStart** function begins listening for client connections on the specified local address and port number. The server is started in its own thread and manages the client sessions independently of the calling thread. All interaction with the server and its client sessions takes place inside the callback function specified by the caller.

Parameters

lpszLocalHost

A null-terminated string which specifies the local hostname or IP address address that the server should be bound to. If this parameter is NULL or an empty string, then an appropriate address will automatically be used. If a specific address is used, the server will only accept client connections on the network interface that is bound to that address.

nLocalPort

The port number the server should use to accept client connections. If a value of zero is specified, the server will use the standard port number 21 to listen for connections, or port 990 if the server is configured to use implicit TLS. The port number used by the application must be unique and multiple instances of a server cannot use the same port number. It is recommended that a port number greater than 5000 be used for private, application-specific implementations.

dwOptions

An unsigned integer value that specifies the options used when creating an instance of the server. For a list of options, see Server Option Constants.

lpServerConfig

A pointer to an **HTTPSERVERCONFIG** structure that specifies the configuration options for the server. If this parameter is NULL, then default configuration parameters will be used that starts the server in a restrictive mode.

lpServerProc

Specifies the address of the application defined callback function. For more information about the callback function, see the description of the **HttpServerProc** callback function. If this parameter is NULL, a default internal handler is used to process client commands.

dwServerParam

A user-defined integer value that is passed to the callback function. If the ***lpServerProc*** parameter is NULL, this value should be zero. This value is guaranteed to be large enough to store a pointer or handle value on both 32-bit and 64-bit platforms.

lpCredentials

Pointer to a **SECURITYCREDENTIALS** structure. If this parameter is NULL, the default security credentials for the server host name will be used. If security is enabled for the server, it is

recommended that you provide a pointer to this structure with specific information about the server certificate that should be used. If the security options are not specified in the server configuration, this parameter is ignored.

Return Value

If the function succeeds, the return value is a handle to a server session. If the function fails, the return value is INVALID_SERVER. To get extended error information, call **HttpGetServerError**.

Remarks

In most cases, the *lpszLocalHost* parameter should be a NULL pointer or an empty string. On a multihomed system, this will enable the server to accept connections on any appropriately configured network adapter. Specifying a hostname or IP address will limit client connections to that particular address. Note that the hostname or address must be one that is assigned to the local system, otherwise an error will occur.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the function will fail.

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

The handle returned by this function references the listening socket that was created when the server was started. The service is managed in another thread, and all interaction with the server and active client connections are performed inside the event handler. To disconnect all active connections, close the listening socket and terminate the server thread, call the **HttpServerStop** function.

The host UUID that is defined as part of the server configuration should be generated using the **uuidgen** utility that is included with the Windows SDK. You should not use the UUID that is provided in the example code, it is for demonstration purposes only. If no host UUID is specified in the server configuration, an ephemeral UUID will be generated automatically when the server is started.

If the server is started with security enabled, the *lpCredentials* parameter should be used to provide the server certificate information in a **SECURITYCREDENTIALS** structure. If the pointer is NULL, this function will search for a certificate that matches the hostname provided as part of the server configuration. This requires that the server certificate be installed in the personal certificate store of the current process user, and it must have a private key associated with it. To use a certificate with a different name, or one that is stored in a PFX file, a **SECURITYCREDENTIALS** structure must be defined and passed to this function.

Example

```
HSERVER hServer;
HTTPSERVERCONFIG httpConfig;

// Initialize the server configuration
ZeroMemory(&httpConfig, sizeof(HTTPSERVERCONFIG));
httpConfig.dwSize = sizeof(httpConfig);
httpConfig.nMaxClients = 100;
httpConfig.nMaxClientsPerAdress = 8;
httpConfig.nMaxRequests = 5;
httpConfig.nLogFormat = HTTP_LOGFILE_EXTENDED;
```

```
httpConfig.nLogLevel = 5;
httpConfig.lpszIdentity = _T("MyProgram");
httpConfig.lpszHostName = _T("server.company.com");
httpConfig.lpszHostUuid = _T("10000000-1000-1000-1000-100000000000");
httpConfig.lpszDirectory = _T("%ProgramData%\\MyProgram\\Files");
httpConfig.lpszLogFile = _T("%ProgramData%\\MyProgram\\Server.log");

// Start the server
hServer = HttpServerStart(lpszLocalHost,
                          HTTP_PORT_DEFAULT,
                          HTTP_SERVER_DEFAULT,
                          &httpConfig,
                          lpEventHandler,
                          0,
                          NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerStop Function

```
BOOL WINAPI HttpServerStop(
   HSERVER hServer
);
```

Stop the server, terminating all active client sessions and releasing the resources that were allocated for the server.

Parameters

hServer

The server handle.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **HttpServerStop** function instructs the server to stop accepting client connections, disconnects all active client connections and terminates the thread that is managing the server session. The handle is no longer valid after the server has been stopped and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new server is started. An application should always consider the server handle to be opaque and never depend on it being a specific value.

If an application calls this function from within an event handler, the active client session (the client for which the event handler was invoked) may not get a disconnect notification. It is recommended that this function only be called by the same thread that created the server using the **HttpServerStart** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpServerRestart, HttpServerStart

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerSuspend Function

```
BOOL WINAPI HttpServerSuspend(
    HSERVER hServer
);
```

Suspend the server and reject new client connections.

Parameters

hServer

Handle to the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerSuspend** function instructs the server to suspend accepting new client connections. Any incoming client connections will be rejected with an error message indicating that the server is currently unavailable. To resume accepting client connections, call the **HttpServerResume** function. Suspending the server will have no effect on clients that have already established a connection with the server.

It is recommended that you only suspend a server if absolutely necessary, and only for brief periods of time. If you want to limit the number of active client connections or control the connection rate for clients, use the **HttpServerThrottle** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpServerRestart, HttpServerResume, HttpServerStart, HttpServerStop, HttpServerThrottle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerThrottle Function

```
BOOL WINAPI HttpServerThrottle(
  HSERVER hServer,
  UINT nMaxClients,
  UINT nMaxClientsPerAddress,
  DWORD dwConnectionRate
);
```

The **HttpServerThrottle** function limits the number of active client connections, connections per address and connection rate.

Parameters

hServer

Handle to the server.

nMaxClients

A value which specifies the maximum number of clients that may connect to the server. A value of zero specifies that there is no fixed limit to the number of client connections.

nMaxClientsPerAddress

A value which specifies the maximum number of clients that may connect to the server from the same IP address. A value of zero specifies that there is no fixed limit to the number of client connections per address. By default, there is a limit of four client connections per address.

dwConnectionRate

A value which specifies a restriction on the rate of client connections, limiting the number of connections that will be accepted within that period of time. A value of zero specifies that there is no restriction on the rate of client connections. The higher this value, the fewer the number of connections that will be accepted within a specific period of time. By default, there is no limit on the client connection rate.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpServerThrottle** function is used to limit the number of connections and the connection rate to minimize the potential impact of a large number of client connections over a short period of time. This can be used to protect the server from a client application that is malfunctioning or a deliberate denial-of-service attack in which the attacker attempts to flood the server with connection attempts.

If the maximum number of client connections or maximum number of connections per address is exceeded, the server will reject subsequent connection attempts until the number of active client sessions drops below the specified threshold. Note that adjusting these values lower than the current connection limits will not affect clients that have already connected to the server. For example, if the **HttpServerStart** function is called with the maximum number of clients set to 100, and then **HttpServerThrottle** is called lowering that value to 75, no existing client connections will be affected by the change. However, the server will not accept any new connections until the number of active clients drops below 75.

Increasing the connection rate value will force the server to slow down the rate at which it will accept incoming client connection requests. For example, setting this parameter to a value of 1000 would

limit the server to accepting one client connection every second, while a value of 250 would allow the server to accept four client connections per second. Note that significantly increasing the amount of time the server must wait to accept client connections can exceed the connection backlog queue, resulting in client connections being rejected.

It is recommended that you always specify conservative connection limits for your server application based on expected usage. Allowing an unlimited number of client connections can potentially expose the system to denial-of-service attacks and should never be done for servers that are accessible over the Internet.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpServerRestart, HttpServerResume, HttpServerStart, HttpServerSuspend

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpServerUninitialize Function

```
VOID WINAPI HttpServerUninitialize();
```

The **HttpServerUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **HttpServerInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **HttpServerUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **HttpServerUninitialize** for every successful call to **HttpServerInitialize** made by a process. Operations for all threads in the server are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpServerInitialize, HttpServerStart, HttpServerStop

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpSetClientAccess Function

```
BOOL WINAPI HttpSetClientAccess(
    HSERVER hServer,
    UINT nClientId,
    DWORD dwUserAccess
);
```

Change the access rights associated with the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see User and File Access Constants.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. This function can only be used with authenticated clients. If the client session has not been authenticated, the return value will be zero.

Remarks

The **HttpSetClientAccess** function can change the multiple access rights for a client session. The **HttpEnableClientAccess** function can be used to grant or revoke a specific permission for the client session.

If the *dwUserAccess* parameter has a value of HTTP_ACCESS_DEFAULT, then default permissions will be granted to the client session based on the configuration of the server. This is the recommended value for most clients. It is important to consider the implications of changing the access permissions granted to a client session. For example, if you do not grant clients HTTP_ACCESS_READ permission, it can effectively disable the site because the server will return 403 Forbidden errors for all GET and HEAD requests.

This function should typically be called in the HTTP_CLIENT_CONNECT event handler to assign general permissions to the client, or in the HTTP_CLIENT_COMMAND event handler after the client has issued a request and provided any authentication credentials that are required.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpAuthenticateClient, HttpEnableClientAccess, HttpGetClientAccess

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HttpSetClientHeader Function

```
BOOL WINAPI HttpSetClientHeader(
   HSERVER hServer,
   UINT nClientId,
   UINT nHeaderType,
   LPCTSTR lpszHeaderName,
   LPCTSTR lpszHeaderValue
);
```

Create or change the value of a request or response header for the client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nHeaderType

Specifies the type of header to create or modify. It may be one of the following values:

Value	Description
HTTP_HEADERS_REQUEST	Change a request header that was provided by the client. Request header values provide additional information to the server about the type of request being made.
HTTP_HEADERS_RESPONSE	Change a response header that was created by the server. Response header values provide additional information to the client about the type of information that is being returned by the server.

lpszHeaderName

A null-terminated string that specifies the name of the header that should be created or modified. Header names are not case-sensitive and should not include the colon which acts as a delimiter that separates the header name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszHeaderValue

A null-terminated string that specifies the new value of the header. If this parameter is a NULL pointer or an empty string, it has the same effect as deleting the header value from the list of request or response headers.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpSetClientHeader** function will change the value of a request or response header for the specified client session. If the ***lpszHeaderName*** value matches an existing header field, its value will be replaced. If the header name is not defined, then a new header will be created with the given value.

You should not change the value of most standard response header values unless you are certain of the impact that it would have on the normal operation of the client.

If you wish to define a custom header value that would be included in the response to a client request, you should prefix the header name with "X-" to avoid potential conflicts with the standard response headers. For example, if you wanted to identify a customer, you could create a header field with the name "X-Customer-ID" and set the value to the customer ID number. The client application would receive this custom header value as part of the response to its request for a document.

Refer to Hypertext Transfer Protocol Headers for a list of common request and response headers that are used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpSetClientIdleTime Function

```
UINT WINAPI HttpSetClientIdleTime(
    HSERVER hServer,
    UINT nClientId,
    UINT nTimeout
);
```

Change the idle timeout period for the specified client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

nTimeout

An unsigned integer value that specifies the number of seconds that the client may remain idle. If this value is zero, the default idle timeout period for the server will be used.

Return Value

If the function succeeds, the return value is the previous client idle timeout period in seconds. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpSetClientIdleTime** function is will change the number of seconds that the client may remain idle before being automatically disconnected by the server. The minimum timeout period for a client is 10 seconds, the maximum is 300 seconds (5 minutes). The idle time of a client session is based on the last time a command was issued to the server or when a data transfer completed.

If the value INFINITE is specified as the timeout period, the client activity timer will be refreshed, extending the idle timeout period for the session. This is typically done inside an event handler to prevent the client from being disconnected due to inactivity.

To obtain the current idle timeout period for a client, along with the amount of time the client has been idle, use the **HttpGetClientIdleTime** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpSetClientVariable Function

```
BOOL WINAPI HttpSetClientVariable(
    HSERVER hServer,
    UINT nClientId,
    LPCTSTR lpszName,
    LPCTSTR lpszValue
);
```

Create or change the value of a CGI environment variable for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszName

A null-terminated string that specifies the name of the environment variable that should be created or modified. Environment variables are not case-sensitive and should not include the equal sign which acts as a delimiter that separates the variable name from its value. This parameter cannot be a NULL pointer or an empty string.

lpszValue

A null-terminated string that specifies the new value of the environment variable. If this parameter is a NULL pointer or an empty string, it has the same effect as deleting the variable from the environment block for the client session.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero. If the function fails, the **HttpGetServerError** function will return more information about the last error that has occurred.

Remarks

The **HttpSetClientVariable** function will change the value of a environment variable for the specified client session. If the ***lpszName*** value matches an existing variable, its value will be replaced. If the variable is not defined, then a new variable will be created with the given value. The value of an environment variable can be obtained using the **HttpGetClientVariable** function.

The server will automatically create a number of different environment variables that will be passed to a program or script executed by the server. These variables are defined in RFC 3875 as part of the Common Gateway Interface (CGI) 1.1 specification. The following variables are defined by the server and should not be modified directly by the application:

Variable Name	Description
AUTH_TYPE	The authorization scheme used by the server to authenticate the client session
CONTENT_LENGTH	The length of the request data provided by the client
CONTENT_TYPE	The MIME type that identifies the type of content provided by the client
DOCUMENT_ROOT	The full path to the local document root directory on the server

GATEWAY_INTERFACE	The version of the Common Gateway Interface that is being used by the server
PATH_INFO	The resource or sub-resource that is to be returned by the program or script
PATH_TRANSLATED	The path information mapped to the server root document directory structure
QUERY_STRING	The URL encoded query parameters passed to the program or script
REMOTE_ADDR	The network address of the client sending the request to the server
REMOTE_HOST	The same value as the REMOTE_ADDR variable
REMOTE_USER	The username specified as part of the authentication credentials provided by the client
REQUEST_METHOD	The method used by the client to request the resource
REQUEST_URI	The URI for the script provided by the client
SCRIPT_FILENAME	The full path to the program or script on the server
SCRIPT_NAME	The path to the program or script specified by the client
SERVER_NAME	The hostname or IP address of the server that the client connected to
SERVER_PORT	The port number that the client used to connect to the server
SERVER_PORT_SECURE	This variable has a value of "1" if the client connection to the server is secure
SERVER_PROTOCOL	The version of the server protocol used
SERVER_SOFTWARE	The server identity string which specifies the application name and version

In addition to the environment variables listed, the server will also create variables that are prefixed with "HTTP_" that are set to the value of request headers that are not otherwise defined. For example, the HTTP_USER_AGENT variable will be set to the value of the User-Agent header provided by the client as part of the request.

Calling the **HttpSetClientVariable** function in response to an HTTP_CLIENT_EXECUTE event notification will have no effect because it occurs after the CGI program or script has completed execution. To create or modify environment variables for the client session, it should be done in response to the HTTP_CLIENT_COMMAND event notification.

This function will not change the environment block for the server process. Each client session is allocated its own private environment block which is inherited by the CGI program. When the client session terminates, the memory allocated for its environment is released.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpSetCommandFile Function

```
BOOL WINAPI HttpSetCommandFile(
   HSERVER hServer,
   UINT nClientId,
   LPCTSTR lpszFileName
);
```

Change the name of the local file or directory that is the target of the current command.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszFileName

A null-terminated string that specifies the new file name. This parameter may be NULL to specify that the original file or directory name should be used.

Return Value

If the function succeeds, the return value is non-zero. If the server handle and client ID do not specify a valid client session, the function will return zero.

Remarks

The **HttpSetCommandFile** function is used by the application to change the target file or directory name for the current command from within an HTTP_EVENT_COMMAND event handler. This can be used to effectively redirect the client to use a different file than the one that was actually requested. For example, if the client issues the GET command to download a file from the server, this function can be used to redirect the command to use a different file name. To obtain the full path to the file or directory that is the target of the current command, use the **HttpGetCommandFile** function.

The *lpszFileName* parameter specifies the path to the new file or directory name. If the path is absolute, then it will be used as-is. If the path is relative, it will be relative to the root directory for the client session. Because the root document directory for the client can depend on the hostname that the client used when connecting to the server, it is recommended that you always use an absolute path. The full path to this file is not limited to the server root directory or its subdirectory, it can specify a file anywhere on the local system. If this parameter is a NULL pointer, or points to an empty string, then the server will revert to using the actual file or directory name specified by the command. This enables the application to effectively undo a previous call to this function to change the target file name.

Typically this function would be used to redirect a client to a file or directory that it may not normally have access to. Exercise caution when using this function to provide access to data that is stored outside of the server root directory. Incorrect use of this function could expose the server to security risks or cause unpredictable behavior by client applications. In most cases it is preferable to use the **HttpAddVirtualPath** function to create a virtual path or file name on the server, or the **HttpRedirectRequest** function to request the client use a different URL to access the resource.

This function should only be called within the context of the HTTP_EVENT_COMMAND event, and only for those commands that perform an action on a file or directory. If the current command does not target a file or directory, this function will return zero and the last error code will be set to

ST_ERROR_INVALID_COMMAND.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

HttpSetServerError Function

```
VOID WINAPI HttpSetServerError(
    HSERVER hServer,
    DWORD dwError
);
```

Set the last error code for the specified server session.

Parameters

hServer

The server handle.

dwError

An unsigned integer that specifies an error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each server session. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SERVER or HTTP_ERROR.

If the ***hServer*** parameter is specified as INVALID_SERVER, this function will set the last error code for the current thread, but will not change the error code associated with any server session. This should only be done if the application does not have access to a valid server handle.

If the ***dwError*** parameter is specified with a value of zero, this effectively clears the error code for the last function that failed. Those functions which clear the last error code when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **HttpGetServerError** function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

HttpSetServerIdentity Function

```
BOOL WINAPI HttpSetServerIdentity(
    HSERVER hServer,
    LPCTSTR lpszIdentity
);
```

Change the identity of the specified server.

Parameters

hServer

The server handle.

lpszIdentity

A null-terminated string that identifies the server. If this parameter is NULL or specifies an empty string, the current identity for the server is reset to a default value. The maximum length of the identity string is 64 characters, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid, the function will return a value of zero.

Remarks

The **HttpSetClientIdentity** function changes a string value used by the server to identify itself to clients. The identity string does not have any standard format and is used for informational purposes only. Typically it consists of the application name and a version number. Changing the server identity has no effect on the operation of the server. To obtain the identity string currently associated with the server, use the **HttpGetServerIdentity** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetServerIdentity

HttpSetServerLogFile Function

```
BOOL WINAPI HttpSetServerLogFile(
   HSERVER hServer,
   UINT nLogFormat,
   UINT nLogLevel,
   LPCTSTR lpszFileName
);
```

Change the current log format, level of detail and file name.

Parameters

hServer

The server handle.

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Value	Description
HTTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about GET, PUT and POST requests.
HTTP_LOGFILE_COMBINED	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session. This format typically generates the largest logfiles.

nLogLevel

An integer value that specifies the level of detail that should generated in the log file. The minimum value is 1 and the maximum value is 10. If this parameter is zero, it is the same as specifying a log file format of HTTP_LOGFILE_NONE and will disable logging by the server.

lpszFileName

A null-terminated string that specifies the name of the log file that should be created or appended to. If the server was configured with logging enabled and this parameter is NULL or an empty string, the current log file name will not be changed. If the log file does not exist, it will be created. If it does exist, the contents of the log file will be appended to.

Return Value

If the function succeeds, the return value is non-zero. If the server handle does not specify a valid server, the function will return zero.

Remarks

The **HttpSetServerLogFile** function can be used to change the current log file name, the format of the log file or the level of detail recorded in the log file. In some situations it may be desirable to delete the current log file contents when changing the format or ensure that a new log file is created. To do this, combine the ***nLogFormat*** parameter with the constant HTTP_LOGFILE_DELETE.

The higher the value of the ***nLogLevel*** parameter, the greater the level of detail that is recorded by the server. A log level of 1 instructs the server to only record GET, POST and PUT requests, while a level of 10 instructs the server to record all commands processed by the server. Because a higher level of logging detail can negatively impact the performance of the server, it is recommended that you do not exceed a level of 5 for most applications. A log level of 10 should only be used for debugging purposes.

Example

```
UINT nLogFormat = HTTP_LOGFILE_NONE;
UINT nLogLevel = 0;
UINT nNewLevel = 5;
BOOL bChanged = FALSE;

// Change the level of detail for the current log file if logging
// has been enabled and the current level is a lower value

if (HttpGetServerLogFile(hServer, &nLogFormat, &nLogLevel, NULL, 0))
{
    if (nLogFormat != HTTP_LOGFILE_NONE && nLogLevel < nNewLevel)
        bChanged = HttpSetServerLogFile(hServer, nLogFormat, nNewLevel, NULL);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpGetServerLogFile, HttpRenameServerLogFile

HttpSetServerName Function

```
BOOL WINAPI HttpSetServerName(
   HSERVER hServer,
   UINT nClientId,
   LPCTSTR lpszHostName
);
```

Change the host name assigned to the specified server or client session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session. This value may be zero.

lpszHostName

A null-terminated string that specifies the new host name assigned to the server or client session. If this value is NULL or points to an empty string, the current host name will be changed to use the default host name.

Return Value

If the function succeeds, the return value is non-zero. If either the server handle or the client ID is invalid, or the buffer is not large enough to store the complete hostname, the function will return a value of zero.

Remarks

This function will change the host name assigned to the specified client session. If the ***nClientId*** parameter has a value of zero, the function will change default host name that was assigned to the server as part of the server configuration. If the ***nClientId*** parameter specifies a valid client session and the ***lpszHostName*** parameter is NULL, the host name associated with the client session will be changed to the current host name assigned to the server.

When a client connects to the server, it can specify the host name that it used to establish the connection by sending the HOST command. This is typically used with virtual hosting, where one server may accept client connections for multiple domains. The **HttpGetServerName** function will return the host name specified by the client, and **HttpSetServerName** can be used by the application to either explicitly assign a different host name to the client session, or override the host name provided by the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

HttpSetServerPriority Function

```
INT WINAPI HttpSetServerPriority(
    HSERVER hServer,
    INT nPriority
);
```

Change the priority assigned to the specified server.

Parameters

hServer

The server handle.

nPriority

An integer value which specifies the new priority for the server. It may be one of the following values:

Value	Description
HTTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the server. It is typically used with lightweight services running in the background that are designed for few client connections. The server thread will be assigned a lower scheduling priority and will be frequently forced to yield execution to other threads.
HTTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the server and meters the processor utilization for the server thread. The server thread will be assigned a lower scheduling priority and will occasionally be forced to yield execution to other threads.
HTTP_PRIORITY_NORMAL	The default priority which balances resource and processor utilization. This is the priority that is initially assigned to the server when it is started, and it is recommended that most applications use this priority.
HTTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the server and the thread will be given higher scheduling priority. It is not recommended that this priority be used on a system with a single processor.
HTTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization. The server thread will be given higher scheduling priority and will be more responsive to client connection requests. It is not recommended that this priority be used on a system with a single processor.

Return Value

If the function succeeds, the return value is the previous priority assigned to the server. If the function fails, the return value is HTTP_PRIORITY_INVALID. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSetServerPriority** function can be used to change the current priority assigned to the specified server. Client connections that are accepted after this function is called will inherit the new priority as their default priority. Previously existing client connections will not be affected by this function.

Higher priority values increase the thread priority and processor utilization for each client session. You should only change the server priority if you understand the impact it will have on the system and have thoroughly tested your application. Configuring the server to run with a higher priority can have a negative effect on the performance of other programs running on the system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

See Also

HttpGetServerPriority, HttpServerStart

HttpSetServerStackSize Function

```
BOOL WINAPI HttpSetServerStackSize(
    SOCKET hServer,
    DWORD dwStackSize
);
```

Change the initial size of the stack allocated for threads created by the server.

Parameters

hServer

Handle to the server socket.

dwStackSize

The amount of memory that will be committed to the stack for each thread created by the server. If this value is zero, a default stack size will be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **HttpGetServerError**.

Remarks

The **HttpSetServerStackSize** function changes the initial amount of memory that is committed to the stack for each thread created by the server. By default, the stack size for each thread is set to 256K for 32-bit processes and 512K for 64-bit processes. Increasing or decreasing the stack size will only affect new threads that are created by the server, it will not affect those threads that have already been created to manage active client sessions. It is recommended that most applications use the default stack size.

You should not change the stack size unless you understand the impact that it will have on your system and have thoroughly tested your application. Increasing the initial commit size of the stack will remove pages from the total system commit limit, and every page of memory that is reserved for stack cannot be used for any other purpose.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtsv12.lib

Hypertext Transfer Protocol Server Data Structures

- HTTPCLIENTCREDENTIALS
- HTTPREQUEST
- HTTPRESPONSE
- HTTPSERVERCONFIG
- HTTPSERVERTRANSFER
- SECURITYCREDENTIALS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HTTPCLIENTCREDENTIALS

The **HTTPCLIENTCREDENTIALS** structure defines the credentials used to authenticate a specific user.

```
typedef struct _HTTPCLIENTCREDENTIALS
{
    DWORD dwSize;
    DWORD dwFlags;
    UINT  nAuthType;
    UINT  nHostPort;
    TCHAR szHostName[HTTP_MAXHOSTNAME];
    TCHAR szUserName[HTTP_MAXUSERNAME];
    TCHAR szPassword[HTTP_MAXPASSWORD];
} HTTPCLIENTCREDENTIALS, *LPHTTPCLIENTCREDENTIALS;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value is reserved for future use. This value will always be zero.

nAuthType

An unsigned integer value that identifies the authentication method.

nHostPort

The server port number.

szHostName

A null-terminated string that specifies the server host name.

szUserName

A null-terminated string that specifies the user name.

szPassword

A null-terminated string that specifies the user password.

Remarks

When an instance of this structure is passed to the **HttpGetClientCredentials** function, this member must be initialized to the size of the structure and all other members must be initialized with a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

HttpGetClientCredentials

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HTTPREQUEST

The **HTTPREQUEST** structure provides information about the request made by the client.

```
typedef struct _HTTPREQUEST
{
    DWORD  dwSize;
    DWORD  dwFlags;
    DWORD  dwVersion;
    DWORD  dwAccess;
    DWORD  dwLength;
    DWORD  dwReserved;
    UINT   nHostId;
    UINT   nHostPort;
    LPCSTR lpszCommand;
    LPCSTR lpszHostName;
    LPCSTR lpszUserName;
    LPCSTR lpszPassword;
    LPCSTR lpszResource;
    LPCSTR lpszParameters;
    LPCSTR lpszDirectory;
    LPCSTR lpszPathInfo;
    LPCSTR lpszProgram;
    LPCSTR lpszScriptFile;
    LPCSTR lpszLocalFile;
    LPCSTR lpszMediaType;
} HTTPREQUEST, *LPHTTPREQUEST;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value that provides additional information about the request. It may be one or more of the following values:

Value	Description
HTTP_REQUEST_FLAG_PROTECTED	The resource that the client has requested is protected. The client should only be permitted to access the resource if the client session has been authenticated.
HTTP_REQUEST_FLAG_PROGRAM	The resource that the client has requested is a CGI program or an executable script. The output from the program or script should be returned to the client in the response. If this flag is specified, the ***lpszProgram*** member of the structure specifies the name of the program that should be executed.
HTTP_REQUEST_FLAG_SCRIPT	The resource that the client has requested is an executable script. This flag is set when the request URL is mapped to a registered script handler. The ***lpszProgram*** member specifies the name of the program that is responsible for executing the script, and the ***lpszScriptFile*** parameter specifies the full

	path to the script itself.

dwVersion

An unsigned integer value that specifies the protocol version used. It may be one of the following values:

Value	Description
HTTP_VERSION_09	The client issued a GET command without specifying a protocol version.
HTTP_VERISON_10	The client issued a command that specified version 1.0 of the protocol.
HTTP_VERSION_11	The client issued a command that specified version 1.1 of the protocol.

dwAccess

An unsigned integer value that specifies the access permissions that were assigned to the resource. For a list of file access permissions, see User and File Access Constants.

dwLength

An unsigned integer value that will specify the number of bytes of request data provided by the client. If the client did not submit any data with the request, this member will have a value of zero.

dwReserved

An unsigned integer value that is reserved for future use.

nHostId

An integer value that identifies the virtual host that was specified by the client. This is based on the value of the Host request header included in the request. This value will be zero if a host name is not specified by the client, or does not match one of the virtual hosts that have been created.

nHostPort

An integer value that specifies the port number that the client used to establish the connection. This will be the same port number that was used when starting the server.

lpszCommand

A null-terminated string that specifies the command that was issued by the client. The command will always be in upper case. Refer to Hypertext Transfer Protocol Commands for a list of standard commands.

lpszHostName

A null-terminated string that identifies the hostname or IP address that the client used to establish the connection. This will typically correspond to the hostname assigned to the server, or to one of the virtual hosts that have been created.

lpszUserName

A null-terminated string that specifies the username provided with the request. This member is only set if the client has included authentication credentials as part of the request. If the client has not provided any credentials, this member will be NULL.

lpszPassword

A null-terminated string that specifies the password provided with the request. This member is only set if the client has included authentication credentials as part of the request. If the client has not provided any credentials, this member will be NULL.

lpszResource

A null-terminated string that specifies the URL path provided by the client.

lpszParameters

A null-terminated string that specifies any query parameters that were included in the request made by the client. If the URL did not include any query parameters, this member will be NULL.

lpszDirectory

A null-terminated string the specifies the full path to the root directory for the virtual host.

lpszPathInfo

A null-terminated string that specifies additional path information provided by the client when referencing an executable CGI program or script in the URL. For example, if a program is mapped to the virtual path "/orders/invoice" and the client requests "/orders/invoice/pdf/10001" this member will be the string "/pdf/10001". If there is no path information associated with the request, this member will be NULL.

lpszProgram

A null-terminated string that specifies the local path to the CGI program that should be executed to process the request made by the client. If this member is NULL, it indicates that the client has provided a URL that maps to a local file or directory.

lpszScriptFile

A null-terminated string that specifies the local path to the script file that will be executed by the handler. If this member is NULL, it indicates that the request URL was not mapped to registered script handler.

lpszLocalFile

A null-terminated string that specifies the local path to the directory or file name referenced by the URL. If the ***lpszPathInfo*** member is not NULL, then this member will point to a local file name based the path information appended to the root directory for the virtual host.

lpszMediaType

A null-terminated string that identifies the request data using the standard Internet media types defined in RFC 2046. It is used to designate the format for various types of content and has two parts, a primary and secondary media type separated by a forward slash. Common examples are "text/plain", "text/html" and "application/octet-stream". If the client did not submit any data with the request, this member will be NULL.

Remarks

This structure is used with the **HttpReceiveRequest** function and all members should be initialized to a value of zero, except for the ***dwSize*** member which should be initialized to size of the structure. Failure to properly initialize the structure will cause the function call to fail.

The value of the ***lpszLocalFile*** member depends on whether the client has requested a static document, or if the URL is mapped to a registered program or script handler. If the request is for a static document, then the ***dwFlags*** member will not have the HTTP_REQUEST_FLAG_PROGRAM bit flag set and the ***lpszLocalFile*** member will be the full path to the document. If the URL is mapped to a registered program or script, then the ***lpszLocalFile*** member will be the full path to the server root directory, If the request URL included additional path information, that will be appended to the root directory.

The value of the ***lpszScriptFile*** member is only defined if the ***dwFlags*** member has the HTTP_REQUEST_FLAG_SCRIPT bit flag set. This indicates that the request URL references a file that is an executable script with a handler that was registered using the **HttpRegisterHandler** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

HttpReceiveRequest, HttpSendResponse, HTTPRESPONSE

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HTTPRESPONSE

The **HTTPRESPONSE** structure provides additional information about the response to the client.

```
typedef struct _HTTPRESPONSE
{
    DWORD   dwSize;
    DWORD   dwFlags;
    DWORD   dwVersion;
    DWORD   dwReserved;
    UINT    nExpires;
    UINT    nResultCode;
    LPCTSTR lpszReason;
    LPCTSTR lpszMediaType;
} HTTPRESPONSE, *LPHTTPRESPONSE;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwFlags

An unsigned integer value that specifies one or more response flags. This member is reserved for future use and should always have a value of zero.

dwVersion

An unsigned integer value that specifies the protocol version used. It may be one of the following values:

Value	Description
HTTP_VERSION_DEFAULT	The server should respond to the client using the same version specified in the request.
HTTP_VERISON_10	The server should respond to the client using version 1.0 of the protocol.
HTTP_VERSION_11	The server should respond to the client using version 1.1 of the protocol.

dwReserved

An unsigned integer value that is reserved for future use.

nExpires

An integer value that specifies the number of seconds until the client should consider any cached response data to be stale. If this value is zero, the default cache expiration time for the server will be used. The default cache expiration time is 7200 seconds (2 hours). The value of this structure member is ignored if the HTTP_RESPONSE_NOCACHE option is specified when the response is sent to the client.

nResultCode

An integer value that specifies the result code that should be sent in response to the client request. The result code is a three-digit number that indicates success or failure. For more information, refer to the **HttpGetCommandResult** function.

lpszReason

A string that that describes the result code sent to the client. The description should be brief and

should not contain any formatting characters or HTML markup. This parameter may be NULL, in which case a default description of the result code will be used.

lpszMediaType

A string that specifies the Internet media type for the data that is being sent to the client as defined in RFC 2046. The format for the content type string consists of two parts, a primary and secondary media type separated by a forward slash. Common examples are "text/plain", "text/html" and "application/octet-stream". If this member is NULL, the library will attempt to automatically determine the appropriate media type.

Remarks

This structure is used with the **HttpSendResponse** function and the *dwSize* member must be initialized to size of the structure. Failure to properly initialize the structure will cause the function call to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

HTTPSERVERCONFIG

The **HTTPSERVERCONFIG** structure provides the configuration information used to create an instance of an HTTP server.

```
typedef struct _HTTPSERVERCONFIG
{
    DWORD   dwSize;
    UINT    nMaxClients;
    UINT    nMaxClientsPerAddress;
    UINT    nMaxRequests;
    UINT    nMaxPostSize;
    UINT    nLogFormat;
    UINT    nLogLevel;
    UINT    nCacheTime;
    UINT    nIdleTime;
    UINT    nExecTime;
    LPCTSTR lpszIdentity;
    LPCTSTR lpszHostUuid;
    LPCTSTR lpszHostName;
    LPCTSTR lpszRootPath;
    LPCTSTR lpszTempPath;
    LPCTSTR lpszLogFile;
} HTTPSERVERCONFIG, *LPHTTPSERVERCONFIG;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

nMaxClients

An integer value that specifies the maximum number of active client connections that will be accepted by the server. If the maximum number of clients is reached, any further connections are rejected by the server until one or more clients close their connection to the server or are disconnected. A value of zero specifies the default configuration value of 100 connections should be used.

nMaxClientsPerAddress

An integer value that specifies the maximum number of active client connections per IP address that will be accepted by the server. If the maximum number of clients from the same IP address is reached, any further connections are rejected until one of the clients closes its connection to the server. A value of zero specifies the default configuration value of 8 connections per address should be used.

nMaxRequests

An integer value that specifies the maximum number of a requests a client may make per connection. When a client reaches the maximum number of requests, the server will close the connection and the client must establish a new connection to send another request. If this member has a value of zero, the server will allow 5 requests per connection. The minimum value is 1 and the maximum is 100.

nMaxPostSize

An integer value that specifies the maximum size of the request data that may be submitted by a client with a POST command. If the amount of request data submitted to the server exceeds this limit, the server will return a 413 error to the client and the connection will be closed. If this member

has a value of zero, the server will permit the client to submit up to 4 MB (4,194,304 bytes) of data. The minimum value is 100 KB (102,400 bytes) and the maximum value is 100 MB (104,857,600 bytes).

nLogFormat

An integer value that specifies the format used when creating or updating the server log file. The following formats are supported:

Value	Description
HTTP_LOGFILE_NONE	This value specifies that the server should not create or update a log file.
HTTP_LOGFILE_COMMON	This value specifies that the log file should use the common log format that records a subset of information in a fixed format. This log format usually only provides information about file transfers.
HTTP_LOGFILE_COMBINED	This value specifies that the server should use the combined log file format. This format is similar to the common format, however it includes the client referrer and user agent. This is the format that most Apache web servers use by default.
HTTP_LOGFILE_EXTENDED	This value specifies that the log file should use the standard W3C extended log file format. This is an extensible format that can provide additional information about the client session.

nLogLevel

An integer value that specifies the level of detail that should generated in the log file. The minimum value is 1 and the maximum value is 10. If the ***nLogFormat*** member specifies a valid log file format and this value is zero, a default level of detail will be selected based on the format. The common log file format generally contains less information by default, only logging the data transfers between the client and server. The W3C extended log file format defaults to a higher level of detail that includes additional information about the client session. The higher the level of detail, the larger the log file will be.

nCacheTime

An integer value that specifies the amount of time that the client should store a document in its cache before requesting it from the server again. A value of zero specifies that the default value of 7200 seconds (2 hours) should be used.

nIdleTime

An integer value that specifies the maximum number of seconds that a client session may be idle before the server closes the control connection to the client. A value of zero specifies the default value of 60 seconds. If the value is non-zero, the minimum value is 10 seconds and the maximum value is 300 seconds (5 minutes). This value is used to initialize the default idle timeout period for each client session. The server determines if a client is idle based on the time the last command was issued and whether or not a file transfer is in progress.

nExecTime

An unsigned integer value that specifies the maximum number of seconds that an external CGI program is permitted to run on the server. Programs are registered using the **HttpRegisterProgram** function, and are executed when the client sends a request for a resource that is associated with the program. If this value is zero, the default timeout period of 5 seconds will

be used. The minimum execution time is 1 second and the maximum time limit is 30 seconds.

lpszIdentity

A null-terminated string that identifies the server. It is used for informational purposes only and has no effect on the operation of the server. If this member is not initialized to a value, then a default identity will be used. The server identity is provided when a client establishes the initial connection and when the client sends the STAT or CSID commands. If this member is defined, it is recommended that you only use printable ASCII characters.

lpszHostUuid

A null-terminated string that specifies a Universally Unique Identifier (UUID) that is used to uniquely identify the server. This value can be used when storing information about the server, and should be generated using a utility such as **uuidgen** which is included with Visual Studio. This structure member may be initialized to an empty string, in which case a temporary UUID will be randomly generated.

lpszHostName

A null-terminated string that specifies the fully-qualified host name for the server. If this structure member is initialized with an empty string, the local host name assigned to the Windows system will be used. This value does not need to correspond to the actual host name associated with the server's IP address. This value is used for informational purposes only and has no effect on the operation of the server.

lpszRootPath

A null-terminated string that specifies the path to the root directory for the server. If this structure member is initialized with an empty string, the current working directory for the process will be used as the root directory. It is recommended that you provide a full path to an existing directory and do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszTempPath

A null-terminated string that specifies the path to the temporary directory for the server. If this structure member is initialized with an empty string, the current temporary directory for the process will be used. The temporary directory cannot be the same as the root directory, and it is strongly recommended that you do not specify the root of a local or network drive. If the path does not exist at the time the server is started, it will be automatically created.

lpszLogFile

A null-terminated string that specifies the name of the server log file to create, if a logging format has been specified. If logging is enabled and this member is an empty string, then a default log file name will be created. If the file name does not include a path, then the file is created in the server log directory. If the file name includes a path, the log file will be created using that specific name. If the server is in multi-user mode, then the default location for log files will be the Logs subdirectory in the server root directory. If the server is not in multi-user mode, the default location for log files will be the temporary directory for the current process.

Remarks

When an instance of this structure is passed to the **HttpServerStart** function, the *dwSize* member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the configuration is invalid.

The *nMaxClients* member limits the total number of client connections and the *nMaxClientsPerAddress* member limits the number of simultaneous connections can originate from the same address. If either client limit is exceeded, the server will automatically close the connection.

For more control over how the server accepts client connections, use the **HttpServerThrottle** function. It is not recommended that you set the maximum clients per address below a value of 4. Lower values can negatively impact the performance of some clients, particularly web browsers.

The ***nMaxPostSize*** member limits the amount of data that a client can submit to the server using a POST command. The default limit is 4 MB which should be sufficient for most applications. One situation where you may need to increase this value is if you expect the client to upload large files using the POST command. Increasing this limit will potentially increase the amount of virtual memory that the server will allocate. Note that this value does not limit amount of data that can be uploaded using the PUT command.

When specifying the root directory for the server configuration, it is important to consider that a client's default access to files on the system will be limited to these directories and any subdirectories. If a root directory is not specified, then one will be created using the current working directory for the process. The root directory path may include environment variables surrounded by % symbols and these will be expanded.

For servers that are publicly accessible, or where you want files to be a accessible across multiple server sessions, you should always populate the ***szHostUuid*** member with a valid UUID string, and the ***lpszRootPath*** member should specify an absolute path to an existing directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

HTTPSERVERTRANSFER

The **HTTPSERVERTRANSFER** structure provides information about the last file transfer performed by a client.

```
typedef struct _HTTPSERVERTRANSFER
{
    DWORD          dwSize;
    DWORD          dwReserved;
    DWORD          dwFileAccess;
    DWORD          dwTimeElapsed;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szFileName[MAX_PATH];
} HTTPSERVERTRANSFER, *LPHTTPSERVERTRANSFER;
```

Members

dwSize

An unsigned integer value that specifies the size of the structure.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

dwFileAccess

An unsigned integer value that specifies the how the local file was accessed. It can be one of the following values:

Value	Description
HTTP_FILE_READ	The file was opened for reading. This mode indicates that the client issued the GET command to download the contents of a file from the server to the client system. The ***szFileName*** member specifies the name of the local file on the server that was downloaded by the client.
HTTP_FILE_WRITE	The file was opened for writing. This mode indicates that the client issued the PUT command to upload the contents of a file from the client system to server. The ***szFileName*** member specifies the name of the local file on the server that was created by the client. If a file already existed with the name name, it was replaced.

dwTimeElapsed

The amount of time that it took for the file transfer to complete in milliseconds. This value is limited to the resolution of the system timer, which is typically in the range of 10 to 16 milliseconds. This value may be zero if the transfer occurred over a local network or on the same host using a loopback address.

uiBytesCopied

A 64-bit integer value that specifies the total number of bytes copied during the file transfer. This value is represented by a ULARGE_INTEGER union which provides support for those programming languages that do not have intrinsic support for 64-bit integers. For more information, refer to the Windows SDK documentation. The application should not make the assumption that this is the actual size of the file.

szFileName

A null-terminated string value that will contain the full path to the local file that was transferred. The ***dwFileAccess*** member determines whether the file name represents a file that was downloaded by

the client, or uploaded from the client and stored on the server.

Remarks

When an instance of this structure is passed to the **HttpGetServerTransferInfo** function, the *dwSize* member must be initialized to the size of the structure, otherwise the function will fail with an error indicating that the parameter is invalid. All other members should be initialized to a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify the security protocol and server certificate when accepting a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Internet Control Message Protocol Library

Determine if a remote host is reachable and how packets of data are routed to that system.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSICMV12.DLL
Version	12.0.3024.1286
LibID	66D5E749-831F-40CF-9B36-77A849C6C0E5
Import Library	CSICMV12.LIB
Dependencies	None
Standards	RFC 792

Overview

The Internet Control Message Protocol (ICMP) is commonly used to determine if a remote host is reachable and how packets of data are routed to that system. Users are most familiar with this protocol as it is implemented in the ping and traceroute command line utilities. The ping command is used to check if a system is reachable and the amount of time that it takes for a packet of data to make a round trip from the local system, to the remote host and then back again. The traceroute command is used to trace the route that a packet of data takes from the local system to the remote host, and can be used to identify potential problems with overall throughput and latency. The library can be used to build in this type of functionality in your own applications, giving you the ability to send and receive ICMP echo datagrams in order to perform your own analysis.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports

native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Internet Control Message Protocol Functions

Function	Description
IcmpCancel	Cancel the current blocking operation
IcmpCloseHandle	Close the current client session
IcmpCreateHandle	Create a new handle for the current client session
IcmpDisableEvents	Disable asynchronous event notification
IcmpDisableTrace	Disable logging of network-level calls to the trace log
IcmpEcho	Send one or more echo datagrams to the specified host
IcmpEnableEvents	Enable asynchronous event notification
IcmpEnableTrace	Enable logging of network function calls to a file
IcmpEventProc	Callback function that processes events generated by the client
IcmpFormatAddress	Convert a numeric IP address to a string
IcmpFreezeEvents	Suspend or resume event handling by the calling process
IcmpGetErrorString	Return a description for the specified error code
IcmpGetHostAddress	Return the current host IP address
IcmpGetHostName	Return the current host name
IcmpGetLastError	Return the last error code
IcmpGetPacketSize	Return the ICMP datagram packet size
IcmpGetRecvCount	Return the number of packets received
IcmpGetSendCount	Return the number of packets sent
IcmpGetSequenceId	Return the current sequence identifier
IcmpGetTimeout	Return the number of milliseconds until an operation times out
IcmpGetTimeToLive	Return the current time-to-live for the ICMP datagram
IcmpGetTripTime	Return the current trip time statistics
IcmpInitialize	Initialize the library and validates the specified license key at runtime
IcmpIsBlocking	Determine if the client is blocked, waiting for information
IcmpRecvEcho	Read an ICMP datagram returned by the remote host
IcmpRegisterEvent	Register an event callback function
IcmpReset	Reset the current client state
IcmpResolveAddress	Resolve an IP address into a fully qualified host name
IcmpSendEcho	Send an ICMP datagram to the specified host
IcmpSetHostAddress	Set the IP address of the host to receive the next datagram
IcmpSetHostName	Set the name of the host to receive the next datagram

IcmpSetLastError	Set the last error code
IcmpSetPacketSize	Set the ICMP datagram packet size
IcmpSetSequenceId	Set the sequence identifier for the next datagram
IcmpSetTimeout	Set the number of milliseconds until an operation times out
IcmpSetTimeToLive	Set the time-to-live for the next datagram
IcmpTraceRoute	Trace the route from the local system to a remote host
IcmpUninitialize	Terminate use of the library by the application

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IcmpCancel Function

```
INT WINAPI IcmpCancel(
   HCLIENT hClient
);
```

The **IcmpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

When the **IcmpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpCloseHandle Function

```
INT WINAPI IcmpCloseHandle(
   HCLIENT hClient
);
```

The **IcmpCloseHandle** function closes the socket and releases the memory allocated for the client session.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

IcmpCreateHandle Function

```
HCLIENT WINAPI IcmpCreateHandle(
    UINT nPacketSize,
    UINT nTimeToLive,
    DWORD dwTimeout,
    DWORD dwReserved,
    HWND hEventWnd,
    UINT uEventMsg
);
```

The **IcmpCreateHandle** function creates a client handle for sending and receiving ICMP echo datagrams. If an event notification window is specified, the client will be notified when a network event occurs.

Parameters

nPacketSize

An unsigned integer which specifies the default packet size used when generating ICMP echo datagrams. The minimum packet size is 32 bytes and the maximum size is 65,535 bytes.

nTimeToLive

An unsigned integer which specifies the default time-to-live for ICMP echo datagrams. This determines the maximum number of times that a packet will be routed from one system to another while en route to its destination. The minimum time-to-live value is 1, the maximum is 255. The recommend value for this parameter is 255, and typical applications should use a time-to-live value of at least 30.

dwTimeout

An unsigned integer which specifies the maximum number of milliseconds to wait before the current operation times out.

dwReserved

A reserved parameter. This value should always be zero.

hEventWnd

The handle to an asynchronous notification window. This window receives messages which notify the client when asynchronous network events occur. If asynchronous event notification is not required, this parameter may be NULL.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to the client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpCreateHandle** function creates a client handle that is used with subsequent calls to the library. This library uses a special type of socket called a raw socket, which is created to send and receive ICMP echo datagrams. Raw socket support is optional under the Windows Sockets specification, and may not be available if a non-standard networking libraries are used or may only be

available to privileged accounts.

If the ***hEventWnd*** parameter is not NULL, the client operates in asynchronous mode and messages will be posted to the notification window when a network event occurs. When a message is posted to the window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation.
ICMP_EVENT_CANCEL	The current operation has been canceled. TThe client application may attempt to retry the operation or close the handle.

To cancel asynchronous notification and return the client to a blocking mode, use the **IcmpDisableEvents** function.

The ability to create and send ICMP echo datagrams is limited to privileged users. Non-administrator users will receive an error if they attempt to create a client handle. On Windows NT it is possible to disable this security check by creating or modifying the system registry. Microsoft Knowledge Base article 195445 has additional information and instructions for making this change.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

IcmpDisableEvents Function

```
INT WINAPI IcmpDisableEvents(
    HCLIENT hClient
);
```

The **IcmpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

This function affects both event notification and event callbacks. Any outstanding events in the message queue should be ignored by the client application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpDisableTrace Function

```
BOOL WINAPI IcmpDisableTrace();
```

The **IcmpDisableTrace** function disables the logging of network function calls file.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

IcmpEcho Function

```
INT WINAPI IcmpEcho(
   LPCTSTR lpszHostName,
   UINT nIterations,
   UINT nPacketSize,
   DWORD dwTimeout,
   DWORD dwReserved,
   LPICMPTIME lpTime
);
```

The **IcmpEcho** function sends one or more ICMP echo datagrams, collecting information about the reliability and latency of a connection between the local and remote host.

Parameters

lpszHostName

A null-terminated string which specifies the fully qualified domain name of the remote host, or the IP address in dotted notation.

nIterations

An unsigned integer value which specifies the number of echo datagrams that will be sent to the remote host. The minimum value for this parameter is 1 and the maximum value is 512.

nPacketSize

An unsigned integer value which specifies the size of the echo datagram in bytes. The minimum size is 1 byte and the maximum size is 65,535 bytes. It is recommended that most applications use the minimum size of 32 bytes for this parameter.

dwTimeout

An unsigned integer which specifies the number of milliseconds the function will wait for a response to an echo datagram.

dwReserved

A reserved parameter. This value should always be zero.

lpTime

A pointer to an ICMPTIME structure which will contain the minimum, maximum and average round trip times for the echo datagrams sent and received.

Return Value

If the function succeeds, the return value is the number of replies received from the remote host. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpEcho** function sends a series of ICMP echo datagrams to the specified host, providing a simplified interface for pinging a remote system. If the function returns the same value as the number of iterations, then replies were received for all of the echo datagrams that were sent. This would typically indicate that the client can establish a reliable connection to the server; the values returned in the ICMPTIME structure provide information on the latency between the two hosts. Higher average time values would indicate greater latency and reduced throughput between the systems. If the function returns a value less than the specified number of iterations, this indicates that replies were not received for one or more of the echo datagrams. This may indicate that there are problems routing

data between the local and remote host. A return value of zero indicates that there was no response to the echo datagrams. The remote host may not exist or may not be available.

The failure for a host to respond to an ICMP echo datagram may not indicate a problem with the remote system. In some cases, a router between the local and remote host may be malfunctioning or discarding the datagrams. Systems can also be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of Denial of Service attacks.

The ability to send ICMP datagrams may be restricted to users with administrative privileges, depending on the policies and configuration of the local system. If you are unable to send or receive any ICMP datagrams, it is recommended that you check the firewall settings and any third-party security software that could impact the normal operation of this component.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

IcmpEnableEvents Function

```
INT WINAPI IcmpEnableEvents(
   HCLIENT hClient,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **IcmpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **IcmpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the event notification window. This window receives a user-defined message which specifies the event that has occurred. If this value is NULL, event notification is disabled.

uEventMsg

An unsigned integer which specifies the user-defined message that is sent when an event occurs. This parameter's value must be greater than the value of WM_USER.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation.
ICMP_EVENT_CANCEL	The current operation has been canceled. TThe client application may attempt to retry the operation or close the handle.

To cancel asynchronous notification and return the client to a blocking mode, use the **IcmpDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

IcmpEnableTrace Function

```
BOOL WINAPI IcmpEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **IcmpEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

IcmpEventProc Function

```
VOID CALLBACK IcmpEventProc(
   HCLIENT hClient,
   UINT nEventId,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **IcmpEventProc** function is an application-defined callback function that processes events generated by the calling process.

Parameters

hClient

The handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **IcmpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **IcmpRegisterEvent** function. The **IcmpEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpFormatAddress Function

```
INT WINAPI IcmpFormatAddress(
   DWORD dwAddress,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **IcmpFormatAddress** function converts a numeric IP address to a string.

Parameters

dwAddress

A unsigned 32-bit integer which specifies the IP address to be converted into a string.

lpszAddress

A null-terminated string which will contain the converted IP address in dot-notation. This string should be at least 16 characters in length.

nMaxLength

The maximum number of characters which may be copied in to the string buffer.

Return Value

If the function succeeds, the return value is the length of the string buffer. If the function fails, the return value is zero. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

IcmpFreezeEvents Function

```
INT WINAPI IcmpFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **IcmpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

IcmpGetErrorString Function

```
INT WINAPI IcmpGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **IcmpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **IcmpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

IcmpGetHostAddress Function

```
INT WINAPI IcmpGetHostAddress(
   HCLIENT hClient,
   LPTSTR lpszHostAddress,
   INT nMaxLength
);
```

The **IcmpGetHostAddress** copies the IP address of the current host into the specified buffer as a string using dot-notation.

Parameters

hClient

A handle to the client session.

lpszHostAddress

The buffer that will contain the IP address of the current remote host in dot-notation. This buffer should be at least 16 characters in length.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character character.

Return Value

If the function succeeds, the return value is the length of the address string. If the return value is zero, this indicates that no remote host has been specified. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

IcmpGetHostName Function

```
INT WINAPI IcmpGetHostName(
   HCLIENT hClient,
   LPTSTR lpszHostName,
   INT cbHostName
);
```

The **IcmpGetHostName** copies the name of the current host into the specified buffer.

Parameters

hClient

A handle to the client session.

lpszHostName

The buffer that will contain the name of the current remote host. This buffer should be at least 64 characters in length.

cbHostName

The maximum number of characters that may be copied into the buffer, including the terminating null character character.

Return Value

If the function succeeds, the return value is the length of the host name string. If the return value is zero, this indicates that no remote host has been specified. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

IcmpGetLastError Function

```
DWORD WINAPI IcmpGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **IcmpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **IcmpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **IcmpSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or ICMP_ERROR. Those functions which call **IcmpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

IcmpGetPacketSize Function

```
UINT WINAPI IcmpGetPacketSize(
    HCLIENT hClient
);
```

The **IcmpGetPacketSize** function returns the size of the ICMP echo datagram that will be sent to the remote host. The minimum packet size is 1 byte, the maximum packet size is 65,535 bytes.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the size of the datagram. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

IcmpGetSequenceId Function

```
INT WINAPI IcmpGetSequenceId(
    HCLIENT hClient
);
```

The **IcmpGetSequenceId** function returns the sequence identifier for the last ICMP echo datagram received by the client.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the sequence identifier. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpGetPacketSize, IcmpGetRecvCount, IcmpGetSendCount, IcmpGetTimeToLive, IcmpGetTripTime, IcmpSetSequenceId, IcmpSetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IcmpGetTimeout Function

```
DWORD WINAPI IcmpGetTimeout(
    HCLIENT hClient
);
```

The **IcmpGetTimeout** function returns the number of milliseconds the client will wait for a response from the remote host. Once the specified number of milliseconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in milliseconds. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpGetTimeToLive Function

```
INT WINAPI IcmpGetTimeToLive(
    HCLIENT hClient
);
```

The **IcmpGetTimeToLive** function returns the time-to-live for the last ICMP echo datagram received by the client.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the time-to-live for the last datagram. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The time-to-live (TTL) value is specified in the IP header of a datagram, and is used to control the number of routers that the datagram is passed through. Each router that handles the datagram decrements the TTL value by one. When it drops to zero, a datagram is returned to the sender, specifying that the TTL has been exceeded. The default value is 255.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

IcmpGetTripTime Function

```
INT WINAPI IcmpGetTripTime(
   HCLIENT hClient,
   LPICMPTIME lpIcmpTime
);
```

The **IcmpGetTripTime** returns round-trip statistics for the datagrams sent to the current remote host.

Parameters

hClient

A handle to the client session.

lpIcmpTime

A pointer to an ICMPTIME data structure which will contain the round-trip statistics for the current remote host.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IcmpInitialize Function

```
BOOL WINAPI IcmpInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **IcmpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **IcmpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **IcmpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **IcmpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **IcmpInitialize** or **IcmpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

IcmpIsBlocking Function

```
BOOL WINAPI IcmpIsBlocking(
    HCLIENT hClient
);
```

The **IcmpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IcmpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpCancel

IcmpRecvEcho Function

```
INT WINAPI IcmpRecvEcho(
   HCLIENT hClient
);
```

The **IcmpRecvEcho** function reads the reply to an ICMP echo datagram generated by the client. This function should only be called by asynchronous client sessions in response to an event notification that a datagram has been received.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpRegisterEvent Function

```
INT WINAPI IcmpRegisterEvent(
   HCLIENT hClient,
   UINT nEventId,
   INETEVENTPROC lpfnEvent,
   DWORD_PTR dwParam
);
```

The **IcmpRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One or more of the following values may be used:

Value	Description
ICMP_EVENT_ECHO	The client has generated an ICMP echo datagram and has sent it to the specified host. If the datagram is received, the remote host should generate a reply and return it to the sender.
ICMP_EVENT_REPLY	The client has received an ICMP echo reply datagram from the remote host. At this point the client can collect statistical information.
ICMP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation.
ICMP_EVENT_CANCEL	The current operation has been canceled. The client application may attempt to retry the operation or close the handle.

lpfnEvent

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **IcmpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpRegisterEvent** function associates a callback function with a specific event. The event handler is an **IcmpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will

be provided to the handler.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IcmpReset Function

```
INT WINAPI IcmpReset(
   HCLIENT hClient
);
```

The **IcmpReset** function resets the client session, clearing the packet trip statistics, time-to-live, sequence identifier, send and receive counts.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpSetHostAddress, IcmpSetHostName, IcmpSetSequenceId, IcmpSetTimeToLive

IcmpResolveAddress Function

```
INT WINAPI IcmpResolveAddress(
   DWORD dwAddress,
   LPTSTR lpszHostName,
   INT nMaxLength
);
```

The **IcmpResolveAddress** function resolves a numeric IP address into a fully qualified domain name.

Parameters

dwAddress

The IP address to be resolved, specified as an unsigned 32-bit integer in network byte order.

lpszHostName

A buffer that will contain a null-terminated string that specifies the fully qualified domain name for the host. It is recommended that this buffer be at least 64 characters in length.

nMaxLength

The maximum number of characters that can be copied into the string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the host name. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpResolveAddress** function is used to perform a reverse DNS lookup, converting a numeric IP address into a fully qualified domain name. This is useful for functions like **IcmpTraceRoute**, which return host addresses as numeric values in network byte order. If the reverse DNS lookup fails because there is no PTR record for the given IP address, a printable form of the address in dotted notation will be returned in the string buffer.

Calling this function will cause the thread to block until the IP address is resolved, or until the DNS query times out because there is no reverse record for the address. In some cases, a reverse lookup can take several seconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

IcmpSendEcho Function

```
INT WINAPI IcmpSendEcho(
   HCLIENT hClient
);
```

The **IcmpSendEcho** function sends an ICMP echo datagram to the remote host.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

For asynchronous client sessions, this function returns immediately. Otherwise, the client enters a blocking state and waits for a reply from the remote host. The function returns when a reply has been received, or the operation times-out.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

IcmpSetHostAddress Function

```
INT WINAPI IcmpSetHostAddress(
    HCLIENT hClient,
    DWORD dwAddress
);
```

The **IcmpSetHostAddress** function specifies the IP address of the host to receive an ICMP echo datagram. If the address specifies a new host, the current client statistics are reset.

Parameters

hClient

A handle to the client session.

dwAddress

The IP address of the remote host as a 32-bit integer value, specified in network byte order.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

To specify a remote host name or an IP address as a string in dot notation, use the **IcmpSetHostName** function instead.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IcmpSetHostName Function

```
INT WINAPI IcmpSetHostName(
   HCLIENT hClient,
   LPCTSTR lpszHostName
);
```

The **IcmpSetHostName** function specifies the name of the host to receive an ICMP echo datagram. If the name specifies a new host, the current client statistics are reset.

Parameters

hClient

A handle to the client session.

lpszHostName

A null-terminated string which specifies the name, or IP address in dot-notation, of the remote host.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

IcmpSetLastError Function

```
VOID WINAPI IcmpSetLastError(
   DWORD dwErrorCode
);
```

The **IcmpSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or ICMP_ERROR. Those functions which call **IcmpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **IcmpGetLastError** function. The use of **IcmpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

IcmpSetPacketSize Function

```
UINT WINAPI IcmpSetPacketSize(
    HCLIENT hClient,
    UINT nPacketSize
);
```

The **IcmpSetPacketSize** function sets the size of the ICMP datagram packet that is sent to the remote host.

Parameters

hClient

Handle to the client session.

nPacketSize

Size of the ICMP datagram packet in bytes. The minimum packet size is 1 byte and the maximum packet size is 65,535 bytes.

Return Value

If the function succeeds, the return value is the previous ICMP datagram packet size. If the function fails, the return value is zero. To get extended error information, call **IcmpGetLastError**.

Remarks

Note that packet sizes over 512 bytes may not be supported by your networking software or configuration. It is recommended that most applications use the minimum packet size of 32 bytes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpGetPacketSize, IcmpSetSequenceId, IcmpSetTimeToLive

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IcmpSetSequenceId Function

```
INT WINAPI IcmpSetSequenceId(
    HCLIENT hClient,
    INT nSequenceId
);
```

The **IcmpSetSequenceId** function sets the sequence identifier for the next ICMP echo datagram sent by the client. The default sequence identifier for the first datagram is one.

Parameters

hClient

A handle to the client session.

nSequenceId

The sequence identifier for the next datagram sent by the client.

Return Value

If the function succeeds, the return value is the previous sequence identifier. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IcmpSetTimeout Function

```
DWORD WINAPI IcmpSetTimeout(
    HCLIENT hClient,
    DWORD dwTimeout
);
```

The **IcmpSetTimeout** function sets the number of milliseconds the client will wait for a response from the remote host. Once the specified number of milliseconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

dwTimeout

The number of milliseconds until a blocking operation fails.

Return Value

If the function succeeds, the return value is the value of the timeout before the function was called. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IcmpSetTimeToLive Function

```
INT WINAPI IcmpSetTimeToLive(
    HCLIENT hClient,
    INT nTimeToLive
);
```

The **IcmpSetTimeToLive** function sets the maximum time-to-live for the next ICMP datagram sent by the client.

Parameters

hClient

A handle to the client session.

nTimeToLive

The time-to-live value for the next ICMP echo datagram.

Return Value

If the function succeeds, the return value is the previous time-to-live value. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The time-to-live (TTL) value is specified in the IP header of a datagram, and is used to control the number of routers that the datagram is passed through. Each router that handles the datagram decrements the TTL value by one. When it drops to zero, a datagram is returned to the sender, specifying that the TTL has been exceeded.

Calling this function changes the default TTL value for all subsequent ICMP datagrams sent by the library, with the default value being 255. Note that not all Windows Sockets implementations support setting the time-to-live value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

See Also

IcmpTraceRoute Function

```
INT WINAPI IcmpTraceRoute(
   LPCTSTR lpszHostName,
   UINT nMaxHops,
   DWORD dwTimeout,
   DWORD dwReserved,
   LPICMPTRACE lpTrace,
   LPDWORD lpdwSize
);
```

The **IcmpTraceRoute** function sends a series of ICMP echo datagrams to trace the route taken from the local system to the remote host.

Parameters

lpszHostName

A null-terminated string which specifies the fully qualified domain name of the remote host, or the IP address in dotted notation.

nMaxHops

An unsigned integer which specifies the maximum number of routers the datagram will be forwarded through (the number of hops) to the remote host. The minimum value is 1 and the maximum value is 255. It is recommended that most applications specify a value of at least 30.

dwTimeout

An unsigned integer which specifies the number of milliseconds the function will wait for a response to an echo datagram.

dwReserved

A reserved parameter. This value should always be zero.

lpTrace

A pointer to an array of ICMPTRACE structures which will contain information about each intermediate host between the local and remote system. The number of structures must be at least the same as the maximum number of hops specified by the ***nMaxHops*** parameter. To determine the total number of bytes that must be allocated for the structure array, this parameter can be passed as NULL and the total size will be returned in the ***lpdwSize*** parameter.

lpdwSize

A pointer to an unsigned integer which should be initialized to the size of the ICMPTRACE array passed to the function. If the ***lpTrace*** parameter is NULL, the function will calculate the size of the array buffer that must be allocated and return that value. If both the ***lpTrace*** and ***lpdwSize*** parameters are NULL, no statistical information about the intermediate hosts will be collected.

Return Value

If the function succeeds, the return value is the number of intermediate hosts between the local and remote system. If the function fails, the return value is ICMP_ERROR. To get extended error information, call **IcmpGetLastError**.

Remarks

The **IcmpTraceRoute** function sends a series of ICMP echo datagrams to the specified host, adjusting the time-to-live value to determine the intermediate hosts that route the packet. The function returns the number of hops to the remote host.

It is important to note that the failure of an intermediate host to respond to an ICMP echo datagram may not indicate a problem with the remote system. Systems can be configured to specifically ignore ICMP echo datagrams and not respond to them; this is often a security measure to prevent certain kinds of Denial of Service attacks.

The ability to send ICMP datagrams may be restricted to users with administrative privileges, depending on the policies and configuration of the local system. If you are unable to send or receive any ICMP datagrams, it is recommended that you check the firewall settings and any third-party security software that could impact the normal operation of this component.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib
Unicode: Implemented as Unicode and ANSI versions

IcmpUninitialize Function

```
VOID WINAPI IcmpUninitialize();
```

The **IcmpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **IcmpInitialize** call before it can call any of the other the library functions. When it has finished using the library, the application must call **IcmpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **IcmpUninitialize** for every successful call to **IcmpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csicmv12.lib

ICMPTIME

This structure is used by the IcmpGetTripTime function to return the round-trip times of an ICMP datagram.

```
typedef struct _ICMPTIME {
    DWORD dwTripAverage;
    DWORD dwTripMaximum;
    DWORD dwTripMinimum;
    DWORD dwTripTime;
} ICMPTIME, *LPICMPTIME;
```

Members

dwTripAverage

The average round-trip time in milliseconds for all datagrams sent to the current host.

dwTripMaximum

The maximum round-trip time in milliseconds for all datagrams sent to current host.

dwTripMinimum

The minimum round-trip time in milliseconds for all datagrams sent to the current host.

dwTripTime

The current round-trip time in milliseconds for the last datagram sent to the current host.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

ICMPTRACE

This structure is used by the IcmpTraceRoute function to return the route of an ICMP datagram.

```
typedef struct _ICMPTRACE
{
    UINT        nDistance;
    DWORD       dwHostAddress;
    DWORD       dwTripAverage;
    DWORD       dwTripMaximum;
    DWORD       dwTripMinimum;
} ICMPTRACE, *LPICMPTRACE;
```

Members

nDistance

The distance from the local host to the remote host for this route.

dwHostAddress

An unsigned integer which specifies the IP address of the remote host in network byte order.

dwTripAverage

The average round-trip time in milliseconds for all datagrams sent to the specified host.

dwTripMaximum

The maximum round-trip time in milliseconds for all datagrams sent to specified host.

dwTripMinimum

The minimum round-trip time in milliseconds for all datagrams sent to the specified host.

dwTripTime

The current round-trip time in milliseconds for the last datagram sent to the specified host.

Requirements

INTERNET_ADDRESS

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
     INT    ipFamily;
     BYTE   ipNumber[16];
}  INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the ***ipNumber*** array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the ***ipNumber*** array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the ***ipNumber*** array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the ***ipFamily*** member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Internet Message Access Protocol Library

Manage email messages and mailboxes on a mail server.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSMAPV12.DLL
Version	12.0.3024.1286
LibID	8A55FC0D-5E12-4932-9E86-1F88C1DF5024
Import Library	CSMAPV12.LIB
Dependencies	None
Standards	RFC 3501

Overview

The Internet Message Access Protocol (IMAP) is an application protocol which is used to access a user's email messages which are stored on a mail server. However, unlike the Post Office Protocol (POP) where messages are downloaded and processed on the local system, the messages on an IMAP server are retained on the server and processed remotely. This is ideal for users who need access to a centralized store of messages or have limited bandwidth. For example, traveling salesmen who have notebook computers or mobile users on a wireless network would be ideal candidates for using IMAP.

The SocketTools IMAP library implements the current standard for this protocol, and provides functions to retrieve messages, or just certain parts of a message, create and manage mailboxes, search for specific messages based on certain criteria and so on. The API is designed as a superset of the Post Office Protocol API, so developers who are used to working with the POP3 library will find the IMAP library very easy to integrate into an existing application.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy

development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Internet Message Access Protocol Functions

Function	Description
ImapAsyncConnect	Connect asynchronously to the specified server
ImapAttachThread	Attach the specified client handle to another thread
ImapCancel	Cancel the current blocking operation
ImapCheckMailbox	Check the current mailbox for new messages
ImapCloseMessage	Close the current message
ImapCommand	Send a command to the server
ImapConnect	Connect to the specified server
ImapCopyMessage	Copy a message from the current mailbox to another mailbox
ImapCreateMailbox	Create a new mailbox on the server
ImapCreateMessage	Create a new message in the specified mailbox
ImapCreateSecurityCredentials	Allocate a structure to establish client security credentials
ImapDecodeMailboxName	Decode a UTF-7 encoded mailbox name using the specified code page
ImapDeleteMailbox	Delete the specified mailbox from the server
ImapDeleteMessage	Delete the specified message from the mailbox
ImapDeleteSecurityCredentials	Delete the specified client security credentials
ImapDisableEvents	Disable the event notification mechanism
ImapDisableTrace	Disable logging of network function calls
ImapDisconnect	Disconnect from the current server
ImapEnableEvents	Enable the client event notification mechanism
ImapEnableTrace	Enable logging of network function calls to a file
ImapEncodeMailboxName	Encode a mailbox name using modified UTF-7 encoding
ImapEnumMessages	Enumerate the messages in the current mailbox
ImapEventProc	Callback function that processes events generated by the client
ImapExamineMailbox	Select the specified mailbox in read-only mode
ImapExpungeMailbox	Remove messages that have been marked for deletion from the current mailbox
ImapFreezeEvents	Suspend and resume event handling by the client
ImapGetCapability	Return a string which identifies the capabilities of the server
ImapGetCurrentMailbox	Return the name of the currently selected mailbox
ImapGetDeletedMessages	Return the messages that have been marked for deletion
ImapGetErrorString	Return a description for the specified error code
ImapGetFirstMailbox	Return the first mailbox according to specified criteria
ImapGetHeaderValue	Return the value of the specified header field
ImapGetHeaderValueEx	Return the value of a header field in the specified message part

ImapGetIdleThreadId	Return the ID of the thread created to monitor the client session
ImapGetLastError	Return the last error code
ImapGetMailboxDelimiter	Get the path delimiter for the specified mailbox hierarchy
ImapGetMailboxSize	Return the size of the specified mailbox
ImapGetMailboxStatus	Return the status of the specified mailbox
ImapGetMailboxUid	Return the unique identifier for the specified mailbox
ImapGetMessage	Retrieve the specified message from the server
ImapGetMessageCount	Return the number of messages available in the mailbox
ImapGetMessageCountEx	Return the number of messages available in the mailbox
ImapGetMessageFlags	Return the status flags for the specified message
ImapGetMessageHeaders	Retrieve the specified message header from the server
ImapGetMessageHeadersEx	Retrieve the specified message header, UID and flags from the server
ImapGetMessageId	Return the message ID string for the specified message
ImapGetMessageParts	Return the number of MIME message parts in the specified message
ImapGetMessageSender	Return the address of the message sender
ImapGetMessageSize	Return the size of the specified message
ImapGetMessageUid	Return the unique identifier for the specified message
ImapGetNewMessages	Return a list of the new messages in the current mailbox
ImapGetNextMailbox	Return the next mailbox name on the server
ImapGetResultCode	Return the result code from the previous command
ImapGetResultString	Return the result string from the previous command
ImapGetSecurityInformation	Return security information about the current client connection
ImapGetStatus	Return the current status of the client
ImapGetTimeout	Return the number of seconds until an operation times out
ImapGetTransferStatus	Return data transfer statistics
ImapGetUnseenMessages	Return a list of messages from the current mailbox that have not been read
ImapIdle	Enables mailbox status monitoring for the client session
ImapIdleProc	Callback function that receives update notifications from the server
ImapInitialize	Initialize the library and validates the specified license key at runtime
ImapIsBlocking	Determine if the client is blocked, waiting for information
ImapIsConnected	Determine if the client is connected to the server
ImapIsReadable	Determine if data can be read from the server
ImapIsWritable	Determine if data can be written to the server
ImapLogin	Login to the server
ImapOpenMessage	Open the specified message for reading on the server
ImapOpenMessageEx	Open the specified message for reading on the server, with additional options

ImapRead	Read data returned by the server
ImapRegisterEvent	Register an event handler for the specified event
ImapRenameMailbox	Rename the specified mailbox
ImapReselectMailbox	Reselect the current mailbox and return updated status information
ImapSearchMailbox	Search the mailbox according to specified criteria
ImapSelectMailbox	Select the specified mailbox in read-write mode
ImapSetLastError	Set the last error code for the current thread
ImapSetMessageFlags	Set one or more status flags for the specified message
ImapSetTimeout	Set the number of seconds until an operation times out
ImapStoreMessage	Store the contents of a message to the specified file
ImapSubscribeMailbox	Subscribe to the specified mailbox
ImapUndeleteMessage	Undelete the specified message from the current mailbox
ImapUninitialize	Terminate use of the library by the application
ImapUnselectMailbox	Unselect the current mailbox and expunge any deleted messages
ImapUnsubscribeMailbox	Unsubscribe from the specified mailbox
ImapWrite	Write data to the server

ImapAsyncConnect Function

```
HCLIENT WINAPI ImapAsyncConnect(
   LPCTSTR lpszHostName,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **ImapAsyncConnect** function is used to establish a connection with the server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **ImapConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszHostName

A null-terminated string which specifies the host name or IP address of the IMAP server.

nRemotePort

The port number the client should use to establish the connection. A value of zero specifies that default port 143 should be used, which is the standard port number assigned to the IMAP service. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
IMAP_OPTION_IDENTIFY	This option specifies the client should identify itself to the server. If enabled, the client will send the ID command to the server as defined in RFC 2971. This option has no effect if the server does not support the ID command.
IMAP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior

	of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
IMAP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
IMAP_OPTION_SECURE	This option specifies that a secure connection should be established with the server and requires that the server support the TLS protocol. This option is the same as specifying IMAP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STARTTLS command.
IMAP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol and the STARTTLS command.
IMAP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
IMAP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
HTTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
IMAP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which is used to establish the client credentials for a secure connection to the server. The function **ImapCreateSecurityCredentials** can be used to

create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

hEventWnd

The handle to the asynchronous notification window. This window receives messages which notify the client of various asynchronous client events that occur. Specifying this parameter and a message identifier causes the connection to be non-blocking. If this parameter is NULL, then a blocking connection is established.

uEventMsg

The message identifier that is used when an asynchronous client event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** parameter is NULL, this parameter should be specified as WM_NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **ImapGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
IMAP_EVENT_CONNECT	The connection to the server has completed. The high word of the lParam parameter should be checked, since this notification message will be posted if an error has occurred.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
IMAP_EVENT_CANCEL	The client has canceled the current operation.
IMAP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the lParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
IMAP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking

	operations, such as retrieving a complete message from the server.

To cancel asynchronous notification and return the client to a blocking mode, use the **ImapDisableEvents** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **ImapAttachThread** function.

Specifying the IMAP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapAttachThread Function

```
DWORD WINAPI ImapAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **ImapAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **ImapAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **ImapAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **ImapCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **ImapUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapConnect, ImapDisconnect, ImapUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapCancel Function

```
INT WINAPI ImapCancel(
   HCLIENT hClient
);
```

The **ImapCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When the **ImapCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapCheckMailbox Function

```
INT WINAPI ImapCheckMailbox(
   HCLIENT hClient,
   UINT *lpnMessages,
   UINT *lpnUnseen
);
```

The **ImapCheckMailbox** function requests that the server create a checkpoint of the currently selected mailbox, and returns the current number of messages and unseen messages.

Parameters

hClient

Handle to the client session.

lpnMessages

A pointer to an unsigned integer value which will contain the number of messages in the currently selected mailbox when the function returns.

lpnUnseen

A pointer to an unsigned integer value which will contain the number of unseen messages in the currently selected mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When the client requests a checkpoint, the server may perform implementation-dependent housekeeping for that mailbox, such updating the mailbox on disk with the current state of the mailbox in memory. On some systems this command has no effect other than to update the client with the current number of messages in the mailbox.

This function actually sends two IMAP commands. The first is the CHECK command, followed by the NOOP command to poll for any new messages that have arrived. In addition to polling the server for new messages, this command can also be used to ensure the idle timer on the server does not expire and force a disconnect from the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapCloseMessage Function

```
INT WINAPI ImapCloseMessage(
    HCLIENT hClient
);
```

The **ImapCloseMessage** function closes the current message.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapCloseMessage** function closes the current message. If there is any remaining data left to be read from the message, it will be read and discarded.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapCommand Function

```
INT WINAPI ImapCommand(
   HCLIENT hClient,
   LPCTSTR lpszCommand,
   LPCTSTR lpszParameter
);
```

The **ImapCommand** function sends a command to the server. This function is typically used for site-specific commands not directly supported by the API.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the function succeeds, it returns an IMAP result code. If the command was successful, it returns IMAP_RESULT_OK. A return value of IMAP_RESULT_CONTINUE indicates the command was accepted and the caller should proceed with the next command. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

A list of valid commands can be found in the technical specification for the protocol. The current version of the protocol which is supported by this library is version 4rev1 as defined in RFC 3501.

Use the **ImapGetResultCode** function to determine the result of the command that was sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapConnect Function

```
HCLIENT WINAPI ImapConnect(
   LPCTSTR lpszHostName,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **ImapConnect** function is used to establish a connection with the server.

Parameters

lpszHostName

A null-terminated string which specifies the host name or IP address of the IMAP server.

nRemotePort

The port number the client should use to establish the connection. A value of zero specifies that default port 143 should be used, which is the standard port number assigned to the IMAP service. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
IMAP_OPTION_IDENTIFY	This option specifies the client should identify itself to the server. If enabled, the client will send the ID command to the server as defined in RFC 2971. This option has no effect if the server does not support the ID command.
IMAP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
IMAP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
IMAP_OPTION_SECURE	This option specifies that a secure connection should

	be established with the server and requires that the server support the TLS protocol. This option is the same as specifying IMAP_OPTION_SECURE_EXPLICIT, which initiates the secure session using the STARTTLS command.
IMAP_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
IMAP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to establish a secure connection with the server. The server must support secure connections using the TLS protocol, and the secure session must be negotiated immediately after the connection has been established.
IMAP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
IMAP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
IMAP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure which is used to establish the client credentials for a secure connection to the server. The function **ImapCreateSecurityCredentials** can be used to create this structure if necessary. If a standard non-secure connection is being established, or client credentials are not required by the server, this parameter can be NULL.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **ImapGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should

create a background worker thread and establish a connection by calling **ImapConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **ImapAttachThread** function.

Specifying the IMAP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapCopyMessage Function

```
INT WINAPI ImapCopyMessage(
   HCLIENT hClient,
   UINT nMessageId,
   LPCTSTR lpszMailbox
);
```

The **ImapCopyMessage** function copies a message from the current mailbox to the specified mailbox. The message is appended to the mailbox, and the message flags and internal date are preserved.

Parameters

hClient

Handle to the client session.

nMessageId

The message identifier which specifies which message is to be copied to the mailbox. This value must be greater than zero and specify a valid message number.

lpszMailbox

A null-terminated string which specifies the name of the mailbox that the message will be copied to. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

Return Value

If the function succeeds, it returns a value of zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the mailbox does not exist, the function will fail. To create a new mailbox, use the **ImapCreateMailbox** function. A message can be copied within the same mailbox, in which case the server may flag it as a new message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapCreateMailbox Function

```
INT WINAPI ImapCreateMailbox(
   HCLIENT hClient,
   LPCTSTR lpszMailbox
);
```

The **ImapCreateMailbox** function creates a new mailbox on the server.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string which specifies the new mailbox to be created.

Return Value

If the function succeeds, it returns a value of zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the mailbox name is suffixed with the server's hierarchy delimiter, this indicates to the server that the client intends to create mailbox names under the specified name in the hierarchy. If superior hierarchical names are specified in the mailbox name, then the server may automatically create them as needed. For example, if the mailbox name "Mail/Office/Projects" is specified and "Mail/Office" does not exist, it may be automatically created by the server.

The special mailbox name INBOX is reserved, and cannot be created. It is recommended that mailbox names only consist of printable ASCII characters, and the special characters "*" and "%" should be avoided.

If you need to create a mailbox which contains Unicode characters or symbols, it is recommended you always use the Unicode version of this function. The mailbox name will automatically be converted to modified UTF-7 encoding as defined by the IMAP4 standard. The ANSI version of this function will only accept mailbox names using either modified UTF-7 encoding or UTF-8 encoding.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapDecodeMailboxName, ImapDeleteMailbox, ImapEncodeMailboxName, ImapGetFirstMailbox, ImapGetNextMailbox, ImapRenameMailbox

ImapCreateMessage Function

```
INT WINAPI ImapCreateMessage(
   HCLIENT hClient,
   LPCTSTR lpszMailbox,
   DWORD dwReserved,
   LPVOID lpMessage,
   DWORD dwMessageSize,
   DWORD dwFlags
);
```

The **ImapCreateMessage** function creates a message, appending it to the contents of the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string which specifies the name of the mailbox that the message will be created in. The mailbox must already exist, and the client must have the appropriate access rights to modify the mailbox.

dwReserved

A reserved parameter. This value should always be zero.

lpMessage

The buffer which contains the message to be created.

dwMessageSize

An unsigned integer value which specifies the size of the message in bytes. If this value is zero, then it is assumed that the ***lpMessage*** parameter points to a string.

dwFlags

An unsigned integer that specifies one or more message flags. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_FLAG_NONE	No value.
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DRAFT	The message is not completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message is flagged for urgent or special attention.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the mailbox does not exist, the function will fail. To create a new mailbox, use the **ImapCreateMailbox** function. If the message is created in the mailbox that is currently selected, the server may flag it as recent.

This function is typically used by applications to store messages which have already been sent to a user. After a message has been delivered using the SMTP protocol, that same message may be created in a mailbox on the IMAP server so that the user has access to those messages.

If the Unicode version of this function is called and the ***dwMessageSize*** parameter is zero, the ***lpMessage*** parameter must point to a wide string terminated with a null character. The string will be automatically converted to UTF-8 when the message is created. In all other cases, the ***lpMessage*** parameter is treated as a pointer to a byte array which contains the message contents and the ***dwMessageSize*** parameter specifies the number of bytes in the array.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapCopyMessage, ImapDeleteMessage, ImapGetMessageFlags, ImapSetMessageFlags

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapCreateSecurityCredentials Function

```
BOOL WINAPI ImapCreateSecurityCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **ImapCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **ImapDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **ImapConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user,

or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPSECURITYCREDENTIALS lpSecCred = NULL;
ImapCreateSecurityCredentials(SECURITY_PROTOCOL_DEFAULT,
                              0,
                              NULL,
                              NULL,
                              lpszCertStore,
                              lpszCertName,
                              NULL,
                              &lpSecCred);

hClient = ImapConnect(lpszHostName,
                      IMAP_PORT_SECURE,
                      IMAP_TIMEOUT,
                      IMAP_OPTION_SECURE,
                      lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapDecodeMailboxName Function

```
INT WINAPI ImapDecodeMailboxName(
   INT nCodePage,
   LPCSTR lpszMailboxName,
   LPTSTR lpszDecodedName,
   INT nMaxLength
);
```

The **ImapDecodeMailboxName** function decodes a UTF-7 encoded mailbox name using the specified code page.

Parameters

nCodePage

An integer value which specifies the code page which should be used when decoding the mailbox name. If the ANSI version of this function is called, this parameter can be any valid code page, or the constant CP_ACP which specifies the current active code page for the locale. If the Unicode version of this function is called, this parameter should always be zero.

lpszMailboxName

A null-terminated string which contains the UTF-7 encoded name of the mailbox. The encoded string must use the modified UTF-7 format defined in the IMAP4 protocol standard. This parameter cannot be a NULL pointer or an empty string.

lpszDecodedName

A null-terminated string buffer which will contain the decoded mailbox name. This parameter cannot be NULL and must be large enough to contain the entire name.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the *lpszDecodedName* string buffer. This value must be greater than zero and the buffer must be large enough to store the entire name.

Return Value

If the function succeeds, it returns the number of characters in the decoded mailbox name. If an error occurs, the function returns zero. To get extended error information, call **ImapGetLastError**.

Remarks

Mailbox names which contain non-ASCII characters must be converted to a modified version of UTF-7 encoding as defined by the IMAP4 protocol. This encoding allows applications to reference mailbox names which contain Unicode characters and provides support for languages other than English. This function is used to convert a UTF-7 encoded mailbox name using the current locale, primarily for display purposes.

For example, if the *lpszMailboxName* parameter specifies the string **"&A5QDvw06A7kDvA0u-"**, this function will convert it to the Greek word **"Δοκιμή"** and return that value in the *lpszDecodedName* buffer. It is recommended you use the Unicode version of this function whenever possible to ensure the mailbox name is decoded correctly.

The ANSI version of this function should only be used with legacy applications which do not support Unicode. The decoded mailbox name will be converted using the code page specified by the *nCodePage* parameter. If the code page does not support the characters used in the mailbox name, this can result in an incorrect conversion. Using the previous example, the mailbox name will always

decode correctly if the Unicode version of the function is used, but the ANSI version of the function will only decode it correctly if the code page is specified as 1253 (Greek).

This function should not be used to convert strings between Unicode and UTF-7. The encoding format is specifically intended for use with the IMAP4 protocol and should never be used for general purpose encoding or decoding. If you need to convert a UTF-7 encoded string to Unicode, use the Win32 API function **MultiByteToWideChar**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapDeleteMailbox Function

```
INT WINAPI ImapDeleteMailbox(
   HCLIENT hClient,
   LPCTSTR lpszMailbox
);
```

The **ImapDeleteMailbox** function deletes a mailbox on the server.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string which specifies the mailbox to be deleted.

Return Value

If the function succeeds, it returns value of zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

A mailbox cannot be deleted if it contains inferior hierarchical names and has the IMAP_FLAG_NOSELECT attribute. On most systems this is the case when the mailbox name references a directory on the server, and that directory contains other subdirectories or mailboxes. To remove the mailbox, you must first delete any child mailboxes that exist.

If the mailbox that is deleted is the currently selected mailbox, it will be automatically unselected and any messages marked for deletion will be expunged before the mailbox is removed. If the delete operation fails, the client will remain in an unselected state until either the **ImapExamineMailbox** or **ImapSelectMailbox** function is called.

The special mailbox name INBOX is reserved, and cannot be deleted.

If you need to delete a mailbox which contains Unicode characters or symbols, it is recommended you always use the Unicode version of this function. The mailbox name will automatically be converted to modified UTF-7 encoding as defined by the IMAP4 standard. The ANSI version of this function will accept mailbox names using either modified UTF-7 encoding or UTF-8 encoding.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapCreateMailbox, ImapGetFirstMailbox, ImapGetNextMailbox, ImapRenameMailbox

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapDeleteMessage Function

```
INT WINAPI ImapDeleteMessage(
   HCLIENT hClient,
   UINT nMessageId
);
```

The **ImapDeleteMessage** function marks the specified message for deletion from the current mailbox.

Parameters

hClient

Handle to the client session.

nMessage

Number of message to delete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

This function only marks the message for deletion. The message is not actually deleted until the mailbox is expunged or another mailbox is selected. This function will return an error if the current mailbox is in read-only mode, such as if it was selected using the **ImapExamineMailbox** function.

It is important to note that unlike the POP3 protocol, a message that is marked for deletion is still accessible on the IMAP server until the mailbox is expunged. This means, for example, that a deleted message can still be retrieved using the **ImapGetMessage** function.

To determine if a message has been marked for deletion, use the **ImapGetMessageFlags** function and check if the IMAP_FLAG_DELETED bit flag has been set. To list all of the deleted messages in the current mailbox, use the **ImapGetDeletedMessages** function.

To remove the deletion flag from the message, use the **ImapUndeleteMessage** function. To prevent all messages in the current mailbox from being expunged, use the **ImapReselectMailbox** function to reset the current mailbox state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapDeleteSecurityCredentials Function

```
VOID WINAPI ImapDeleteSecurityCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **ImapDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred)
    ImapDeleteSecurityCredentials(&lpSecCred);

ImapUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapCreateSecurityCredentials, ImapUninitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapDisableEvents Function

```
INT WINAPI ImapDisableEvents(
    HCLIENT hClient
);
```

The **ImapDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapDisableEvents** function is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this function has been called.

This function is automatically called if the client has event notification enabled, and the **ImapDisconnect** function is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapEnableEvents, ImapRegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapDisableTrace Function

```
BOOL WINAPI ImapDisableTrace();
```

The **ImapDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapDisconnect Function

```
INT WINAPI ImapDisconnect(
   HCLIENT hClient
);
```

The **ImapDisconnect** function terminates the connection with the server, releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If a mailbox is selected at the time that **ImapDisconnect** is called, the current mailbox will be unselected and any messages that are marked for deletion will be expunged. To prevent any deleted messages from being removed from the mailbox, use the **ImapUnselectMailbox** function to unselect the current mailbox prior to disconnecting from the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapConnect, ImapUninitialize, ImapUnselectMailbox

ImapEnableEvents Function

```
INT WINAPI ImapEnableEvents(
   HCLIENT hClient,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **ImapEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **ImapRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. To avoid conflict with standard Windows messages, this value must be greater than WM_USER (1024) or an error will be returned. If the *hEventWnd* parameter is NULL, this value should be WM_NULL.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapEnableEvents** function is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer. The client must create a window message handler, which processes the various events. The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event identifier, and the high word will contain any error code. If no error has occurred, the high word will have a value of zero. The following events may be generated:

Value	Description
IMAP_EVENT_CONNECT	The connection to the server has completed. The high word of the lParam parameter should be checked, since this notification message will be posted if an error has occurred.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the client. No additional messages will be

	posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
IMAP_EVENT_CANCEL	The client has canceled the current operation.
IMAP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command. The high word of the lParam parameter should be checked, since this notification message will also be posed if the command cannot be executed.
IMAP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

It is not required that the client be placed in asynchronous (non-blocking) mode in order to receive event notifications, except for the connect, disconnect, read and write events. To disable event notification, call the **ImapDisableEvents** function.

Requirements

ImapEnableTrace Function

```
BOOL WINAPI ImapEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **ImapEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapEncodeMailboxName Function

```
INT WINAPI ImapEncodeMailboxName(
   INT nCodePage,
   LPCTSTR lpszMailboxName,
   LPTSTR lpszEncodedName,
   INT nMaxLength
);
```

The **ImapEncodeMailboxName** function encodes a mailbox name using modified UTF-7 encoding.

Parameters

nCodePage

An integer value which specifies the code page which should be used when converting the mailbox name to Unicode. If the ANSI version of this function is called, this parameter can be any valid code page or a value of zero, which specifies the current active code page for the locale. If the Unicode version of this function is called, no conversion is required and this parameter should always be zero.

lpszMailboxName

A null-terminated string which contains the name of the mailbox. If the ANSI version of this function is called, this string is automatically converted to Unicode using the code page specified by the *nCodePage* parameter. This parameter cannot be a NULL pointer or an empty string.

lpszEncodedName

A null-terminated string buffer which will contain the UTF-7 encoded mailbox name. This parameter cannot be NULL and must be large enough to contain the entire name. The string will be null-terminated and will only contain printable ASCII characters.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the *lpszEncodedName* string buffer. This value must be greater than zero and the buffer must be large enough to store the entire name.

Return Value

If the function succeeds, it returns the number of characters in the encoded mailbox name. If an error occurs, the function returns zero. To get extended error information, call **ImapGetLastError**.

Remarks

Mailbox names which contain non-ASCII characters must be converted to a modified version of UTF-7 encoding as defined by the IMAP4 protocol. This encoding allows applications to reference mailbox names which contain Unicode characters and provides support for languages other than English. This function is used to convert a mailbox name which contains non-ASCII characters to the UTF-7 encoded format required by IMAP servers.

For example, if the *lpszMailboxName* parameter specifies the string **"Δοκιμή"**, this function will encode it as **"&A5QDvw06A7kDvA0u-"** and return that value in the *lpszEncodedName* buffer. It is recommended you use the Unicode version of this function whenever possible to ensure the mailbox name is encoded correctly.

The ANSI version of this function should only be used with legacy applications which do not support Unicode. The mailbox name will be converted to Unicode using the code page specified by the *nCodePage* parameter. If the code page does not support the characters used in the mailbox name,

this can result in an incorrect conversion. Using the previous example, the mailbox name will always encode correctly if the Unicode version of the function is used, but the ANSI version of the function will only encode it correctly if the code page is specified as 1253 (Greek).

If the ANSI version of this function is used and the ***nCodePage*** parameter is zero, this function will attempt to determine if the ***lpszMailboxName*** parameter specifies UTF-8 text as the mailbox name. If it does, the name will be converted from UTF-8 to modified UTF-7; otherwise, the name will be encoded as modified UTF-7 using the current active code page for the process.

This function should not be used to convert strings between Unicode and UTF-7. The encoding format is specifically intended for use with the IMAP4 protocol and should never be used for general purpose encoding or decoding. If you need to convert a Unicode string to UTF-7, use the Win32 API function **WideCharToMultiByte**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapEnumMessages Function

```
INT WINAPI ImapEnumMessages(
   HCLIENT hClient,
   UINT nFirstMessageId,
   UINT nLastMessageId,
   DWORD dwMessageFlags,
   DWORD dwReserved,
   LPIMAPMESSAGE lpMessageList,
   INT nMaxMessages
);
```

The **ImapEnumMessages** function enumerates the messages in the current mailbox, populating an array of IMAPMESSAGE structures which contain information about each message.

Parameters

hClient

Handle to the client session.

nFirstMessageId

An unsigned integer value which specifies the first message to enumerate. This value must be greater than zero and specify a valid message identifier. The first message in the mailbox has a value of one.

nLastMessageId

An unsigned integer value which specifies the last message to enumerate. This value must be greater than or equal to the value of the ***nFirstMessageId*** parameter. A special value of 0xFFFFFFFF can be used to specify the last message in the mailbox.

dwMessageFlags

This parameter is used to determine which messages are enumerated. If the value is zero, then all applicable messages will be enumerated. If the value is non-zero, only those messages which have at least one of the specified flags will be returned. More than one flag can be specified by using a bitwise operator.

Value	Description
IMAP_FLAG_ANSWERED	Return only those messages which have been answered.
IMAP_FLAG_DELETED	Return only those messages which have been marked for deletion.
IMAP_FLAG_DRAFT	Return only those messages which have been marked as draft copies.
IMAP_FLAG_URGENT	Return only those messages which have been flagged for urgent or special attention.
IMAP_FLAG_RECENT	Return only those messages which have been recently added to the mailbox.
IMAP_FLAG_SEEN	Return only those messages which have been read.

dwReserved

A reserved parameter. This value should always be set to zero.

lpMessageList

A pointer to an array of IMAPMESSAGE structures which will contain information about each of the messages returned by the server. This parameter cannot be NULL.

nMaxMessages

An integer value which specifies the maximum size of the IMAPMESSAGE array that was passed to the function. This value must be at least one.

Return Value

If the function succeeds, the return value is the number of messages that were enumerated. If no messages match the specified criteria, the function will return a value of zero. If an error is encountered, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the message UID is being stored locally by the client to identify the message over multiple sessions, it must also store the mailbox UID. Only the combination of the mailbox name, mailbox UID and message UID can be used to uniquely identify a given message on the server. Although IMAP server implementations are encouraged to maintain persistent message UIDs, they are not required to do so and those values may change if the mailbox UID changes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapEnumMessageUids Function

```
INT WINAPI ImapEnumMessageUids(
   HCLIENT hClient,
   UINT nFirstMessageId,
   UINT nLastMessageId,
   DWORD dwMessageFlags,
   UINT* lpSequenceIdList,
   UINT* lpMessageUidList
   INT nMaxMessages
);
```

The **ImapEnumMessageUids** function populates an array of message sequence IDs and their corresponding message UIDs.

Parameters

hClient

Handle to the client session.

nFirstMessageId

An unsigned integer value which specifies the first message to enumerate. This value must be greater than zero and specify a valid message identifier. The first message in the mailbox has a value of one.

nLastMessageId

An unsigned integer value which specifies the last message to enumerate. This value must be greater than or equal to the value of the ***nFirstMessageId*** parameter. A special value of 0xFFFFFFFF (-1) can be used to specify the last message in the mailbox.

dwMessageFlags

This parameter is used to determine which messages are enumerated. If the value is zero, then all messages in the mailbox will be enumerated. If the value is non-zero, only those messages which have at least one of the specified flags will be returned. The following flags can be used to filter which messages are included in the result:

Value	Description
IMAP_FLAG_ANSWERED	Return only those messages which have been answered.
IMAP_FLAG_DELETED	Return only those messages which have been marked for deletion.
IMAP_FLAG_DRAFT	Return only those messages which have been marked as draft copies.
IMAP_FLAG_URGENT	Return only those messages which have been flagged for urgent or special attention.
IMAP_FLAG_RECENT	Return only those messages which have been recently added to the mailbox.
IMAP_FLAG_SEEN	Return only those messages which have been read.

lpSequenceIdList

A pointer to an array of unsigned integers that will receive the message sequence numbers for each enumerated message. The message sequence numbers are what most functions use to specify a

message in the current mailbox. These values should never be stored by your application. This parameter must not be NULL.

lpMessageUidList

A pointer to an array of unsigned integers that will receive the message UIDs corresponding to the messages in the sequence. The message UIDs are unique values which persist across multiple client sessions. These values can be stored by your application and then mapped to their corresponding sequential message ID. This parameter must not be NULL.

nMaxMessages

An integer value which specifies the maximum size of both arrays. This value cannot be zero.

Return Value

If the function succeeds, the return value is the number of entities populated in both the *lpSequenceIdList* and *lpMessageUidList* arrays. If no messages match the specified criteria, the function will return a value of zero. If an error is encountered, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapEnumMessageUids** function retrieves a list of messages in the specified range and populates parallel arrays with each message's sequence number and corresponding unique identifier (UID). This enables applications to correlate transient message numbers with persistent UIDs for more reliable tracking across sessions. The *lpSequenceIdList* and *lpMessageUidList* arrays must be the same size, and both must be large enough to store the number of values specified by the *nMaxMessages* parameter. Both the sequential and unique message IDs are unsigned integer values, but they cannot be used interchangeably. Note that functions such as **ImapGetMessage** and **ImapDeleteMessage** expect sequential message numbers, not message UIDs.

If your application stores the message UIDs to maintain some persistent information about the mailbox, this function will enable you to lookup those message UIDs and find the corresponding sequential message number. In most cases, you would want to call this function immediately after calling **ImapSelectMailbox**. This will cause the client to request a list of message UIDs in the selected mailbox within the range that you specify. Mailboxes with a very large number of messages may cause the application to block for an extended period of time while the list is returned and processed.

To map all messages in the selected mailbox, set `nFirstMessageId = 1`, `nLastMessageId = (UINT)-1` and `dwMessageFlags = 0`.

If the message UID is being stored locally by the client to identify the message over multiple sessions, it must also store the mailbox UID. Only the combination of the mailbox name, mailbox UID and message UID can be used to uniquely identify a given message on the server. Although IMAP server implementations are encouraged to maintain persistent message UIDs, they are not required to do so. Message UIDs may change if the mailbox is recreated or its unique identifier (UIDVALIDITY) is reset.

In some cases, particularly with newly created or infrequently used mailboxes, the message sequence numbers may *coincidentally* match the UIDs assigned by the server. For example, the first message in a new mailbox might have both a message sequence number and UID of 1. However, this is not guaranteed, and applications should never assume that sequence numbers and UIDs are interchangeable. Sequence numbers are dynamic and reflect the current ordering of messages in the selected mailbox. They can change between sessions or when messages are added or deleted. UIDs, on the other hand, are intended to be persistent identifiers that remain associated with a specific message, even if its sequence number changes.

It is important to note that a message UID is not the same as the Message-ID header field found

within the message content. The UID is a unique numeric identifier assigned by the IMAP server to a message in a specific mailbox. It is used by the protocol to track messages even as their sequence numbers change due to mailbox activity (e.g.: new messages arriving or messages being deleted). In contrast, the Message-ID header is a string value generated by the sending email client when the message is created. It is part of the message headers and intended to be globally unique for email threading and deduplication purposes, but it has no direct relationship to the UID used by the server.

Example

This example demonstrates how to enumerate all messages in the currently selected mailbox and retrieve the mapping between their sequential message numbers and server-assigned UIDs. This is useful when your application needs to track messages persistently across sessions using UIDs, while still interacting with the API functions that require sequence numbers such as **ImapGetMessage**.

```
// Get some information about the currently selected mailbox
UINT nLastMessage = 0;
DWORD dwMailboxSize = 0;
INT nMessageCount = ImapGetMessageCountEx(hClient, &nLastMessage, &dwMailboxSize);

_tprintf(_T("There are %d messages in %s (last message is %u, mailbox size is %lu
bytes)\n"),
         nMessageCount, szMailbox, nLastMessage, dwMailboxSize);

if (nMessageCount < 1)
{
    // There are no messages in the current mailbox
    return;
}

// Allocate memory for the array of sequence numbers and UIDs
UINT *pSeqList = (UINT *)malloc(nMessageCount * sizeof(UINT));
if (pSeqList == NULL)
{
    // Allocation failed
    return;
}

UINT *pUidList = (UINT *)malloc(nMessageCount * sizeof(UINT));
if (pUidList == NULL)
{
    free(pSeqList); // Clean up previously allocated memory
    return;
}

// Populate the arrays with message sequence numbers and corresponding UIDs
INT nUidCount = ImapEnumMessageUids(
                    hClient,        // Handle to the client session
                    1,              // First message
                    (UINT)-1,       // Last message (all messages)
                    0,              // Any message flags
                    pSeqList,       // Array of sequential message IDs
                    pUidList,       // Array of unique message IDs
                    nMessageCount); // Maximum number of IDs in the arrays

if (nUidCount > 0 && nUidCount <= nMessageCount)
{
    // Display the mapping of message sequence numbers to UIDs
    for (INT nIndex = 0; nIndex < nUidCount; nIndex++)
```

```
    {
        _tprintf(_T("\tMessage %u was assigned UID %u\n"), pSeqList[nIndex],
pUidList[nIndex]);
    }
}
else
{
    // Enumeration failed or no matching messages
    DWORD dwError = ImapGetLastError();
    _tprintf(_T("Unable to enumerate message UIDs (error code: 0x%lx)\n"),
dwError);
}

// Free the memory allocated for our arrays
free(pSeqList);
free(pUidList);
```

Requirements

ImapEventProc Function

```
VOID CALLBACK ImapEventProc(
   HCLIENT hClient,
   UINT nEvent,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **ImapEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **ImapRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **ImapRegisterEvent** function. The **ImapEventProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapExamineMailbox Function

```
INT WINAPI ImapExamineMailbox(
   HCLIENT hClient,
   LPCTSTR lpszMailbox,
   LPIMAPMAILBOX lpMailboxInfo
);
```

The **ImapExamineMailbox** function selects the specified mailbox for read-only access.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string which specifies the new mailbox to be examined.

lpMailboxInfo

A pointer to an IMAPMAILBOX structure which contains information about the mailbox when the function returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapExamineMailbox** function is used to select a mailbox in read-only mode. Messages can be read, but they cannot be modified or deleted from the mailbox and new messages will not lose their status as new messages if they are accessed.

If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **ImapUnselectMailbox** function prior to examining the new mailbox.

If an application wishes to update the information returned in the IMAPMAILBOX structure for the current mailbox, simply call **ImapExamineMailbox** again with the same mailbox name.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-write mode, use the **ImapSelectMailbox** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapExpungeMailbox Function

```
INT WINAPI ImapExpungeMailbox(
   HCLIENT hClient,
   LPIMAPMAILBOX lpMailboxInfo
);
```

The **ImapExpungeMailbox** function removes all messages marked for deletion from the current mailbox.

Parameters

hClient

Handle to the client session.

lpMailboxInfo

A pointer to an IMAPMAILBOX structure which contains information about the mailbox when the function returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapExpungeMailbox** function causes all messages marked for deletion to be removed from the mailbox. Note that this can cause the mailbox's UID to change, and potentially invalidate the current message UIDs. It is recommended that applications use the information returned in the IMAPMAILBOX structure to update any internal state information stored on the local system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapFreezeEvents Function

```
INT WINAPI ImapFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **ImapFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four events of the same type occur, once event handling is resumed only one of those events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetCapability Function

```
INT WINAPI ImapGetCapability(
   HCLIENT hClient,
   LPTSTR lpszCapability,
   INT nMaxLength
);
```

The **ImapGetCapability** function returns a string which identifies the capabilities of the IMAP server.

Parameters

hClient

Handle to the client session.

lpszCapability

A null-terminated string buffer that will contain one or more tokens separated by spaces which identify the capabilities of the IMAP server.

nMaxLength

The maximum length of the capability string, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the capability string, not including the terminating null character. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

This function returns a string that contains one or more tokens separated by whitespace. Each token identifies a capability of the server. The following table lists some of the common capabilities:

Capability	Description
ACL	The RFC 2086 ACL extension
BINARY	The RFC 3516 binary content extension
CHILDREN	The RFC 3348 child mailbox extension
ID	The RFC 2971 ID extension
IDLE	The RFC 2177 IDLE extension
LOGINDISABLED	The RFC 2595 TLS/SSL extension
LOGINREFERRALS	The RFC 2221 login referrals extension
MAILBOXREFERRALS	The RFC 2193 mailbox referrals extension
MULTIAPPEND	The RFC 3501 MULTIAPPEND extension
NAMESPACE	The RFC 2342 namespace Extension
QUOTA	The RFC 2087 QUOTA extension
STARTTLS	The RFC 2595 TLS/SSL extension
UNSELECT	The RFC 3691 UNSELECT extension

Additional capabilities may be supported by your server. Note that experimental or custom capabilities

are always prefixed with the letter X. A list of standard IMAP capabilities is maintained by the Internet Assigned Numbers Authority (IANA) at www.iana.org.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapGetCurrentMailbox Function

```
INT WINAPI ImapGetCurrentMailbox(
    HCLIENT hClient,
    LPTSTR lpszMailbox,
    INT nMaxLength
);
```

The **ImapGetCurrentMailbox** function returns the name of the current mailbox that has been selected.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string buffer that will contain the current mailbox name. If the Unicode version of this function is called, the mailbox name will automatically be converted from modified UTF-7 encoding to Unicode. If the ANSI version of this function is called, the name will be returned using modified UTF-7 encoding. This parameter cannot be NULL and the buffer must be large enough to store the complete mailbox name.

nMaxLength

The maximum length of the mailbox string, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the current mailbox name, not including the terminating null character. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

It is recommended you use the Unicode version of this function, particularly if it is possible that mailbox names will contain Unicode characters or symbols. If the ANSI version of this function is called and a mailbox name contains Unicode characters, the name will be returned using a modified UTF-7 encoding format as defined by the IMAP4 standard. The mailbox name will not be returned as UTF-8 Unicode or as ANSI text converted to the current locale. If the Unicode version of this function is called, mailbox names will be automatically converted from modified UTF-7 to UTF-16 Unicode.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapGetDeletedMessages Function

```
INT WINAPI ImapGetDeletedMessages(
    HCLIENT hClient,
    UINT *lpnMessageIds,
    INT nMaxMessages
);
```

The **ImapGetDeletedMessages** function returns the message identifiers for those messages that have been marked for deletion in the current mailbox.

Parameters

hClient

Handle to the client session.

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages which have been marked for deletion in the current mailbox. This parameter may be NULL, in which case the function will return the number of deleted messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the ***lpnMessageIds*** array. If the ***lpnMessageIds*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of messages marked for deletion in the current mailbox. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The message identifiers returned by this function are only valid until the mailbox is expunged or another mailbox is selected.

To remove the deleted flag from a message, use the **ImapUndeleteMessage** function. To prevent all messages in the current mailbox from being expunged, use the **ImapReselectMailbox** function to reset the current mailbox state.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetErrorString Function

```
INT WINAPI ImapGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **ImapGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **ImapGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description should be returned. If this value is zero, then the description of the last error will be returned. If the last error code is zero, indicating no error, then this function will return zero.

lpszDescription

The buffer that will contain a description of the specified error code. It is recommended that this buffer be at least 128 characters in length. If a NULL pointer is specified, then no message will be returned but the function will return the length of the error string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapGetFirstMailbox Function

```
INT WINAPI ImapGetFirstMailbox(
   HCLIENT hClient,
   LPCTSTR lpszReference,
   LPCTSTR lpszWildcard,
   DWORD dwOptions,
   LPVOID lpvReserved,
   LPTSTR lpszMailbox,
   INT nMaxLength
   LPDWORD lpdwFlags
);
```

The **ImapGetFirstMailbox** function returns the name of the first matching mailbox.

Parameters

hClient

Handle to the client session.

lpszReference

A null-terminated string which specifies the reference name. An empty string or NULL pointer specifies that the default mailbox hierarchy for the current user is returned. If the reference name is provided, this must be the name of a mailbox or a level of the mailbox hierarchy which provides the context in which the mailbox name is interpreted.

lpszWildcard

A null-terminated string which specifies the mailbox name to match. The wildcard character "*" may be used to match any portion of the mailbox hierarchy, including the delimiter. The wildcard character "%" matches any portion of the mailbox name, but does not match the mailbox delimiter. An empty string or NULL pointer specifies that all mailboxes in the context of the *lpszReference* parameter should be returned.

dwOptions

Specifies one or more options which controls how mailboxes are returned by the function. The options are bit flags which may be combined using a bitwise operator. One or more of the following values may be used:

Value	Description
IMAP_LIST_DEFAULT	This option specifies that all regular, selectable mailboxes should be returned.
IMAP_LIST_SUBSCRIBED	This option specifies that only subscribed mailboxes should be returned.
IMAP_LIST_FOLDERS	This option specifies that non-selectable mailbox folders should also be returned.
IMAP_LIST_HIDDEN	This option specifies that hidden mailboxes should be returned.
IMAP_LIST_INFERIOR	This option specifies that inferior mailboxes should be returned if an explicit wildcard mask is not specified.

lpvReserved

A reserved parameter. This value should always be set to NULL.

lpszMailbox

A null-terminated string buffer which will contain the first matching mailbox. This parameter cannot be NULL. A minimum buffer size of at least 128 character is recommended. If the Unicode version of this function is called, the mailbox name will automatically be converted from modified UTF-7 encoding to Unicode. If the ANSI version of this function is called, the mailbox name will be returned using modified UTF-7 encoding.

nMaxLength

Specifies the maximum length of the string buffer. The maximum length of the buffer should be large enough to accommodate most path names on the IMAP server.

lpdwFlags

A pointer to an unsigned integer which will contain the mailbox flags for the first matching mailbox. This parameter may be NULL, in which case the mailbox flags are not returned. Otherwise, one or more of the following bit flags may be returned:

Value	Description
IMAP_FLAG_NOINFERIORS	The mailbox does not contain any sub-mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
IMAP_FLAG_NOSELECT	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not a mailbox file.
IMAP_FLAG_MARKED	The mailbox is marked as being of interest to a client. If this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
IMAP_FLAG_UNMARKED	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

Return Value

If the function succeeds, it returns the length of the mailbox name. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetFirstMailbox** function is used to begin enumerating the available mailboxes for the current user on the IMAP server. Subsequent mailbox names are returned by calling **ImapGetNextMailbox** until the function returns IMAP_ERROR with an error code of ST_ERROR_NO_MORE_MAILBOXES.

It is recommended you use the Unicode version of this function, particularly if it is possible that mailbox names will contain Unicode characters or symbols. If the ANSI version of this function is called and a mailbox name contains Unicode characters, the name will be returned using a modified UTF-7 encoding format as defined by the IMAP4 standard. The mailbox name will not be returned as UTF-8 Unicode or as ANSI text converted to the current locale. If the Unicode version of this function is

called, mailbox names will be automatically converted from modified UTF-7 to UTF-16 Unicode.

The function of the *lpszReference* and *lpszWildcard* parameters are implementation dependent and generally are tied to the underlying operating system. On a UNIX based system, it can be helpful to think of the reference name as the directory where mailbox folders are stored, and the mailbox name as the name to search for in that directory and any subdirectories, if applicable. If the reference name is an empty string or NULL pointer, this typically refers to the current user's home directory.

Generally speaking, a reference name should only be specified if you or the user of the application knows the directory structure on the IMAP server. Incorrectly using a reference name can have serious negative side-effects. For example, specifying a reference name of "/" on a UNIX based system could cause the IMAP server to return search every directory on the system for a matching mailbox name. Similarly, the IMAP server may be unable to distinguish between regular files in the user's home directory and mailboxes. For this reason, most IMAP clients require that the user specify the directory on the server where their mailboxes are stored. Typically this is subdirectory named "mail" or "Mail" under the user's home directory. For non-UNIX servers, the mailbox hierarchy may represented differently, including a flat hierarchy.

Hidden mailboxes are those mailboxes which use the UNIX convention of the name beginning with a period. Therefore, a mailbox named ".secrets" would not normally be returned by the **ImapGetFirstMailbox** and **ImapGetNextMailbox** functions. The IMAP_LIST_HIDDEN option causes all mailboxes to be returned.

The IMAP_LIST_INFERIOR option will return inferior mailboxes (mailboxes located in folders or subdirectories) if a wildcard mask is not specified. If a wildcard mask is specified, this option has no effect and only those mailboxes which match the wildcard will be returned.

Subscribed mailboxes are those which were specified using the **ImapSubscribeMailbox** function. Marked mailboxes are typically those which have some special importance to the user.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapGetHeaderValue Function

```
INT WINAPI ImapGetHeaderValue(
   HCLIENT hClient,
   UINT nMessageId,
   LPCTSTR lpszHeader,
   LPTSTR lpszValue,
   INT nMaxLength
);
```

The **ImapGetHeaderValue** function returns the value of a header field in the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszHeader

Pointer to a string which specifies the message header to retrieve. The colon should not be included in this string.

lpszValue

Pointer to a string buffer that will contain the value of the specified message header.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the header field value. If the header field is not present in the message, the function will return a value of zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetHeaderValue** function returns the value of header field from the specified message. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this function.

To return the value of a header field from a specific part of a multipart MIME message, use the **ImapGetHeaderValueEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapGetHeaderValueEx, ImapGetMessageHeaders, ImapGetMessageId, ImapGetMessageSender

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapGetHeaderValueEx Function

```
INT WINAPI ImapGetHeaderValueEx(
    HCLIENT hClient,
    UINT nMessageId,
    UINT nMessagePart,
    LPVOID lpvReserved,
    LPCTSTR lpszHeader,
    LPTSTR lpszValue,
    INT nMaxLength
);
```

The **ImapGetHeaderValueEx** function returns the value of a header field from the specified message part.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

nMessagePart

The message part that the header value will be be retrieved from. Message parts start with a value of one. A value of zero specifies that the RFC822 header field for the message will be used.

lpvReserved

A reserved parameter. This value should always be NULL.

lpszHeader

Pointer to a string which specifies the message header to retrieve. The colon should not be included in this string.

lpszValue

Pointer to a string buffer that will contain the value of the specified message header.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the header field value. If the header field is not present in the message, the function will return a value of zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetHeaderValueEx** function returns the value of a header field from the specified message part. This allows an application to be able to easily determine the value of a header such as the sender, or the subject of the message. Any header field, including non-standard extensions, may be returned by this function.

To determine if a message is a multipart MIME message, use the **ImapGetMessageParts** function. The return value specifies the number of parts in the message, with a value greater than one

indicating that it is a multipart message.

Note that unlike the SocketTools MIME API which considers the first message part to be zero, the IMAP protocol defines the first message part to be one.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapGetIdleThreadId Function

```
DWORD WINAPI ImapGetIdleThreadId(
    HCLIENT hClient
);
```

The **ImapGetIdleThreadId** function returns ID of the thread that is monitoring the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, it returns the ID of the thread that is checking for update notifications from the server. If there is no active thread monitoring the client session, the function will return zero.

Remarks

The worker thread that monitors the client connection in the background can terminate if an IMAP command is sent to the server, if the **ImapCancel** function is called or if the client disconnects from the server. The **ImapGetIdleThreadId** function enables the application to determine if this background thread is still active or not.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapIdle, ImapIdleProc

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapGetLastError Function

```
DWORD WINAPI ImapGetLastError();
```

Parameters

None.

Return Value

The return value is the calling thread's last error code value. Functions set this value by calling the **ImapSetLastError** function. The return value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

You should call the **ImapGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **ImapSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_CLIENT or IMAP_ERROR. Those functions which call **ImapSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapGetMailboxDelimiter Function

```
INT WINAPI ImapGetMailboxDelimiter(
    HCLIENT hClient,
    LPCTSTR lpszMailbox,
    LPTSTR lpszDelimiter,
    INT nMaxLength
);
```

The **ImapGetMailboxDelimiter** function returns the hierarchical path delimiter used for the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string which specifies the mailbox name. This parameter may be NULL or an empty string, in which case the default delimiter will be returned.

lpszDelimiter

A null-terminated string buffer that will contain the mailbox delimiter.

nMaxLength

The maximum length of the delimiter string, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the delimiter for the specified mailbox, not including the terminating null character. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

If the IMAP server supports multiple levels of mailboxes, then a special character or sequence of characters are used as delimiters between different levels of the mailbox hierarchy. On most systems, including most UNIX and Windows platforms, the delimiter is the forward slash "/" character.

It is possible that an IMAP server may only support a flat namespace, in which case this function will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapExamineMailbox, ImapSelectMailbox, ImapUnselectMailbox

ImapGetMailboxSize Function

```
DWORD WINAPI ImapGetMailboxSize(
    HCLIENT hClient,
    LPCTSTR lpszMailbox
);
```

The **ImapGetMailboxSize** function returns the size of the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string which specifies the mailbox name.

Return Value

If the function succeeds, it returns the size of the mailbox. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMailboxSize** function may require a significant amount of time to calculate the mailbox size if there are a large number of messages in the mailbox. If the specified mailbox is not currently selected, then the current mailbox is unselected, the new mailbox is selected and the size calculated, and then the original mailbox is re-selected. This will have the side-effect of causing any messages marked for deletion to be expunged from the mailbox.

Because it can potentially result in long delays, it is not recommended that an application calculate the mailbox size unless it is absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapCreateMailbox, ImapGetFirstMailbox, ImapGetNextMailbox, ImapRenameMailbox

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapGetMailboxStatus Function

```
INT WINAPI ImapGetMailboxStatus(
   HCLIENT hClient,
   LPCTSTR lpszMailbox,
   LPIMAPMAILBOXSTATUS lpMailboxStatus
);
```

The **ImapGetMailboxStatus** function returns status information about the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string that specifies the mailbox to return information about.

lpMailboxStatus

A pointer to an IMAPMAILBOXSTATUS structure which contains status information about the specified mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMailboxStatus** function enables an application to obtain status information about a mailbox without having to select another mailbox or open a second connection to the IMAP server to examine the mailbox. The information returned is a subset of the information returned when a mailbox is selected.

If you need to check the status of a mailbox which contains Unicode characters or symbols, it is recommended you use the Unicode version of this function. The mailbox name will automatically be converted to modified UTF-7 encoding as defined by the IMAP4 standard. The ANSI version of this function will only accept mailbox names using modified UTF-7 encoding or UTF-8 encoding.

Requesting information for a mailbox may be a slow operation, requiring the server to open the mailbox in read-only mode internally in order to obtain some of the status information. For this reason, this function should not be used to check for new messages; use the **ImapCheckMailbox** function instead.

Some IMAP servers may return an error if you attempt to obtain status information about the currently selected mailbox. The protocol standard states that clients should not use this method on the currently selected mailbox, and should instead use the information returned by the **ImapSelectMailbox** or **ImapExamineMailbox** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapCheckMailbox, ImapCreateMailbox, ImapExamineMailbox, ImapSelectMailbox

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapGetMailboxUid Function

```
DWORD WINAPI ImapGetMailboxUid(
   HCLIENT hClient,
   LPCTSTR lpszMailbox
);
```

The **ImapGetMailboxUid** function returns the unique identifier for the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string that specifies the mailbox name.

Return Value

If the function succeeds, it returns a non-zero value. If no unique identifier is assigned to the mailbox, the function will return zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMailboxUid** function returns an unsigned 32-bit value which uniquely identifies the mailbox and corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

An application can use the mailbox UID value in combination with the message UID in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update it's local copy of that mailbox.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapGetMessage Function

```
INT WINAPI ImapGetMessage(
   HCLIENT hClient,
   UINT nMessageId,
   UINT nMessagePart,
   LPVOID lpvMessage,
   LPDWORD lpdwLength,
   DWORD dwOptions
);
```

The **ImapGetMessage** function retrieves a message from the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

nMessagePart

The message part that will be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

lpvMessage

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvMessage*** parameter. If the ***lpvMessage*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_SECTION_DEFAULT	All headers and the complete body of the specified message or message part are to be retrieved. The client application is responsible for parsing the header block. If the message is a MIME multipart message and the complete message is returned, the application is responsible for parsing the individual message parts if necessary.
IMAP_SECTION_HEADER	All headers for the specified message or message part are to be retrieved. The client application is responsible for parsing the header block.
IMAP_SECTION_MIMEHEADER	The MIME headers for the specified message or message are to be retrieved. Only those header fields which are

	used in MIME messages, such as Content-Type will be returned to the client. This is typically useful when processing the header for a multipart message which contains file attachments. The client application is responsible for parsing the header block.
IMAP_SECTION_BODY	The body of the specified message or message part is to be retrieved. For a MIME formatted message, this may include data that is uuencoded or base64 encoded. The application is responsible for decoding this data.
IMAP_SECTION_PREVIEW	The message header or body is being previewed and should not be marked as read by the server. This prevents the message from having the IMAP_FLAG_SEEN flag from being automatically set when the message data is retrieved.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessage** function is used to retrieve a message from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the message. In this case, the *lpvMessage* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvMessage* parameter point to a global memory handle which will contain the message data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

This function will cause the current thread to block until the transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the IMAP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **ImapEnableEvents**, or by registering a callback function using the **ImapRegisterEvent** function.

To determine if a message is a multipart MIME message, use the **ImapGetMessageParts** function. The return value specifies the number of parts in the message, with a value greater than one indicating that it is a multipart message. Combining the IMAP_SECTION_HEADER and IMAP_SECTION_BODY options will only return the header and body for the specified message if the *nMessagePart* parameter is zero. Due to a limitation of the IMAP FETCH command, if a message part is specified then only the body of that message part will be returned.

Note that unlike the SocketTools MIME API which considers the first message part to be zero, the IMAP protocol defines the first message part to be one.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csmapv12.lib

ImapGetMessageCount Function

```
INT WINAPI ImapGetMessageCount(
    HCLIENT hClient
);
```

The **ImapGetMessageCount** function returns the number of messages that are available in the currently selected mailbox.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, it returns the number of messages in the currently selected mailbox. If no messages are available, this function will return zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageCount** function does not distinguish between messages that are marked for deletion and those which are not. This is because messages that are marked for deletion on an IMAP server can still be accessed until the mailbox is expunged or unselected. This differs from the POP3 protocol, where messages cannot be accessed once they have been marked for deletion.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapDeleteMessage, ImapGetHeaderValue, ImapGetMessage, ImapGetMessageCountEx, ImapGetMessageHeaders, ImapStoreMessage

ImapGetMessageCountEx Function

```
INT WINAPI ImapGetMessageCountEx(
   HCLIENT hClient,
   UINT *lpnLastMessage,
   DWORD *lpdwMailboxSize
);
```

The **ImapGetMessageCountEx** function returns the number of messages that are available in the currently selected mailbox, and optionally the size of the mailbox in bytes.

Parameters

hClient

Handle to the client session.

lpnLastMessage

Address of a variable that receives the number of the last valid message in the mailbox. If a NULL value is specified, this argument is ignored.

lpdwMailboxSize

Address of a variable that receives the current size of the mailbox. If a NULL value is specified, this argument is ignored.

Return Value

If the function succeeds, it returns the number of messages that are currently available. If no messages are available, this function will return zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageCountEx** function is provided for compatibility with the POP3 API. The *lpnLastMessage* parameter will always contain the same value returned by the function since there is no distinction between the message count and the last available message. This is because messages that are marked for deletion on an IMAP server can still be accessed until the mailbox is expunged or unselected. This differs from the POP3 protocol, where messages cannot be accessed once they have been marked for deletion.

If the *lpdwMailboxSize* parameter is specified, this function will call **ImapGetMailboxSize** to determine the size of the currently selected mailbox. Unlike the POP3 protocol, calculating the mailbox size may require a significant amount of time if there are a large number of messages in the mailbox. It is not recommended that an application request the mailbox size unless it is absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetMessageFlags Function

```
BOOL WINAPI ImapGetMessageFlags(
   HCLIENT hClient,
   UINT nMessageId,
   LPDWORD lpdwMessageFlags
);
```

The **ImapGetMessageFlags** function returns the message flags for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to obtain the message flags for. This value must be greater than zero. The first message in the mailbox is message number one.

lpdwMessageFlags

Pointer to an unsigned integer that will contain the message flags for the specified message. The value may be zero, or one or more of the following values:

Value	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the function succeeds, the return value is non-zero and the *lpdwMessageFlags* parameter contains the status flags for the specified message. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetMessageHeaders Function

```
INT WINAPI ImapGetMessageHeaders(
    HCLIENT hClient,
    UINT nMessageId,
    LPVOID lpvHeaders,
    LPDWORD lpdwLength
);
```

The **ImapGetMessageHeaders** function retrieves the headers for the specified message from the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

lpvHeaders

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvHeaders*** parameter. If the ***lpvHeaders*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessagHeaders** function is used to retrieve a message header block from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the ***lpvHeaders*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvHeaders*** parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the IMAP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **ImapEnableEvents**, or by registering a callback function using the **ImapRegisterEvent** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapGetMessageHeadersEx Function

```
INT WINAPI ImapGetMessageHeadersEx(
   HCLIENT hClient,
   UINT nMessageId,
   DWORD dwReserved,
   LPDWORD lpdwMessageUID,
   LPDWORD lpdwMessageFlags,
   LPVOID lpvHeaders,
   LPDWORD lpdwLength
);
```

The **ImapGetMessageHeadersEx** function retrieves the headers, unique ID and flags for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve from the server. This value must be greater than zero. The first message in the mailbox is message number one.

dwReserved

A reserved parameter, this value should always be zero.

lpdwMessageUID

A pointer to an unsigned integer which will contain the unique ID assigned to the message by the server when the function returns. This parameter may be NULL if this information is not required.

lpdwMessageFlags

A pointer to an unsigned integer which will contain the message flags when the function returns. This parameter may be NULL if this information is not required, otherwise the value may be zero or one or more of the following bit flags:

Value	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

lpvHeaders

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvHeaders*** parameter. If the ***lpvHeaders*** parameter

points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the message that was downloaded.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessagHeadersEx** function is used to retrieve a message header block from the server and copy it into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the *lpvHeaders* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the *lpvHeaders* parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur.

If the *lpdwMessageUID* and/or *lpdwMessageFlags* parameters are NULL, they will be ignored. Otherwise, the function will always initialize the values to zero and only sets them if the header block for the message can be retrieved.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the IMAP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **ImapEnableEvents**, or by registering a callback function using the **ImapRegisterEvent** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetMessageId Function

```
INT WINAPI ImapGetMessageId(
   HCLIENT hClient,
   UINT nMessageId,
   LPTSTR lpszMessageId,
   INT nMaxLength
);
```

The **ImapGetMessageId** function returns the message identifier string for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

lpszMessageId

Address of a string buffer to receive the message identifier. This should be at least 64 bytes in length.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the length of the unique identifier string. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageId** function returns the message identifier from the Message-ID header of the specified message. The returned value is a string which can be used to identify a specific message, regardless if the message is moved to a different mailbox.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapGetMessageParts Function

```
INT WINAPI ImapGetMessageParts(
    HCLIENT hClient,
    UINT nMessageId
);
```

The **ImapGetMessageParts** function returns the number of parts in a MIME multipart message on the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve the part count for. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is the number of parts in the specified message. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageParts** function can be used to determine if a message on the server contains multiple parts. A multipart MIME message typically contains file attachments or multiple representations of the message, such as a version of the message in plain text and another using HTML markup.

If the function returns a value of one, then the message does not contain multiple parts and is a standard RFC822 formatted message. A value greater than one indicates that the message does have multiple parts. The **ImapGetMessageEx** function may be used to retrieve the data for a specific part of the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetMessageSender Function

```
INT WINAPI ImapGetMessageSender(
   HCLIENT hClient,
   UINT nMessageId,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **ImapGetMessageSender** function returns the sender's address for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve header value from. This value must be greater than zero. The first message in the mailbox is message number one.

lpszAddress

Pointer to a string buffer that will contain the address of the message sender.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, it returns the length of the address. If the sender cannot be determined, the function will return a value of zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageSender** function returns the email address specified in the Return-Path header field. This allows an application to be able to easily determine the sender, without parsing the header or downloading the contents of the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapGetMessageSize Function

```
DWORD WINAPI ImapGetMessageSize(
    HCLIENT hClient,
    UINT nMessageId
);
```

The **ImapGetMessageSize** function returns the size of the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve size of. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is the size of the specified message in bytes. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapGetMessageUid Function

```
DWORD WINAPI ImapGetMessageUid(
    HCLIENT hClient,
    UINT nMessageId
);
```

The **ImapGetMessageUid** function returns the unique identifier (UID) for the specified message in the current mailbox.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to obtain the unique identifier for. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, it returns a non-zero value. If no unique identifier is assigned to the message, the function will return zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetMessageUid** function returns an unsigned integer value which specifies a unique identifier for this message. The actual value is determined by the server and should be considered opaque.

An application can use the message UID value in combination with the mailbox UID in order to uniquely identify a message on the server. However, the application must take into consideration that the IMAP server can reassign new message UIDs when the mailbox is modified. If the mailbox and message UIDs are being stored on the local system to track what messages have been retrieved from the server, the application must check the UID of the mailbox whenever it is selected. If the mailbox UID has changed, this means that the UIDs for the messages in that mailbox may have changed. The client should resynchronize with the server, and update it's local copy of that mailbox.

Although the IMAP4 protocol supports returning the UID assigned to a sequential message ID, there is no corresponding capability which does the reverse. If you wish to map a message UID back to the sequential message number in the mailbox, you can use the **ImapEnumMessageUids** function which will populate two arrays: one which contains the sequential message ID and a corresponding array which contains its UID.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetNewMessages Function

```
INT WINAPI ImapGetNewMessages(
   HCLIENT hClient,
   UINT *lpnMessageIds,
   INT nMaxMessages
);
```

The **ImapGetNewMessages** function returns the message identifiers for those messages that have recently been added to the mailbox and have not been read.

Parameters

hClient

Handle to the client session.

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages that have recently been added to the mailbox and have not been read. This parameter may be NULL, in which case the function will return the number of new messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the ***lpnMessageIds*** array. If the ***lpnMessageIds*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of new messages in the current mailbox. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The message identifiers returned by this function are only valid until the mailbox is expunged or another mailbox is selected. Once a message has been read using **ImapGetMessage** or **ImapStoreMessage**, it is no longer considered to be a new message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapGetNextMailbox Function

```
INT WINAPI ImapGetNextMailbox(
   HCLIENT hClient,
   LPTSTR lpszMailbox,
   INT nMaxLength
   LPDWORD lpdwFlags
);
```

The **ImapGetNextMailbox** function returns the name of the next matching mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string buffer which will contain the next matching mailbox. This parameter cannot be NULL. A minimum buffer size of at least 128 character is recommended. If the Unicode version of this function is called, the mailbox name will automatically be converted from modified UTF-7 encoding to Unicode. If the ANSI version of this function is called, the mailbox name will be returned using modified UTF-7 encoding.

nMaxLength

Specifies the maximum length of the string buffer. The maximum length of the buffer should be large enough to accommodate most path names on the IMAP server.

lpdwFlags

A pointer to an unsigned integer which will contain the mailbox flags for the next matching mailbox. This parameter may be NULL, in which case the mailbox flags are not returned. Otherwise, one or more of the following bit flags may be returned:

Value	Description
IMAP_FLAG_NOINFERIORS	The mailbox does not contain any sub-mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
IMAP_FLAG_NOSELECT	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not a mailbox file.
IMAP_FLAG_MARKED	The mailbox is marked as being of interest to a client. If this flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
IMAP_FLAG_UNMARKED	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

Return Value

If the function succeeds, it returns the length of the mailbox name. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetNextMailbox** function returns the next matching mailbox name. When the last mailbox has been returned, the next call to this function will result in an error, with the last error code set to ST_ERROR_NO_MORE_MAILBOXES.

It is recommended you use the Unicode version of this function, particularly if it is possible that mailbox names will contain Unicode characters or symbols. If the ANSI version of this function is called and a mailbox name contains Unicode characters, the name will be returned using a modified UTF-7 encoding format as defined by the IMAP4 standard. The mailbox name will not be returned as UTF-8 Unicode or as ANSI text converted to the current locale. If the Unicode version of this function is called, mailbox names will be automatically converted from modified UTF-7 to UTF-16 Unicode.

Subscribed mailboxes are those which were specified using the **ImapSubscribeMailbox** function. Marked mailboxes are typically those which have some special importance to the user.

For more information about enumerating the available mailboxes on the IMAP server, refer to the **ImapGetFirstMailbox** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapGetResultCode Function

```
INT WINAPI ImapGetResultCode(
    HCLIENT hClient
);
```

The **ImapGetResultCode** function reads the result code returned by the server in response to a command. The result code is an integer value, and indicates if the operation succeeded or failed.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, it returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The following result codes may be returned by the IMAP server:

Value	Description
IMAP_RESULT_UNKNOWN	An unknown result code was returned by the server.
IMAP_RESULT_OK	The previous command completed successfully. The result string contains information about the results of the command.
IMAP_RESULT_NO	The previous command could not be completed. The result string contains information about why the command failed.
IMAP_RESULT_BAD	The previous command could not be completed, the command may be invalid or not supported on the server. The result string contains information about why the command failed.
IMAP_RESULT_CONTINUE	The command has executed and is waiting for additional data from the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapCommand, ImapGetResultString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapGetResultString Function

```
INT WINAPI ImapGetResultString(
    HCLIENT hClient,
    LPTSTR lpszResult,
    INT nMaxLength
);
```

The **ImapGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

The buffer that will contain the result string returned by the server.

nMaxLength

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **ImapGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetSecurityInformation Function

```
BOOL WINAPI ImapGetSecurityInformation(
   HCLIENT hClient,
   LPSECURITYINFO lpSecurityInfo
);
```

The **ImapGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Notifies the user if the connection is secure or not
SECURITYINFO securityInfo;

securityInfo.dwSize = sizeof(SECURITYINFO);
if (ImapGetSecurityInformation(hClient, &securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
```

```
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapGetStatus Function

```
INT WINAPI ImapGetStatus(
   HCLIENT hClient
);
```

The **ImapGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
IMAP_STATUS_IDLE	The client is current idle and not sending or receiving data.
IMAP_STATUS_CONNECT	The client is establishing a connection with the server.
IMAP_STATUS_READ	The client is reading data from the server.
IMAP_STATUS_WRITE	The client is writing data to the server.
IMAP_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetTimeout Function

```
INT WINAPI ImapGetTimeout(
   HCLIENT hClient
);
```

The **ImapGetTimeout** function returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetTransferStatus Function

```
INT WINAPI ImapGetTransferStatus(
   HCLIENT hClient,
   LPIMAPTRANSFERSTATUS lpStatus
);
```

The **ImapGetTransferStatus** function returns information about the current file transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an IMAPTRANSFERSTATUS structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapGetTransferStatus** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapGetUnseenMessages Function

```
INT WINAPI ImapGetUnseenMessages(
   HCLIENT hClient,
   UINT *lpnMessageIds,
   INT nMaxMessages
);
```

The **ImapGetUnseenMessages** function returns the message identifiers for those messages that have not been read.

Parameters

hClient

Handle to the client session.

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages that have not been read. This parameter may be NULL, in which case the function will return the number of unseen messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the ***lpnMessageIds*** array. If the ***lpnMessageIds*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of unseen messages in the current mailbox. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The message identifiers returned by this function are only valid until the mailbox is expunged or another mailbox is selected. Once a message has been read using **ImapGetMessage** or **ImapStoreMessage**, it is no longer considered to be an unseen message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapIdle Function

```
INT WINAPI ImapIdle(
   HCLIENT hClient,
   UINT nTimeout,
   DWORD dwOptions,
   IMAPIDLEPROC lpfnIdleProc,
   DWORD_PTR dwParam
);
```

The **ImapIdle** function enables mailbox status monitoring for the client session, allowing the client to receive notifications from the server whenever a new message arrives or a message is expunged from the currently selected mailbox. This is typically used as an alternative to the client periodically polling the server for status information.

Parameters

hClient

Handle to the client session.

nTimeout

Specifies the timeout period in seconds to wait for a notification from the server. This parameter is only used when the IMAP_IDLE_WAIT option has been specified.

dwOptions

Specifies the options which should be used when enabling idle monitoring. The following options are supported:

Value	Description
IMAP_IDLE_NOWAIT	The function should return immediately after idle processing has been enabled. When this option is used, the application may continue to perform other functions while the client session is monitored for status updates sent by the server. The client will continue to monitor status changes until an IMAP command issued or the client disconnects from the server.
IMAP_IDLE_WAIT	The function should wait until the server sends a status update, or until the timeout period is reached. The client will stop monitoring status changes when the function returns. If this option is used in a single-threaded application, normal message processing can be impeded, causing the application to appear non-responsive until the timeout period is reached. It is strongly recommended that single-threaded applications with a user interface specify the IMAP_IDLE_NOWAIT option instead.

lpfnIdleProc

A pointer to an IMAPIDLEPROC callback function that will be invoked whenever the server sends an update notification to the client. This parameter must specify a valid function address and cannot be a NULL pointer.

dwParam

A user-defined value that is passed back to the caller whenever the callback function is invoked. This can be used to provide additional state information to the client. If it is not needed, the caller should

use a value of zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

Many IMAP servers support the ability to asynchronously send status updates to the client, rather than have the client periodically poll the server. The client enables this feature by calling **ImapIdle** and providing the address of a callback function that will be invoked whenever the server sends an update notification to the client. Typically these updates inform the client that a new message has arrived or that a message has been expunged from the mailbox.

The **ImapIdle** function can operate in two modes, based on the options specified by the caller. If the option IMAP_IDLE_NOWAIT is specified, the function begins monitoring the client session and returns control immediately to the caller. If the server sends a update notification, the callback function will be invoked with information about the status change. If the option IMAP_IDLE_WAIT is specified, the function will block waiting for the server to send a notification message to the client. The function will return when either a message is received or the timeout period is exceeded.

Sending an IMAP command to the server will cause the client to stop monitoring the session for status changes. To explicitly stop monitoring the session, use the **ImapCancel** function. To determine if the current client session is being monitored, use the **ImapGetIdleThreadId** function. A non-zero return value indicates that the client session is idle and being monitored.

This function works by sending the IDLE command to the server and starting a worker thread which monitors the connection and looks for untagged responses issued by the server. Callbacks will be invoked for EXISTS, EXPUNGE and RECENT messages. Note that some servers may periodically send untagged OK messages to the client, indicating that the connection is still active; these messages are explicitly ignored. Because the monitoring is performed in a different thread, the callback function is invoked in the context of that thread. Client event notifications are disabled while inside the callback function, and the **ImapIdle** function cannot be used to restart monitoring from within a callback function.

Applications should not perform any operation that takes a significant amount of time or updates the user interface from within the callback function. Instead, use flags or send application defined messages to indicate a change in state. For example, if the server sends a notification that a new email message has arrived, the application should not attempt to read the new message and update the user interface from within the callback function. Instead, it could use the **PostMessage** function to send an application-defined message to the UI thread indicating the change in state. The application would have a message handler for that Windows message and update the user interface, indicating that a new message has arrived.

An application should never make an assumption about how a particular server may send update notifications to the client. Servers can be configured to use different intervals at which notifications are sent. For example, a server may send new message notifications immediately, but may periodically notify the client when a message has been expunged. Alternatively, a server may only send notifications at fixed intervals, in which case the client would not be notified of any new messages until the interval period is reached. It is not possible for a client to know what a particular server's update interval is. Applications that require that degree of control should not use **ImapIdle** and should poll the server instead.

Example

```
// Begin monitoring the client session for status changes; when a new
// message arrives or a message is expunged, the UpdateHandler callback
// function will be invoked.
BOOL MonitorUpdates(HWND hwndNotify)
{
    INT nResult;

    nResult = ImapIdle(hClient, 0, IMAP_IDLE_NOWAIT, UpdateHandler, hwndNotify);

    if (nResult == IMAP_ERROR)
    {
        ShowError(ImapGetLastError());
        return FALSE;
    }

    return TRUE;
}

// This function is called whenever the server notifies the client
// that a new message has arrived or a message has been expunged from
// the current mailbox
#define WM_APP_NEWMESSAGE (WM_APP+1)
#define WM_APP_EXPUNGED   (WM_APP+2)

VOID CALLBACK UpdateHandler(HCLIENT hClient, UINT nUpdateId, UINT nMessageId,
DWORD_PTR dwParam)
{
    switch (nUpdateId)
    {
    case IMAP_UPDATE_MESSAGE:
        {
            // Send a message indicating that a new message has arrived
            PostMessage((HWND)dwParam, WM_APP_NEWMESSAGE, nMessageId, 0);
        }
        break;

    case IMAP_UPDATE_EXPUNGE:
        {
            // Send a message indicating that a message has been expunged
            PostMessage((HWND)dwParam, WM_APP_EXPUNGED, nMessageId, 0);
        }
        break;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapIdleProc Function

```
VOID CALLBACK ImapIdleProc(
   HCLIENT hClient,
   UINT nUpdateId,
   UINT nMessageId,
   DWORD_PTR dwParam
);
```

The **ImapIdleProc** function is an application-defined callback function that is invoked whenever the server sends a status update to the client. For more information about status monitoring, refer to the **ImapIdle** function.

Parameters

hClient

Handle to the client session.

nUpdateId

An unsigned integer which specifies the type of update notification that has been sent by the server. It may be one of the following values:

Value	Description
IMAP_UPDATE_UNKNOWN	The server has sent an unrecognized notification message. The value of the ***nMessageId*** argument is undefined for this type of notification. This does not necessarily reflect an error condition, as some servers may send additional notification messages beyond the standard EXISTS, EXPUNGE and RECENT messages. Most applications should ignore this type of notification.
IMAP_UPDATE_MESSAGE	The server has sent notification message to the client indicating that a new message has arrived. The ***nMessageId*** argument will contain the message number for the new message. Typically this update notification occurs shortly after the new message has been stored in the current mailbox.
IMAP_UPDATE_EXPUNGE	The server has sent a notification message to the client indicating that a message has been removed from the current mailbox. The ***nMessageId*** argument will contain the message number for the message that has been removed. It is recommended that the application re-examine the mailbox when this notification is received. Typically this notification is only sent periodically by the server, and may not be sent immediately after a message has been expunged from the mailbox.
IMAP_UPDATE_MAILBOX	The server has sent notification message to the client indicating that the state of the mailbox has changed. The ***nMessageId*** argument is not used with this notification. This message is sent periodically by the server and may not be sent immediately after a new message arrives or a message is flagged as unread. It is recommended that the application re-

	examine the mailbox when this notification is received.

nMessageId

An unsigned integer which specifies the message number associated with the status change. Note that this argument is not used with the IMAP_UPDATE_MAILBOX notification and will contain a value of zero.

dwParam

A user-defined integer value which was specified when the **ImapIdle** function was called.

Return Value

None.

Remarks

An application must enable this callback function by passing its address to the **ImapIdle** function. The **ImapIdleProc** function is a placeholder for the application-defined function name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapInitialize Function

```
BOOL WINAPI ImapInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **ImapInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **ImapInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **ImapUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **ImapInitialize** or **ImapUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapIsBlocking Function

```
BOOL WINAPI ImapIsBlocking(
   HCLIENT hClient
);
```

The **ImapIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **ImapIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action such as warning the user that they must wait for the operation to complete.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapCancel, ImapIsConnected, ImapIsReadable, ImapIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapIsConnected Function

```
BOOL WINAPI ImapIsConnected(
    HCLIENT hClient
);
```

The **ImapIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapIsBlocking, ImapIsReadable, ImapIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapIsReadable Function

```
BOOL WINAPI ImapIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **ImapIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapGetStatus, ImapIsBlocking, ImapIsConnected, ImapIsWritable, ImapRead

ImapIsWritable Function

```
BOOL WINAPI ImapIsWritable(
   HCLIENT hClient,
   INT nTimeout
);
```

The **ImapIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapLogin Function

```
INT WINAPI ImapLogin(
   HCLIENT hClient,
   UINT nAuthType,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

The **ImapLogin** function authenticates the specified user in on the server. This function must be called after the connection has been established, and before attempting to retrieve messages or perform any other function on the server.

Parameters

hClient

Handle to the client session.

nAuthType

Identifies the type of authentication that should be used when the client logs in to the mail server. The following authentication methods are supported:

Value	Description
IMAP_AUTH_LOGIN	Standard cleartext username and password is sent to the server. This authentication method is supported by all servers. Note that some servers may only support LOGIN authentication if a secure connection has been established.
IMAP_AUTH_PLAIN	Login using the PLAIN authentication mechanism as defined in RFC 4959. This authentication method is supported by most servers, although some may require that client establish a secure connection.
IMAP_AUTH_XOAUTH2	This authentication type will use the XOAUTH2 method to authenticate the client session. This authentication method does not require the user password, instead the *lpszPassword* parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.
IMAP_AUTH_BEARER	This authentication type will use the OAUTHBEARER method to authenticate the client session as defined in RFC 7628. This authentication method does not require the user password, instead the *lpszPassword* parameter must specify the OAuth 2.0 bearer token issued by the service provider. The application must provide a valid access token which has not expired, or this function will fail.
IMAP_AUTH_ANONYMOUS	Login using the anonymous Simple Authentication and Security Layer (SASL) mechanism as defined in RFC 4505. If this authentication method is specified, the *lpszUserName* parameter should specify a name or email address acceptable to the mail server. The *lpszPassword* parameter is

	ignored and may be NULL.

lpszUserName

A null-terminated string which specifies the user name to be used to authenticate the current client session.

lpszPassword

A null-terminated string which specifies the password to be used when authenticating the current client session. If you are using the IMAP_AUTH_XOAUTH2 or IMAP_AUTH_BEARER authentication methods, this parameter is not a password, instead it specifies the OAuth 2.0 bearer token provided by the mail service.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

In some cases, the user may be pre-authenticated by the server. In this case, the function will fail with the last error set to ST_ERROR_ALREADY_AUTHENTICATED. If a particular authentication method is not supported by the server, the last error will be set to ST_ERROR_INVALID_AUTHENTICATION_TYPE. For compatibility with the greatest number of servers, it is recommended that you use IMAP_AUTH_LOGIN as the authentication method.

You should only use an OAuth 2.0 authentication method if you understand the process of how to request the access token. Obtaining an access token requires registering your application with the mail service provider (e.g.: Microsoft or Google), getting a unique client ID associated with your application and then requesting the access token using the appropriate scope for the service. Obtaining the initial token will typically involve interactive confirmation on the part of the user, requiring they grant permission to your application to access their mail account.

The IMAP_AUTH_XOAUTH2 and IMAP_AUTH_BEARER authentication methods are similar, but they are not interchangeable. Both use an OAuth 2.0 bearer token to authenticate the client session, but they differ in how the token is presented to the server. It is currently preferable to use the XOAUTH2 method because it is more widely available and some service providers do not yet support the OAUTHBEARER method.

Your application should not store an OAuth 2.0 bearer token for later use. They have a relatively short lifespan, typically about an hour, and are designed to be used with that session. You should specify offline access as part of the OAuth 2.0 scope if necessary and store the refresh token provided by the service. The refresh token has a much longer validity period and can be used to obtain a new bearer token when needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapOpenMessage Function

```
INT WINAPI ImapOpenMessage(
   HCLIENT hClient,
   UINT nMessageId,
   DWORD dwReserved
);
```

The **ImapOpenMessage** function opens the specified message on the server.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapOpenMessage** function uses the FETCH command to access the specified message on the server. The client can then use the **ImapRead** function to read the contents of the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapOpenMessageEx Function

```
INT WINAPI ImapOpenMessageEx(
   HCLIENT hClient,
   UINT nMessageId,
   UINT nMessagePart,
   DWORD dwOffset,
   LPDWORD lpdwLength,
   DWORD dwOptions
);
```

The **ImapOpenMessageEx** function opens a message or a specific part of a multipart message in the current mailbox. The message data may also be limited a specific byte offset and length, which can be useful for previewing the contents.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

nMessagePart

The message part that will be retrieved. A value of zero specifies that the complete message should be returned. If the message is a multipart MIME message, message parts start with a value of one.

dwOffset

The byte offset into the message. This parameter can be used in conjunction with the ***lpdwLength*** parameter to return a specific part of a message. A value of zero specifies the beginning of the message.

lpdwLength

A pointer to an unsigned integer value which should be initialized to the maximum number of bytes to be read, and will contain the size of the message when the function returns. To specify the entire message, from the offset specified by the ***dwOffset*** parameter to the end of the message, initialize the ***lpdwLength*** parameter to a value of -1. This parameter may be NULL if the message size is not needed.

dwOptions

The low order word of this parameter specifies how the message data will be returned. It may be one of the following values:

Value	Description
IMAP_SECTION_DEFAULT	All headers and the complete body of the specified message or message part are to be retrieved. The client application is responsible for parsing the header block. If the message is a MIME multipart message and the complete message is returned, the application is responsible for parsing the individual message parts if necessary.

IMAP_SECTION_HEADER	All headers for the specified message or message part are to be retrieved. The client application is responsible for parsing the header block.
IMAP_SECTION_MIMEHEADER	The MIME headers for the specified message or message are to be retrieved. Only those header fields which are used in MIME messages, such as Content-Type will be returned to the client. This is typically useful when processing the header for a multipart message which contains file attachments. The client application is responsible for parsing the header block.
IMAP_SECTION_BODY	The body of the specified message or message part is to be retrieved. For a MIME formatted message, this may include data that is uuencoded or base64 encoded. The application is responsible for decoding this data.
IMAP_SECTION_PREVIEW	The message header or body is being previewed and should not be marked as read by the server. This prevents the message from having the IMAP_FLAG_SEEN flag from being automatically set when the message data is retrieved.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapOpenMessageEx** function uses the FETCH command to access the specified message on the server. The client can then use the **ImapRead** function to read the contents of the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

);
```

The **ImapRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that there is no more data available to be read. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

When **ImapRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapGetMessage, ImapGetMessageHeaders, ImapIsBlocking

ImapRegisterEvent Function

```
INT WINAPI ImapRegisterEvent(
   HCLIENT hClient,
   UINT nEvent,
   IMAPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **ImapRegisterEvent** function registers a callback function for the specified event.

Parameters

hClient

Handle to the client session.

nEvent

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
IMAP_EVENT_CONNECT	The connection to the server has completed.
IMAP_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
IMAP_EVENT_READ	Data is available to read by the client. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the calling process is in asynchronous mode.
IMAP_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
IMAP_EVENT_TIMEOUT	The client has timed out while waiting for a response from the server. Note that under some circumstances this event can be generated for a non-blocking connection, such as when the client is establishing a secure connection.
IMAP_EVENT_CANCEL	The client has canceled the current operation.
IMAP_EVENT_COMMAND	The client has processed a command that was sent to the server. The result code and result string can be used to determine if the response to the command.
IMAP_EVENT_PROGRESS	This event notification is sent periodically during lengthy blocking operations, such as retrieving a complete message from the server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **ImapEventProc** callback

function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapRegisterEvent** function associates a callback function with a specific event. The event handler is an **ImapEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a message is being retrieved. The IMAP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one IMAP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapRenameMailbox Function

```
INT WINAPI ImapRenameMailbox(
   HCLIENT hClient,
   LPCTSTR lpszOldMailbox,
   LPCTSTR lpszNewMailbox
);
```

The **ImapRenameMailbox** function renames an existing mailbox.

Parameters

hClient

Handle to the client session.

lpszOldMailbox

A null-terminated string which specifies the mailbox to be renamed.

lpszNewMailbox

A null-terminated string which specifies the new mailbox name.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapRenameMailbox** function renames an existing mailbox on the server. The new mailbox name cannot exist on the server, or the function will fail.

If the existing mailbox name contains inferior hierarchical names (mailboxes under the specified mailbox) then those mailboxes will also be renamed. For example, if the mailbox "Mail/Pictures" contains two mailboxes, "Personal" and "Work" and it is renamed to "Mail/Images" then the two mailboxes under it would be automatically renamed to "Mail/Images/Personal" and "Mail/Images/Work".

If the mailbox being renamed is the currently selected mailbox, the current mailbox will be unselected and any messages marked for deletion will be expunged. The new mailbox name will then automatically be re-selected. To prevent deleted messages from being removed from the mailbox prior to being renamed, use the **ImapUnselectMailbox** function to unselect the current mailbox before calling **ImapRenameMailbox**. Note that if the rename operation fails, the client may be left in an unselected state.

It is permitted to rename the special mailbox INBOX. In this case, the messages will be moved from the INBOX mailbox to the new mailbox. If the INBOX mailbox is currently selected, the new mailbox will not automatically be selected. INBOX will remain the selected mailbox.

If you need to delete a mailbox which contains Unicode characters or symbols, it is recommended you always use the Unicode version of this function. The mailbox name will automatically be converted to modified UTF-7 encoding as defined by the IMAP4 standard. The ANSI version of this function will accept mailbox names using either modified UTF-7 encoding or UTF-8 encoding.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapCreateMailbox, ImapDeleteMailbox, ImapGetFirstMailbox, ImapGetNextMailbox

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ImapReselectMailbox Function

```
BOOL WINAPI ImapReselectMailbox(
   HCLIENT hClient,
   LPIMAPMAILBOX lpMailboxInfo
);
```

The **ImapReselectMailbox** function reselects the current mailbox and returns updated information about the status of the mailbox.

Parameters

hClient

Handle to the client session.

lpMailboxInfo

A pointer to an IMAPMAILBOX structure which contains updated information about the mailbox when the function returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapReselectMailbox** function forces the current mailbox to be reselected and returns updated information about the status of the mailbox. Deleted messages are not expunged from the mailbox and remain marked for deletion.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapExamineMailbox, ImapSelectMailbox, ImapUnselectMailbox

ImapSearchMailbox Function

```
LONG WINAPI ImapSearchMailbox(
   HCLIENT hClient,
   LPCTSTR lpszCriteria,
   LPCTSTR lpszCharacterSet,
   DWORD dwReserved,
   UINT *lpnMessageIds,
   LONG nMaxMessages
);
```

The **ImapSearchMailbox** function searches the current mailbox for messages that match the specified criteria, returning matching message identifiers.

Parameters

hClient

Handle to the client session.

lpszCriteria

A null-terminated string which specifies the search criteria.

lpszCharacterSet

A null-terminated string which specifies the character set to use when searching the mailbox. If this parameter is NULL or an empty string, the default UTF-8 character set will be used.

dwReserved

A reserved parameter which should be set to the value 0.

lpnMessageIds

A pointer to an array of unsigned integers that will contain the message identifiers of those messages which match the search criteria in the current mailbox. This parameter may be NULL, in which case the function will return the number of matching messages but will not return their identifiers.

nMaxMessages

The maximum number of message identifiers that may be stored in the ***lpnMessageIds*** array. If the ***lpnMessageIds*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of messages that meet the search criteria in the current mailbox. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapSearchMailbox** function is used to search a mailbox for messages which match a given criteria and return a list of the matching message identifiers. The search criteria is composed of one or more search keywords and and optional value to match against. String searches are not case sensitive and partial matches in the message are returned.

The following search keywords are recognized:

Keyword	Description
ANSWERED	Match those messages which have the IMAP_FLAG_ANSWERED flag set.

BCC *address*	Match those messages which contain the specified address in the BCC header field.
BEFORE *date*	Match those messages which were added to the mailbox prior to the specified date.
BODY *string*	Match those messages where the body contains the specified string.
CC *address*	Match those messages which contain the specified address in the CC header field.
DELETED	Match those messages which have the IMAP_FLAG_DELETED flag set.
DRAFT	Match those messages which have the IMAP_FLAG_DRAFT flag set.
FLAGGED	Match those messages which have the IMAP_FLAG_URGENT flag set.
FROM *address*	Match those messages which contain the specified address in the FROM header field.
HEADER *field string*	Match those messages which contain the string in the specified header field. If no string is specified, then all messages which contain the header will be matched.
LARGER *size*	Match those messages which are larger than the specified size in bytes.
NEW	Match those messages which have the IMAP_FLAG_RECENT flag set, but not the IMAP_FLAG_SEEN flag.
OLD	Match those messages which do not have the IMAP_FLAG_RECENT flag set.
ON *date*	Match those messages which were added on the specified date.
RECENT	Match those messages which have the IMAP_FLAG_RECENT flag set.
SEEN	Match those messages which have the IMAP_FLAG_SEEN flag set.
SENTBEFORE *date*	Match those messages whose Date header value is earlier than the specified date.
SENTON *date*	Match those messages whose Date header value is the same as the specified date.
SENTSINCE *date*	Match those messages whose Date header value is later than the specified date.
SINCE *date*	Match those messages added to the mailbox after the specified date.
SMALLER *size*	Match those messages which are smaller than the specified size in bytes.
SUBJECT *string*	Match those messages whose Subject header contains the specified string.
TEXT *string*	Match those messages whose headers or body contains the specified string.
TO *address*	Match those messages which contain the specified address in the TO header field.
UID *sequence*	Match those messages with unique identifiers in the sequence set.
UNANSWERED	Match those messages which do not have the IMAP_FLAG_ANSWERED

	flag set.
UNDELETED	Match those messages which do not have the IMAP_FLAG_DELETED flag set.
UNDRAFT	Match those messages which do not have the IMAP_FLAG_DRAFT flag set.
UNFLAGGED	Match those messages which do not have the IMAP_FLAG_URGENT flag set.
UNSEEN	Match those messages which do not have the IMAP_FLAG_SEEN flag set.

In addition to the listed keywords, the keyword NOT may prefix a keyword to return those messages which do not match the search criteria. For example, "NOT TO user@domain.com" would return those messages which were not addressed to user@domain.com.

If multiple search keywords are specified, the result is the intersection of all those messages which meet the search criteria. For example, a search criteria of "DELETED SINCE 1-Jan-2003" would return all those messages which are marked for deletion and were added to the mailbox after 1 January 2003.

Those search keywords which expect dates must be specified in format ***dd-mmm-yyyy*** where the month is the three letter abbreviation for the month name. Note that the internal date the message was added to the mailbox is not the same as the value of the Date header field in the message.

The UID keyword expects a one or more unique message identifiers. These values may provided as comma separated list, or a range delimited by a colon. For example, "UID 23000:24000" would return all those messages who have UIDs ranging from 23000 through to 24000.

The message identifiers returned by this function are only valid until the mailbox is expunged or another mailbox is selected.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapSelectMailbox Function

```
INT WINAPI ImapSelectMailbox(
   HCLIENT hClient,
   LPCTSTR lpszMailbox,
   LPIMAPMAILBOX lpMailboxInfo
);
```

The **ImapSelectMailbox** function selects the specified mailbox for read-write access.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string which specifies the new mailbox to be selected. If this parameter is NULL or an empty string, the default INBOX mailbox will be selected.

lpMailboxInfo

A pointer to an IMAPMAILBOX structure which contains information about the mailbox when the function returns. This parameter may be NULL if the caller does not require any information about the mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapSelectMailbox** function is used to select a mailbox in read-write mode. If the client has a different mailbox currently selected, that mailbox will be closed and any messages marked for deletion will be expunged. To prevent deleted messages from being removed from the previous mailbox, use the **ImapUnselectMailbox** function prior to selecting the new mailbox.

If you need to select a mailbox which contains Unicode characters or symbols, it is recommended you use the Unicode version of this function. The mailbox name will automatically be converted to modified UTF-7 encoding as defined by the IMAP4 standard. The ANSI version of this function will only accept mailbox names using modified UTF-7 encoding or UTF-8 encoding.

If an application wishes to update the information returned in the IMAPMAILBOX structure for the current mailbox, simply call **ImapSelectMailbox** again with the same mailbox name. Note that this will not cause any messages marked for deletion to be expunged.

The special case-insensitive mailbox name INBOX is used for new messages. Other mailbox names may or may not be case-sensitive depending on the IMAP server's operating system and implementation.

To access a mailbox in read-only mode, use the **ImapExamineMailbox** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

Unicode: Implemented as Unicode and ANSI versions

ImapSetLastError Function

```
VOID WINAPI ImapSetLastError(
   DWORD dwErrorCode
);
```

The **ImapSetLastError** function sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the caller. A value of zero clears the last error code.

Return Value

None.

Remarks

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value error code such as FALSE, NULL, INVALID_CLIENT or IMAP_ERROR. Those functions which call **ImapSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **ImapGetLastError** function. The use of **ImapGetLastError** is optional. An application can call it to find out the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapSetMessageFlags Function

```
INT WINAPI ImapSetMessageFlags(
   HCLIENT hClient,
   UINT nMessageId,
   UINT nMode
   DWORD dwMessageFlags
);
```

The **ImapSetMessageFlags** function returns the message flags for the specified message.

Parameters

hClient

Handle to the client session.

nMessageId

Number of message to obtain the message flags for. This value must be greater than zero. The first message in the mailbox is message number one.

nMode

An unsigned integer value which specifies one of the following modes which determines how the message flags are set:

Value	Description
IMAP_FLAGS_REPLACE	All message flags are replaced with the flags specified by the ***dwMessageFlags*** parameter.
IMAP_FLAGS_ADD	The message flags specified by the ***dwMessageFlags*** parameter will be set for the message. Message flags that have been previously set will remain unmodified.
IMAP_FLAGS_REMOVE	The message flags specified by the ***dwMessageFlags*** parameter will be removed from the message. Message flags that are not specified will remain unmodified.

dwMessageFlags

An unsigned integer value which specifies one or more message flags. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

Return Value

If the function succeeds, it returns IMAP_RESULT_OK. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapSetTimeout Function

```
INT WINAPI ImapSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **ImapSetTimeout** function sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the function will fail and return to the caller.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The timeout value is only used with blocking network operations.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapConnect, ImapGetTimeout, ImapRead

ImapStoreMessage Function

```
INT WINAPI ImapStoreMessage(
   HCLIENT hClient,
   UINT nMessageId,
   LPCTSTR lpszFileName
);
```

The **ImapStoreMessage** function retrieves a message from the current mailbox and stores it in a local file or the system clipboard.

Parameters

hClient

Handle to the client session.

nMessageId

Number of the message to retrieve. This value must be greater than zero. The first message in the mailbox is message number one.

lpszFileName

Pointer to a string which specifies the file that the message will be stored in. If an empty string or NULL pointer is passed as an argument, the message is copied to the system clipboard.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapStoreMessage** function provides a method of retrieving and storing a message on the local system. The contents of the message is stored as a text file, using the specified file name. This function always causes the caller to block until the entire message has been retrieved, even if the client has been put in asynchronous mode.

If event handling is enabled, the IMAP_EVENT_PROGRESS event will fire periodically during the transfer of the message to the local system. An application can determine how much of the message has been retrieved by calling the **ImapGetTransferStatus** function.

To retrieve the message into a global memory buffer so that it can be passed to the MIME or SMTP libraries, use the **ImapGetMessage** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

ImapSubscribeMailbox Function

```
INT WINAPI ImapSubscribeMailbox(
   HCLIENT hClient,
   LPCTSTR lpszMailbox
);
```

The **ImapSubscribeMailbox** function subscribes the user to the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string which specifies the mailbox to subscribe to.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapSubscribeMailbox** function adds the specified mailbox to the current user's list of active or subscribed mailboxes. The user will remain subscribed to the mailbox across multiple sessions, until the **ImapUnsubscribeMailbox** function is called to remove the mailbox from the subscription list.

To list those mailboxes which the user has subscribed to, use the **ImapGetFirstMailbox** function and specify the IMAP_LIST_SUBSCRIBED option.

Note that if a user subscribes to a mailbox and that mailbox is later renamed or deleted, the mailbox will not be automatically removed from the user's subscription list. An application must not assume that because a mailbox name is included in the list of subscribed mailboxes, it exists and can be selected. To check if the mailbox exists, use the **ImapGetMailboxStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapUndeleteMessage Function

```
INT WINAPI ImapUndeleteMessage(
    HCLIENT hClient,
    UINT nMessageId
);
```

The **ImapUndeleteMessage** function removes the deletion flag for the specified message.

Parameters

hClient

Handle to the client session.

nMessage

Number of message to undelete from the server. This value must be greater than zero. The first message in the mailbox is message number one.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapUninitialize Function

```
VOID WINAPI ImapUninitialize();
```

The **ImapUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **ImapInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **ImapUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **ImapUninitialize** for every successful call to **ImapInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

See Also

ImapUnselectMailbox Function

```
INT WINAPI ImapUnselectMailbox(
    HCLIENT hClient,
    BOOL bExpunge
);
```

The **ImapUnselectMailbox** function unselects the current mailbox.

Parameters

hClient

Handle to the client session.

bExpunge

A boolean flag which determines if deleted messages will be expunged from the mailbox. A non-zero value specifies that messages that have been marked for deletion will be removed from the mailbox. A zero value specifies that no messages will be removed from the mailbox.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

ImapUnsubscribeMailbox Function

```
INT WINAPI ImapUnsubscribeMailbox(
    HCLIENT hClient,
    LPCTSTR lpszMailbox
);
```

The **ImapUnsubscribeMailbox** function unsubscribes the user from the specified mailbox.

Parameters

hClient

Handle to the client session.

lpszMailbox

A null-terminated string which specifies the mailbox to unsubscribe from.

Return Value

If the function succeeds, it returns zero. If an error occurs, the function returns IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The **ImapUnsubscribeMailbox** function removes the specified mailbox from the current user's list of active or subscribed mailboxes.

To list those mailboxes which the user has subscribed to, use the **ImapGetFirstMailbox** function and specify the IMAP_LIST_SUBSCRIBED option.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib
Unicode: Implemented as Unicode and ANSI versions

ImapWrite Function

```
INT WINAPI ImapWrite(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **ImapWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is IMAP_ERROR. To get extended error information, call **ImapGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the IMAP_EVENT_WRITE asynchronous notification message before it resumes sending data.

The **ImapWrite** function should not be used to send commands to the IMAP server. Use the **ImapCommand** function instead.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

    DWORD   dwReserved2;
} IMAPMAILBOX, *LPIMAPMAILBOX;
```

Members

nMessages

A value specifies the total number of messages in the mailbox.

nRecentMessages

A value which specifies the number of new messages that have recently arrived in the mailbox.

nUnseenMessageId

A value which specifies the message ID of the first unseen message in the mailbox.

dwMailboxUID

A value which specifies a unique identifier for this mailbox which corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

dwNextMessageUID

A value which specifies the predicted unique identifier that will be assigned to a new message in the mailbox. This corresponds to the UIDNEXT value returned by the IMAP server. The protocol specification requires that as long as the mailbox UID is unchanged, messages that are added to the mailbox will be assigned a UID greater than or equal to the next UID value.

dwFlags

A value which specifies one or more mailbox flags. One or more of the following values may be specified:

Value	Description
IMAP_FLAG_NOINFERIORS	The mailbox does not contain any child mailboxes. In the IMAP protocol, these are referred to as inferior hierarchical mailbox names.
IMAP_FLAG_NOSELECT	The mailbox cannot be selected or examined. This flag is typically used by servers to indicate that the mailbox name refers to a directory on the server, not a mailbox file.
IMAP_FLAG_MARKED	The mailbox is marked as being of interest to a client. If this

	flag is used, it typically means that the mailbox contains messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.
IMAP_FLAG_UNMARKED	The mailbox is marked as not being of interest to a client. If this flag is used, it typically means that the mailbox does not contain any messages. An application should not depend on this flag being present for any given mailbox. Some IMAP servers do not support marked or unmarked flags for mailboxes.

dwPermanentFlags

A value which specifies the message flags that a client can change permanently. If this value is zero, then no permanent flags are defined for the mailbox and the client may assume that all message flags may be set permanently. Otherwise, one or more of the following values may be specified:

Value	Description
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_SEEN	The message has been read.

dwAccessMode

A value which specifies the access mode for the mailbox. It may be one of the following values:

Value	Description
IMAP_ACCESS_READONLY	The mailbox has been selected in read-only mode. Messages may not be created in the mailbox, nor can message flags be modified.
IMAP_ACCESS_READWRITE	The mailbox has been selected in read-write mode. Messages may be modified by the client, and messages marked for deletion can be expunged.

dwReserved1

A reserved value that is undefined.

dwReserved2

A reserved value that is undefined.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

IMAPMAILBOXSTATUS

This structure contains information about a mailbox.

```
typedef struct _IMAPMAILBOXSTATUS
{
    UINT    nMessages;
    UINT    nRecentMessages;
    UINT    nUnseenMessages;
    DWORD   dwMailboxUID;
    DWORD   dwNextMessageUID;
    DWORD   dwReserved;
} IMAPMAILBOXSTATUS, *LPIMAPMAILBOXSTATUS;
```

Members

nMessages

A value specifies the total number of messages in the mailbox.

nRecentMessages

A value which specifies the number of new messages that have recently arrived in the mailbox.

nUnseenMessages

A value which specifies the number of unread messages in the mailbox.

dwMailboxUID

A value which specifies a unique identifier for this mailbox which corresponds to the UIDVALIDITY value returned by the IMAP server. The actual value is determined by the server and should be considered opaque. The protocol specification requires that a mailbox's UID must not change unless the mailbox contents are modified or existing messages in the mailbox have been assigned new UIDs.

dwNextMessageUID

A value which specifies the predicted unique identifier that will be assigned to a new message in the mailbox. This corresponds to the UIDNEXT value returned by the IMAP server. The protocol specification requires that as long as the mailbox UID is unchanged, messages that are added to the mailbox will be assigned a UID greater than or equal to the next UID value.

dwReserved

A reserved value that is undefined.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

IMAPMESSAGE

This structure contains information about a message.

```
typedef struct _IMAPMESSAGE
{
    UINT    nMessageId;
    DWORD   dwMessageUID;
    DWORD   dwSize;
    DWORD   dwFlags;
    DWORD   dwTimestamp;
    DWORD   dwReserved;
} IMAPMESSAGE, *LPIMAPMESSAGE;
```

Members

nMessageId

A sequential integer value which identifies the message. The message identifier is only valid while the mailbox is selected and no messages marked for deletion have been expunged. To maintain a persistent identifier for the message, use a combination of the mailbox UID and message UID.

dwMessageUID

An integer value which specifies a unique identifier for this message. The actual value is determined by the server and should be considered opaque. If the client application stores the message UID on the local system, it should also store the UID for the mailbox that contains the message. If the mailbox UID changes, the message UID may no longer be valid.

dwSize

Specifies the size of the message in bytes. This value may not be the same as the number of characters in the message, particularly if the message text uses Unicode or extended multibyte ANSI sequences. For a structured multipart MIME message, this includes the combined size of all message parts.

dwFlags

A value which specifies one or more message flags. One or more of the following values may be specified:

Value	Description
IMAP_FLAG_NONE	No value.
IMAP_FLAG_ANSWERED	The message has been answered.
IMAP_FLAG_DELETED	The message has been marked for deletion.
IMAP_FLAG_DRAFT	The message has not been completed and is marked as a draft copy.
IMAP_FLAG_URGENT	The message has been flagged for urgent or special attention.
IMAP_FLAG_RECENT	The message has been added to the mailbox recently.
IMAP_FLAG_SEEN	The message has been read.

dwTimestamp

An integer value which specifies the date and time that the message was added to the mailbox. The value is expressed as the number of seconds since midnight, 1 January 1970 and is the same value that is used for the standard C runtime library time methods. Note that the date and time used is

the message's internal date from the mail server, not the value of the **Date** header field in the message.

dwReserved

A reserved value that is undefined.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmapv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IMAPTRANSFERSTATUS

This structure is used by the ImapGetTransferStatus function to return information about a file transfer in progress.

```
typedef struct _IMAPTRANSFERSTATUS
{
   UINT    nMessageId;
   DWORD   dwBytesTotal;
   DWORD   dwBytesCopied;
   DWORD   dwBytesPerSecond;
   DWORD   dwTimeElapsed;
   DWORD   dwTimeEstimated;
} IMAPTRANSFERSTATUS, *LPIMAPTRANSFERSTATUS;
```

Members

nMessageId

The message ID of the current message that is being transferred.

dwBytesTotal

The total number of bytes that will be transferred. If the file is being copied from the server to the local host, this is the size of the remote file. If the file is being copied from the local host to the server, it is the size of the local file. If the file size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the file transfer is completed. This is based on the average number of bytes transferred per second.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Large Language Model Library

The Large Language Model API provides a unified, high-level interface for integrating large language model capabilities into applications. It simplifies working with different providers by handling connections, messaging, and conversation state internally, while still giving developers control over configuration, performance, and behavior. The API is designed to support both simple use cases and more advanced scenarios involving model selection, token management, and session control.

Reference

- Functions
- Constants
- Data Structures
- Providers
- Error Codes

Library Information

File Name	CSLLMV12.DLL
Version	12.0.3024.1286
LibID	E77A6A0A-3B86-49D9-9A3D-A0B425BDA66D
Import Library	CSLLMV12.LIB
Dependencies	None

Overview

The SocketTools LLM API is built around a session-based architecture that encapsulates all aspects of interacting with a language model, including connection details, configuration settings, and conversation history. This design allows developers to treat each interaction as part of a managed context, making it easier to maintain state across multiple requests without needing to manually track prior messages or model parameters. Sessions can be configured with defaults or customized with options such as system prompts, token limits, and behavioral settings, depending on the needs of the application.

A central goal of the API is to abstract the differences between providers and models, presenting a unified interface that works consistently regardless of the underlying service. Developers can discover available providers and models, query their capabilities, and select appropriate configurations at runtime. This flexibility makes it possible to switch between services or adapt to new models with minimal code changes, while still exposing enough detail to fine-tune behavior when needed.

The API also provides robust support for managing conversation data. It maintains a structured history of messages and responses, enabling applications to iterate through prior interactions, search for specific content, or limit the amount of retained context to control memory usage and token consumption. This is particularly important when working with models that have strict context limits, as it allows developers to balance response quality with performance and cost considerations.

In addition to core messaging functionality, the API includes a range of utility features that help developers monitor and optimize their applications. These include estimating and tracking token usage, managing cache lifetimes for model metadata, handling errors in a consistent way, and optionally logging network activity for debugging purposes. Together, these capabilities provide

insight into how the application is interacting with the model and help identify potential performance or configuration issues.

Overall, the LLM API is designed to provide a practical balance between simplicity and control. It enables developers to quickly add AI-powered features to their applications while retaining the flexibility to customize behavior, manage resources, and integrate with different providers as requirements evolve.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Large Language Model Functions

Function	Description
LlmAskModel	Sends a prompt to the specified service provider and model.
LlmAttachThread	Attaches the specified client handle to another thread.
LlmCancelRequest	Cancels the current blocking request.
LlmClearHeaders	Clears the custom HTTP request headers for the client session.
LlmClearHistory	Clears the current conversation history for a client.
LlmConnect	Establishes a connection using the specified provider, URL, model, API key, and options.
LlmConnectEx	Establishes a connection using an existing session structure.
LlmConvertTimestamp	Converts a message or response timestamp value into a SYSTEMTIME structure.
LlmCreateSession	Creates a session object using the specified provider settings.
LlmCreateSessionEx	Creates a session object with extended configuration such as prompt, token limit, and sampling settings.
LlmDeleteSession	Deletes a session object and releases its resources.
LlmDisableTrace	Disables logging of network function calls.
LlmDisconnect	Disconnects from the provider and releases the session handle.
LlmEnableTrace	Enables logging of network function calls to a file.
LlmEnumModels	Enumerates the models available for the connected provider.
LlmEnumProviders	Enumerates the supported LLM providers.
LlmEstimateTokenCount	Estimates the number of tokens in a text string for a specific provider.
LlmExportHistory	Exports the current conversation history to a JSON-formatted file.
LlmFindMessage	Searches the conversation history for a message matching the specified text or flags.
LlmFormatTimestamp	Formats a message timestamp as an ISO 8601 date and time string.
LlmGetCacheTime	Returns the current model or metadata cache lifetime for a client.
LlmGetClientOptions	Returns the current client option flags.
LlmGetClientProvider	Returns the provider associated with a client, and optionally its base URL.
LlmGetDefaultModelFlags	Returns the default capability flags for the specified model.
LlmGetDefaultModelName	Returns the default model name for the specified provider.
LlmGetErrorString	Returns a text description for the specified error code.
LlmGetFirstMessage	Retrieves the first message in the conversation history.
LlmGetIdleTime	Returns the current idle timeout period for a client session.
LlmGetHistorySize	Returns the maximum number of messages which can be stored in the conversation history.
LlmGetLastError	Returns the last error code set for the current thread.
LlmGetMemoryUsage	Returns the amount of memory currently used by a client session.
LlmGetMessage	Retrieves a specific message prompt and response using the history index.
LlmGetMessageById	Retrieves a specific message prompt and response using a message ID.
LlmGetMessageCount	Returns the current number of messages in the conversation history.
LlmGetModelContextSize	Returns the context window size for the specified model.
LlmGetModelFlags	Returns the current model behavior flags for a client.
LlmGetModelInfo	Returns detailed information about a specific model.
LlmGetModelName	Returns the name of the current model used with a client session.
LlmGetNextMessage	Retrieves the next message in the conversation history.

LlmGetProviderFlags	Returns the capability flags associated with a provider.
LlmGetProviderId	Returns a provider ID based on a provider name, endpoint URL or model name.
LlmGetProviderInfo	Retrieves detailed information about a provider.
LlmGetProviderName	Returns the display name of a provider.
LlmGetProviderUrl	Returns the base endpoint URL for the specified provider.
LlmGetResponseHeader	Returns the value of an HTTP header from the server response.
LLmGetStatusCode	Returns the most recent HTTP status code for a client request.
LlmGetSystemPrompt	Returns the current system prompt for a client session.
LlmGetTimeout	Returns the number of seconds until a request times out.
LlmGetTokenUsage	Returns token usage statistics for the client session.
LlmGetUserAgent	Returns the current user-agent string used by the client.
LlmImportHistory	Imports a conversation history from the specified JSON-formatted file.
LlmInitialize	Initializes the library and validates the specified license key at runtime.
LlmIsBlocking	Returns whether the client is currently processing a blocking operation.
LlmIsConnected	Returns whether the client session is valid and connected to a server.
LlmNormalizeText	Normalizes message text into a consistent format.
LlmResetSession	Resets the current client session to its initial state.
LlmSendMessage	Sends a prompt to the model and returns the response as a string.
LlmSendMessageEx	Sends a structured message to the model and returns a structured response.
LlmSetCacheTime	Sets the cache lifetime used by the client for model or provider data.
LlmSetClientOptions	Sets the current client option flags.
LlmSetHistorySize	Sets the maximum number of messages retained in the conversation history.
LlmSetIdleTime	Sets the idle timeout period for a client session.
LlmSetLastError	Sets the last error code for the current thread.
LlmSetModelFlags	Sets model behavior flags for a client session.
LlmSetModelName	Changes the current model for a client session.
LlmSetRequestHeader	Sets the value of a custom HTTP header issued with subsequent requests.
LlmSetSystemPrompt	Sets the system prompt for a client session.
LlmSetTimeout	Sets the number of seconds until a blocking operation times out.
LlmSetUserAgent	Sets the user-agent string used by the client.
LlmTrimHistory	Removes messages from the conversation history, optionally constrained by token usage.
LlmUninitialize	Terminates use of the library by the calling process.
LlmValidateModel	Validates that a model name is recognized or supported by the current provider.
LlmValidateText	Performs basic validation on message text before it is submitted to a model.

LlmAskModel Function

```
BOOL WINAPI LlmAskModel (
   DWORD dwProviderId,
   LPCTSTR lpszBaseUrl,
   LPCTSTR lpszModelName,
   LPCTSTR lpszApiKey,
   LPCTSTR lpszPrompt,
   LPTSTR lpszResponse,
   INT nMaxLength
);
```

The **LlmAskModel** function sends a single prompt to a model and returns the generated response without requiring the application to manage a client session.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. See the remarks below for more information about service providers.

lpszBaseUrl

A pointer to a null-terminated string that specifies the base URL for the provider endpoint. This parameter may be NULL to use the default endpoint for the selected provider. Some providers, such as Microsoft Foundry or local services, require a specific base URL.

lpszModelName

A pointer to a null-terminated string that specifies the model name to use for the session. This parameter may be NULL to use the provider default model, if one is defined. Providers without a default model require an explicit model name. This typically includes models accessed using the Microsoft Foundry or locally hosted inference providers.

lpszApiKey

A pointer to a null-terminated string that specifies the API key used to authenticate with the provider. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries.

lpszPrompt

A pointer to a null-terminated string which specifies the prompt which should be sent to the model. This parameter cannot be NULL or a zero-length string. If the string consists only of whitespace characters, or contains invalid Unicode or non-text data, this function will fail.

lpszResponse

A pointer to a string buffer which will contain the model's response to the prompt. The response will always be null terminated and if the buffer is not large enough to store the complete response, the response will be truncated. When the function is called, this buffer is always initialized to an empty string and will contain the response if the function returns successfully.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the response buffer, including the terminating null character. If the length is an invalid value, such as zero or a negative number, the function will fail.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmAskModel** function provides a simplified way to send a single prompt to a model and return the generated response. It does not require a client handle. It creates a connection using the default options and timeout period, sends the request and then closes the connection. This function manages the session automatically and is intended for simple request and response operations.

This function does not preserve conversation history between calls. Applications which require conversational context, persistent connections or advanced session management should create a session using the **LlmConnect** function and then send prompts using the **LlmSendMessage** function.

The *dwProviderId* parameter specifies the numeric identifier assigned to a supported provider. Refer to the providers page for a list of supported service providers and their default models.

If the *lpszBaseUrl* parameter is NULL or a zero-length string, the library will use a provider-specific default endpoint. Some providers, such as Microsoft Foundry services or locally hosted models, require an explicit endpoint and will fail if one is not provided.

If the *lpszModelName* parameter is NULL or a zero-length string, the library will attempt to use a default model for the selected provider. Not all providers define a default model, and in those cases an explicit model name must be provided when establishing the connection. This typically includes models accessed using the Microsoft Foundry or locally hosted inference providers.

If the service provider requires authentication, the API key can be provided in several formats, allowing applications to provide credentials in a way that balances convenience and security:

- **Literal string**
  The API key is provided directly as a string. This is the simplest approach and is convenient for testing or small internal tools, but it is not recommended for production applications. A literal key may be exposed in source code, configuration files, diagnostic logs or the compiled application binary.
- **Environment variable**
  The name of an environment variable enclosed in percent symbols, for example `"%OPENAI_API_KEY%"`. The value of the environment variable is used as the API key. This avoids embedding the key directly in the application and is useful for development, scripts and deployment environments. However, environment variables may still be visible to the current user, inherited by child processes or exposed through system configuration, so they should still be protected appropriately.
- **Windows credential**
  A credential name enclosed in braces, for example `"{MyAppName/OpenAI}"`. The API key is retrieved from the Windows Credential Manager using the specified name. This is the recommended approach for most Windows applications because the secret is stored outside the application and managed by the operating system. The credential can be created manually using Credential Manager, or programmatically by the application using the Windows Credential Management API. Applications should choose a unique credential name and document it clearly if users or administrators are expected to configure the value themselves.

For production applications, it is recommended that you avoid using literal API key strings and instead use an environment variable or a value stored in the Windows Credential Manager. If you must

provide the API key as a literal string, you should take additional steps to protect it, such as storing the key in an encrypted form and limiting access to authorized users or processes. Avoid embedding API keys directly in application source code, configuration files, installers or other content that could be exposed through version control systems, logs or public repositories.

This function will block the calling thread until the server returns a response or the default timeout period has elapsed. Larger or more complex models may take longer to generate a response. Locally hosted models may also take longer to respond than cloud-based models, depending on the model type and size.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    // Initialize the SocketTools library
    if (!LlmInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Initialization failed: %lu\n"), LlmGetLastError());
        return 1;
    }

    LPCTSTR lpszPrompt = _T("What is the capital of the state of California?");
    TCHAR szResponse[4096] = _T("");

    // Use a locally hosted model with LM Studio
    BOOL bResult = LlmAskModel(
            LLM_PROVIDER_LOCAL,              // Local provider
            _T("http://127.0.0.1:1234/v1/"), // Localhost endpoint
            _T("nvidia/nemotron-3-nano-4b"), // Model name
            NULL,
            lpszPrompt,
            szResponse,
            _countof(szResponse));

    if (bResult)
    {
        _tprintf(_T("The response was %d characters:\n"), lstrlen(szResponse));
        _putts(szResponse);
    }
    else
    {
        DWORD dwError = LlmGetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    LlmUninitialize();
    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

Unicode: Implemented as Unicode and ANSI versions

LlmAttachThread Function

```
DWORD WINAPI LlmAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **LlmAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

When a client handle is created, it is associated with the thread that created it. If another thread attempts to use the handle, the function will fail because that thread does not own the handle. This prevents other threads from interfering with an operation being performed by the owner thread. The **LlmAttachThread** function changes the thread that owns the client handle. This is useful when one thread creates the client session and then passes it to a worker thread for processing. The function returns the thread ID of the previous owner, which can be saved and used later to restore ownership of the handle.

This function should normally be called by the new owner thread immediately after it has been created. If the worker thread does not release the handle itself, ownership should be restored to the original thread before the worker thread terminates. Do not use **LlmAttachThread** to forcibly take ownership of a handle from another thread while a blocking operation is in progress. The handle should only be transferred when no other thread is actively using it.

The ***dwThreadId*** parameter is assumed to be a valid thread ID. This function does not verify that the specified thread exists. Specifying an invalid thread ID will orphan the handle until **LlmUninitialize** is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmCancelRequest Function

```
BOOL WINAPI LlmCancelRequest(
    HCLIENT hClient
);
```

The **LlmCancelRequest** function cancels the current blocking request.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmCancelRequest** function cancels the current blocking request by closing the active HTTP connection associated with the client session. This causes the blocking function to fail and return control to the calling thread. The last error code for the blocking function will be set to indicate the operation was canceled.

This function cancels the request locally. It does not guarantee that the provider will stop processing a request that has already been received. The provider may still complete the request and may charge for any processing or tokens used before the connection was closed.

Canceling a request does not delete the client session or clear the conversation history. The client handle remains valid, and a new HTTP connection will be established automatically if it is needed for a subsequent request.

If no blocking request is currently in progress, this function succeeds and has no effect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

LlmClearHeaders Function

```
BOOL WINAPI LlmClearHeaders(
    HCLIENT hClient
);
```

The **LlmClearHeaders** function removes all custom HTTP request headers for the client session.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmClearHeaders** function removes all custom request header values set using the **LlmSetRequestHeader** method. This is useful when you want to ensure that custom headers used for a previous call to **LlmSendMessage** are not included with subsequent requests made during the same session.

This method does not clear authentication credentials, organization identifiers, project identifiers, or any required headers automatically generated by the control.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

LlmGetResponseHeader, LlmResetSession, LlmSendMessage, LlmSetRequestHeader

LlmClearHistory Function

```
BOOL WINAPI LlmClearHistory(
    HCLIENT hClient
);
```

The **LlmClearHistory** function clears the conversation history for the current client session.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmClearHistory** function removes all messages and responses stored in the conversation history for the specified client session. This can be used to begin a new conversation while preserving the current connection, provider settings, model selection, timeout, system prompt and other session options.

This function only clears the local history maintained by the client. It does not reset provider-specific settings, delete cached model information or close the active HTTP connection. It also does not change the current system prompt.

After the history has been cleared, subsequent calls to **LlmSendMessage** or **LlmSendMessageEx** will not include any previous messages from the conversation history.

Clearing the conversation history invalidates any string pointers previously returned in LLM_RESPONSE structures or by message history functions. Applications must not use those pointers after this function returns. If the application needs to keep any message or response text, it should make its own copy before clearing the history.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmConnect Function

```
HCLIENT WINAPI LlmConnect(
   DWORD dwProviderId,
   DWORD dwOptions,
   INT nTimeout,
   LPCTSTR lpszBaseUrl,
   LPCTSTR lpszModelName,
   LPCTSTR lpszApiKey
);
```

The **LlmConnect** function establishes a connection to the specified large language model service provider and creates a client session.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. See the remarks below for more information about service providers.

dwOptions

Specifies one or more option flags that control how the connection is established. This parameter can be zero or a combination of the following values:

Value	Description
LLM_OPTION_NONE	A standard connection to the server is established using the default behavior for the selected provider. No additional options are enabled, and the connection will use the provider's default protocol, caching behavior and request headers.
LLM_OPTION_NOCACHE	Disables provider and model metadata caching for the client session. When this option is specified, the library will not reuse cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
LLM_OPTION_KEEPALIVE	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
LLM_OPTION_PROXY	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
LLM_OPTION_NOUSERAGENT	Prevents the library from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be

	used when a provider does not require a User-Agent header.
LLM_OPTION_SECURE	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base URL or provider default would normally use an insecure protocol, it will be upgraded to a secure connection. Connections to providers such as OpenAI, Google and Anthropic will always be secure.
LLM_OPTION_DEFAULT	Specifies the default option set, which is equivalent to `LLM_OPTION_NONE`. No additional flags are enabled and the connection uses standard behavior.

nTimeout

The timeout period for connection and request operations, in seconds. A value of zero indicates that the default timeout should be used.

lpszBaseUrl

A pointer to a null-terminated string that specifies the base URL for the provider endpoint. This parameter may be NULL to use the default endpoint for the selected provider. Some providers, such as Microsoft Foundry or local services, require a specific base URL.

lpszModelName

A pointer to a null-terminated string that specifies the model name to use for the session. This parameter may be NULL to use the provider default model, if one is defined. Providers without a default model require an explicit model name. This typically includes models accessed using the Microsoft Foundry or locally hosted inference providers.

lpszApiKey

A pointer to a null-terminated string that specifies the API key used to authenticate with the provider. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmConnect** function creates a client session that is used for all subsequent operations with the selected provider. The returned handle maintains the connection settings, authentication information, selected model, and conversation history for the session.

The ***dwProviderId*** parameter specifies the numeric identifier assigned to a supported provider. Provider identifiers are predefined constants built into the library and are assigned fixed values beginning at 1 and increasing sequentially for each provider. These identifiers are stable and are intended to uniquely identify a provider regardless of its display name. Applications should use the predefined constants (such as `LLM_PROVIDER_OPENAI` or `LLM_PROVIDER_MICROSOFT`) rather than hard-coding numeric values directly in source code.

Refer to the providers page for a list of supported service providers and their default models.

If the ***lpszBaseUrl*** parmeter is NULL or a zero-length string, the library will use a provider-specific

default endpoint. Some providers, such as Microsoft Foundry services or locally hosted models, require an explicit endpoint and will fail if one is not provided.

If the *lpszModelName* parameter is NULL or a zero-length string, the library will attempt to use a default model for the selected provider. Not all providers define a default model, and in those cases an explicit model name must be provided when establishing the connection. This typically includes models accessed using the Microsoft Foundry or locally hosted inference providers.

If the service provider requires authentication, the API key can be provided in several formats, allowing applications to provide credentials in a way that balances convenience and security:

- **Literal string**
  The API key is provided directly as a string. This is the simplest approach and is convenient for testing or small internal tools, but it is not recommended for production applications. A literal key may be exposed in source code, configuration files, diagnostic logs or the compiled application binary.
- **Environment variable**
  The name of an environment variable enclosed in percent symbols, for example `"%OPENAI_API_KEY%"`. The value of the environment variable is used as the API key. This avoids embedding the key directly in the application and is useful for development, scripts and deployment environments. However, environment variables may still be visible to the current user, inherited by child processes or exposed through system configuration, so they should still be protected appropriately.
- **Windows credential**
  A credential name enclosed in braces, for example `"{MyAppName/OpenAI}"`. The API key is retrieved from the Windows Credential Manager using the specified name. This is the recommended approach for most Windows applications because the secret is stored outside the application and managed by the operating system. The credential can be created manually using Credential Manager, or programmatically by the application using the Windows Credential Management API. Applications should choose a unique credential name and document it clearly if users or administrators are expected to configure the value themselves.

For production applications, it is recommended that you avoid using literal API key strings and instead use an environment variable or a value stored in the Windows Credential Manager. If you must provide the API key as a literal string, you should take additional steps to protect it, such as storing the key in an encrypted form and limiting access to authorized users or processes. Avoid embedding API keys directly in application source code, configuration files, installers or other content that could be exposed through version control systems, logs or public repositories.

This method will block the calling thread until the connection has been established or the timeout period has elapsed. The connection established by this method represents a logical session. Depending on the provider and options specified, the underlying HTTP connection may be reused across requests or recreated as needed. Options such as `LLM_OPTION_KEEPALIVE` can be used to control connection behavior.

The client handle returned by this function is owned by the thread that created it. To transfer ownership to another thread, use the **LlmAttachThread** function.

Example

```
#include "cstools12.h"
#include <stdio.h>
```

```
int _tmain(void)
{
    HCLIENT hClient = INVALID_CLIENT;
    DWORD dwError = NO_ERROR;

    // Initialize the SocketTools library
    if (!LlmInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Initialization failed: %lu\n"), LlmGetLastError());
        return 1;
    }

    // Establish a connection to OpenAI using the default endpoint
    // and a lightweight model
    hClient = LlmConnect(
        LLM_PROVIDER_OPENAI,
        LLM_OPTION_DEFAULT,
        LLM_TIMEOUT,
        NULL,                   // Use default URL
        _T("gpt-5.4-nano"),     // Model name
        _T("%OPENAI_API_KEY%") // Environment variable name
    );

    if (hClient == INVALID_CLIENT)
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
        LlmUninitialize();
        return 1;
    }

    TCHAR szResponse[4096] = {0};
    DWORD dwResponseLength = _countof(szResponse); // number of TCHARs
    DWORD dwMessageId = 0;

    // Send a simple message to the model
    if (LlmSendMessage(hClient,
                       _T("What is the capital city of Denmark?"),
                       szResponse,
                       &dwResponseLength,
                       &dwMessageId))
    {
        _tprintf(_T("Response:\n%s\n"), szResponse);
    }
    else
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    // Clean up
    LlmDisconnect(hClient);
    LlmUninitialize();

    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmConnectEx Function

```
HCLIENT WINAPI LlmConnectEx(
   DWORD dwProviderId,
   DWORD dwOptions,
   LPLLM_SESSION lpSession
);
```

The **LlmConnectEx** function establishes a connection to the specified large language model service provider using an extended session configuration.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. See the remarks below for more information about service providers.

dwOptions

Specifies one or more option flags that control how the connection is established. This parameter can be zero or a combination of **LLM_OPTION** values. These options control behavior such as connection security, proxy usage, and HTTP connection handling.

Value	Description
LLM_OPTION_NONE	A standard connection to the server is established using the default behavior for the selected provider. No additional options are enabled, and the connection will use the provider's default protocol, caching behavior and request headers.
LLM_OPTION_NOCACHE	Disables provider and model metadata caching for the client session. When this option is specified, the library will not reuse cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
LLM_OPTION_KEEPALIVE	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
LLM_OPTION_PROXY	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
LLM_OPTION_NOUSERAGENT	Prevents the library from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be used when a provider does not require a User-Agent header.

LLM_OPTION_SECURE	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base URL or provider default would normally use an insecure protocol, it will be upgraded to a secure connection. Connections to providers such as OpenAI, Google and Anthropic will always be secure.
LLM_OPTION_DEFAULT	Specifies the default option set, which is equivalent to `LLM_OPTION_NONE`. No additional flags are enabled and the connection uses standard behavior.

lpSession

A pointer to an `LLM_SESSION` structure that specifies extended configuration options for the client session. This structure can be used to define parameters such as the base URL, model name, authentication information, timeout values, token limits and sampling settings.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmConnectEx** function creates a client session using the configuration specified in the ***lpSession*** structure. This provides more control over how the connection is established compared to **LlmConnect**, and is intended for applications that require advanced configuration.

The ***dwProviderId*** parameter specifies the numeric identifier assigned to a supported provider. Provider identifiers are predefined constants built into the library and are assigned fixed values beginning at 1 and increasing sequentially for each provider. These identifiers are stable and are intended to uniquely identify a provider regardless of its display name. Applications should use the predefined constants (such as `LLM_PROVIDER_OPENAI` or `LLM_PROVIDER_MICROSOFT`) rather than hard-coding numeric values directly in source code.

Refer to the providers page for a list of supported service providers and their default models.

The ***lpSession*** structure allows the application to specify connection parameters such as the provider endpoint, model name, API key, timeout values, token limits and sampling options. Any values not explicitly specified will use provider defaults.

Applications using languages other than C or C++ may find it easier to create and manage session structures using the **LlmCreateSession**, **LlmCreateSessionEx** and **LlmDeleteSession** functions. These helper functions allocate and initialize a compatible structure that can be passed to this function.

The library makes an internal copy of the string members in the LLM_SESSION structure when the connection is established. The application does not need to retain them after the call to **LlmConnectEx** returns.

This function will block the calling thread until the connection has been established or the timeout period has elapsed. Applications should avoid calling this function on the main user interface thread. For best results, create a worker thread to establish the connection, especially when multiple connections are required.

The connection established by this function represents a logical session. Depending on the provider and options specified, the underlying HTTP connection may be reused across requests or recreated as

needed. Options such as `LLM_OPTION_KEEPALIVE` can be used to control connection behavior.

The client handle returned by this function is owned by the thread that created it. To transfer ownership to another thread, use the **LlmAttachThread** function.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    HCLIENT hClient = INVALID_CLIENT;
    DWORD dwError = NO_ERROR;

    // Initialize the SocketTools library
    if (!LlmInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Initialization failed: %lu\n"), LlmGetLastError());
        return 1;
    }

    // Additional options such as temperature, token limits and timeouts
    // can be configured using members of the LLM_SESSION structure
    LLM_SESSION sessionInfo;

    ZeroMemory(&sessionInfo, sizeof(sessionInfo));
    sessionInfo.dwSize = sizeof(sessionInfo);
    sessionInfo.lpszModelName = _T("gpt-5.4-nano");
    sessionInfo.lpszApiKey = _T("%OPENAI_API_KEY%");
    sessionInfo.lpszSystemPrompt = _T("You are a helpful assistant.");

    // Establish a connection to OpenAI using a lightweight model
    // with the default connection options
    hClient = LlmConnectEx(LLM_PROVIDER_OPENAI,
                           LLM_OPTION_DEFAULT,
                           &sessionInfo);

    if (hClient == INVALID_CLIENT)
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
        LlmUninitialize();
        return 1;
    }

    TCHAR szResponse[4096] = {0};
    DWORD dwResponseLength = _countof(szResponse); // number of TCHARs
    DWORD dwMessageId = 0;

    // Send a simple message to the model
    if (LlmSendMessage(hClient,
                       _T("What is the capital city of Denmark?"),
                       szResponse,
                       &dwResponseLength,
                       &dwMessageId))
    {
        _tprintf(_T("Response:\n%s\n"), szResponse);
    }
```

```
    else
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    // Clean up
    LlmDisconnect(hClient);
    LlmUninitialize();

    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmConvertTimestamp Function

```
BOOL WINAPI LlmConvertTimestamp(
   TIME_T tTimestamp,
   LPSYSTEMTIME lpSystemTime
   BOOL bLocalTime
);
```

The **LlmConvertTimestamp** function converts a message or response timestamp to a SYSTEMTIME structure.

Parameters

tTimestamp

A 64-bit timestamp value associated with a message or response. This value represents the number of seconds that have elapsed since January 1, 1970 UTC.

lpSystemTime

A pointer to a `SYSTEMTIME` structure that receives the converted date and time value.

bLocalTime

If this parameter is non-zero, the timestamp is converted to the local system time. If this parameter is zero, the timestamp is converted to Coordinated Universal Time (UTC).

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmConvertTimestamp** function converts an internal timestamp value used by the library into a standard `SYSTEMTIME` structure. This allows applications to display message and response times in a human-readable format. These timestamps are used in the client history of requests sent to the model and the responses it returned.

The *tTimestamp* parameter is a standard 64-bit Unix time value and can be used interchangeably with functions in the C standard library such as **gmtime** or **localtime**. Because it is a 64-bit integer, it is not impacted by the Year 2038 problem. Timestamps are returned by functions such as **LlmSendMessage** and can be converted into a local date and time using the **LlmConvertTimestamp** function.

The converted time can be returned as either local time or UTC by specifying the *bLocalTime* parameter. Applications should use local time for display purposes and UTC when storing or comparing timestamps across systems. The SYSTEMTIME value can be formatted using standard Windows functions such as **GetDateFormatEx** and **GetTimeFormatEx** to display locale-specific date and time values.

If you wish to convert the message timestamp to a standardized ISO 8601 string value, use the **LlmFormatTimestamp** function.

Example

```
// Enumerate the message history and display message details
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE), 0 };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE), 0 };
```

```
if (LlmGetFirstMessage(hClient, 0, &clientMessage, &serverResponse))
{
    do
    {
        SYSTEMTIME stMessage = {0};
        TCHAR szDate[64] = {0};
        TCHAR szTime[64] = {0};

        LlmConvertTimestamp(clientMessage.tTimestamp, &stMessage, TRUE);

        GetDateFormat(LOCALE_USER_DEFAULT, 0,
                      &stMessage, NULL,
                      szDate, _countof(szDate));

        GetTimeFormat(LOCALE_USER_DEFAULT, 0,
                      &stMessage, NULL,
                      szTime, _countof(szTime));

        _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
        _tprintf(_T("  Timestamp:       %s %s\n"), szDate, szTime);
        _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
        _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);

        SYSTEMTIME stResponse = {0};
        LlmConvertTimestamp(serverResponse.tTimestamp, &stResponse, TRUE);

        GetDateFormat(LOCALE_USER_DEFAULT, 0,
                      &stResponse, NULL,
                      szDate, _countof(szDate));

        GetTimeFormat(LOCALE_USER_DEFAULT, 0,
                      &stResponse, NULL,
                      szTime, _countof(szTime));

        _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
        _tprintf(_T("  Timestamp:       %s %s\n"), szDate, szTime);
        _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
        _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
    }
    while (LlmGetNextMessage(hClient, &clientMessage, &serverResponse));
}
```

This example uses the **GetDateFormat** and **GetTimeFormat** functions for simplicity and compatibility with both ANSI and Unicode builds. On current Windows platforms, applications should prefer using **GetDateFormatEx** and **GetTimeFormatEx**, which provide improved locale support and are recommended for new development. Note that these newer functions are implemented as Unicode-only APIs.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmCreateSession Function

```
BOOL WINAPI LlmCreateSession(
   DWORD dwProviderId,
   LPCTSTR lpszBaseUrl,
   LPCTSTR lpszModelName,
   LPCTSTR lpszApiKey,
   LPCTSTR lpszApiVersion,
   LPLLM_SESSION *lppSession
);
```

The **LlmCreateSession** function allocates and initializes an `LLM_SESSION` structure using the specified connection parameters.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the `LLM_PROVIDER` constants. Refer to the providers page for a list of supported providers and their default models.

lpszBaseUrl

A pointer to a null-terminated string that specifies the base URL for the provider endpoint. This parameter may be NULL to use the default endpoint for the selected provider. Some providers, such as Microsoft Foundry or local services, require a specific base URL.

lpszModelName

A pointer to a null-terminated string that specifies the model name to use for the session. This parameter may be NULL to use the provider default model, if one is defined. Providers without a default model require an explicit model name.

lpszApiKey

A pointer to a null-terminated string that specifies the API key used to authenticate with the provider. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries.

lpszApiVersion

A pointer to a null-terminated string that specifies the API version required by the provider. This parameter may be NULL if the provider does not require an explicit version. Some providers, such as Microsoft and Anthropic, may require a version string when establishing a connection.

lppSession

A pointer to a variable that receives a pointer to an allocated `LLM_SESSION` structure. On successful return, this parameter will contain a pointer to a structure that can be passed to **LlmConnectEx**. The structure must be released using the **LlmDeleteSession** function when it is no longer needed.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmCreateSession** function is a helper function that allocates and initializes an `LLM_SESSION` structure using the specified parameters. This simplifies working with session structures, particularly in

languages that do not easily support structure initialization or require explicit memory management. This function is typically used in conjunction with **LlmConnectEx** when an application requires extended session configuration.

The structure returned by this function is allocated by the library and must be released using the **LlmDeleteSession** function. Failing to release the structure will result in a memory leak.

Applications using languages that do not support pointer-to-pointer parameters may treat the *lppSession* parameter as an opaque pointer value. In this case, the variable should be defined using an integer type that is large enough to hold a pointer value, such as UINT_PTR or an equivalent type. Applications must ensure that the correct pointer size is used for the target platform.

Once a connection has been established using **LlmConnectEx**, the session structure is no longer required and may be released using **LlmDeleteSession**. The library creates an internal copy of the session configuration, so the original structure does not need to remain allocated for the lifetime of the client session.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    HCLIENT hClient = INVALID_CLIENT;
    LPLLM_SESSION lpSession = NULL;
    DWORD dwError = NO_ERROR;

    // Initialize the SocketTools library
    if (!LlmInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Initialization failed: %lu\n"), LlmGetLastError());
        return 1;
    }

    // Create a session structure using helper function
    if (!LlmCreateSession(LLM_PROVIDER_OPENAI,
                          NULL,                      // Default URL
                          _T("gpt-5.4-nano"),        // Model name
                          _T("%OPENAI_API_KEY%"),    // API key
                          NULL,                      // API version
                          &lpSession))
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Unable to create session, error %lu\n"), dwError);
        LlmUninitialize();
        return 1;
    }

    // Establish a connection using the session structure
    hClient = LlmConnectEx(LLM_PROVIDER_OPENAI,
                           LLM_OPTION_DEFAULT,
                           lpSession);

    if (hClient == INVALID_CLIENT)
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
```

```
        // Clean up session before exit
        LlmDeleteSession(&lpSession);
        LlmUninitialize();
        return 1;
    }

    // The session structure is no longer needed after connecting
    LlmDeleteSession(&lpSession);

    TCHAR szResponse[4096] = {0};
    DWORD dwResponseLength = _countof(szResponse);
    DWORD dwMessageId = 0;

    if (LlmSendMessage(hClient,
                       _T("What is the capital city of Denmark?"),
                       szResponse,
                       &dwResponseLength,
                       &dwMessageId))
    {
        _tprintf(_T("Response:\n%s\n"), szResponse);
    }
    else
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    LlmDisconnect(hClient);
    LlmUninitialize();

    return 0;
}
```

Requirements

LlmCreateSessionEx Function

```
BOOL WINAPI LlmCreateSessionEx(
   DWORD dwProviderId,
   DWORD dwReserved,
   LPCTSTR lpszBaseUrl,
   LPCTSTR lpszModelName,
   LPCTSTR lpszApiKey,
   LPCTSTR lpszApiVersion,
   LPCTSTR lpszSystemPrompt,
   LONG nMaxTokens,
   FLOAT fTemperature,
   FLOAT fTopP,
   LPLLM_SESSION *lppSession
);
```

The **LlmCreateSessionEx** function allocates and initializes an `LLM_SESSION` structure using the specified session parameters.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the `LLM_PROVIDER` constants. Refer to the providers page for a list of supported providers and their default models.

dwReserved

Reserved for future use. This parameter must be zero.

lpszBaseUrl

A pointer to a null-terminated string that specifies the base URL for the provider endpoint. This parameter may be NULL to use the default endpoint for the selected provider. Some providers, such as Microsoft Foundry or local services, require a specific base URL.

lpszModelName

A pointer to a null-terminated string that specifies the model name to use for the session. This parameter may be NULL to use the provider default model, if one is defined. Providers without a default model require an explicit model name.

lpszApiKey

A pointer to a null-terminated string that specifies the API key used to authenticate with the provider. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries.

lpszApiVersion

A pointer to a null-terminated string that specifies the API version required by the provider. This parameter may be NULL if the provider does not require an explicit version. Some providers, such as Microsoft and Anthropic, may require a version string when establishing a connection.

lpszSystemPrompt

A pointer to a null-terminated string that specifies the system prompt used to provide instructions to the model. This parameter may be NULL if no system prompt is required.

nMaxTokens

The maximum number of tokens that may be generated in the response. Specify zero to use the provider or model default.

fTemperature

The temperature value used to control response variability. Lower values produce more predictable responses, while higher values allow more variation. Specify `LLM_TEMPERATURE_DEFAULT` to use the default value.

fTopP

The nucleus sampling value used to limit token selection based on probability. Specify `LLM_TOP_P_DEFAULT` to use the default behavior. Most applications should leave this value at the default unless they specifically need to tune sampling behavior.

lppSession

A pointer to a variable that receives a pointer to an allocated `LLM_SESSION` structure. On successful return, this parameter will contain a pointer to a structure that can be passed to **LlmConnectEx**. The structure must be released using the **LlmDeleteSession** function when it is no longer needed.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmCreateSessionEx** function is a helper function that allocates and initializes an `LLM_SESSION` structure using the specified parameters. This simplifies working with session structures, particularly in languages that do not easily support structure initialization or require explicit memory management. This function is typically used in conjunction with **LlmConnectEx** when an application requires extended session configuration.

This function is intended for applications that want to configure commonly used session values without directly initializing the `LLM_SESSION` structure. Applications that need more control can allocate and initialize the structure themselves, or use the **LlmCreateSession** function and modify the returned structure before calling **LlmConnectEx**.

The structure returned by this function is allocated by the library and must be released using the **LlmDeleteSession** function. Failing to release the structure will result in a memory leak.

Applications using languages that do not support pointer-to-pointer parameters may treat the *lppSession* parameter as an opaque pointer value. In this case, the variable should be defined using an integer type that is large enough to hold a pointer value, such as UINT_PTR or an equivalent type. Applications must ensure that the correct pointer size is used for the target platform.

Once a connection has been established using **LlmConnectEx**, the session structure is no longer required and may be released using **LlmDeleteSession**. The library creates an internal copy of the session configuration, so the original structure does not need to remain allocated for the lifetime of the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmDeleteSession Function

```
BOOL WINAPI LlmDeleteSession(
   LPLLM_SESSION *lppSession
);
```

The **LlmDeleteSession** function releases an `LLM_SESSION` structure allocated by **LlmCreateSession** or **LlmCreateSessionEx**.

Parameters

lppSession

A pointer to a variable that contains a pointer to an `LLM_SESSION` structure previously allocated by **LlmCreateSession** or **LlmCreateSessionEx**. On successful return, the pointer is set to NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmDeleteSession** function releases the memory allocated for an `LLM_SESSION` structure created by **LlmCreateSession** or **LlmCreateSessionEx**. This function should be used only with session structures allocated by the library.

Do not call this function with an `LLM_SESSION` structure allocated by the application, declared on the stack, or embedded in another structure. Only the exact pointer returned by **LlmCreateSession** or **LlmCreateSessionEx** should be passed to this function. Passing any other pointer may cause the application to fail.

After a session structure has been used with **LlmConnectEx**, it may be deleted immediately. The library makes an internal copy of the session configuration when the client session is created, so the original structure does not need to remain allocated for the lifetime of the client handle.

This function does not disconnect an active client session. To close a connection created by **LlmConnect** or **LlmConnectEx**, call **LlmDisconnect**.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    HCLIENT hClient = INVALID_CLIENT;
    LPLLM_SESSION lpSession = NULL;
    DWORD dwError = NO_ERROR;

    // Initialize the SocketTools library
    if (!LlmInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Initialization failed: %lu\n"), LlmGetLastError());
        return 1;
    }

    // Create a session structure using helper function
    if (!LlmCreateSession(LLM_PROVIDER_OPENAI,
```

```
                        NULL,                       // Default base URL
                        _T("gpt-5.4-nano"),         // Model name
                        _T("%OPENAI_API_KEY%"),     // Provider API key
                        NULL,                       // API version
                        &lpSession))
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Unable to create session, error %lu\n"), dwError);
        LlmUninitialize();
        return 1;
    }

    // Establish a connection using the session structure
    hClient = LlmConnectEx(LLM_PROVIDER_OPENAI,
                           LLM_OPTION_DEFAULT,
                           lpSession);

    if (hClient == INVALID_CLIENT)
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);

        // Clean up session before exit
        LlmDeleteSession(&lpSession);
        LlmUninitialize();
        return 1;
    }

    // The session structure is no longer needed after connecting
    LlmDeleteSession(&lpSession);

    TCHAR szResponse[4096] = {0};
    DWORD dwResponseLength = _countof(szResponse);
    DWORD dwMessageId = 0;

    if (LlmSendMessage(hClient,
                       0,
                       _T("What is the capital city of Denmark?"),
                       szResponse,
                       &dwResponseLength,
                       &dwMessageId))
    {
        _tprintf(_T("Response:\n%s\n"), szResponse);
    }
    else
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    LlmDisconnect(hClient);
    LlmUninitialize();

    return 0;
}
```

LlmDisableTrace Function

```
BOOL WINAPI LlmDisableTrace();
```

The **LlmDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, a value of zero is returned.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

LlmEnableTrace

LlmDisconnect Function

```
INT WINAPI LlmDisconnect(
   HCLIENT hClient
);
```

The **LlmDisconnect** function closes the connection and releases the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmDisconnect** function closes the active connection and releases all memory and resources associated with the specified client session. After this function returns successfully, the client handle is no longer valid and must not be used with any other function.

This function also releases the conversation history, cached message and response data, provider information and any other state maintained for the client session. To preserve information from the session, retrieve it before calling this function.

Applications should call **LlmDisconnect** for every successful call to **LlmConnect** or **LlmConnectEx**. This function should be called before **LlmUninitialize**.

Avoid calling this function while another thread is using the client handle or while a blocking request is in progress. If a request must be canceled, call **LlmCancelRequest** first and wait for the blocking function to return before disconnecting the client session. The **LlmIsBlocking** function can tell you if the library is in the middle of processing a blocking operation, such as retrieving the response to a message prompt.

Requirements

LlmEnableTrace Function

```
BOOL WINAPI LlmEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **LlmEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmEnumModels Function

```
LONG WINAPI LlmEnumModels(
   HCLIENT hClient,
   LPLLM_MODEL_INFO lpModelList,
   LONG nMaxModels,
   DWORD dwOptions
);
```

The **LlmEnumModels** function returns a list of available models which match the provided options.

Parameters

hClient

A handle to the client session.

lpModelList

A pointer to an array of LLM_MODEL_INFO structures that will receive information about the models which match the specified options. This parameter may be NULL, in which case the function only returns the number of matching models.

nMaxModels

The maximum number of LLM_MODEL_INFO structures in the array specified by the ***lpModelList*** parameter. If ***lpModelList*** is NULL, this value should be zero.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
LLM_MODEL_OPTION_DEFAULT	Returns the default list of chat models for the connected provider.
LLM_MODEL_OPTION_PREVIEW	Include preview or experimental models.
LLM_MODEL_OPTION_STREAMING	Include models that support streaming responses.
LLM_MODEL_OPTION_STRUCTURED	Include models that support structured output, such as JSON mode or schema-constrained responses.
LLM_MODEL_OPTION_REASONING	Include models that support reasoning-oriented generation.
LLM_MODEL_OPTION_VISION	Include models that support image input.
LLM_MODEL_OPTION_AUDIO	Include models that support audio output, such as text-to-speech.
LLM_MODEL_OPTION_IMAGE	Include models that support image generation.
LLM_MODEL_OPTION_VIDEO	Include models that support video generation.
LLM_MODEL_OPTION_TRANSCRIPTION	Include models that support audio transcription, such as speech-to-text.
LLM_MODEL_OPTION_DEPRECATED	Include deprecated, retired, or legacy models

	that are not normally returned.
LLM_MODEL_OPTION_ALL_MODELS	Include all known model types for the connected provider.

Return Value

If the function succeeds, the return value is the number of models which match the specified options. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmEnumModels** function enumerates the models available for the provider associated with the client session. The client must have been successfully connected before calling this function. The returned list is based on the provider metadata available to the library and, when supported by the provider, information returned by the provider itself.

To determine how many models match the specified options, call this function with the *lpModelList* parameter set to NULL and the *nMaxModels* parameter set to zero. If the function succeeds, the return value is the number of matching models. You can then allocate an array of LLM_MODEL_INFO structures and call the function again to retrieve the model information.

Each LLM_MODEL_INFO structure should have its *dwSize* member initialized to the size of the structure before calling this function. This enables the library to validate the structure version and maintain compatibility with future releases.

The model list may be cached for a limited period of time to avoid unnecessary requests to the provider. Use **LlmGetCacheTime** and **LlmSetCacheTime** to determine or change the cache lifetime for the client session.

The model capabilities reported by this function are intended to help an application select an appropriate model. Providers may change their model availability, capabilities, or status over time, and the provider remains the final authority on whether a specific model can be used for a request.

Example

```
LONG nModels = LlmEnumModels(hClient, NULL, 0, LLM_MODEL_OPTION_DEFAULT);

if (nModels > 0)
{
    LPLLM_MODEL_INFO lpModelList;

    lpModelList = (LPLLM_MODEL_INFO)calloc(nModels, sizeof(LLM_MODEL_INFO));

    if (lpModelList != NULL)
    {
        for (LONG nIndex = 0; nIndex < nModels; nIndex++)
            lpModelList[nIndex].dwSize = sizeof(LLM_MODEL_INFO);

        nModels = LlmEnumModels(hClient, lpModelList, nModels,
LLM_MODEL_OPTION_DEFAULT);

        if (nModels != LLM_ERROR)
        {
            for (LONG nIndex = 0; nIndex < nModels; nIndex++)
                _tprintf(_T("%s\n"), lpModelList[nIndex].szName);
        }
```

```
        free(lpModelList);
    }
}
else if (nModels == LLM_ERROR)
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to enumerate models, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmEnumProviders Function

```
LONG WINAPI LlmEnumProviders(
   LPLLM_PROVIDER_INFO lpProviderList,
   LONG nMaxProviders,
   DWORD dwReserved
);
```

The **LlmEnumProviders** function returns a list of supported service providers.

Parameters

lpProviderList

A pointer to an array of LLM_PROVIDER_INFO structures that will receive information about the supported providers. This parameter may be NULL, in which case the function only returns the number of providers.

nMaxProviders

The maximum number of LLM_PROVIDER_INFO structures in the array specified by the *lpProviderList* parameter. If *lpProviderList* is NULL, this value should be zero.

dwReserved

Reserved for future use. This parameter must be zero.

Return Value

If the function succeeds, the return value is the number of providers. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmEnumProviders** function returns information about the LLM service providers supported by the library. This includes the provider identifier, provider name, host name, default model name, protocol, port number, and capability flags.

To determine how many providers are available, call this function with the *lpProviderList* parameter set to NULL and the *nMaxProviders* parameter set to zero. If the function succeeds, the return value is the number of providers. You can then allocate an array of LLM_PROVIDER_INFO structures and call the function again to retrieve the provider information.

Each LLM_PROVIDER_INFO structure should have its *dwSize* member initialized to the size of the structure before calling this function. This enables the library to validate the structure version and maintain compatibility with future releases.

The list returned by this function only identifies providers that are known to the library. It does not verify that the provider is currently reachable, that an account is active, or that a valid API key has been configured.

Example

```
LONG nProviders = LlmEnumProviders(NULL, 0, 0);

if (nProviders > 0)
{
    LPLLM_PROVIDER_INFO lpProviderList;

    lpProviderList = (LPLLM_PROVIDER_INFO)calloc(nProviders,
sizeof(LLM_PROVIDER_INFO));
```

```
    if (lpProviderList != NULL)
    {
        for (LONG nIndex = 0; nIndex < nProviders; nIndex++)
            lpProviderList[nIndex].dwSize = sizeof(LLM_PROVIDER_INFO);

        nProviders = LlmEnumProviders(lpProviderList, nProviders, 0);

        if (nProviders != LLM_ERROR)
        {
            for (LONG nIndex = 0; nIndex < nProviders; nIndex++)
                _tprintf(_T("%s\n"), lpProviderList[nIndex].szDisplayName);
        }

        free(lpProviderList);
    }
}
else if (nProviders == LLM_ERROR)
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to enumerate providers, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmEstimateTokenCount Function

```
LONG WINAPI LlmEstimateTokenCount(
   DWORD dwProviderId
   LPCTSTR lpszMessageText,
   INT cchMessageText
);
```

The **LlmEstimateTokenCount** function estimates the number of tokens in a string.

Parameters

dwProviderId

The identifier of the provider used to estimate the token count. This value determines the tokenization rules that are applied, as different providers may use different tokenization algorithms.

lpszMessageText

A pointer to a null-terminated string containing the text to be analyzed. This parameter cannot be NULL.

cchMessageText

The number of characters in the string specified by the ***lpszMessageText*** parameter. If this value is -1, the string is assumed to be null-terminated.

Return Value

If the function succeeds, the return value is the estimated number of tokens in the specified string. If there are no text characters, or the string only contains whitespace, the function will return zero. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmEstimateTokenCount** function provides an approximate count of the number of tokens that would be required to represent the specified text for a given provider. This can be useful when estimating prompt size and ensuring that requests remain within model limits.

The ***lpszMessageText*** parameter must contain valid Unicode text and cannot contain arbitrary binary data or embedded null characters. If malformed Unicode is detected, the function will fail and return LLM_ERROR, with the last error code set to ST_ERROR_INVALID_UNICODE. If the string consists only of whitespace characters, including non-breaking spaces, the function will return zero.

The ANSI version of this function expects the input string to contain either ASCII or UTF-8 encoded text. Strings encoded using a localized ANSI code page are not supported and may fail validation if they contain non-ASCII characters. To ensure internationalized text is processed correctly, it is recommended that you use the Unicode version of this function whenever possible.

A token is a unit of text used internally by large language models. Tokens are not the same as characters or words. In general, a token may represent a single word, part of a word, or a short sequence of characters. For example, common words may be represented as a single token, while less common or longer words may be split into multiple tokens. Punctuation and whitespace may also be represented as separate tokens.

As a general rule of thumb, one token corresponds to approximately three to four characters of English text. This can vary significantly depending on the content, language, and tokenization rules used by the provider.

Most providers distinguish between input tokens (the text sent to the model) and output tokens (the text generated by the model in response). Usage and billing are typically based on the total number of tokens processed, including both the prompt and the generated response. Monitoring token usage can help applications control costs and ensure that requests remain within the limits imposed by the selected model.

The tokenization rules used by each provider can vary, and the exact number of tokens used in a request is determined by the provider at runtime. The value returned by this function is an estimate only and should not be relied on as an exact measurement.

This function does not require an active client session and can be used independently to estimate token usage before establishing a connection or sending a request.

To determine how many input and output tokens have been used in a session, use the **LlmGetTokenUsage** function.

Example

```
LPCTSTR lpszMessageText = _T("Explain how a TCP connection is established.");

LONG nTokens = LlmEstimateTokenCount(LLM_PROVIDER_OPENAI, lpszMessageText, -1);

if (nTokens != LLM_ERROR)
{
    _tprintf(_T("Estimated token count: %d\n"), nTokens);
}
else
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to estimate token count, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmExportHistory Function

```
BOOL WINAPI LlmExportHistory(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LONG nMessageCount,
   LPLONG lpnExported
);
```

The **LlmExportHistory** function exports the conversation history to a JSON-formatted file.

Parameters

hClient

A handle to the client session.

lpszFileName

A pointer to a null-terminated string which specifies the name of the file to be created. This parameter cannot be NULL or a zero-length string.

nMessageCount

The number of the most recent messages and responses which should be exported. If this value is zero, all messages in the current conversation are exported.

lpnExported

A pointer to an integer which will receive the number of messages which were exported when the function returns. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmExportHistory** function exports the current conversation history associated with the client session to a JSON-formatted file. The exported history includes both client messages and model responses stored in the current session history.

This function only exports conversation history currently stored in memory for the client session. It cannot be used if the conversation history has been disabled by setting the history size to zero.

If the *lpszFileName* parameter specifies a directory or device name, the function will fail. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters, they will be removed. If the file already exists, the current process must have permission to overwrite the file. If the file has the read-only attribute set, the function will fail and the last error code will be set to `ST_ERROR_ACCESS_DENIED`.

If the *nMessageCount* parameter is non-zero, the function exports only the most recent messages in the conversation history. Older messages are skipped. If the specified count exceeds the number of available messages, all available messages are exported.

The exported file uses UTF-8 encoded JSON text and is intended to be human-readable. Applications should not depend on the exact formatting or internal structure of the file because future versions of the library may include additional metadata or fields. To help prevent data loss, the function writes the exported history to a temporary file and only replaces the destination file after the export operation

has completed successfully. If the export fails, any existing file specified by the *lpszFileName* parameter is left unchanged.

The exported file is intended to provide a simple mechanism for persisting conversation state between application sessions. A previously exported history file can later be restored using the **LlmImportHistory** function.

Important: The conversation history may contain sensitive or private information. Applications should take reasonable precautions to protect exported history files, such as limiting access permissions or encrypting the exported file. Applications which allow users to export conversation history should consider informing users that the exported file may contain private information.

Example

```
LONG nExported = 0;

// Export the complete conversation history to a JSON file
if (LlmExportHistory(hClient,
                     _T("%USERPROFILE%\\Documents\\conversation.json"),
                     0,
                     &nExported))
{
    _tprintf(_T("Exported %ld messages\n"), nExported);
}
else
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to export conversation history, error 0x%08lX\n"),
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmFindMessage Function

```
DWORD WINAPI LlmFindMessage(
   HCLIENT hClient,
   LPCTSTR lpszPattern,
   DWORD dwStartMessageId,
   DWORD dwOptions
);
```

The **LlmFindMessage** function searches the client conversation history for matching text.

Parameters

hClient

A handle to the client session.

lpszPattern

A null-terminated string which specifies the text that should be searched for. This may be a literal string or it may specify a simplified regular expression. The search options can be used to specify if the search is case-sensitive. This parameter cannot be NULL or a string which only contains whitespace.

dwStartMessageId

An unsigned integer which specifies the message ID that the search should begin with. If this parameter value is zero, the search begins with the oldest message in the client history.

dwOptions

An unsigned integer that specifies one or more search options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
LLM_SEARCH_DEFAULT	Search the entire message history for matching text.
LLM_SEARCH_PROMPT	Search the history of message prompts for matching text.
LLM_SEARCH_CASE_SENSITIVE	The pattern match will be case-sensitive. If this option is not specified, matches are not case-sensitive.
LLM_SEARCH_LITERAL_MATCH	Perform a literal string search instead of using a regular expression.

Return Value

If a matching message is found, the function returns a non-zero message ID. If no message prompts and/or responses match the search pattern, the function returns zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmFindMessage** function searches the message history for text that matches a specific pattern. The search can be limited to prompts, responses, or both, depending on the options specified by the *dwOptions* parameter. The pattern you are matching against must be a null-terminated string and it cannot consist of only whitespace characters (spaces, tabs, carriage returns and linefeeds).

If the *dwStartMessageId* parameter is non-zero, the function will begin searching with the first message whose identifier is equal to or greater than the specified value. Message identifiers are unique within a client session and are assigned incrementally, so newer messages will always have

higher identifier values than older messages.

If the ***lpszPattern*** parameter does not contain any regular expression constructs (such as **^**, **$**, **[ ]**, or quantifiers like ***** and **+**), the search is performed using a simple substring comparison. Regular expression matching is automatically enabled when the pattern contains recognized regular expression constructs, unless the LLM_SEARCH_LITERAL_MATCH option is specified.

If a regular expression pattern is specified, the function compiles the pattern and searches the message content for a match. The regular expression matching uses a simplified version which only supports anchors, wildcards, match classes (enclosed in brackets) and a limited number of escape sequences such as **\d** to match any digit or **\s** to match any space character. It does not support grouping or replacement.

Supported regular expression constructs include:

- The caret **^** and dollar symbol **$** for the beginning and end of the content.
- The period **.** to match any character.
- Character classes such as **[abc]** which would match any of the characters enclosed in brackets.
- Negated classes such as **[^abc]** which would match if none of those characters are found.
- Escaped matches such as **\d** for digits, **\w** for word characters and **\s** for whitespace characters
- The **+** quantifier can be used to match one or more occurrences.
- The ***** quantifier will match zero or more occurrences.

This function uses a minimal regular expression parser and does not include support for complex constructs such as grouping, backreferences or alternation using the pipe **|** character. If you want to search for text which may contain characters typically used in regular expressions such as **[** or **$**, you can either escape them using a backslash, or you can use the LLM_SEARCH_LITERAL_MATCH option which forces the function to only perform a substring search.

Applications searching for arbitrary user-entered text should usually specify the LLM_SEARCH_LITERAL_MATCH option to avoid unintended interpretation of regular expression characters. This will avoid situations where a user may unexpectedly enter search text which appears to be a regular expression pattern.

Regular expression matches are performed against the entire prompt or response text and are not implicitly anchored. It is also important to keep in mind that matches can span multiple lines (they do not end at line breaks) and will attempt to match as much text as possible (this is sometimes referred to as a "greedy match"). This can yield unexpected results if you use wildcards in the pattern which are overly broad, matching large sections of the prompt or response text. For example, a pattern like ".*abc" will match everything until the last instance of "abc" is found.

If you are calling this function in C, C++ or another C-like language and want to use a backslash in your regular expression, remember you will need to escape the backslash (in other words, use double backslashes). For example, if you wanted to use the regular expression \d+\s+ in your pattern, the C string literal would look like "\\d+\\s+", otherwise the compiler will probably warn you about unrecognized escape sequences.

If neither the LLM_SEARCH_PROMPT nor LLM_SEARCH_RESPONSE options are explicitly specified, the search will match against both message prompts and responses.

The **LlmGetMessageById** function can be used to obtain the complete contents of the prompt and/or response for a matching message.

Example

```
LPCTSTR lpszPattern = _T("exception.*handler");
DWORD dwOptions = LLM_SEARCH_DEFAULT;
DWORD dwMessageId = 0;

// Find the first message that contains the specified text
dwMessageId = LlmFindMessage(hClient, lpszPattern, dwMessageId, dwOptions))

if (dwMessageId != 0)
{
    _tprintf(_T("Found match in message ID %lu\n"), dwMessageId);

    // Continue searching for additional matches
    do
    {
        dwMessageId = LlmFindMessage(hClient, lpszPattern, dwMessageId + 1,
dwOptions);

        if (dwMessageId != 0)
            _tprintf(_T("Found another match in message ID %lu\n"), dwMessageId);
    }
    while (dwMessageId != 0);
}
else
{
    _tprintf(_T("No matching messages were found.\n"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmFormatTimestamp Function

```
BOOL INT LlmFormatTimestamp(
   TIME_T tTimestamp,
   LPTSTR lpszDateTime,
   INT nMaxLength,
   BOOL bLocalTime
);
```

The **LlmFormatTimestamp** function converts a timestamp value to an ISO 8601 formatted date and time string.

Parameters

tTimestamp

A 64-bit timestamp value associated with a message or response. This value represents the number of seconds that have elapsed since January 1, 1970 UTC.

lpszDateTime

A pointer to a buffer that receives the formatted date and time string. This parameter cannot be NULL and must be large enough to store the entire string, including the terminating null character.

nMaxLength

The size of the buffer specified by the lpszDateTime parameter, in characters. This value must be large enough to store the formatted string. A buffer of at least 32 characters is recommended.

bLocalTime

If this parameter is non-zero, the timestamp is converted to the local system time before formatting. If this parameter is zero, the timestamp is formatted as Coordinated Universal Time (UTC).

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmFormatTimestamp** function converts a timestamp value returned by the library into a human-readable date and time string using the ISO 8601 format. This format is consistent, unambiguous, and suitable for logging, display, or storage.

The *tTimestamp* parameter is a standard 64-bit Unix time value and can be used interchangeably with functions in the C standard library such as **`gmtime`** or **`localtime`**. Because it is a 64-bit integer, it is not impacted by the Year 2038 problem. Timestamps are returned by functions such as **LlmSendMessage** and can be converted into a local date and time using the **LlmConvertTimestamp** function.

The formatted string is returned in the form "YYYY-MM-DDThh:mm:ssZ" when UTC is specified. When local time is specified, the string is returned in the form "YYYY-MM-DDThh:mm:ss+hh:mm" or "YYYY-MM-DDThh:mm:ss-hh:mm", depending on the current time zone offset.

When *bLocalTime* is non-zero, the formatted string includes the local time zone offset. This ensures that the resulting value is not ambiguous and preserves the ISO 8601 format.

Applications that require locale-specific formatting or alternative date and time representations should convert the timestamp using **LlmConvertTimestamp** and apply additional formatting as needed. If you need to display the date and time using conventions for the current locale, use functions such as

GetDateFormatEx and **GetTimeFormatEx** in the Windows API.

Example

```
// Enumerate the message history and display message details
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE), 0 };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE), 0 };

if (LlmGetFirstMessage(hClient, 0, &clientMessage, &serverResponse))
{
    do
    {
        TCHAR szDateTime[64] = {0};

        LlmFormatTimestamp(clientMessage.tTimestamp, szDateTime,
_countof(szDateTime), FALSE);

        _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
        _tprintf(_T("  Timestamp:       %s\n"), szDateTime);
        _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
        _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);

        LlmFormatTimestamp(serverResponse.tTimestamp, szDateTime,
_countof(szDateTime), FALSE);

        _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
        _tprintf(_T("  Timestamp:       %s\n"), szDateTime);
        _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
        _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
    }
    while (LlmGetNextMessage(hClient, &clientMessage, &serverResponse));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetCacheTime Function

```
INT WINAPI LlmGetCacheTime(
   HCLIENT hClient
);
```

The **LlmGetCacheTime** function returns the current cache lifetime, in seconds, for the specified client session.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the current cache time in seconds. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetCacheTime** function retrieves the amount of time, in seconds, that provider and model information is cached by the client session. Caching this information reduces the number of requests made to the provider and can improve performance when repeatedly querying for models or provider metadata.

By default, the cache lifetime for a client session is one hour (3600 seconds). The cache time can be adjusted using the **LlmSetCacheTime** function. Shorter cache times will refresh provider and model information more frequently, while longer cache times can reduce network activity.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmGetClientOptions Function

```
BOOL WINAPI LlmGetClientOptions(
    HCLIENT hClient,
    LPDWORD lpdwOptions
);
```

The **LlmGetClientOptions** function returns the current client option flags.

Parameters

hClient

A handle to the client session.

lpdwOptions

A pointer to an unsigned integer that will be set to the current client options when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetClientOptions** function returns the current option flags for the client session. The variable specified by the *lpdwOptions* parameter will be initialized to LLM_OPTION_NONE and then updated with the client options before the function returns. The value may contain one or more of the following flags combined with a bitwise OR operation.

Value	Description
LLM_OPTION_NOCACHE	Disables provider and model metadata caching for the client session. When this option is specified, the library will not reuse cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
LLM_OPTION_KEEPALIVE	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
LLM_OPTION_PROXY	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
LLM_OPTION_NOUSERAGENT	Prevents the library from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be used when a provider does not require a User-Agent

	header.
LLM_OPTION_SECURE	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base URL or provider default would normally use an insecure protocol, it will be upgraded to a secure connection. Connections to providers such as OpenAI, Google and Anthropic will always be secure.

This function can be used in conjunction with **LlmSetClientOptions** to query and modify client behavior at runtime.

Example

```
DWORD dwProviderId = LLM_PROVIDER_NONE;
TCHAR szBaseUrl[MAX_PATH] = {0};

// Determine the provider ID for the current session and get
// the base URL used for API requests
dwProviderId = LlmGetClientProvider(hClient, szBaseUrl, _countof(szBaseUrl));

if (dwProviderId == LLM_PROVIDER_NONE)
{
    _tprintf(_T("Unable to get provider ID for this session\n"));
    return;
}

// Get the current client options
DWORD dwOptions = LLM_OPTION_NONE;

if (!LlmGetClientOptions(hClient, &dwOptions))
{
    _tprintf(_T("Unable to get client options for this session\n"));
    return;
}

// Get information about the current provider
LLM_PROVIDER_INFO providerInfo = { sizeof(providerInfo), 0 };

if (!LlmGetProviderInfo(dwProviderId, &providerInfo))
{
    _tprintf(_T("Unable to get provider information\n"));
    return;
}

_tprintf(_T("Connected to %s using %s, the connection is %s\n"),
         providerInfo.szDisplayName,
         szBaseUrl,
         ((dwOptions & LLM_OPTION_SECURE) ? _T("secure") : _T("not secure")));
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmGetClientProvider Function

```
DWORD WINAPI LlmGetClientProvider(
    HCLIENT hClient,
    LPCTSTR lpszBaseUrl,
    INT nMaxLength
);
```

The **LlmGetClientProvider** function returns the provider associated with the specified client session and, optionally, the base URL used for requests.

Parameters

hClient

A handle to the client session.

lpszBaseUrl

A pointer to a buffer that receives the base URL used by the client session when making requests to the provider. This parameter may be NULL if the base URL is not required.

nMaxLength

The size of the buffer specified by the ***lpszBaseUrl*** parameter, in characters. If ***lpszBaseUrl*** is NULL, this value should be zero. If a buffer is provided, it must be large enough to store the complete URL, including the terminating null character.

Return Value

If the function succeeds, the return value is the provider ID. If the function fails, the return value is LLM_PROVIDER_UNKNOWN. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetClientProvider** function can be used to determine which provider is currently associated with a client session. This is useful when an application supports multiple providers and needs to adjust its behavior based on the active provider.

If the ***lpszBaseUrl*** parameter is specified, the function also returns the base URL used by the client when communicating with the provider. This may be a default URL defined by the library or a custom URL specified when the session was created or connected.

The base URL is returned as a null-terminated string. If the buffer is not large enough to receive the entire string, the function fails and sets the error code to ST_ERROR_BUFFER_TOO_SMALL. We recommend a buffer size of at least 256 characters when retrieving the base URL.

To determine the default endpoint URL used by a specific service provider, use the **LlmGetProviderUrl** function.

Example

```
TCHAR szBaseUrl[256] = {0};

DWORD dwProviderId = LlmGetClientProvider(hClient, szBaseUrl, _countof(szBaseUrl));

if (dwProviderId != LLM_PROVIDER_UNKNOWN)
{
    _tprintf(_T("Provider ID: %lu\n"), dwProviderId);
    _tprintf(_T("Base URL: %s\n"), szBaseUrl);
}
```

```
else
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to get provider information, error 0x%08lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

LlmGetProviderFlags, LlmGetProviderId, LlmGetProviderInfo, LlmGetProviderName, LlmGetProviderUrl

LlmGetDefaultModelFlags Function

```
BOOL WINAPI LlmGetDefaultModelFlags(
    DWORD dwProviderId
    LPCTSTR lpszModelName,
    LPDWORD lpdwFlags
);
```

The **LlmGetDefaultModelFlags** function returns the default capability flags for the specified model.

Parameters

dwProviderId

The identifier of the provider associated with the model.

lpszModelName

A null-terminated string which contains the name of the new model. If this parameter is NULL or a zero-length string, the default model for the specified provider will be used.

lpdwFlags

A pointer to an unsigned integer which may have one or more bit flags set when the function returns. If there are no capabilities defined for the specified model, this value will be set to `LLM_MODEL_FLAG_NONE`. This parameter cannot be NULL and the value does not need to be initialized by the caller.

Constant	Description
LLM_MODEL_FLAG_NONE	No model capabilities defined
LLM_MODEL_FLAG_CHAT	Supports conversational text generation
LLM_MODEL_FLAG_SYSTEM_ROLE	Accepts a system role message in the input
LLM_MODEL_FLAG_STREAMING	Supports streaming responses
LLM_MODEL_FLAG_STRUCTURED	Supports structured output (e.g., JSON or schema)
LLM_MODEL_FLAG_VISION	Supports image inputs (multimodal)
LLM_MODEL_FLAG_TOOLS	Supports tool or function calling
LLM_MODEL_FLAG_REASONING	Supports reasoning-oriented generation
LLM_MODEL_FLAG_RESPONSES	Supports the Responses API (unified endpoint)
LLM_MODEL_FLAG_FUNCTIONS	Supports OpenAI-style function calling with schemas
LLM_MODEL_FLAG_AUDIO	Supports audio output (text-to-speech)
LLM_MODEL_FLAG_IMAGE	Supports image generation
LLM_MODEL_FLAG_VIDEO	Supports video generation
LLM_MODEL_FLAG_TRANSCRIPTION	Supports speech-to-text transcription

LLM_MODEL_FLAG_INSTRUCTIONS	Supports a dedicated instruction field outside message lists
LLM_MODEL_FLAG_MAX_COMPLETION_TOKENS	Uses `max_completion_tokens` instead of `max_tokens` in requests
LLM_MODEL_FLAG_INFERRED	Capabilities are inferred rather than explicitly defined

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetDefaultModelFlags** function returns the default capability flags for a model associated with the specified provider. If the model name is recognized, the library will return the inferred capabilities associated with that model. If the model name is not recognized, the *dwFlags* parameter will return `LLM_MODEL_FLAG_NONE`.

This function does not require the application to be connected to a service provider. These capabilities are inferred from an internal table of recognized models and may not always reflect the current behavior of a provider, particularly when providers update, rename or replace models. The **LlmGetModelFlags** function can be used to determine the capabilities of the model that was selected when a connection was established with a provider.

Because the capability flags are derived from the model name rather than explicitly provided by the service provider, the `LLM_MODEL_FLAG_INFERRED` flag will be set for recognized models.

To obtain the name of the default model the library uses for a specific provider, call the **LlmGetDefaultModelName** function.

Example

```
DWORD dwProviderId = LLM_PROVIDER_OPENAI;
TCHAR szModelName[LLM_MODEL_NAMELEN] = _T("");

if (LlmGetDefaultModelName(dwProviderId, szModelName, _countof(szModelName)) > 0)
{
    DWORD dwFlags = LLM_MODEL_FLAG_NONE;

    if (LlmGetDefaultModelFlags(dwProviderId, szModelName, &dwFlags))
    {
        if (dwFlags & LLM_MODEL_FLAG_REASONING)
            _tprintf(_T("The %s model has reasoning capability\n"), szModelName);
    }
    else
    {
        DWORD dwError = LlmGetLastError();
       _tprintf(_T("Unable to retrieve default model flags, error 0x%08lx\n"),
dwError);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmEnumModels, LlmGetDefaultModelName, LlmGetModelInfo, LlmValidateModel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

LlmGetDefaultModelName Function

```
INT WINAPI LlmGetDefaultModelName(
    DWORD dwProviderId
    LPTSTR lpszModelName,
    INT nMaxLength
);
```

The **LlmGetDefaultModelName** function returns the name of the default model for a service provider.

Parameters

dwProviderId

The identifier of the provider whose default model name will be returned.

lpszModelName

A pointer to a buffer that receives the default model name. This parameter may be NULL, in which case the function returns the length of the model name without copying it.

nMaxLength

The size of the buffer specified by the ***lpszModelName*** parameter, in characters. If ***lpszModelName*** is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetDefaultModelName** function returns the default model name associated with the specified provider. This is the model that will be used if a session is created or connected without explicitly specifying a model name. In most cases, the default model is selected to provide a balance of performance and cost, typically favoring smaller, faster models that are suitable for general use. For more information about providers and their default models, refer to the Large Language Model Providers section.

Applications can call this function to determine a suitable default model for a provider, or to present a default selection to the user. The default model may change over time as providers update or replace their models.

If the ***lpszModelName*** parameter is NULL, the function returns the length of the model name, in characters, not including the terminating null character. This allows an application to determine the required buffer size before retrieving the string.

The model name is returned as a null-terminated string. If a buffer is provided but is not large enough to receive the entire string, the function fails and sets the error code to ST_ERROR_BUFFER_TOO_SMALL. A buffer of 128 characters is typically sufficient for most model names.

Example

```
INT cchModelName = LlmGetDefaultModelName(LLM_PROVIDER_OPENAI, NULL, 0);

if (cchModelName > 0)
```

```
{
    LPTSTR lpszModelName;
    lpszModelName = (LPTSTR)malloc((cchModelName + 1) * sizeof(TCHAR));

    if (lpszModelName != NULL)
    {
        if (LlmGetDefaultModelName(LLM_PROVIDER_OPENAI, lpszModelName, cchModelName
+ 1) > 0)
        {
             _tprintf(_T("The default model is %s\n"), lpszModelName);
        }

        free(lpszModelName);
    }
}
else
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to retrieve default model name, error 0x%08lx\n"),
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmGetErrorString Function

```
INT WINAPI LlmGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **LlmGetErrorString** function returns the description of a specific error code.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Remarks

This function is used in conjunction with the **LlmGetLastError** function for use with warning dialogs or as diagnostic messages. Applications should not rely on the returned description text for program logic. Use the numeric error code for comparisons and handling specific conditions.

The error descriptions returned by this function are provided in English only. Applications that require localized error messages should provide their own translations based on the returned error code.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetFirstMessage Function

```
BOOL WINAPI LlmGetFirstMessage(
   HCLIENT hClient,
   DWORD dwReserved,
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **LlmGetFirstMessage** function returns the first available message in the client history.

Parameters

hClient

A handle to the client session.

dwReserved

An integer value reserved for future use. This parameter should always be zero.

lpMessage

A pointer to an LLM_MESSAGE structure that receives information about the client request. This parameter may be NULL, in which case no message information is returned.

lpResponse

A pointer to an LLM_RESPONSE structure that receives information about the server response. This parameter may be NULL, in which case no response information is returned.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**. If there are no messages in the client history, the error code will be set to `ST_ERROR_END_OF_MESSAGES`.

Remarks

The **LlmGetFirstMessage** function retrieves the first message and associated response from the client session history. This function is typically used in conjunction with the **LlmGetNextMessage** function to enumerate all messages in the session.

If the *lpMessage* and/or *lpResponse* parameters are specified, their respective structures must be initialized with the *dwSize* member set to the size of the structure before calling this function. This enables the library to validate the structure version and maintain compatibility with future releases.

Messages are returned in chronological order, beginning with the oldest message in the client history. New messages are always appended to the end of the history, and if the history is trimmed, older messages are removed first. The order of messages is stable and reflects the sequence in which they were submitted.

If there are no messages in the client history, the function fails and sets the error code to ST_ERROR_END_OF_MESSAGES. Applications can use this condition to determine that no messages are available for enumeration.

Either the *lpMessage* or *lpResponse* parameter may be NULL if only one type of information is required. At least one of these parameters must be specified. If both parameters are NULL, the function fails and sets the error code to ST_ERROR_INVALID_PARAMETER.

Example

```
// Enumerate the message history and display message details
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE), 0 };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE), 0 };

if (LlmGetFirstMessage(hClient, 0, &clientMessage, &serverResponse))
{
    do
    {
        _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
        _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
        _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);

        _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
        _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
        _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
    }
    while (LlmGetNextMessage(hClient, &clientMessage, &serverResponse));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetHistorySize Function

```
LONG WINAPI LlmGetHistorySize(
    HCLIENT hClient
);
```

The **LlmGetHistorySize** function returns the maximum number of message exchanges that can be stored in the conversation history.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the maximum size of the conversation history for the client session. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetHistorySize** function returns the maximum number of messages which can be stored in the client conversation history. Each message represents a single request submitted to the model and its associated response.

The conversation history is maintained on a per-session basis and reflects the sequence of interactions performed using the client handle. Messages are stored in chronological order, with new messages appended to the end of the history. To retrieve the contents of a specific message and response from the history, use either the **LlmGetMessage** or **LlmGetMessageById** functions.

It is possible to disable the conversation history by calling the **LlmSetHistorySize** function and specifying a maximum history size of zero. In this case, this function will always return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmGetIdleTime Function

```
INT WINAPI LlmGetIdleTime(
   HCLIENT hClient
);
```

The **LlmGetIdleTime** function returns the current idle time for the specified client session.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the current idle timeout period in seconds. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetIdleTime** function returns the current idle timeout period, in seconds, for the specified client session. This value determines how long a connection can remain idle between requests before the library automatically closes and re-establishes the underlying HTTP connection.

Idle time is used to balance performance and reliability. Reusing an existing connection can reduce overhead and improve performance, particularly when multiple requests are made in quick succession. However, connections that remain idle for extended periods may be closed by the server or by intermediate network infrastructure. When the idle time is exceeded, the library will proactively establish a new connection before sending the next request.

This value is distinct from the timeout period and cache time. The timeout period specifies how long the client will wait for a response to a request before failing, while the cache time controls how long certain responses or metadata may be reused without making a new request. The idle time only affects how long an existing connection is retained between requests.

The idle time can be modified using the **LlmSetIdleTime** function. If a value of zero is specified, a new connection is established for each request. In most cases, the default idle time provides a good balance between performance and compatibility.

It is important to note that this setting only affects client-side behavior. Increasing the idle time does not guarantee that a server will keep the connection open for that duration. Many servers will close idle connections after a shorter period of time, in which case the library will automatically reconnect as needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmGetLastError Function

```
DWORD WINAPI LlmGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **LlmGetLastError** function immediately when a function's return value indicates that an error has occurred. Functions set this value by calling **LlmSetLastError**. The Return Value section of each reference page notes the conditions under which a function sets the last error code.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or LLM_ERROR. Those functions which call **LlmSetLastError** when they succeed are noted on the function reference page.

This function should only be called when a preceding function indicates failure. Calling this function after a successful call may return a value unrelated to the most recent operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmGetMemoryUsage Function

```
BOOL WINAPI LlmGetMemoryUsage(
   HCLIENT hClient,
   PLARGE_INTEGER lpMemUsage
);
```

The **LlmGetMemoryUsage** function returns the number of bytes of memory allocated for the client session.

Parameters

hClient

A handle to the client session.

lpMemUsage

A pointer to a `LARGE_INTEGER` variable which will contain the number of bytes allocated for the client session when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetMemoryUsage** function returns an approximate amount of memory currently allocated for the specified client session. This includes the client session structure, dynamically allocated session data, cached model information, and message history retained by the session.

This function is primarily intended for diagnostics, monitoring, and testing. Applications that maintain long-running sessions or retain large message histories can use this function to monitor how much memory is being used by a client session.

The value returned by this function is rounded up to the nearest system page size and should be treated as an estimate of memory usage rather than an exact byte-for-byte allocation total.

The *lpMemUsage* parameter points to a LARGE_INTEGER structure. The memory usage value is returned in the QuadPart member. In languages that support 64-bit integer values directly, it is safe to pass a pointer to a compatible 64-bit integer variable.

The memory usage reported by this function is limited to memory allocated for the specified client session. It does not include memory used internally by the operating system, networking libraries, provider services, or other process-wide resources.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmGetMessage Function

```
BOOL WINAPI LlmGetMessage(
   HCLIENT hClient,
   LONG nMessageIndex,
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **LlmGetMessage** function retrieves a message turn in the client history using an index value.

Parameters

hClient

A handle to the client session.

nMessageIndex

An integer value which identifies the message using a zero-based index value. This value cannot be less than zero or greater than the number of messages in the conversation history.

lpMessage

A pointer to an LLM_MESSAGE structure that receives information about the client request. This parameter may be NULL, in which case no message information is returned.

lpResponse

A pointer to an LLM_RESPONSE structure that receives information about the server response. This parameter may be NULL, in which case no response information is returned.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetMessage** function retrieves a message and its corresponding response from the client history using a zero-based index value. The index value of zero refers to the oldest message currently stored in the history.

The message history is managed as a first-in, first-out (FIFO) queue. When the number of messages exceeds the configured history size, older messages are automatically removed. As a result, the index value for a given message may change over time. Applications that need to reliably reference a specific message should use the **LlmGetMessageById** function instead.

If message history has been disabled, the library does not retain previous messages. However, the most recent message and response are still available and may be retrieved using an index value of zero. This also means the data returned in the LLM_MESSAGE and LLM_RESPONSE structures will only remain valid until the next call to **LlmSendMessage**, **LlmSendMessageEx**, or until the session is reset or disconnected. Applications that need to preserve this information should make a copy of the data before issuing another request.

If the *nMessageIndex* parameter is less than zero or greater than or equal to the number of messages currently stored in the history, the function will fail and set the error code to ST_ERROR_INVALID_PARAMETER.

If the *lpMessage* and/or *lpResponse* parameters are specified, their respective structures must be initialized with the *dwSize* member set to the size of the structure before calling this function. This

enables the library to validate the structure version and maintain compatibility with future releases.

Either the *lpMessage* or *lpResponse* parameter may be NULL if only one type of information is required. At least one of these parameters must be specified. If both parameters are NULL, the function fails and sets the error code to ST_ERROR_INVALID_PARAMETER.

Example

```
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE) };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE) };
LONG nMessageIndex = 0;

// If conversation history is enabled, retrieve the most recent message.
// If history is disabled, an index of 0 refers to the most recent
// message and response from the previous request.

LONG nCount = LlmGetMessageCount(hClient);

if (LlmGetHistorySize(hClient) > 0 && nCount > 0)
    nMessageIndex = nCount - 1;

if (LlmGetMessage(hClient, nMessageIndex, &clientMessage, &serverResponse))
{
    _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
    _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
    _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
    _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);

    _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
    _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
    _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
    _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
    _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
    _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
    _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
    _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
}
else
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to retrieve message at index %ld (error 0x%08lX)\n"),
nMessageIndex, dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetMessageById Function

```
BOOL WINAPI LlmGetMessageById(
   HCLIENT hClient,
   DWORD dwMessageId,
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **LlmGetMessageById** function retrieves a message turn in the client history based on a numeric identifier.

Parameters

hClient

A handle to the client session.

dwMessageId

A numeric value which identifies a specific message and response.

lpMessage

A pointer to an LLM_MESSAGE structure that receives information about the client request. This parameter may be NULL, in which case no message information is returned.

lpResponse

A pointer to an LLM_RESPONSE structure that receives information about the server response. This parameter may be NULL, in which case no response information is returned.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetMessageById** function retrieves a specific message and its associated response from the client session history. This function can be used when an application has stored a message identifier or has obtained one using functions such as **LlmFindMessage**. Message identifiers are returned when sending requests using **LlmSendMessage** or **LlmSendMessageEx**.

If message history has been disabled, the library does not retain previous messages. However, the most recent message and response are still available and may be retrieved specifying its message identifier. This also means the data returned in the LLM_MESSAGE and LLM_RESPONSE structures will only be valid until the next call to **LlmSendMessage**, **LlmSendMessageEx**, or until the session is reset or disconnected. Applications that need to preserve this information should make a copy of the data before issuing another request.

If the *lpMessage* and/or *lpResponse* parameters are specified, their respective structures must be initialized with the *dwSize* member set to the size of the structure before calling this function. This enables the library to validate the structure version and maintain compatibility with future releases.

Either the *lpMessage* or *lpResponse* parameter may be NULL if only one type of information is required. At least one of these parameters must be specified. If both parameters are NULL, the function fails and sets the error code to ST_ERROR_INVALID_PARAMETER.

Message identifiers are session-specific and are guaranteed to be unique only within the client session in which they were created. Applications must not rely on the internal assignment strategy used to

generate these identifiers. The only guaranteed behavior is that message identifiers are assigned values which ensure newer messages always receive larger values than older messages.

If the specified message identifier does not match a message currently stored in the client history, the function fails. This can occur if the message has been removed because the history was cleared or trimmed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmGetMessageCount Function

```
LONG WINAPI LlmGetMessageCount(
    HCLIENT hClient
);
```

The **LlmGetMessageCount** function returns the current number of messages in the client history.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the number of messages in the client history. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetMessageCount** function returns the number of messages currently stored in the client session history. Each message represents a single request submitted to the model and its associated response.

The conversation history is maintained on a per-session basis and reflects the sequence of interactions performed using the client handle. Messages are stored in chronological order, with new messages appended to the end of the history. To retrieve the contents of a specific message and response from the history, use either the **LlmGetMessage** or **LlmGetMessageById** functions.

It is possible to disable the conversation history by calling the **LlmSetHistorySize** function and specifying a maximum history size of zero. In this case, this function will always return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmGetModelContextSize Function

```
LONG WINAPI LlmGetModelContextSize(
    HCLIENT hClient,
    LPCTSTR lpszModelName
);
```

The **LlmGetModelContextSize** function returns the context size for the specified model.

Parameters

hClient

A handle to the client session. The provider associated with this session is used to determine the context size for the specified model.

lpszModelName

A pointer to a null-terminated string that specifies the name of the model. This parameter may be NULL or an empty string, in which case the context size is returned for the model selected for the current client session. If a model name is specified, it must be valid for the provider associated with the client session.

Return Value

If the function succeeds, the return value is the context size for the model. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetModelContextSize** function returns the maximum number of tokens that can be processed by the specified model in a single request. This value is commonly referred to as the model's context size or context window.

The context size includes both the input provided to the model and the output generated in response. This means that the total number of tokens in a request, including the prompt, conversation history, and generated response, must not exceed this limit.

If the combined number of tokens exceeds the model's context size, the request may be rejected by the provider or the response may be truncated. Applications should take this limit into account when constructing prompts or maintaining long conversation histories.

In general, larger context sizes allow a model to retain more information from previous interactions, but may also increase latency and cost depending on the provider and model being used.

The context size returned by this function should be treated as an approximate limit rather than an absolute value. For some providers, particularly locally hosted models, the effective context size may be configured or adjusted outside of the application. In these cases, the reported value serves as a guideline and may not reflect the exact limit enforced by the model at runtime.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmGetModelFlags Function

```
BOOL WINAPI LlmGetModelFlags(
    HCLIENT hClient,
    LPDWORD lpdwFlags
);
```

The **LlmGetModelFlags** function returns the flags associated with the current model.

Parameters

hClient

A handle to the client session.

lpdwFlags

A pointer to an unsigned integer which may have one or more bit flags set when the function returns. If there are no capabilities defined for the provider, this value will be set to **LLM_MODEL_FLAG_NONE**. This parameter cannot be NULL and the value does not need to be initialized by the caller.

Constant	Description
LLM_MODEL_FLAG_NONE	No model capabilities defined
LLM_MODEL_FLAG_CHAT	Supports conversational text generation
LLM_MODEL_FLAG_SYSTEM_ROLE	Accepts a system role message in the input
LLM_MODEL_FLAG_STREAMING	Supports streaming responses
LLM_MODEL_FLAG_STRUCTURED	Supports structured output (e.g., JSON or schema)
LLM_MODEL_FLAG_VISION	Supports image inputs (multimodal)
LLM_MODEL_FLAG_TOOLS	Supports tool or function calling
LLM_MODEL_FLAG_REASONING	Supports reasoning-oriented generation
LLM_MODEL_FLAG_RESPONSES	Supports the Responses API (unified endpoint)
LLM_MODEL_FLAG_FUNCTIONS	Supports OpenAI-style function calling with schemas
LLM_MODEL_FLAG_AUDIO	Supports audio output (text-to-speech)
LLM_MODEL_FLAG_IMAGE	Supports image generation
LLM_MODEL_FLAG_VIDEO	Supports video generation
LLM_MODEL_FLAG_TRANSCRIPTION	Supports speech-to-text transcription
LLM_MODEL_FLAG_INSTRUCTIONS	Supports a dedicated instruction field outside message lists
LLM_MODEL_FLAG_MAX_COMPLETION_TOKENS	Uses **max_completion_tokens** instead of **max_tokens** in requests

LLM_MODEL_FLAG_INFERRED	Capabilities are inferred rather than explicitly defined

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetModelFlags** function returns a set of bit flags that describe the capabilities supported by the current model associated with the client session. These flags can be used by applications to determine which features are available and adjust behavior accordingly.

Model capabilities may vary between providers and even between models offered by the same provider. Not all providers return complete capability information when enumerating models. In these cases, some flags may be inferred by the library based on the model name and known characteristics of the provider.

Because capability information may be incomplete or inferred, applications should treat these flags as guidance rather than absolute guarantees of behavior. The provider ultimately determines which features are supported and how they are implemented.

The value returned in the *lpdwFlags* parameter is a bitmask and may contain multiple flags combined using a bitwise OR operation. If no capabilities are defined or available for the model, the value will be set to `LLM_MODEL_FLAG_NONE`. In practice, most supported models provide at least basic conversational capabilities, so a value of zero is uncommon and typically indicates that capability information is not available or could not be determined.

In some cases, capability information may be incomplete or inferred. If necessary, applications can override the detected capabilities using the **LlmSetModelFlags** function. This can be useful when working with providers or models that require specific options which are not automatically detected. In general, applications should rely on the default capability detection unless a specific compatibility issue is encountered.

Some flags may be reserved for internal use or represent provider-specific capabilities. Applications should not rely on undocumented flag values and should only test for defined LLM_MODEL_FLAG constants.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

LlmEnumModels, LlmGetModelContextSize, LlmGetModelInfo, LlmGetModelName, LlmSetModelFlags

LlmGetModelInfo Function

```
BOOL WINAPI LlmGetModelInfo(
   HCLIENT hClient,
   LPCTSTR lpszModelName,
   LPLLM_MODEL_INFO lpModelInfo
);
```

The **LlmGetModelInfo** function returns information about a specific model for the current provider.

Parameters

hClient

A handle to the client session.

lpszModelName

A pointer to a null-terminated string that specifies the name of the model. This parameter may be NULL or an empty string, in which case information about the current model associated with the client session is returned.

lpModelInfo

A pointer to an LLM_MODEL_INFO structure that receives information about the model. This parameter cannot be NULL. The ***dwSize*** member of the structure must be initialized before calling this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetModelInfo** function retrieves detailed information about a model associated with the provider used by the client session. If a model name is specified, it must be valid for the current provider. If no model name is specified, the function returns information about the model currently associated with the session.

The ***lpModelInfo*** parameter must point to an LLM_MODEL_INFO structure whose ***dwSize*** member has been initialized to `sizeof(LLM_MODEL_INFO)`. This enables the library to validate the structure version and maintain compatibility with future releases.

The information returned by this function includes the model identifier, provider, capability flags, status flags, token limits, context size, and optional metadata such as display name, owner, version, and creation date. Not all providers supply complete metadata for every model, and some values may be empty or unspecified.

Model capability and limit information should be treated as descriptive metadata rather than an absolute guarantee of behavior. Providers may change model availability, limits, or capabilities over time, and locally hosted models may allow some values, such as context size, to be configured outside of the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

Unicode: Implemented as Unicode and ANSI versions

LlmGetNextMessage Function

```
BOOL WINAPI LlmGetNextMessage(
   HCLIENT hClient,
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **LlmGetNextMessage** function returns the next available message in the client history.

Parameters

hClient

A handle to the client session.

lpMessage

A pointer to an LLM_MESSAGE structure which receives information about the next message in the client history. This parameter may be NULL if the message information is not needed.

lpResponse

A pointer to an LLM_RESPONSE structure which receives information about the response associated with the message. This parameter may be NULL if the response information is not needed.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**. When the last message in the history is reached, the error code will be set to `ST_ERROR_END_OF_MESSAGES`.

Remarks

The **LlmGetNextMessage** function is used to enumerate the messages stored in the client history. Each successful call advances the internal enumeration position and returns information about the next message and, if available, the response associated with that message.

If the *lpMessage* or *lpResponse* parameters are specified, the structures must be initialized before calling this function. The dwSize member must be set to the size of the corresponding structure. This enables the function to validate the structure version and safely return the requested information.

Either *lpMessage* or *lpResponse* may be NULL. This is useful when an application only needs to enumerate the original messages or only needs information about the responses. At least one of these parameters should be specified.

To begin enumerating messages, call **LlmGetFirstMessage** to retrieve the first message in the client history. Subsequent messages can then be retrieved by calling **LlmGetNextMessage** until the function returns zero and the last error code is set to ST_ERROR_END_OF_MESSAGES. This condition indicates the enumeration has completed and should not be treated as a failure.

Example

```
// Enumerate the message history and display message details
LLM_MESSAGE clientMessage = { sizeof(LLM_MESSAGE), 0 };
LLM_RESPONSE serverResponse = { sizeof(LLM_RESPONSE), 0 };

if (LlmGetFirstMessage(hClient, 0, &clientMessage, &serverResponse))
{
    do
    {
```

```
        _tprintf(_T("\nMessage %u\n"), clientMessage.dwMessageId);
        _tprintf(_T("  Input Tokens:    %u\n"), clientMessage.nInputTokens);
        _tprintf(_T("  Content Length:  %u\n"), clientMessage.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), clientMessage.lpszContent);

        _tprintf(_T("\nResponse %u\n"), serverResponse.dwMessageId);
        _tprintf(_T("  Elapsed:         %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("  Output Tokens:   %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("  Content Length:  %u\n"), serverResponse.nContentLength);
        _tprintf(_T("  Content:         \"%s\"\n"), serverResponse.lpszContent);
        _tprintf(_T("  Response ID:     %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("  Model Name:      %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("  Status Text:     %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));
    }
    while (LlmGetNextMessage(hClient, &clientMessage, &serverResponse));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmGetProviderFlags Function

```
BOOL WINAPI LlmGetProviderFlags(
    DWORD dwProviderId,
    LPDWORD lpdwFlags
);
```

The **LlmGetProviderFlags** function returns the capability flags associated with a provider.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. Refer to the providers page for a list of supported providers and their default models.

lpdwFlags

A pointer to an unsigned integer which receives one or more bit flags when the function returns. If there are no capabilities defined for the provider, this value will be set to LLM_PROVIDER_FLAG_NONE. This parameter cannot be NULL and does not need to be initialized by the caller.

Name	Description
LLM_PROVIDER_FLAG_NONE	No provider requirements specified
LLM_PROVIDER_FLAG_REQUIRE_TLS	Requires a secure TLS (HTTPS) connection
LLM_PROVIDER_FLAG_REQUIRE_AUTH	Requires authentication (e.g., API key or token)
LLM_PROVIDER_FLAG_API_VERSION	Requires an explicit API version parameter
LLM_PROVIDER_FLAG_MODEL_LIST	Supports enumerating available models
LLM_PROVIDER_FLAG_MODEL_INFO	Supports retrieving detailed model information

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetProviderFlags** function retrieves the capability flags associated with the specified provider. These flags describe the features and requirements supported by the provider, such as whether authentication is required or if model enumeration is available.

The value returned in ***lpdwFlags*** may contain one or more LLM_PROVIDER_FLAG values combined with a bitwise OR operation. If no capabilities are defined for the provider, the value will be LLM_PROVIDER_FLAG_NONE.

This function does not require an active client session and can be used to query provider capabilities before establishing a connection. This can be useful when determining how to configure a session or which features are available for a given provider.

If ***dwProviderId*** specifies an invalid provider, the function fails and returns zero.

Example

```
DWORD dwFlags = LLM_PROVIDER_FLAG_NONE;
```

```
if (!LlmGetProviderFlags(dwProviderId, &dwFlags))
{
    _tprintf(_T("Unable to get provider flags\n"));
    return;
}

if (dwFlags & LLM_PROVIDER_FLAG_REQUIRE_AUTH)
{
    _tprintf(_T("Provider requires authentication\n"));
}

if (dwFlags & LLM_PROVIDER_FLAG_MODEL_LIST)
{
    _tprintf(_T("Provider supports model enumeration\n"));
}
```

Requirements

LlmGetProviderId Function

```
DWORD WINAPI LlmGetProviderId(
   LPCTSTR lpszProviderName,
   LPCTSTR lpszBaseUrl,
   LPCTSTR lpszModelName
);
```

The **LlmGetProviderId** function returns a provider ID based on a provider name, endpoint URL or model name.

Parameters

lpszProviderName

A null-terminated string which specifies the name of the provider. This parameter may be NULL if you do not wish to match against a provider name. At least one parameter must be specified. If a provider name is specified, it is given precedence over the other parameters.

lpszBaseUrl

A null-terminated string which specifies an endpoint URL. This parameter may be NULL if you do not wish to match against an endpoint URL. At least one parameter must be specified. An endpoint URL will only be used if the function is unable to determine the provider ID from the *lpszProviderName* parameter. If an endpoint URL is specified, it is given precedence over a model name.

lpszModelName

A null-terminated string which specifies a model name. This parameter may be NULL if you do not wish to match against a model name. At least one parameter must be specified. A model name will only be used if the function is unable to determine the provider ID from the *lpszProviderName* or *lpszBaseUrl* parameters.

Return Value

If the function succeeds, the return value is the numeric provider ID. If the function fails, it returns `LLM_PROVIDER_UNKNOWN`. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetProviderId** function attempts to determine the provider ID using the parameters in order of precedence. If a provider name is specified and recognized, that value is considered authoritative and the remaining parameters are ignored. If the provider name is not recognized, the function will attempt to determine the provider from the endpoint URL. If the provider cannot be determined from the endpoint URL, the function will attempt to infer the provider from the model name.

The function performs normalization on the input values before matching them against known providers. Leading and trailing whitespace is ignored, provider names are matched without regard to case and common variations of provider names are recognized.

When matching against a model name, the function identifies the company or organization most commonly associated with the model family. This may not reflect the actual service endpoint hosting the model. For example, a model hosted by a local inference server or aggregate provider may still be identified as the company who originally created the model.

This function only recognizes well-known providers, endpoint URLs and model families. If the provider cannot be determined, the function will return `LLM_PROVIDER_UNKNOWN` and the last error code will be set to `ST_ERROR_PROVIDER_NOT_FOUND`.

The **LlmGetClientProvider** function can be used to return the provider ID associated with a specific client session.

Example

```
DWORD dwProviderId;

// Determine the provider based on a model name
dwProviderId = LlmGetProviderId(NULL, NULL,
                                _T("claude-sonnet-4"));

if (dwProviderId == LLM_PROVIDER_ANTHROPIC)
    _tprintf(_T("Anthropic provider selected\n"));

// Determine the provider using an endpoint URL
dwProviderId = LlmGetProviderId(NULL,
                                _T("https://api.openai.com/v1/"),
                                NULL);

if (dwProviderId == LLM_PROVIDER_OPENAI)
    _tprintf(_T("OpenAI provider selected\n"));
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetProviderInfo Function

```
BOOL WINAPI LlmGetProviderInfo(
   DWORD dwProviderId,
   LPLLM_PROVIDER_INFO lpProviderInfo
);
```

The **LlmGetProviderInfo** function returns information about the specified service provider type.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. Refer to the providers page for a list of supported providers and their default models.

lpProviderInfo

A pointer to an LLM_PROVIDER_INFO structure which receives information about the specified provider. The dwSize member must be initialized to the size of the structure before calling this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetProviderInfo** function returns general information about a provider, including its display name, description, default host name, default model and related configuration values.

The *lpProviderInfo* parameter must point to an LLM_PROVIDER_INFO structure initialized by the caller. The dwSize member must be set to the size of the structure. This enables the function to validate the structure version before returning provider information.

This function does not require an active client session. It can be used to query provider information before creating a session or connecting to a provider.

The information returned by this function describes the provider defaults defined by the library. A client session may use different values if the application overrides the provider, host name, base URL, model name or other session settings.

Example

```
DWORD dwProviderId = LLM_PROVIDER_NONE;
TCHAR szBaseUrl[MAX_PATH] = {0};

// Determine the provider ID for the current session and get
// the base URL used for API requests
dwProviderId = LlmGetClientProvider(hClient, szBaseUrl, _countof(szBaseUrl));

if (dwProviderId == LLM_PROVIDER_NONE)
{
    _tprintf(_T("Unable to get provider ID for this session\n"));
    return;
}

// Get the current client options
DWORD dwOptions = LLM_OPTION_NONE;
```

```
if (!LlmGetClientOptions(hClient, &dwOptions))
{
    _tprintf(_T("Unable to get client options for this session\n"));
    return;
}

// Get information about the current provider
LLM_PROVIDER_INFO providerInfo = { sizeof(providerInfo), 0 };

if (!LlmGetProviderInfo(dwProviderId, &providerInfo))
{
    _tprintf(_T("Unable to get provider information\n"));
    return;
}

_tprintf(_T("Connected to %s using %s, the connection is %s\n"),
         providerInfo.szDisplayName,
         szBaseUrl,
         ((dwOptions & LLM_OPTION_SECURE) ? _T("secure") : _T("not secure")));
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetProviderName Function

```
INT WINAPI LlmGetProviderName(
   DWORD dwProviderId,
   LPTSTR lpszProviderName,
   INT nMaxLength
);
```

The **LlmGetProviderName** function returns the display name of the specified provider.

Parameters

dwProviderId

Specifies the service provider. This parameter must be one of the **LLM_PROVIDER** constants. Refer to the providers page for a list of supported providers and their default models.

lpszProviderName

A pointer to a string buffer which will contain the display name for the specified provider when the function returns. This parameter cannot be NULL and must be large enough to contain the display name, including the terminating null character. If the buffer is not large enough to contain the entire name, it will be truncated.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null character. This parameter cannot be zero and the function will fail if an invalid size is provided by the caller.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetProviderName** function returns the display name associated with the specified provider. This is a human-readable string which can be used for logging, status messages or user interface display.

This function is a convenience wrapper which returns the provider display name without requiring the caller to retrieve the full provider information structure using **LlmGetProviderInfo**.

If the buffer specified by ***lpszProviderName*** is not large enough to contain the entire provider name, the string will be truncated. The value returned by the function indicates the number of characters copied to the buffer, not including the terminating null character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetResponseHeader Function

```
INT WINAPI LlmGetResponseHeader(
   HCLIENT hClient,
   LPCTSTR lpszHeaderName,
   LPTSTR lpszHeaderValue,
   INT nMaxLength
);
```

The **LlmGetResponseHeader** function returns the value of an HTTP header from the server response.

Parameters

hClient

A handle to the client session.

lpszHeaderName

A pointer to a null-terminated string which specifies the name of the HTTP response header. The header names are not case-sensitive. Header names may only contain ASCII letters, numbers and a restricted subset of punctuation characters. Header names cannot contain Unicode or ANSI multi-byte character sequences.

lpszHeaderValue

A pointer to a string buffer which will contain the header value when the function returns. If this parameter is NULL, the header value will not be copied and the function will return the length. If the buffer is not large enough to contain the entire header value, it will be truncated.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderValue* string buffer. If *lpszHeaderValue* is NULL, this value should be zero. The maximum length must include room for the terminating null character.

Return Value

If the function succeeds, the return value is the length of the header value in characters, not including the terminating null character. If the header is undefined or the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**. If the header field does not exist, the error code will be `ST_ERROR_HEADER_NOT_FOUND`.

Remarks

The **LlmGetResponseHeader** function returns the value of a response header from the last request made to the service provider.

This function is intended for applications that need lower-level access to provider-specific response headers. Most applications do not need to call this function. Standard response information, such as the HTTP status code, response text, token usage, model name, and elapsed time, is available through the API.

The headers returned by a service provider can vary depending on the provider, model, endpoint, account configuration, and the specific request being made. Applications should not assume that a particular header will always be present unless it is documented by the service provider.

If the header field specified by *lpszHeaderName* was not returned by the server, this function will return zero. If the *lpszHeaderValue* parameter is not NULL, it will contain an empty string when the function returns. The response headers are only available after a request has been sent to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetStatusCode Function

```
INT WINAPI LlmGetStatusCode(
    HCLIENT hClient
);
```

The **LlmGetStatusCode** function returns the most recent HTTP status code for a client request.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the HTTP status code. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetStatusCode** function returns the HTTP status code returned by the provider for the most recent request associated with the specified client session. This value reflects the result of the underlying HTTP operation used to communicate with the provider.

HTTP status codes are three-digit numeric values which indicate whether a request was successful or if an error occurred. They may be interpreted using the following general ranges:

Value	Description
100-199	Informational responses. These are rarely used in practice and indicate that the request has been received and processing is continuing.
200-299	Successful responses. The request was successfully processed by the provider. A value of 200 (OK) is typically returned for successful API requests.
300-399	Redirection responses. These indicate that additional action may be required to complete the request. These responses are uncommon when using API endpoints.
400-499	Client errors. The request was invalid or could not be processed by the provider. This may indicate issues such as invalid parameters, missing authentication credentials or rate limiting.
500-599	Server errors. The provider encountered an error while processing the request. These errors are typically transient and may succeed if the request is retried.

This function can be used in conjunction with the return value of a function such as **LlmSendMessage** or **LlmConnect**. The status code may provide additional information about why a request was rejected or processed with an error condition by the provider. For example, if a request fails and the status code is 503, this indicates the service is temporarily unavailable.

HTTP status codes are returned by the provider service and their exact meaning may vary slightly between providers. Some providers may also return additional diagnostic information in the response body which can help identify the specific cause of the error. Here are some common error status codes and what they could mean in the context of the client session:

- **400 Bad Request** - The request was malformed or contained invalid parameters. This usually indicates an internal error in the library where a request was not composed correctly. This could occur if the service provider does not support certain functionality, an invalid option was used,

or an incorrect endpoint was specified.

- **401 Unauthorized** - The API key is missing, invalid, or expired. If you are using an environment variable or Windows credential, check to make sure it is defined and contains the correct value. If you continue to experience this error, check the provider account to ensure the key has not been revoked or replaced.
- **403 Forbidden** - The request was understood, but the provider refused to process it. This can occur if the account does not have permission to use the selected model, endpoint, organization, or project. Verify that the API key has access to the requested resource and that billing or account restrictions are not preventing the request.
- **404 Not Found** - The requested resource could not be found. This commonly indicates an incorrect endpoint URL, deployment name, model name, or provider-specific path. Verify that the provider, base URL, and model name are correct for the account being used.
- **408 Request Timeout** - The provider did not complete the request before the timeout expired. This can occur because of network latency, a temporary service issue, a large prompt, or a model that requires more time to generate a response. Consider increasing the timeout value, reducing the prompt or history size, or retrying the request later.
- **409 Conflict** - The request conflicts with the current state of the service or resource. This is uncommon for simple message requests, but may occur with provider-specific operations, duplicate requests, or incompatible settings. Review the request options and retry the operation after any pending provider-side operation has completed.
- **413 Payload Too Large** - The request body is larger than the provider allows. This usually means the prompt, conversation history, attached content, or generated request JSON exceeds the model or endpoint limit. Reduce the prompt size, clear or shorten the conversation history, or select a model with a larger context size. The **LlmTrimHistory** function can be used to reduce the amount of conversation history included with a prompt.
- **415 Unsupported Media Type** - The provider does not support the request content type or encoding. This can indicate that the request was not submitted as JSON, that the wrong endpoint was used, or that the provider does not support the submitted content format. Verify the endpoint and make sure the request format matches the provider requirements.
- **422 Unprocessable Entity** - The provider accepted the request format, but could not process the request contents. This can occur if a model option, reasoning level, response format, tool definition, or other provider-specific setting is not valid for the selected model. Review the selected model and options, and disable unsupported features.
- **429 Too Many Requests** - The provider rejected the request because a rate limit, usage limit, or account quota was exceeded. Applications should wait before retrying the request, reduce the request rate, and avoid retrying immediately in a tight loop. If the error persists, review the provider account limits, billing status, and usage quotas.
- **500 Internal Server Error** - The provider encountered an unexpected server-side error while processing the request. This usually indicates a temporary problem with the provider rather than the application. Retry the request later, and check the provider status page if the problem continues.
- **502 Bad Gateway** - A gateway or proxy received an invalid response from an upstream service. This is typically a temporary provider-side or network condition. Retry the request after a short delay, and check whether the provider is experiencing a service disruption.

- **503 Service Unavailable** - The service is temporarily unavailable because of maintenance, overload, or resource limits. Retry the request after a delay. If the provider returns a retry interval, the application should wait at least that long before trying again.
- **504 Gateway Timeout** - A gateway or proxy timed out waiting for an upstream service to complete the request. This can occur when the provider is under heavy load or when a response takes too long to generate. Retry the request later, reduce the prompt size, or request a shorter response.

If no request has been made, or if the client has not yet received a response from the provider, the return value may be zero. If the client handle is invalid or a request is currently in progress, the function will return LLM_ERROR (-1). In this case, a status code is not available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmGetSystemPrompt Function

```
INT WINAPI LlmGetSystemPrompt(
   HCLIENT hClient,
   LPTSTR lpszSystemPrompt,
   INT nMaxLength
);
```

The **LlmGetSystemPrompt** function returns the current system prompt for a client session.

Parameters

hClient

A handle to the client session.

lpszSystemPrompt

A pointer to a string buffer which receives the system prompt for the current session. If this parameter is NULL, the function returns the length of the system prompt without copying any characters. If a buffer is provided, it must be large enough to contain the entire prompt, including the terminating null character, or the function will fail.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null character. If the ***lpszSystemPrompt*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetSystemPrompt** function retrieves the system prompt associated with the specified client session. The system prompt provides initial instructions to the model and influences how responses are generated for subsequent requests.

To retrieve the system prompt, an application can first call this function with a NULL buffer to determine the required length, then allocate a buffer of sufficient size and call the function again to retrieve the prompt.

If a system prompt has not been defined for the session, the function returns zero and the last error code is set to NO_ERROR. This condition indicates that no prompt is currently set and should not be treated as a failure.

The system prompt may be specified when creating a session using **LlmConnectEx** and the LLM_SESSION structure, or modified at runtime using **LlmSetSystemPrompt**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetTimeout Function

```
INT WINAPI LlmGetTimeout(
   HCLIENT hClient
);
```

The **LlmGetTimeout** function returns the number of seconds the client will wait for a response from the server.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetTimeout** function returns the current timeout value for the specified client session. This value specifies the maximum amount of time, in seconds, that the client will wait for a response from the provider before the request is aborted.

The timeout applies to network operations performed when communicating with the provider. If the timeout period is exceeded, the request will fail and the last error code will indicate a timeout condition.

The timeout value may be specified when creating a session using **LlmConnectEx** and the LLM_SESSION structure, or modified at runtime using **LlmSetTimeout**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

LlmGetTokenUsage Function

```
BOOL WINAPI LlmGetTokenUsage(
   HCLIENT hClient,
   LPLLM_TOKEN_USAGE lpUsage
);
```

The **LlmGetTokenUsage** function returns token usage statistics for the client session.

Parameters

hClient

A handle to the client session.

lpUsage

A pointer to an LLM_TOKEN_USAGE structure which receives token usage statistics for the client session. The dwSize member must be initialized to the size of the structure before calling this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetTokenUsage** function returns token usage statistics for the specified client session. This information includes token counts reported by the provider, as well as values maintained by the library for the current conversation history.

The *lpUsage* parameter must point to an LLM_TOKEN_USAGE structure initialized by the caller. The dwSize member must be set to the size of the structure. This enables the function to validate the structure version before returning usage information.

Token usage values are intended to help applications monitor request size, response size and context usage. The exact values reported may vary by provider and model, and should be treated as informational rather than as a guarantee of billing or model behavior.

This function returns the usage information currently associated with the client session. The values are updated as messages are sent and responses are received.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmGetUserAgent Function

```
INT WINAPI LlmGetUserAgent(
   HCLIENT hClient,
   LPTSTR lpszUserAgent,
   INT nMaxLength
);
```

The **LlmGetUserAgent** function returns the current user-agent string used by the client.

Parameters

hClient

A handle to the client session.

lpszUserAgent

A pointer to a string buffer which receives the user-agent string for the current session. If this parameter is NULL, the function returns the length of the user-agent string without copying any characters. If a buffer is provided, it must be large enough to contain the entire string, including the terminating null character, or the function will fail.

nMaxLength

An integer value which specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character. If the ***lpszUserAgent*** parameter is NULL, this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmGetUserAgent** function retrieves the user-agent string currently configured for the client session. This value is included in HTTP requests sent to the provider unless disabled using the LLM_OPTION_NOUSERAGENT option.

If no user-agent string has been explicitly set using **LlmSetUserAgent**, the function may return a default value defined by the library, or no value depending on the current configuration.

To determine the required buffer size, call this function with ***lpszUserAgent*** set to NULL. The return value specifies the number of characters in the string, excluding the terminating null character. If there is no user-agent string defined for the session, the function returns zero and the last error value is cleared (set to NO_ERROR). This condition should not be treated as a failure.

In most cases, the user-agent string will be relatively small. A buffer of 256 characters is typically sufficient for standard user-agent values. If a custom user-agent string is used, a larger buffer (such as 512 characters) may be more appropriate. Applications that require complete flexibility should query the required length and allocate the buffer dynamically.

The user-agent string is typically used by providers for logging or request identification. Developers should avoid including sensitive information in this value.

Example

```
INT cchUserAgent = 0;
```

```
// Query required buffer size
cchUserAgent = LlmGetUserAgent(hClient, NULL, 0);

if (cchUserAgent > 0)
{
    LPTSTR lpszUserAgent = (LPTSTR)malloc((cchUserAgent + 1) * sizeof(TCHAR));

    if (lpszUserAgent != NULL)
    {
        if (LlmGetUserAgent(hClient, lpszUserAgent, cchUserAgent + 1))
        {
            _tprintf(_T("User-Agent: %s\n"), lpszUserAgent);
        }
        else
        {
            DWORD dwError = LlmGetLastError();
            _tprintf(_T("Error retrieving user-agent (0x%08lX)\n"), dwError);
        }

        free(lpszUserAgent);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmImportHistory Function

```
BOOL WINAPI LlmImportHistory(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LONG nMessageCount,
   LPLONG lpnImported
);
```

The **LlmImportHistory** function imports a conversation history from a JSON-formatted file.

Parameters

hClient

A handle to the client session.

lpszFileName

A pointer to a null-terminated string which specifies the name of the import file. This parameter cannot be NULL or a zero-length string.

nMessageCount

The number of the most recent messages and responses which should be imported. If this value is zero, all messages in the file are imported.

lpnImported

A pointer to an integer which will receive the number of messages which were imported when the function returns. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmImportHistory** function imports a previously exported conversation history file and restores it as the active conversation history for the client session. Imported messages and responses become part of the current session history and are treated the same as messages generated during the current session.

Importing conversation history replaces the existing history associated with the client session. This function does not merge imported messages with the current conversation history or append them to the existing session. It is not necessary for your application to call **LlmClearHistory** prior to calling this function.

If the *lpszFileName* parameter specifies a directory or device name, the function will fail. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters, they will be removed. The file must exist and the current process must have permission to read the file.

If the *nMessageCount* parameter is non-zero, only the most recent messages and responses in the import file are restored. If the specified count exceeds the number of available messages in the file, all available messages are imported. If the total number of messages to be imported exceeds the current history size, the function will only import the most recent messages up to that limit. For example, if the import file contains 20 messages and the current history size is 15, the most recent 15 messages will be imported.

The import file must contain valid UTF-8 encoded JSON data in a format compatible with the **LlmExportHistory** function. If the file does not appear to contain a valid conversation history, the import operation fails before the current session history is cleared.

After the JSON data has been successfully parsed, the current session history is cleared before the imported messages and responses are added to the client session. If an error occurs while processing imported messages or responses, the previous conversation history cannot be restored and partial import data may remain in the current session.

If the import file contains malformed message or response data, the **LlmGetLastError** function will return `ST_ERROR_INVALID_MESSAGE_FORMAT`.

Because imported history files may contain sensitive or private information, applications should take reasonable precautions to protect them. Applications which allow users to import conversation history should consider warning users before importing untrusted or unknown files.

Example

```
LONG nImported = 0;

// Replace the current conversation history with the
// messages stored in the import file
if (LlmImportHistory(hClient,
                     _T("%USERPROFILE%\\Documents\\conversation.json"),
                     0,
                     &nImported))
{
    _tprintf(_T("Imported %ld messages\n"), nImported);
}
else
{
    DWORD dwError = LlmGetLastError();
    _tprintf(_T("Unable to import conversation history, error 0x%08lX\n"),
dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmInitialize Function

```
BOOL WINAPI LlmInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **LlmInitialize** function initializes the library and validates the specified license key.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This function should typically be called once during application startup, before any other library functions are used. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **LlmInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **LlmUninitialize**.

This function dynamically loads system libraries and allocates thread-local storage. If you are calling this library from within another DLL, do not call **LlmInitialize** or **LlmUninitialize** from the **DllMain** function. Doing so can result in deadlocks or access violations. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmIsBlocking Function

```
BOOL WINAPI LlmIsBlocking(
   HCLIENT hClient
);
```

The **LlmIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero. To get extended error information, call **LlmGetLastError**.

Remarks

A blocking operation may allow the application to be re-entered. For example, the user may press a button while another request is still in progress. If this causes another blocking function to be called for the same client session, the second operation will fail because only one blocking operation can be active at a time.

The **LlmIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action, such as warning the user that they must wait for the current operation to complete.

When a message is sent to the server using the **LlmSendMessage** or **LlmSendMessageEx** functions, the client will block until the message is sent and the server has responded, or until a timeout has occurred. If you send a request to the server in your application's main UI thread, you should present some visual indicator that the application is waiting for the operation to complete. If you need to ensure your application remains responsive while waiting for a response from the server, you can send messages using a background worker thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

LlmIsConnected Function

```
BOOL WINAPI LlmIsConnected(
   HCLIENT hClient
);
```

The **LlmIsConnected** function verifies that the client session remains valid.

Parameters

hClient

A handle to the client session.

Return Value

If the client session is valid and connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmIsConnected** function determines whether there is a logical connection to the service provider and the client has successfully authenticated with the API server. Calling this function is not simply a passive status check. The network connection to the provider may be transient and can be automatically re-established if the client session has been idle. Calling **LlmIsConnected** may cause the library to reconnect and re-authenticate with the server if necessary.

If the client must re-authenticate, it will attempt to reconnect to the server and validate the selected model for the session. If the server reports an error condition, such as an invalid API key, the connection will not be re-established and the function will return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmNormalizeText Function

```
INT WINAPI LlmNormalizeText(
   LPCTSTR lpszInput,
   INT cchInput,
   LPTSTR lpszOutput,
   INT nMaxLength
);
```

The **LlmNormalizeText** function normalizes message text by removing extraneous whitespace and applying consistent formatting.

Parameters

lpszInput

A pointer to a null-terminated string which specifies the text which should be normalized. This parameter cannot be NULL.

cchInput

An integer which specifies the length of the input string. If this value is -1 the entire input string up to the terminating null character will be normalized.

lpszOutput

A pointer to a string buffer which will contain the normalized text when the function returns. The output string will always be null-terminated. If the string buffer is not large enough to contain all of the normalized text, the function will fail and the last error code will be set to `ST_ERROR_BUFFER_TOO_SMALL`.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the output string buffer. This value must be large enough to include a terminating null character. If this value is too small, or an invalid length is specified, the function will fail.

Return Value

If the function succeeds, the return value is the number of characters copied to the output buffer, not including the terminating null character. If the function fails, the return value is zero and the **LlmGetLastError** function will return a non-zero value.

Remarks

The **LlmNormalizeText** function processes the input string, decomposing Unicode characters to their canonical equivalents, replacing confusable homoglyphs with normalized characters, removing combining characters, normalizing end-of-line characters, and trimming leading and trailing whitespace including non-breaking spaces and other special Unicode space characters. Although removing unnecessary whitespace may slightly reduce token usage, the primary benefit is producing cleaner and more consistent input for the model to process.

Line break characters are normalized to use Windows end-of-line conventions. Isolated carriage return or line feed characters, Unicode line and paragraph separators, and form feed characters are converted to CRLF sequences. Multiple consecutive line breaks are reduced to improve consistency.

Normalization can be useful when comparing prompts, checking for empty or whitespace-only input, or applying simple validation rules before a request is submitted. It does not attempt to determine whether the text is safe, appropriate, or semantically valid. Applications should perform any additional validation required for their own use case.

Using this function is optional. Prompt text does not need to be normalized before it is sent to a provider, and using this function is not a required sanitization step. If preserving the exact formatting of the original text is important, such as indentation, tables, or code samples, the application should send the original text instead.

The ANSI version of this function expects the input to be UTF-8 encoded, but will fall back to using the current active code page if invalid UTF-8 characters are encountered in the string. The output from this function will always be valid Unicode text. For applications using the ANSI version of this function, this means the output string will use UTF-8 encoding.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmResetSession Function

```
BOOL WINAPI LlmResetSession(
    HCLIENT hClient
);
```

The **LlmResetSession** function resets the current client session to its initial state, clearing any existing conversation context.

Parameters

hClient

A handle to the client session.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmResetSession** function resets the client session to its initial state. Any active connection to the service provider is closed, the conversation history is cleared, and token usage statistics for the session are reset.

This function can be used to discard the current conversation context and start a new session using the existing client handle. Configuration settings such as the selected provider, model name, system prompt, and client options are preserved.

If a blocking operation is currently in progress, this function will fail. Applications should call **LlmIsBlocking** to determine if the client is busy before attempting to reset the session.

Because this function clears the conversation history, it also invalidates any string pointers previously returned in LLM_RESPONSE structures or by message history functions. Applications must not use those pointers after this function returns. If the application needs to keep any message or response text, it should make its own copy before resetting the session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmSendMessage Function

```
BOOL WINAPI LlmSendMessage(
   HCLIENT hClient,
   LPCTSTR lpszPrompt,
   LPTSTR lpszResponse,
   LPDWORD lpdwLength,
   LPDWORD lpdwMessageId
);
```

The **LlmSendMessage** function sends a prompt to the model and returns the response as a string.

Parameters

hClient

A handle to the client session.

lpszPrompt

A pointer to a null-terminated string which specifies the prompt which should be sent to the model. This parameter cannot be NULL or a zero-length string. If the string consists only of whitespace characters, or contains invalid Unicode or non-text data, this function will fail.

lpszResponse

A pointer to a string buffer which will contain the model's response to the prompt. The response will always be null terminated and if the buffer is not large enough to store the complete response, the response will be truncated. The ***lpdwLength*** parameter must be initialized with the maximum number of characters which can be copied into the buffer or the function will fail.

lpdwLength

A pointer to an unsigned integer which should be initialized to the size of the ***lpszResponse*** string buffer. When the function returns, this value will be updated with the actual number of characters copied into the buffer, not including the terminating null character. This parameter cannot be NULL and its initial value must be greater than zero.

lpdwMessageId

A pointer to an unsigned integer which will contain the ID for the message when the function returns. This parameter may be NULL if the application does not require the message ID.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmSendMessage** function provides a simplified interface for sending a single text prompt to the model and receiving the response as a string. This function is intended for applications that do not require structured input or detailed control over message formatting.

This function will not return until the request has completed, an error has occurred, or the operation has timed out. Applications that call this function from a user interface thread should provide visual feedback while waiting for the response, or perform the request on a background thread to maintain responsiveness.

Applications that accept user input should apply appropriate validation, filtering, or normalization before sending requests to the service provider. The **LlmValidateText** function verifies that the

prompt contains valid message text and the **LlmNormalizeText** function can be used to normalize text formatting. These functions do not perform any semantic analysis of the prompt and do not provide protection against malicious or intentionally misleading input.

This function does not validate or restrict the content of the input message. It is the responsibility of the application to ensure that user-provided input is appropriate for its intended use. This includes considering scenarios where input may attempt to override instructions, inject unintended prompts, or otherwise influence the behavior of the model.

The response is written to the buffer specified by ***lpszResponse***. If the buffer is not large enough to contain the complete response, the text will be truncated. The ***lpdwLength*** parameter will always contain the number of characters actually copied to the buffer.

Line breaks in the response text are normalized before being stored in the client history. Line feed and carriage return characters are converted to the standard Windows CRLF end-of-line sequence, ensuring consistent formatting across different providers and applications. This also helps ensure compatibility with Windows common controls and other user interface components.

Some models are capable of performing additional internal reasoning before generating a response. The amount of reasoning performed and whether it is exposed by the provider is model-specific. The library returns the final response intended for the user and does not currently expose model reasoning or intermediate processing steps. This behavior ensures consistent results across providers, regardless of how individual models implement or expose reasoning capabilities.

If the ***lpdwMessageId*** parameter is specified, it will receive a unique identifier for the message within the current client session. Message identifiers are assigned sequentially, but applications should treat them as opaque values. They are only guaranteed to be unique within a single session and should not be compared across different client sessions.

This function automatically adds the message to the conversation history for the session. Subsequent calls will include previous messages as context, subject to any configured history or token limits. To clear the conversation context, call **LlmClearHistory** or **LlmResetSession**.

Applications that require more advanced features, such as structured messages, role-based input, or access to detailed response metadata, should use the **LlmSendMessageEx** function instead.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    HCLIENT hClient = INVALID_CLIENT;
    DWORD dwError = NO_ERROR;

    // Initialize the SocketTools library
    if (!LlmInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Initialization failed: %lu\n"), LlmGetLastError());
        return 1;
    }

    // Establish a connection to OpenAI using the default endpoint
    // and a lightweight model
    hClient = LlmConnect(
        LLM_PROVIDER_OPENAI,
        LLM_OPTION_DEFAULT,
```

```
        LLM_TIMEOUT,
        NULL,                   // Use default base URL
        _T("gpt-5.4-nano"),     // Model name
        _T("%OPENAI_API_KEY%")  // Provider API key
    );

    if (hClient == INVALID_CLIENT)
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
        LlmUninitialize();
        return 1;
    }

    TCHAR szResponse[4096] = {0};
    DWORD dwResponseLength = _countof(szResponse); // number of TCHARs
    DWORD dwMessageId = 0;

    // Send a simple message to the model
    if (LlmSendMessage(hClient,
                       _T("What is the capital city of Denmark?"),
                       szResponse,
                       &dwResponseLength,
                       &dwMessageId))
    {
        _tprintf(_T("Response:\n%s\n"), szResponse);
    }
    else
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    // Clean up
    LlmDisconnect(hClient);
    LlmUninitialize();

    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmSendMessageEx Function

```
BOOL WINAPI LlmSendMessageEx(
   HCLIENT hClient,
   DWORD dwReserved,
   LPLLM_MESSAGE lpMessage,
   LPLLM_RESPONSE lpResponse
);
```

The **LlmSendMessageEx** function sends a structured message to the model and returns a structured response.

Parameters

hClient

A handle to the client session.

dwReserved

A parameter reserved for future use. This value should always be zero.

lpMessage

A pointer to a LLM_MESSAGE structure which specifies the message to be sent to the server. This parameter cannot be NULL. The structure must be initialized correctly, with the ***dwSize*** member set to the size of the structure. Unused members of the structure should be initialized to zero or NULL.

lpResponse

A pointer to a LLM_RESPONSE structure which will be populated with information about the response from the server when the function returns. This parameter cannot be NULL. The structure must be initialized correctly, with the ***dwSize*** member set to the size of the structure and all other members set to a value of zero or NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmSendMessageEx** function provides the structured form of **LlmSendMessage**. It should be used by applications that need to specify additional message properties, inspect detailed response metadata, or preserve information such as response identifiers, token usage, status values, elapsed time, and the actual model name returned by the provider.

This function performs a blocking operation. It will not return until the request has completed, an error has occurred, or the operation has timed out. Applications that call this function from a user interface thread should provide visual feedback while waiting for the response, or perform the request on a background thread to maintain responsiveness.

The ***lpMessage*** and ***lpResponse*** structures must be initialized before calling this function. At a minimum, the ***dwSize*** member of each structure must be set to the size of the structure, and all unused members should be initialized to zero or NULL.

If a message identifier is returned in the response structure, it is unique within the current client session. Message identifiers are assigned sequentially by the library, but applications should treat them as opaque values. They are not guaranteed to be globally unique across multiple sessions or between different clients.

This function automatically adds the message and response to the conversation history for the session. Subsequent calls may include previous messages as context, subject to any configured history or token limits. To clear the conversation context, call **LlmClearHistory** or **LlmResetSession**.

Applications that accept user input should apply appropriate validation, filtering, or normalization before sending requests to the service provider. The **LlmValidateText** function verifies that the prompt contains valid message text and the **LlmNormalizeText** function can be used to normalize text formatting. These functions do not perform any semantic analysis of the prompt and do not provide protection against malicious or intentionally misleading input.

Line breaks in the response text are normalized before being stored in the client history. Line feed and carriage return characters are converted to the standard Windows CRLF end-of-line sequence, ensuring consistent formatting across different providers and applications. This also helps ensure compatibility with Windows common controls and other user interface components.

Some models are capable of performing additional internal reasoning before generating a response. The amount of reasoning performed and whether it is exposed by the provider is model-specific. The library returns the final response intended for the user and does not currently expose model reasoning or intermediate processing steps. This behavior ensures consistent results across providers, regardless of how individual models implement or expose reasoning capabilities.

The string members of the LLM_MESSAGE and LLM_RESPONSE structures are managed by the library. When a message is sent, any string pointers provided in the LLM_MESSAGE structure are copied internally, and the application is not required to preserve or maintain those buffers after the function returns.

String pointers returned in the LLM_RESPONSE structure refer to memory managed by the client session. These values remain valid until the message history is cleared or the session is reset or disconnected. Applications should not attempt to free or modify these strings.

The contents of these strings must be treated as read-only. They are owned by the library, and modifying them may result in access violations or other undefined behavior. If your application needs to retain a string beyond the lifetime of the session or modify its contents, it should create its own copy.

Example

```
#include "cstools12.h"
#include <stdio.h>

int _tmain(void)
{
    HCLIENT hClient = INVALID_CLIENT;
    DWORD dwError = NO_ERROR;

    // Initialize the SocketTools library
    if (!LlmInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Initialization failed: %lu\n"), LlmGetLastError());
        return 1;
    }

    // Establish a connection to OpenAI using the default endpoint
    // and a lightweight model
    hClient = LlmConnect(
        LLM_PROVIDER_OPENAI,
        LLM_OPTION_DEFAULT,
        LLM_TIMEOUT,
```

```
        NULL,                   // Use default base URL
        _T("gpt-5.4-nano"),     // Model name
        _T("%OPENAI_API_KEY%")  // Provider API key
    );

    if (hClient == INVALID_CLIENT)
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Unable to connect, error %lu\n"), dwError);
        LlmUninitialize();
        return 1;
    }

    LLM_MESSAGE clientMessage;
    ZeroMemory(&clientMessage, sizeof(LLM_MESSAGE));
    clientMessage.dwSize = sizeof(clientMessage);
    clientMessage.lpszContent = _T("What is the capital city of Denmark?");
    clientMessage.nContentLength = _tcslen(clientMessage.lpszContent);

    LLM_RESPONSE serverResponse;
    ZeroMemory(&serverResponse, sizeof(serverResponse));
    serverResponse.dwSize = sizeof(serverResponse);

    if (LlmSendMessageEx(hClient, 0, &clientMessage, &serverResponse))
    {
        _tprintf(_T("Flags: 0x%08lX\n"), serverResponse.dwFlags);
        _tprintf(_T("Status: %u\n"), serverResponse.dwStatus);
        _tprintf(_T("Elapsed: %u ms\n"), serverResponse.dwElapsed);
        _tprintf(_T("Output Tokens: %u\n"), serverResponse.nOutputTokens);
        _tprintf(_T("Content Length: %u\n"), serverResponse.nContentLength);
        _tprintf(_T("Response ID: %s\n"), (serverResponse.lpszResponseId ?
serverResponse.lpszResponseId : _T("None")));
        _tprintf(_T("Model Name: %s\n"), (serverResponse.lpszModelName ?
serverResponse.lpszModelName : _T("None")));
        _tprintf(_T("Status Text: %s\n"), (serverResponse.lpszStatusText ?
serverResponse.lpszStatusText : _T("None")));

        if (serverResponse.nContentLength > 0)
            _tprintf(_T("\n%s\n"), serverResponse.lpszContent);
    }
    else
    {
        dwError = LlmGetLastError();
        _tprintf(_T("Request failed, error %lu\n"), dwError);
    }

    // Clean up
    LlmDisconnect(hClient);
    LlmUninitialize();

    return 0;
}
```

LlmSetCacheTime Function

```
BOOL WINAPI LlmSetCacheTime(
   HCLIENT hClient,
   INT nCacheTime
);
```

The **LlmSetCacheTime** function sets the cache lifetime used by the client for model or provider data.

Parameters

hClient

A handle to the client session.

nCacheTime

An integer value which specifies the cache lifetime, in seconds, for provider and model metadata. A value of zero disables caching and forces the client to retrieve this information from the server for each request. Larger values reduce network requests but may result in stale information being used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmSetCacheTime** function controls how long the client caches provider and model metadata. This includes information such as the list of available models and details about the currently selected model.

Caching reduces the number of network requests required when retrieving model lists or model information, which can improve performance and reduce latency. However, because model availability and capabilities may change over time, cached data may become stale if it is retained for extended periods.

Changing this value will have no effect if the LLM_OPTION_NOCACHE option has been specified.

Setting the cache time to zero disables caching and is equivalent to specifying the LLM_OPTION_NOCACHE option. Note that this differs from specifying a cache time of zero in the LLM_SESSION structure during initialization, where a value of zero indicates that a default cache lifetime will be used.

The cache time is specified in seconds. If a value greater than or equal to 1000 is specified, it is assumed that the value may have been provided in milliseconds, and it will be automatically scaled to seconds. The specified cache time is clamped to an internal minimum and maximum value if it falls outside the supported range. The default cache time is one hour.

In most cases, the default cache time provides a good balance between performance and accuracy. Applications that frequently query model information or require real-time updates may choose to reduce or disable caching.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmSetClientOptions Function

```
BOOL WINAPI LlmSetClientOptions(
    HCLIENT hClient,
    DWORD dwOptions
);
```

The **LlmSetClientOptions** function changes the current client option flags.

Parameters

hClient

A handle to the client session.

dwOptions

An unsigned integer that specifies one or more options.

Value	Description
LLM_OPTION_NOCACHE	Disables provider and model metadata caching for the client session. When this option is specified, the library will not reuse cached metadata, and provider or model information will be retrieved from the server each time it is required. This may be useful when testing or when current data is required.
LLM_OPTION_KEEPALIVE	Enables persistent HTTP connections using the keep-alive mechanism. When enabled, the underlying HTTP connection may be reused for multiple requests, reducing connection overhead and improving performance. If this option is not specified, the connection may be closed after each request.
LLM_OPTION_PROXY	Specifies that the connection should be made using the current Windows proxy server configuration. If the user does not have a proxy server configuration, this option is ignored. This option is typically used in environments where direct internet access is restricted.
LLM_OPTION_NOUSERAGENT	Prevents the library from sending a User-Agent header with requests to the provider. By default, a User-Agent string is included to identify the client. This option may be used when a provider does not require a User-Agent header.
LLM_OPTION_SECURE	Forces the use of a secure HTTPS connection when communicating with the provider. If the specified base URL or provider default would normally use an insecure protocol, it will be upgraded to a secure connection. Connections to providers such as OpenAI, Google and Anthropic will always be secure.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To

get extended error information, call **LlmGetLastError**.

Remarks

The **LlmSetClientOptions** function replaces the current option flags for the client session. These flags control how the client establishes connections and sends requests to the service provider.

Applications should use care when changing options that affect the underlying connection, such as LLM_OPTION_SECURE or LLM_OPTION_PROXY. Changing these options may require the client to establish a new connection using different settings.

The LLM_OPTION_SECURE option forces the client to use HTTPS when communicating with the provider. This is appropriate for public API providers, but may not be supported by locally hosted providers such as LM Studio or Ollama. Attempting to force a secure connection to a provider that does not support HTTPS will cause the connection to fail.

The LLM_OPTION_PROXY option causes the client to use the configured proxy settings when connecting to the provider. This may be required in managed or corporate network environments, but should not be enabled unless proxy support is actually needed.

The LLM_OPTION_NOUSERAGENT option does not make requests anonymous. The provider may still identify the client based on authentication credentials, IP address information, request patterns, or other HTTP headers included with the request. For more information, refer to the **LlmSetUserAgent** method.

Setting or clearing the LLM_OPTION_NOCACHE option changes whether provider and model metadata may be cached. Applications can also use the **LlmSetCacheTime** function to control caching behavior in seconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmSetHistorySize Function

```
BOOL WINAPI LlmSetHistorySize(
    HCLIENT hClient,
    LONG nMaxMessages
);
```

The **LlmSetHistorySize** function sets the maximum number of message exchanges retained in the conversation history.

Parameters

hClient

A handle to the client session

nMaxMessages

An integer value which specifies the maximum number of messages that will be retained in the conversation history for the client session. Older messages will be discarded automatically as new messages are added once this limit is reached. This value cannot be less than zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmSetHistorySize** function controls the number of messages retained in the conversation history for a client session. This history is used to provide context for subsequent requests to the model.

When the number of messages exceeds the specified limit, the oldest messages are removed automatically. This ensures that the total number of stored messages does not exceed the configured maximum.

Reducing the history size can help limit memory usage and reduce the amount of context sent with each request, which may improve performance and reduce token usage. However, limiting the history size may also reduce the model's ability to maintain context across multiple interactions.

This setting works in conjunction with token limits imposed by the selected model. Even if the maximum number of messages has not been reached, older messages may be excluded from a request if including them would exceed the model's context window.

If *nMaxMessages* has a value of zero, conversation history is effectively disabled. In this mode, only the current message and response are retained for the duration of the request, and no prior messages are included as context for subsequent requests. Disabling conversation history may reduce the model's ability to maintain context across multiple interactions and can impact the quality or relevance of responses. Functions such as **LlmGetFirstMessage** and **LlmGetNextMessage** will fail with the last error code set to ST_ERROR_NO_MESSAGE_HISTORY.

Disabling conversation history does not provide additional security or privacy. It only affects whether previous messages are retained and automatically included in subsequent requests. The content of each request is still transmitted to the service provider and may be processed or stored in accordance with that provider's policies. Applications that require secure handling of sensitive information should avoid including confidential data in requests and review the data handling practices of the selected service provider.

Even when message history is disabled, the model may still produce responses that appear contextually relevant within a single interaction. This is because the current request can include sufficient context for the model to generate an appropriate response. However, without retaining previous messages, the model does not have access to prior exchanges in the conversation, and continuity across multiple requests may be limited. In most cases, retaining a moderate history size provides better results for conversational applications.

The default history size is 100 message exchanges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LlmSetIdleTime Function

```
BOOL WINAPI LlmSetIdleTime(
   HCLIENT hClient,
   INT nIdleTime
);
```

The **LlmSetIdleTime** function sets the idle timeout period for the client session.

Parameters

hClient

A handle to the client session.

nIdleTime

An integer value which specifies the idle timeout period in seconds. A value of zero specifies a reasonable default value should be used.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmSetIdleTime** function sets the idle timeout period, in seconds, for the specified client session. This value determines how long the library will retain an open connection between requests before automatically closing it and establishing a new connection when needed.

Setting a lower idle time may result in more frequent reconnections, which can increase overhead but may be desirable in environments where connections are short-lived. Higher values allow connections to be reused for longer periods, which can improve performance when making repeated requests.

Changing this value is only meaningful when the LLM_OPTION_KEEPALIVE option is enabled. If keep-alive is disabled for the session, the connection will not be reused regardless of the idle time setting. If the ***nIdleTime*** parameter is set to zero, a new connection is established for each request. In most cases, a default idle time of 15 seconds provides a good balance between performance and compatibility.

This setting applies only to the client. It cannot force a server to maintain a persistent connection for a longer period of time. If a connection is closed due to inactivity, the library will automatically reconnect as needed. This behavior is transparent to the application and does not require any additional function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmSetLastError Function

```
VOID WINAPI LlmSetLastError(
   DWORD dwErrorCode
);
```

The **LlmSetLastError** function sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or LLM_ERROR. Those functions which call **LlmSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **LlmGetLastError** function. The use of **LlmGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmSetModelFlags Function

```
BOOL WINAPI LlmSetModelFlags(
   HCLIENT hClient,
   DWORD dwModelFlags
);
```

The **LlmSetModelFlags** function sets model behavior flags for a client session.

Parameters

hClient

A handle to the client session.

dwModelFlags

An unsigned integer which specifies one or more capability flags for the selected model. This value cannot be zero.

Name	Description
LLM_MODEL_FLAG_CHAT	Supports conversational text generation
LLM_MODEL_FLAG_SYSTEM_ROLE	Accepts a system role message in the input
LLM_MODEL_FLAG_STREAMING	Supports streaming responses
LLM_MODEL_FLAG_STRUCTURED	Supports structured output (e.g., JSON or schema)
LLM_MODEL_FLAG_VISION	Supports image inputs (multimodal)
LLM_MODEL_FLAG_TOOLS	Supports tool or function calling
LLM_MODEL_FLAG_REASONING	Supports reasoning-oriented generation
LLM_MODEL_FLAG_RESPONSES	Supports the Responses API (unified endpoint)
LLM_MODEL_FLAG_FUNCTIONS	Supports OpenAI-style function calling with schemas
LLM_MODEL_FLAG_AUDIO	Supports audio output (text-to-speech)
LLM_MODEL_FLAG_IMAGE	Supports image generation
LLM_MODEL_FLAG_VIDEO	Supports video generation
LLM_MODEL_FLAG_TRANSCRIPTION	Supports speech-to-text transcription
LLM_MODEL_FLAG_INSTRUCTIONS	Supports a dedicated instruction field outside message lists
LLM_MODEL_FLAG_MAX_COMPLETION_TOKENS	Uses `max_completion_tokens` instead of `max_tokens` in requests

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To

get extended error information, call **LlmGetLastError**.

Remarks

The **LlmSetModelFlags** function overrides the capability flags associated with the currently selected model. These flags determine how the client formats requests and interprets responses for the model.

Model capability flags are normally determined automatically by the library based on the selected provider and model. This function is primarily intended for advanced scenarios where the default behavior must be adjusted, such as when working with custom providers, locally hosted models, or when a model's capabilities have changed and are not yet reflected in the library.

The specified flags must include `LLM_MODEL_FLAG_CHAT`, as the API requires a chat-based interface for sending and receiving messages. Specifying flags that are not supported by the selected model may result in request failures or undefined behavior.

Changing model flags can affect how requests are constructed, such as which parameters are used, how input is formatted, and which features are enabled. Applications should only modify these flags if they fully understand the capabilities of the target model.

If you enable a capability that is not supported by the model or provider, this will often result in an error condition and may cause subsequent requests to fail. For example, if you attempt to force the use of a system prompt by setting the LLM_MODEL_FLAG_SYSTEM_ROLE flag, this can cause unexpected failures on models hosted locally using an application like LM Studio.

Changing the current model using the **LlmSetModelName** function will reset the model flags for the session back to their default values for the new model.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmSetRequestHeader Function

```
BOOL WINAPI LlmSetRequestHeader(
   HCLIENT hClient,
   LPCTSTR lpszHeaderName,
   LPTSTR lpszHeaderValue
);
```

The **LlmSetRequestHeader** function sets the value of a custom HTTP header issued with subsequent requests.

Parameters

hClient

A handle to the client session.

lpszHeaderName

A pointer to a null-terminated string which specifies the name of the HTTP header field. Header names may only contain ASCII letters, numbers and a restricted subset of punctuation characters. Header names cannot contain Unicode or ANSI multi-byte character sequences.

lpszHeaderValue

A pointer to a null-terminated string which specifies the value of the HTTP header. Header values cannot contain carriage-return or linefeed characters. If the value contains Unicode characters, they will be UTF-8 encoded. If this parameter or NULL or a zero-length string, the header field is deleted from the request headers.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**. If the header name contains illegal characters or cannot be changed (e.g., attempting to change the `Authorization` header), the function will return zero and the last error code will be set to `ST_ERROR_INVALID_HEADER_NAME`. If the header value contains illegal characters, the last error code will be set to `ST_ERROR_INVALID_HEADER_VALUE`.

Remarks

The **LlmSetRequestHeader** function assigns a custom HTTP request header that will be included with subsequent requests made using the current client session. If the specified header already exists in the custom header list, its value will be replaced. If the header value is an empty string, the header will be removed.

This function is intended for advanced applications that require lower-level access to provider-specific functionality. Most applications should not need to use custom request headers. Some headers are managed internally by the library and cannot be overridden using this function. This includes headers required for authentication, content formatting, message length, host identification, and other protocol-specific functionality required by the current provider.

Examples of headers that are managed internally by the library include:

- `Authorization`
- `Content-Length`
- `Content-Type`
- `Host`
- `User-Agent`

Custom headers remain associated with the current client session until they are removed using the **LlmClearHeaders** function, the **LlmResetSession** function is called, or the connection is closed using the **LlmDisconnect** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmSetSystemPrompt Function

```
BOOL WINAPI LlmSetSystemPrompt(
   HCLIENT hClient,
   LPCTSTR lpszSystemPrompt
);
```

The **LlmSetSystemPrompt** function changes the current system prompt for a client session.

Parameters

hClient

A handle to the client session.

lpszSystemPrompt

A pointer to a string buffer which will contain the new system prompt for the current session. If this parameter is NULL or an empty string, a system prompt will not be included with new requests.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

A system prompt provides instructions that are included with each request sent to the model. It can be used to define the expected role, tone, response style, formatting rules, or other application-specific guidance that should apply to the session.

For example, an application might use a system prompt to request short responses, avoid Markdown formatting, return structured text, or answer only within the context of a specific feature or workflow.

Because conversation history is included with each request, messages that were generated using a previous system prompt may still influence subsequent responses. Changing or clearing the system prompt does not retroactively modify existing messages in the history. If the new prompt represents a significant change in behavior, applications may want to clear the history to avoid unintended interactions between the previous and current instructions.

If the new prompt represents a significant change in behavior, applications may want to call **LlmClearHistory** before sending additional messages.

The system prompt should be treated as guidance, not a guarantee. Different providers and models may interpret system instructions differently, and user messages may still influence the response. If ***lpszSystemPrompt*** is NULL or points to an empty string, the current system prompt is cleared and no system prompt will be included with new requests.

Support for system prompts may vary between providers and models. Some providers treat the system prompt as a distinct message role, while others incorporate it as part of a separate instruction field. The library will map the system prompt to the appropriate format for the selected provider, but the exact behavior and influence on the response may differ. Applications should test system prompt behavior with their selected provider to ensure it produces the desired results.

Note that some providers or models will not provide any support for a system role. This is more common with locally hosted models using applications like LM Studio or Ollama. To determine if a model supports system prompts, use the **LlmGetModelFlags** function and check for the LLM_MODEL_FLAG_SYSTEM_ROLE flag.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

LlmSetTimeout Function

```
BOOL WINAPI LlmSetTimeout(
   HCLIENT hClient,
   UINT nTimeout
);
```

The **LlmSetTimeout** function sets the number of seconds the client will wait for a blocking operation to complete.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmSetTimeout** function sets the timeout period, in seconds, for blocking operations such as sending a message to the server. If a request does not complete within the specified time, the operation will fail and return a timeout error.

The minimum timeout period is 5 seconds and the maximum timeout period is 300 seconds. If a value outside this range is specified, it will be clamped to the nearest supported value. Specifying a value of zero resets the timeout to the default value of 60 seconds.

The appropriate timeout value may vary depending on the selected provider, model, and network conditions. Larger or more complex models may require additional time to generate a response. Locally hosted models may also require longer timeouts depending on the available hardware resources, such as CPU or GPU performance.

The maximum timeout period is intended to prevent applications from waiting indefinitely for a response. If an operation consistently requires several minutes to complete, applications should consider performing the request on a background thread or using a smaller or faster model.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

See Also

LlmSetUserAgent Function

```
BOOL WINAPI LlmSetUserAgent(
   HCLIENT hClient,
   LPCTSTR lpszUserAgent
);
```

The **LlmSetUserAgent** function changes the current user-agent string used by the client.

Parameters

hClient

A handle to the client session.

lpszUserAgent

A pointer to a string buffer which will contain the new user-agent string for the current session. If this parameter is NULL or a zero-length string, the function will reset the user-agent string to a default value.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmSetUserAgent** function changes the user-agent string used by the client session. The specified string is trimmed to remove leading and trailing whitespace and will be used the next time the client establishes a connection to the provider.

If *lpszUserAgent* is NULL or points to an empty string, the current user-agent string is cleared and a new default value is generated for the session.

The default user-agent string uses a format similar to Chromium-based browsers and includes information about the current Windows platform and the SocketTools version. If an application name was specified when the session was created, it may also be included in the default value.

For example, a default user-agent string may look similar to the following:

```
Mozilla/5.0 (Windows NT 10.0; Win64; x64) Chrome/134.0.0.0 Safari/537.36
SocketTools/12.0
```

Applications normally do not need to change the user-agent string. However, a custom value may be useful when an application needs to identify itself to a provider, gateway, proxy, or logging system.

Developers should avoid including sensitive information, such as API keys, account identifiers, or user-specific data, in the user-agent string.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

LlmTrimHistory Function

```
LONG WINAPI LlmTrimHistory(
   HCLIENT hClient,
   LONG nMessageCount,
   LONG nMaxTokens
);
```

The **LlmTrimHistory** function removes older messages from the conversation history for the current client session.

Parameters

hClient

A handle to the client session.

nMessageCount

The number of messages to remove from the beginning of the conversation history. If this value is zero, messages are only removed if required by the ***nMaxTokens*** parameter. If this value is equal to or greater than the number of messages in the history, the entire history is cleared.

nMaxTokens

The maximum number of input tokens that should remain in the conversation history. If this value is zero, token usage is not checked. If the current history exceeds this value, additional older messages may be deleted until the total input token count is below the specified limit.

Return Value

If the function succeeds, the return value is the number of messages deleted from the conversation history. If the function fails, the return value is LLM_ERROR. To get extended error information, call **LlmGetLastError**.

If no messages are available to delete, the return value is zero.

Remarks

The **LlmTrimHistory** function removes messages from the beginning of the conversation history. This can be used to reduce memory usage, discard older context, or limit how much previous conversation text is included with future requests.

The ***nMessageCount*** parameter specifies the minimum number of older messages to remove. If ***nMaxTokens*** is greater than zero, the function also checks the total number of input tokens currently stored in the message history. If the token count exceeds the specified limit, additional older messages will be removed until the total input token count is below the specified threshold.

When both parameters are specified, the function may remove more messages than requested by ***nMessageCount*** to reduce the token count below the limit specified by ***nMaxTokens***. The return value always indicates the actual number of messages removed.

If the number of messages to remove is equal to or greater than the number of messages currently stored, the entire conversation history is cleared. This is equivalent to calling **LlmClearHistory**.

This function only removes the local message and response history maintained by the client session. It does not change the current provider, model, system prompt, connection settings or cached provider metadata.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmUninitialize Function

```
VOID WINAPI LlmUninitialize();
```

The **LlmUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application must call **LlmInitialize** successfully before calling any other library functions. When it has finished using the library, the application should call **LlmUninitialize** to release resources allocated by the library. If this function is not called explicitly, the library will release its resources when the application terminates.

Initialization is reference counted. Each successful call to **LlmInitialize** increments the library usage count, and each call to **LlmUninitialize** decrements it. The library is not fully uninitialized until the usage count reaches zero. When the usage count reaches zero, **LlmUninitialize** will terminate all active client sessions, close any open connections, and free memory associated with the library. Any pending blocking operations are canceled and will not complete.

This function should not be called while other threads are actively using the library. Applications should ensure that all operations have completed and that no additional calls will be made before uninitializing the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib

LlmValidateModel Function

```
BOOL WINAPI LlmValidateModel(
   HCLIENT hClient,
   LPCTSTR lpszModelName
);
```

The **LlmValidateModel** function validates that a model name is recognized or supported by the current provider.

Parameters

hClient

A handle to the client session.

lpszModelName

A null-terminated string which specifies the name of the model to validate. This parameter cannot be NULL or a zero-length string.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmValidateModel** function verifies that a model name appears to be valid for the current session. Validation may be performed using locally available information or by querying the provider for a list of supported models. If the provider supports returning model information, this function may perform a lookup to confirm that the specified model name is recognized. This may require a network request and can cause the function to block while the model list is retrieved.

If the provider does not support returning model information, the function only performs basic validation of the model name. For example, it will check the name to ensure it does not contain any illegal characters and uses a format that is common for most service providers. This function is most commonly used with applications to validate user input.

A successful return value from this function only indicates that the model name is syntactically valid. It does not guarantee that the selected service provider will accept or allow the model to be used. A provider may reject a valid model name for several reasons, including the model being unavailable for the current account, restricted to specific subscription tiers, region-limited, deprecated, disabled by administrative policy, or not supported by the endpoint being used. Providers may also change model availability over time without notice. Applications should be prepared to handle errors returned when establishing a session or sending a request, even if the model name was validated successfully.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

LlmValidateText Function

```
BOOL WINAPI LlmValidateText(
   LPCTSTR lpszMessageText,
   INT cchMessageText
);
```

The **LlmValidateText** function performs basic validation on text before it is submitted to a model.

Parameters

lpszMessageText

A pointer to the message text to validate. This parameter cannot be NULL.

cchMessageText

The number of characters in the message text, excluding the terminating null character. If this value is -1, the message text must be null-terminated and the entire string is checked.

Return Value

If the message text appears to be valid, the function returns non-zero. If the message text is empty, contains invalid characters, or appears to contain non-text data, the function returns zero. To get extended error information, call **LlmGetLastError**.

Remarks

The **LlmValidateText** function is intended to help applications detect invalid or malformed input before sending a request to a model. It checks for common problems such as empty strings, text that consists only of spaces or line breaks, illegal Unicode code points, non-printable characters, and input that appears to contain binary data. The message text cannot contain embedded null characters.

Applications that accept messages from users or other external sources should validate the text before submitting it to a model. This can help detect malformed or invalid input before a request is sent, reducing the chance of unexpected results or incurring unnecessary usage costs.

This function does not evaluate the quality, safety, or semantic meaning of the message. Although this function is most commonly used to check prompts sent to a model, it can be used to validate any type of text to ensure it is not malformed and contains printable characters.

There are two versions of this function. The wide character version of this function (**LlmValidateTextW**) validates the message text as UTF-16 Unicode. The ANSI version (**LlmValidateTextA**) first attempts to interpret the input as UTF-8 encoded text. If the input is not valid UTF-8, it attempts to convert the text to Unicode using the active code page and the resulting Unicode text is validated. The generic function name **LlmValidateText** automatically resolves to the ANSI or Unicode version based on whether the application is compiled with Unicode support.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csllmv12.lib
Unicode: Implemented as Unicode and ANSI versions

Large Language Model Data Structures

- LLM_MESSAGE
- LLM_MODEL_INFO
- LLM_PROVIDER_INFO
- LLM_RESPONSE
- LLM_SESSION
- LLM_TOKEN_USAGE

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

LLM_MESSAGE

The **LLM_MESSAGE** structure represents a message sent from the client to the LLM server.

```
typedef struct _LLM_MESSAGE
{
    DWORD   dwSize;
    DWORD   dwRoleId;
    DWORD   dwFlags;
    DWORD   dwReasoningLevel;
    DWORD   dwMessageId;
    DWORD   dwReserved;
    TIME_T  tTimestamp;
    LONG    nMaxTokens;
    LONG    nInputTokens;
    LONG    nContentLength;
    LPCTSTR lpszContent;
} LLM_MESSAGE, *LPLLM_MESSAGE;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_MESSAGE)` before the structure is used.

dwRoleId

The role associated with the message, such as user, assistant or system. This member should be one of the following values:

Constant	Description
LLM_ROLE_UNKNOWN	Unknown or invalid role. This value is typically used when a message has not been initialized correctly or could not be classified.
LLM_ROLE_USER	A message originating from the end-user. This is the most common role and represents input provided by the application or user interface.
LLM_ROLE_ASSISTANT	A response generated by the language model. Messages with this role are typically returned by the library as part of the conversation history.
LLM_ROLE_SYSTEM	A system-level instruction that defines how the model should behave. This is typically used to set context, tone, or constraints for the session before user messages are processed.
LLM_ROLE_FUNCTION	A legacy role used for function call messages in older APIs. This role is retained for compatibility but is generally not used in new implementations.
LLM_ROLE_TOOL	A message generated by an external tool or function invoked by the model. This role is used when integrating tool or function-calling workflows.
LLM_ROLE_TOOLUSER	A user message that is specifically intended for processing by a tool or function, rather than direct model interpretation.

LLM_ROLE_DEFAULT	The default role assigned to messages. This is equivalent to LLM_ROLE_USER.

dwFlags

A value reserved for future use. This member should always be set to zero or `LLM_MESSAGE_FLAG_NONE`.

dwReasoningLevel

The reasoning effort level associated with the message. This member may be set to one of the `LLM_REASONING` constants to control how much reasoning the model should apply when generating a response. A value of `LLM_REASONING_DEFAULT` uses the provider or model default behavior.

dwMessageId

An identifier assigned to the message. For application-supplied input messages, this value is initially zero. When a message has been added to a session or returned from the message history, this member may contain a unique identifier assigned by the library.

dwReserved

A reserved value for future use. This member should always be zero.

tTimestamp

The timestamp associated with the message. For application-supplied input messages, this value is typically zero. When available, this member contains the time the message was created.

nMaxTokens

The maximum number of output tokens associated with the message. This value is primarily used when submitting a request and may be zero to indicate the session or provider default should be used.

nInputTokens

The number of input tokens associated with the message content. This value is typically provided by the library when token usage information is available.

nContentLength

The length of the message content, in characters, not including the terminating null character. If this value is zero, the content length may be determined from the string.

lpszContent

A pointer to a null-terminated string which contains the message text. This member may be NULL if the message consists only of media content.

Remarks

This structure is used to describe a single message in a conversation with a language model. Messages are typically assigned a role using one of the constants, such as `LLM_ROLE_USER` for user input, `LLM_ROLE_ASSISTANT` for a model response, or `LLM_ROLE_SYSTEM` for an instruction message that defines the behavior of the session. In most applications, those roles are required. Other roles are used for advanced scenarios such as tool integration or legacy compatibility.

The **LLM_MESSAGE** structure is used for both input and output operations. When passed to functions such as **LlmSendMessageEx**, it defines a message that will be submitted to the language model. In this case, the application typically initializes only the required members, such as ***dwSize***, ***dwRoleId***, and the content or media fields. When used with functions such as **LlmGetFirstMessage** and **LlmGetNextMessage**, this structure is populated by the library to return messages from the current session history. In this case, additional members such as the message identifier, timestamp, and token

counts may contain values assigned by the library. Applications should treat values returned by the library as read-only unless otherwise documented.

The *lpszContent* member specifies the text associated with the message. For the ANSI version of this structure, this string must be UTF-8 encoded. In the Unicode version, the string is specified as UTF-16 using a wide character pointer.

The *nContentLength* member specifies the content length in characters rather than bytes. If this value is zero, the library may determine the length from the null-terminated string. Applications should not assume that token counts are identical to character counts. The *nInputTokens* member, when available, reflects the tokenized size of the message content as determined by the model or provider.

The *dwReasoningLevel* member controls the reasoning effort requested for the message. Higher reasoning levels may improve the quality, accuracy, or depth of responses, particularly when using reasoning-capable models, but they can also increase response time and token usage costs. Lower reasoning levels generally favor faster responses and reduced usage costs. Not all providers or models support configurable reasoning levels, and unsupported values may be ignored by the provider. If this member is set to `LLM_REASONING_DEFAULT`, the library will use the default reasoning behavior for the current provider or model.

The *tTimestamp* member is a standard 64-bit Unix time value and can be used interchangeably with functions in the C standard library such as **gmtime** or **localtime**. Because it is a 64-bit integer, it is not impacted by the Year 2038 problem. Timestamps can be converted into a local date and time using the **LlmConvertTimestamp** function.

Unless otherwise noted, any reserved members should be set to zero before calling a function which accepts this structure. Applications should also avoid modifying structure members that are returned by the library unless the documentation for a specific function indicates that doing so is supported.

The *lpszContent* member of this structure is managed by the library. Applications should treat this value as read-only and must not attempt to modify the contents of the string. If the application needs to retain or modify this data, it should create its own copy.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LLM_MODEL_INFO

The **LLM_MODEL_INFO** structure contains descriptive information and capability data for a language model.

```
typedef struct _LLM_MODEL_INFO
{
    DWORD    dwSize;
    DWORD    dwProviderId;
    DWORD    dwFlags;
    DWORD    dwStatus;
    DWORD    dwReserved;
    LONG     nMaxTokens;
    LONG     nContextSize;
    FLOAT    fTemperature;
    FLOAT    fMaxTemperature;
    FILETIME ftCreated;
    TCHAR    szName[LLM_MODEL_NAMELEN];
    TCHAR    szDisplayName[LLM_MODEL_NAMELEN];
    TCHAR    szOwner[LLM_MODEL_NAMELEN];
    TCHAR    szVersion[LLM_MODEL_VERLEN];
    TCHAR    szCreated[LLM_MODEL_DATELEN];
} LLM_MODEL_INFO, *LPLLM_MODEL_INFO;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_MODEL_INFO)` before the structure is used.

dwProviderId

The provider associated with the model. This member should be one of the LLM_PROVIDER values.

dwFlags

One or more capability flags associated with the model. This member may contain a combination of LLM_MODEL_FLAG values.

dwStatus

One or more status flags associated with the model. This member may contain a combination of LLM_MODEL_STATUS values.

dwReserved

A reserved value for future use. This member should always be zero.

nMaxTokens

The maximum number of tokens the model can generate in response to a request. A value of zero indicates that this limit is not specified.

nContextSize

The maximum context window size for the model, in tokens. If this value is zero, the context size is unspecified or the provider does not distinguish it from ***nMaxTokens***.

fTemperature

The default temperature value associated with the model. A value of zero may indicate the value is not specified.

fMaxTemperature

The maximum supported temperature value for the model. A value of zero indicates that this limit is not specified.

ftCreated

The creation date and time associated with the model, expressed as a FILETIME value. If this member is zero, the creation time is not available.

szName

A null-terminated string which specifies the model identifier used by the provider, such as `gpt-5` or `claude-4-sonnet`.

szDisplayName

A null-terminated string which specifies an optional display name for the model. This value is intended for presentation to the user and may be an empty string.

szOwner

A null-terminated string which specifies the optional owner, vendor, or organization associated with the model. This value may be an empty string.

szVersion

A null-terminated string which specifies the optional version identifier associated with the model. If this information is not available, the value will be an empty string.

szCreated

A null-terminated string which specifies the optional model creation date in text form. If this information is not available, the value will be an empty string.

Remarks

This structure is used to return information about a model that is available through a specific provider. It is typically populated by the library when enumerating models or retrieving detailed information about a specific model. Applications should treat the contents of this structure as descriptive metadata and should not assume that every member will contain a meaningful value for every model.

The ***dwProviderId*** member identifies which service or platform supplies the model, using one of the `LLM_PROVIDER` constants. The ***dwFlags*** member describes the capabilities supported by the model, such as conversational input, structured output, reasoning, vision, tool calling, or audio support. The ***dwStatus*** member indicates the current state of the model, such as whether it is generally available, in preview, or deprecated. These values are defined by the library using the `LLM_MODEL_FLAG` and `LLM_MODEL_STATUS` constants.

The ***nMaxTokens*** value represents the maximum output token limit reported for the model. This limit only applies to generated content and may be lower than the model's total context window. The client can further restrict the length of generated responses if necessary. If this value is zero, it means the provider does not publish information about the maximum number of output tokens supported for a response. Internally, providers often impose generation limits that are lower than the total context size for a request, even if those limits are not publicly documented.

The ***nContextSize*** value represents the maximum number of tokens the model can process in a single request, including the system prompt, conversation history, user messages and generated output. Most cloud-based service providers offer models which support very large context windows while limiting the maximum number of tokens that can be generated in a single response. For example, a model may support a context window of 1,000,000 tokens, allowing it to process very large conversations or documents, while limiting individual responses to 128,000 output tokens.

The context window and maximum token values are advisory. They are used when the service

provider does not return detailed limit information for a model. These values should be treated as general guidance and are not enforced by the library. The actual limits may vary depending on the provider, model version, deployment, enabled features and account limits. A value of zero for either ***nMaxTokens*** or ***nContextSize*** means those limits cannot be determined for the model. For locally hosted models or cloud-based aggregators, these limits may also be configurable for a specific model.

The metadata strings are provided for identification and display purposes. The ***szName*** member contains the canonical model name used in API requests, while ***szDisplayName*** provides a more user-friendly label when one is available. Other fields, such as ***szOwner***, ***szVersion***, ***szCreated***, and ***ftCreated***, are optional and may not be supplied by every provider.

Applications should set the ***dwSize*** member before passing this structure to a function. Unless otherwise documented, reserved members should be set to zero. When this structure is returned by the library, string members are stored directly in the fixed-length buffers contained within the structure, and may be read safely by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

LLM_PROVIDER_INFO

The **LLM_PROVIDER_INFO** structure provides descriptive information and default connection settings for a language model provider.

```
typedef struct _LLM_PROVIDER_INFO
{
    DWORD   dwSize;
    DWORD   dwProviderId;
    DWORD   dwFlags;
    DWORD   dwReserved;
    LONG    nProtocol;
    LONG    nHostPort;
    TCHAR   szName[LLM_PROVIDER_NAMELEN];
    TCHAR   szHostName[LLM_PROVIDER_HOSTLEN];
    TCHAR   szDefaultModel[LLM_MODEL_NAMELEN];
} LLM_PROVIDER_INFO, *LPLLM_PROVIDER_INFO;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_PROVIDER_INFO)` before the structure is used.

dwProviderId

The provider identifier. This member should be one of the `LLM_PROVIDER` values. Refer to the providers page for a list of supported providers and their default models.

dwFlags

One or more provider capability flags. This member may contain a combination of `LLM_PROVIDER_FLAG` values.

dwReserved

A reserved value for future use. This member should always be zero.

nProtocol

The protocol used by the provider endpoint. Most cloud-based service providers require secure connections and applications should use `LLM_PROTOCOL_HTTPS`. For locally hosted models running on the same system or over a local network, `LLM_PROTOCOL_HTTP` can be used to establish a standard, non-secure connection.

nHostPort

The network port number associated with the provider endpoint. A value of zero indicates that the provider-specific default port should be used.

nHostPort

The network port number associated with the provider endpoint. A value of zero indicates that the provider-specific default port should be used.

szName

A null-terminated string which specifies a canonical provider name, such as `"OpenAI"`. This value may be used for identification or display in a user interface.

szHostName

A null-terminated string which specifies the default host name or IP address for the provider endpoint. This value may be an empty string for custom or application-defined providers.

szDefaultModel

A null-terminated string which specifies the default model name associated with the provider. This value may be an empty string if the provider requires the application to explicitly specify a model name.

Remarks

This structure is used to describe a language model provider, including its identity, endpoint information, and basic capabilities. It is typically populated by the library when enumerating known providers or retrieving information about a specific provider.

The ***dwProviderId*** member identifies the provider using one of the **`LLM_PROVIDER`** constants, while the ***dwFlags*** member indicates provider-level requirements or supported features, such as whether the provider requires TLS, requires authentication, supports enumerating models, or supports returning detailed model information. The ***nProtocol*** member identifies the default protocol used to communicate with the provider endpoint, such as HTTP or HTTPS.

The string members provide descriptive metadata about the provider. The ***szName*** member contains the canonical provider name. The ***szHostName*** member specifies the default network hostname associated with the provider, and ***szDefaultModel*** specifies the default model that may be used if the application does not explicitly choose one.

Not all providers supply the same level of detail. Some values may be empty or unspecified, particularly for custom, local, or application-defined providers. Applications should treat the contents of this structure as descriptive metadata and should not assume that every member will contain a meaningful value in all cases.

Applications should set the ***dwSize*** member before passing this structure to a function. Unless otherwise documented, reserved members should be set to zero. Because all string values are stored directly in the fixed-length buffers contained within the structure, the application may safely read or copy them as needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LLM_RESPONSE

The **LLM_RESPONSE** structure represents the response returned by a language model.

```
typedef struct _LLM_RESPONSE
{
    DWORD   dwSize;
    DWORD   dwRoleId;
    DWORD   dwFlags;
    DWORD   dwMessageId;
    DWORD   dwStatus;
    DWORD   dwElapsed;
    DWORD   dwReserved;
    TIME_T  tTimestamp;
    LONG    nOutputTokens;
    LONG    nContentLength;
    LPCTSTR lpszResponseId;
    LPCTSTR lpszModelName;
    LPCTSTR lpszStatusText;
    LPCTSTR lpszContent;
} LLM_RESPONSE, *LPLLM_RESPONSE;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_RESPONSE)` before the structure is used.

dwRoleId

The role associated with the response. This member will typically be set to `LLM_ROLE_ASSISTANT`, but may vary depending on the type of response returned.

dwFlags

Response flags. This member is reserved for future use and should typically be set to `LLM_RESPONSE_FLAG_NONE`.

dwMessageId

The identifier of the originating request message. This value corresponds to the *dwMessageId* member of the **LLM_MESSAGE** structure that initiated the request.

dwStatus

The response status code. This member should be one of the `LLM_RESPONSE` values, indicating how the request completed.

dwElapsed

The elapsed time, in milliseconds, required to process the request and generate the response.

dwReserved

A reserved value for future use. This member should always be zero.

tTimestamp

A 64-bit integer timestamp associated by the response. This member specifies when the response was received and the value is represented as the number of seconds from January 1, 1970 UTC.

nOutputTokens

The number of tokens generated in the response. This value is provided when token usage information is available.

nContentLength

The length of the response content, in characters, not including the terminating null character.

lpszResponseId

A null-terminated string which specifies a provider-defined identifier for the response. This value may be NULL.

lpszModelName

A null-terminated string which specifies the name of the model used to generate the response. This value may be NULL.

lpszStatusText

A null-terminated string which specifies a provider-specific status or diagnostic message. This value may be NULL.

lpszContent

A null-terminated string which specifies the response text returned by the model.

Remarks

The LLM_RESPONSE structure represents the result of a request submitted to a language model. It is typically returned by functions such as **LlmSendMessageEx** and provides both the generated response content and additional metadata describing how the request was processed.

This structure is logically paired with the **LLM_MESSAGE** structure. While the **LLM_MESSAGE** structure defines the input provided to the model, the **LLM_RESPONSE** structure contains the output generated by the model along with status and diagnostic information. The ***dwMessageId*** member may be used to associate the response with the originating request message.

The ***lpszContent*** member points to a null-terminated string buffer which contains the response from the model. The ***nContentLength*** member specifies how many characters are in the response, not including the terminating null character. Line feed and carriage return characters are converted to the standard Windows CRLF end-of-line sequence, ensuring consistent formatting across different providers and applications. This also helps ensure compatibility with Windows common controls and other user interface components.

The ANSI version of this structure uses UTF-8 encoded strings, while the Unicode version uses UTF-16 encoded strings. Response text returned by a provider may contain Unicode characters, including international text, typographical symbols, emoji, mathematical symbols, or other non-ASCII characters. Applications should ensure that any user interface controls, files, or other components used to display or process response text are capable of handling Unicode text correctly.

Applications which cannot process Unicode text in the response can provide a system prompt requesting that the model limit its output to ASCII characters. However, because model output is non-deterministic, applications should not assume that non-ASCII characters will never be returned.

The ***dwStatus*** member indicates how the request completed. A value of `LLM_RESPONSE_COMPLETE` indicates that the response was generated normally, while other values may indicate that the response was truncated due to token limits, cancelled, timed out, or failed due to an error. Applications should always check this value before processing the response content.

The ***dwElapsed*** member provides the total time required to process the request, which can be useful for performance monitoring or diagnostics. The ***nOutputTokens*** member, when available, indicates the number of tokens generated by the model, which may be useful for usage tracking or cost estimation.

The ***tTimestamp*** member is a standard 64-bit Unix time value which indicates when the response was

received from the service provider. It can be used interchangeably with functions in the C standard library such as **`gmtime`** or **`localtime`**. Because it is a 64-bit integer, it is not impacted by the Year 2038 problem. Timestamps can be converted into a local date and time using the **LlmConvertTimestamp** function.

The string members, such as *lpszContent*, *lpszResponseId*, *lpszModelName*, and *lpszStatusText*, are managed by the library. Applications should treat these pointers as read-only and must not attempt to modify the contents of the referenced strings. If an application needs to retain or modify this data, it should create its own copy.

Calling the **LlmClearHistory** or **LlmResetSession** functions will invalidate these string pointers. Applications must not reference these values after the session history has been cleared.

Unless otherwise documented, reserved members should be set to zero before calling a function which accepts this structure.

LLM_SESSION

The **LLM_SESSION** structure contains extended configuration information used by the **LlmConnectEx** function to establish a session with a language model provider.

```
typedef struct _LLM_SESSION
{
    DWORD dwSize;
    DWORD dwProviderId;
    DWORD dwFlags;
    FLOAT fTemperature;
    FLOAT fTopP;
    LONG  nTopK;
    LONG  nTimeout;
    LONG  nIdleTime;
    LONG  nCacheTime;
    LONG  nMaxTokens;
    DWORD dwReasoningLevel;
    LPCTSTR lpszBaseUrl;
    LPCTSTR lpszModelName;
    LPCTSTR lpszApiKey;
    LPCTSTR lpszApiVersion;
    LPCTSTR lpszAppName;
    LPCTSTR lpszUserId;
    LPCTSTR lpszOrgId;
    LPCTSTR lpszProjectId;
    LPCTSTR lpszSystemPrompt;
} LLM_SESSION, *LPLLM_SESSION;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_SESSION)` before the structure is used. This value is validated by the library and is reserved for future structure versioning.

dwProviderId

The provider associated with the session. This member should be one of the `LLM_PROVIDER` values. If this value is `LLM_PROVIDER_NONE` the provider ID specified when calling the **LlmConnectEx** function will be used. Refer to the providers page for a list of supported providers and their default models.

dwFlags

Reserved flags for internal use. This member should be set to zero.

fTemperature

The temperature value used to control response randomness. A value of zero indicates that the provider or model default should be used. Unless you have a specific need to specify a temperature, it is recommended that you leave this value set to zero. Providers do not interpret temperature values identically and reasoning models may ignore the value entirely.

fTopP

The nucleus (top-p) sampling value. A value of zero disables top-p sampling and causes the default behavior to be used. It is recommended that you leave this value set to zero. Nucleus sampling is not used with most reasoning models and may be ignored. Although some providers still support setting a top-p value, most discourage using it with their current models.

nTopK

The top-k sampling value. A value of zero disables top-k sampling. It is recommended that you leave this value set to zero. Top-k sampling is not used with most reasoning models and in many cases the value is ignored. Although some providers still support setting a top-k value, most discourage using it with their current models.

nTimeout

The timeout period for requests, in seconds. A value of zero indicates that the default timeout should be used.

nIdleTime

The maximum idle time, in seconds, that an existing HTTP connection may be retained when the `LLM_OPTION_KEEPALIVE` connection option is enabled. If the elapsed idle time exceeds this value, the current connection will be closed and a new connection will be established for the next request. A value of zero indicates that the default idle timeout should be used.

nCacheTime

The length of time, in seconds, that the library may cache provider-specific information. This is primarily used when caching model lists returned by a provider. A value of zero indicates that the default cache behavior should be used.

nMaxTokens

The maximum number of tokens to request for generated output. A value of zero indicates that the provider or model default should be used.

dwReasoningLevel

Specifies the default reasoning level used for requests in this session. Higher levels may improve response quality for complex tasks but can increase latency and token usage.

lpszBaseUrl

A pointer to a null-terminated string which specifies the base URL for the provider endpoint. This member may be NULL to use the default endpoint for the selected provider.

lpszModelName

A pointer to a null-terminated string which specifies the model name to use for the session. For Microsoft Foundry models, this member typically specifies the deployment name. This member may be NULL if the provider defines a default model.

lpszApiKey

A pointer to a null-terminated string which specifies the API key or authentication token used to access the provider. This member may be NULL if authentication is not required or is provided by another mechanism.

lpszApiVersion

A pointer to a null-terminated string which specifies the API version associated with the provider. This member may be NULL if no explicit version is required.

lpszAppName

A pointer to a null-terminated string which specifies an optional application name associated with the session. When provided, this value may be included in the user-agent string sent with requests. This value may be sanitized by the library before use and may be NULL.

lpszUserId

A pointer to a null-terminated string which specifies an optional user identifier associated with the session. This member may be NULL.

lpszOrgId

A pointer to a null-terminated string which specifies an optional organization identifier associated with the session. This member may be NULL.

lpszProjectId

A pointer to a null-terminated string which specifies an optional project identifier associated with the session. This member may be NULL.

lpszSystemPrompt

A pointer to a null-terminated string which specifies an optional system prompt used to define the initial behavior of the model for the session. This member may be NULL.

Remarks

This structure is used with the **LlmConnectEx** function to provide extended configuration information when creating a session. It allows an application to customize connection behavior, sampling parameters, model selection, authentication, and other optional settings without requiring a large number of function parameters. Applications that only need to specify the provider, base URL, model name, and API key may use the simpler **LlmConnect** function instead.

The *dwProviderId* member should normally match the provider specified in the **LlmConnectEx** function call. A value of `LLM_PROVIDER_NONE` may be used when the application relies on the function parameter to select the provider. If conflicting provider values are specified, the function will fail.

In most cases, applications only need to initialize *dwSize*, *dwProviderId*, and the specific members they wish to override. All unused numeric members should be set to zero, and all unused string members should be set to NULL. The library will apply provider-specific defaults when optional values are not specified.

The *lpszApiKey* member is a string value that specifies the API key used to authenticate with the provider. The API key may be provided using a literal string, an environment variable, or a value stored in the Windows Credential Manager. Using an environment variable or secure credential storage is recommended for production applications to avoid exposing sensitive information in source code or application binaries. To specify an environment variable, surround the name in percent (%) symbols, such as `"%OPENAI_API_KEY%"`. To specify a Windows Credential, surround it in braces, such as `"{MyAppName/OpenAI}".`

For production applications, it is recommended that you avoid using literal API key strings and instead use an environment variable or a value stored in the Windows Credential Manager. If you must provide the API key as a literal string, you should take additional steps to protect it, such as storing the key in an encrypted form and limiting access to authorized users or processes. Avoid embedding API keys directly in application source code, configuration files, installers or other content that could be exposed through version control systems, logs or public repositories.

The *dwReasoningLevel* member provides a provider-neutral hint that controls how much internal reasoning a model should use when generating a response. Higher levels may improve the quality of results for more complex tasks, but can also increase response time and token usage. Not all models support reasoning controls, and the exact behavior is provider-specific. In most cases, it is recommended that you set this value to LLM_REASONING_DEFAULT, allowing the provider or model to determine the appropriate level automatically.

The sampling-related members *fTemperature*, *fTopP*, and *nTopK* control how responses are generated. In most applications, adjusting the temperature alone is sufficient, while Top-P and Top-K are intended for more advanced tuning scenarios. If these values are not specified, the provider or model defaults are used. Not all providers or models support sampling parameters such as temperature, top-p or top-k. The library will only include those values when they are supported by the selected provider and model. For models that do not support these parameters, the session values are

ignored.

The connection-related members *lpszBaseUrl*, *nTimeout*, and *nIdleTime* control how requests are sent and how long an existing HTTP connection may be reused. When the `LLM_OPTION_KEEPALIVE` option is enabled, connections may be reused across multiple requests, subject to the idle timeout period.

The *nCacheTime* member controls how long the library may cache provider-specific information, such as model lists. This helps reduce unnecessary network requests when applications repeatedly query provider capabilities.

The *lpszAppName* member specifies the application name associated with requests sent by the control. This value is included as part of the default user-agent string and may be used for diagnostic and identification purposes by the provider. A recommended format is to specify both the application name and version number using a convention similar to standard user-agent strings, for example: `"MyApplication/1.0"`.

The *lpszUserId* member is a user identifier associated with requests sent to the current provider. Some providers allow applications to specify a user identifier as part of the request payload for diagnostics, analytics, rate limiting, or request tracking. Some providers may ignore the value or use it only for internal monitoring and logging purposes. Applications should avoid including sensitive or personally identifiable information in the user identifier value unless required by the provider.

The *lpszOrgId* member specifies an optional organization, tenant or account identifier used by some providers when processing requests. This is primarily intended for enterprise or multi-tenant environments where a provider account may be associated with multiple organizations or projects. Most applications will not need to set this value unless specifically required by the provider. If the current provider does not support organization identifiers, the value is ignored.

The *lpszProjectId* member specifies an optional project identifier used by some providers when processing requests. This is primarily intended for providers which support project-based authentication, billing or resource management. Most applications will not need to set this value unless specifically required by the provider or account configuration. If the current provider does not support project identifiers, the value is ignored.

The *lpszSystemPrompt* member may be used to define a session-level system prompt that establishes the behavior of the model. A system prompt provides instructions that are included with each request sent to the model. It can be used to define the expected role, tone, response style, formatting rules, or other application-specific guidance that should apply to the session. For example, an application might use a system prompt to request short responses, avoid Markdown formatting, return structured text, or answer only within the context of a specific feature or workflow.

The string members in this structure are supplied by the application and are treated as input values when the session is created. Applications should ensure that any referenced strings remain valid until a connection is established. The library makes an internal copy of these values, so the application does not need to maintain them after the connection completes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

LLM_TOKEN_USAGE

The **LLM_TOKEN_USAGE** structure contains information about token usage for a client session.

```
typedef struct _LLM_TOKEN_USAGE
{
    DWORD   dwSize;
    DWORD   dwProviderId;
    DWORD   dwReserved;
    LONG    nMessageCount;
    LONG    nInputTokens;
    LONG    nOutputTokens;
    LONG    nContextUsed;
    LONG    nContextSize;
    TCHAR   szModelName[LLM_MODEL_NAMELEN];
} LLM_TOKEN_USAGE, *LPLLM_TOKEN_USAGE;
```

Members

dwSize

The size of this structure, in bytes. This member must be set to `sizeof(LLM_TOKEN_USAGE)` before the structure is used.

dwProviderId

The provider identifier. This member should be one of the `LLM_PROVIDER` values. Refer to the providers page for a list of supported providers and their default models.

dwReserved

A reserved value for future use. This member will always be zero.

nMessageCount

The number of messages currently stored in the session history.

nInputTokens

The number of input tokens associated with system and user messages in the current session.

nOutputTokens

The number of output tokens generated in model responses for the current session.

nContextUsed

The total number of tokens currently used in the active chat context, including input messages and message history.

nContextSize

The maximum number of tokens supported by the current model for the active context. A value of zero indicates that this limit is not available.

szModelName

A null-terminated string which specifies the name of the model associated with the current session. This value may be empty if no model name is available.

Remarks

This structure is used to return token usage information for an active client session. It provides a summary of how many messages are currently in the session history, how many tokens have been used for input and output, and how much of the available context window is currently in use.

The ***nInputTokens*** member reflects tokens associated with user and system input, while

nOutputTokens reflects tokens generated by the model in its responses. The *nContextUsed* member represents the total token usage currently contributing to the active chat context, including prior message history that may be sent with each request.

The *nContextSize* member indicates the maximum context size supported by the current model, when that information is available. Applications may compare *nContextUsed* with *nContextSize* to estimate how much of the available context window has been consumed.

This structure is intended for informational and diagnostic use. Token counts are provider-dependent and may represent estimates rather than exact values, depending on the model or service in use. Applications should not rely on these values to enforce strict limits, as the provider ultimately determines whether a request exceeds its supported context or token constraints.

Applications should set the *dwSize* member before passing this structure to a function. Unless otherwise documented, reserved members should be set to zero. String values are stored directly in the fixed-length buffers contained within the structure and may be read safely by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Large Language Model Constants

Constant	Value	Description
Ports		
LLM_PORT_DEFAULT	0	Use the provider-specific default port.
LLM_PORT_SECURE	443	Default port for secure HTTPS connections.
Protocols		
LLM_PROTOCOL_DEFAULT	0	Use the provider-specific default protocol.
LLM_PROTOCOL_HTTP	1	Use the HTTP protocol.
LLM_PROTOCOL_HTTPS	2	Use the HTTPS protocol.
LLM_PROTOCOL_UNKNOWN	-1	Unknown or invalid protocol.
Options		
LLM_OPTION_NONE	0	No options specified.
LLM_OPTION_NOCACHE	0x000001	Disable provider and model caching for the session.
LLM_OPTION_KEEPALIVE	0x000002	Enable persistent (keep-alive) HTTP connections.
LLM_OPTION_PROXY	0x000008	Use a configured proxy server for the connection.
LLM_OPTION_NOUSERAGENT	0x000020	Do not send a User-Agent header with the request.
LLM_OPTION_SECURE	0x001000	Force use of a secure (HTTPS) connection.
LLM_OPTION_DEFAULT	LLM_OPTION_NONE	Default option set (no flags enabled).
Providers		
LLM_PROVIDER_NONE	0	No provider specified.
LLM_PROVIDER_LOCAL	1	Local inference provider (e.g., LM Studio or Ollama).
LLM_PROVIDER_OPENAI	2	OpenAI provider using the ChatGPT models.

LLM_PROVIDER_ANTHROPIC	3	Anthropic provider using the Claude models.
LLM_PROVIDER_GOOGLE	4	Google AI provider using the Gemini models.
LLM_PROVIDER_MICROSOFT	5	Microsoft Foundry provider using OpenAI-compatible models.
LLM_PROVIDER_MISTRAL	6	Mistral AI provider using the Mistral models.
LLM_PROVIDER_UNKNOWN	((DWORD)-1)	Unknown or unrecognized service provider.
LLM_PROVIDER_DEFAULT	LLM_PROVIDER_LOCAL	Default service provider.
Reasoning		
LLM_REASONING_NONE	0	No reasoning, even if it is available.
LLM_REASONING_DEFAULT	1	Provider or model default.
LLM_REASONING_LOW	2	Prefer faster responses; reduces usage costs.
LLM_REASONING_MEDIUM	3	Balanced reasoning.
LLM_REASONING_HIGH	4	Prefer quality responses; increases usage costs.
LLM_REASONING_MAXIMUM	5	Maximum reasoning quality.
Temperature		
LLM_TEMPERATURE_MINIMUM	0.0	Deterministic output with minimal randomness.
LLM_TEMPERATURE_CONSERVATIVE	0.3	Low variability, more predictable responses.
LLM_TEMPERATURE_BALANCED	0.7	Balanced creativity and coherence.
LLM_TEMPERATURE_DEFAULT	1.0	Standard default sampling behavior.
LLM_TEMPERATURE_CREATIVE	1.2	Increased creativity and variation.
LLM_TEMPERATURE_MAXIMUM	2.0	Maximum randomness with highly varied output.
Top-P Sampling		

LLM_TOP_P_DISABLED	0.0	Nucleus sampling disabled.
LLM_TOP_P_MINIMUM	0.1	Very restrictive token selection.
LLM_TOP_P_CONSERVATIVE	0.8	Conservative token selection.
LLM_TOP_P_BALANCED	0.9	Balanced nucleus sampling.
LLM_TOP_P_CREATIVE	0.95	More diverse token selection.
LLM_TOP_P_MAXIMUM	1.0	Full probability distribution with no filtering.
LLM_TOP_P_DEFAULT	LLM_TOP_P_DISABLED	Default disables nucleus sampling.
Top-K Sampling		
LLM_TOP_K_DISABLED	0	Top-K sampling disabled.
LLM_TOP_K_MINIMUM	0	Equivalent to disabled sampling.
LLM_TOP_K_CONSERVATIVE	10	Restrict to top 10 tokens.
LLM_TOP_K_BALANCED	40	Balanced token selection range.
LLM_TOP_K_CREATIVE	60	More diverse token selection.
LLM_TOP_K_MAXIMUM	100	Wide token selection range.
LLM_TOP_K_DEFAULT	LLM_TOP_K_DISABLED	Default disables Top-K sampling.
Frequency		
LLM_FREQUENCY_DISABLED	0.0	No frequency penalty applied.
LLM_FREQUENCY_MINIMUM	0.0	Minimum frequency penalty.
LLM_FREQUENCY_MAXIMUM	2.0	Maximum frequency penalty.
LLM_FREQUENCY_DEFAULT	LLM_FREQUENCY_DISABLED	Default disables frequency penalty.
Presence		
LLM_PRESENCE_DISABLED	0.0	No presence penalty

		applied.
LLM_PRESENCE_MINIMUM	0.0	Minimum presence penalty.
LLM_PRESENCE_MAXIMUM	2.0	Maximum presence penalty.
LLM_PRESENCE_DEFAULT	LLM_PRESENCE_DISABLED	Default disables presence penalty.
Provider Flags		
LLM_PROVIDER_FLAG_NONE	0	No provider requirements specified.
LLM_PROVIDER_FLAG_REQUIRE_TLS	0x0001	Requires a secure TLS (HTTPS) connection.
LLM_PROVIDER_FLAG_REQUIRE_AUTH	0x0002	Requires authentication (e.g., API key or token).
LLM_PROVIDER_FLAG_API_VERSION	0x0004	Requires an explicit API version parameter.
LLM_PROVIDER_FLAG_LOCAL	0x0008	Locally hosted provider (LM Studio, Ollama, etc.)
LLM_PROVIDER_FLAG_MODEL_LIST	0x0010	Supports enumerating available models.
LLM_PROVIDER_FLAG_MODEL_INFO	0x0020	Supports retrieving detailed model information.
Model Options		
LLM_MODEL_OPTION_DEFAULT	0x0000	default list of chat models for a provider.
LLM_MODEL_OPTION_PREVIEW	0x0001	Include preview or experimental models.
LLM_MODEL_OPTION_STREAMING	0x0002	Include models that support streaming responses.
LLM_MODEL_OPTION_STRUCTURED	0x0004	Include models that support structured outputs.
LLM_MODEL_OPTION_REASONING	0x0008	Include reasoning-oriented models.
LLM_MODEL_OPTION_VISION	0x0010	Include models that support image input.
LLM_MODEL_OPTION_AUDIO	0x0200	Include models that support audio output (text-to-speech).

LLM_MODEL_OPTION_IMAGE	0x0400	Include models that support image generation or input.
LLM_MODEL_OPTION_VIDEO	0x0800	Include models that support video generation.
LLM_MODEL_OPTION_TRANSCRIPTION	0x1000	Include models that support speech-to-text transcription.
LLM_MODEL_OPTION_DEPRECATED	0x8000	Include deprecated or retired models.
LLM_MODEL_OPTION_ALL_MODELS	0xFFFF	Include all available model types.
Model Flags		
LLM_MODEL_FLAG_NONE	0x0000	No model capabilities defined.
LLM_MODEL_FLAG_CHAT	0x0001	Supports conversational text generation.
LLM_MODEL_FLAG_SYSTEM_ROLE	0x0002	Accepts a system role message in the input.
LLM_MODEL_FLAG_STREAMING	0x0004	Supports streaming responses.
LLM_MODEL_FLAG_STRUCTURED	0x0008	Supports structured output (e.g., JSON or schema).
LLM_MODEL_FLAG_VISION	0x0010	Supports image inputs (multimodal).
LLM_MODEL_FLAG_TOOLS	0x0020	Supports tool or function calling.
LLM_MODEL_FLAG_REASONING	0x0040	Supports reasoning-oriented generation.
LLM_MODEL_FLAG_RESPONSES	0x0080	Supports the Responses API (unified endpoint).
LLM_MODEL_FLAG_FUNCTIONS	0x0100	Supports OpenAI-style function calling with schemas.
LLM_MODEL_FLAG_AUDIO	0x0200	Supports audio output (text-to-speech)
LLM_MODEL_FLAG_IMAGE	0x0400	Supports image generation.
LLM_MODEL_FLAG_VIDEO	0x0800	Supports video generation.

LLM_MODEL_FLAG_TRANSCRIPTION	0x1000	Supports speech-to-text transcription.
LLM_MODEL_FLAG_INSTRUCTIONS	0x2000	Supports a dedicated instruction field outside message lists.
LLM_MODEL_FLAG_MAX_COMPLETION_TOKENS	0x4000	Uses `max_completion_tokens` instead of `max_tokens` in requests.
LLM_MODEL_FLAG_INFERRED	0x80000	Capabilities are inferred rather than explicitly defined.
Model Status		
LLM_MODEL_STATUS_NONE	0x0000	No status assigned.
LLM_MODEL_STATUS_AVAILABLE	0x0001	Model is actively available.
LLM_MODEL_STATUS_PREVIEW	0x0002	Model is in preview or experimental stage.
LLM_MODEL_STATUS_DEPRECATED	0x0004	Model is deprecated or legacy.
Limits		
LLM_MAX_MESSAGE_LENGTH	65536	Maximum length of a single input message (64 KB)
LLM_MAX_RESPONSE_LENGTH	262144	Maximum expected response length (256 KB)
LLM_MAX_SYSTEM_PROMPT_LENGTH	32768	Maximum length of the system prompt (32 KB)
LLM_MAX_CHAT_HISTORY	1000	Maximum number of messages stored per session.
LLM_MAX_TOKENS	200000	Maximum token limit per request.
Roles		
LLM_ROLE_UNKNOWN	0	Unknown or invalid role.
LLM_ROLE_USER	1	User input message.
LLM_ROLE_ASSISTANT	2	Assistant response message.
LLM_ROLE_SYSTEM	3	System-level instruction message.

LLM_ROLE_FUNCTION	4	Function call message (legacy)
LLM_ROLE_TOOL	5	Tool-generated message.
LLM_ROLE_TOOLUSER	6	User input directed to a tool.
LLM_ROLE_DEFAULT	LLM_ROLE_USER	Default role is user input.
Responses		
LLM_RESPONSE_UNKNOWN	0	No stop reason specified or unrecognized response state.
LLM_RESPONSE_COMPLETE	1	Response completed normally.
LLM_RESPONSE_LIMITED	2	Stopped due to token or context limits.
LLM_RESPONSE_ABORTED	3	Request was cancelled or interrupted.
LLM_RESPONSE_ERROR	4	An error occurred during processing.
LLM_RESPONSE_TIMEOUT	5	Request timed out.
Session		
LLM_SESSION_FLAG_NONE	0	No session flags specified.
LLM_SESSION_FLAG_DEFAULT	LLM_SESSION_FLAG_NONE	Default session behavior.
Cache		
LLM_INVALID_CACHE_TIME	-1	Indicates an invalid or unspecified cache duration.

Large Language Model Providers

One of the first decisions you will need to make when using the SocketTools Large Language Model API is choosing which service provider to use. The library is designed to support a variety of providers and models, and the provider type is specified using one of following provider constants. The current version supports the following providers:

Constant	Value	Default Model	Description
LLM_PROVIDER_LOCAL	1	None	Locally hosted models using servers like LM Studio or Ollama. This is ideal for development, testing, offline use, or avoiding usage costs. A wide range of open-source models are available; for best results, start with smaller instruction-tuned models such as **qwen2.5-7b-instruct**, **llama-3.2-3b-instruct**, or **mistral-7b-instruct**.
LLM_PROVIDER_OPENAI	2	**gpt-5.4-nano**	OpenAI's public API (ChatGPT) is a recommended starting point for most developers due to ease of use, strong general performance, and comprehensive documentation. For initial development and testing, lightweight models such as the GPT-5 mini series provide fast response times and lower usage costs.
LLM_PROVIDER_ANTHROPIC	3	**claude-haiku-4-5**	Anthropic's Claude models are well suited for structured reasoning, conversational clarity, and safety-focused applications. For initial use, the Haiku models offer lower cost and faster response times while maintaining strong performance.
LLM_PROVIDER_GOOGLE	4	**gemini-2.5-flash**	Google's Gemini models are a good choice for multimodal applications and integration with the Google AI ecosystem. The Flash models are recommended for getting started due to their lower latency and reduced token costs.
LLM_PROVIDER_MICROSOFT	5	None	Microsoft Foundry OpenAI-compatible models are typically used in enterprise environments requiring Azure integration and regional deployment control. This option requires provisioning a model deployment within Foundry and specifying the deployment name and API version when connecting.
LLM_PROVIDER_MISTRAL	6	**mistral-small-3.2**	Mistral AI models provide efficient and cost-effective options for general-purpose and

			reasoning tasks. Smaller models are recommended when getting started due to their performance and lower cost.

Choosing a Model

Although SocketTools provides a default model for most providers, the model names and availability will change over time. The providers which do not have a default model assigned to them will always require a specific model name when establishing the connection. Some providers, notably Microsoft Foundry and locally hosted services, will explicitly require you to provide a model name to establish a connection.

It is important to note that the library is not limited only to those default models listed above. Developers are encouraged to enumerate available models and explicitly select a model that meets their requirements. The library provides functions designed to return information about all of the compatible models supported by a provider. For more information refer to the LlmEnumModels function.

Most language model providers offer multiple models with different capabilities, performance characteristics, and pricing. Rather than selecting a specific model name immediately, it is often more useful to choose a general category of model based on your application's needs.

Common model categories include:

- **Lightweight**. Optimized for speed and low cost. These are ideal for simple tasks such as formatting, summarization, classification, or user interface interactions where responsiveness is important. These are the default models assigned to supported providers. In most cases, we recommend you start with a lightweight model until you determine your application could benefit from a more capable model type.
- **Balanced**. General purpose models that provide good performance across a wide range of tasks. These are typically the best default choice for most applications which need to balance between performance and capability. Examples are **`gpt-5-mini`**, **`claude-sonnet-4-6`**, **`gemini-3.1`** and **`mistral-medium`** models.
- **Reasoning**. Designed for more complex tasks such as multi-step problem solving, analysis, and code generation. These models may produce more detailed responses but typically use more tokens and have higher latency and increased costs. Examples are **`gpt-5`**, **`claude-opus-4-7`**, **`gemini-3.1-pro`** and **`mistral-large`** models.
- **Multimodal**. Support input or output beyond plain text, such as images, audio, or structured data. These are useful when working with media content or advanced integrations.

In most cases, developers should begin with a lightweight or balanced model and only move to more advanced models when additional capability is required. The exact model names and capabilities will vary between providers, but these categories provide a useful framework for selecting an appropriate model. Applications should also avoid relying on strict token limits or attempting to precisely manage context usage. Providers ultimately determine request limits, and applications should be prepared to handle responses that are truncated or rejected when limits are exceeded.

API Keys and Authentication

Most language model providers require an API key (or authentication token) to access their services. An API key is a unique identifier associated with your account that is included with each request to authenticate the client and track usage.

When using the library, the API key is typically provided when establishing a session using the **LlmConnect** or **LlmConnectEx** function. The library will include this key in requests to the selected provider using the appropriate authentication mechanism.

Because API keys grant access to external services and may incur usage charges, they should be handled carefully and not exposed unnecessarily. The library supports several functions for providing API keys, allowing applications to balance convenience and security.

Providing an API Key

The library supports the following functions for supplying an API key:

- **Literal string**
  The API key can be provided directly as a string when creating a session. This is the simplest approach and is often used for testing or development, but it is not recommended for production applications because the key may be exposed in application binaries or source code.
- **Environment variable**
  The API key can be stored in an environment variable and retrieved at runtime. This approach avoids embedding the key directly in the application and is commonly used in development environments, scripts, or deployment pipelines.
- **Windows Credential Manager**
  The API key can be stored securely using the Windows Credential Manager and retrieved by the application at runtime. This is the recommended approach for Windows applications because it provides secure storage and helps prevent accidental exposure of sensitive credentials.

Best Practices

- Do not embed API keys directly in source code for production applications.
- Use secure storage mechanisms, such as the Windows Credential Manager, whenever possible.
- Limit access to API keys and avoid sharing them between applications or users.
- Review provider usage policies and configure usage limits or alerts where available.

Each provider has its own process for creating and managing API keys. Refer to the provider documentation for details on generating keys, rotating credentials, and managing access.

Application Design

When designing an application that uses a language model provider, developers generally have two approaches for managing API keys:

- **Application-managed API key**
  The developer provides an API key that is used by the application for all requests. This approach is simple to implement and provides a consistent user experience, but the developer is responsible for all usage and any associated costs.
- **User-provided API key (Bring Your Own Key)**
  The application allows the end user to supply their own API key, typically through a configuration dialog or settings interface. In this case, the user is responsible for usage and costs, and the application acts as a client using the user's credentials.

Each approach has trade-offs. Using an application-managed key simplifies the user experience but may require safeguards such as rate limiting or usage monitoring. Allowing users to provide their own

key can reduce operational costs and provide greater flexibility, but requires additional user interface considerations and clear instructions for obtaining and configuring API access.

Applications intended for a broad audience often prefer a built-in API key for ease of use, while developer-focused tools frequently support user-provided keys for flexibility.

Provider Overview

The following sections provide more detailed information about the supported providers. One of the advantages of the library is that applications are not limited to a single language model service. Different providers may offer advantages related to pricing, performance, regional availability, deployment flexibility, or model capabilities.

Supporting multiple providers can also provide greater flexibility for end users. Some users or organizations may already have existing accounts, billing arrangements, or infrastructure associated with a specific provider such as OpenAI, Google, Microsoft Foundry, or a locally hosted inference service. Applications can allow users to select the provider and model which best meets their requirements without requiring significant changes to application logic.

LLM_PROVIDER_LOCAL

This provider type is used for locally hosted language model inference. This is particularly useful for development, testing, and experimentation without relying on a cloud-based provider. Local hosting allows developers to evaluate model behavior, test integrations, and work offline or within a private environment. This requires you to install and configure an application on your local system or network which will provide the inference service. For the Windows platform, we recommend one of the following applications, which are free to install and use:

LM Studio

LM Studio provides a full-featured desktop environment for running and testing language models locally. It includes model management, a built-in server, and support for OpenAI-compatible APIs, making it a strong choice for development and evaluation.

- LM Studio
- LM Studio Documentation

Ollama

Ollama is a lightweight local model runtime that makes it easy to download and run models on a local system. It provides a simple API interface and is well suited for basic testing and self-hosted deployments.

- Ollama
- Ollama Documentation

LLM_PROVIDER_OPENAI

The OpenAI provider connects to OpenAI's public API and is generally the recommended starting point for most developers. It offers a wide range of well-documented models, consistent API behavior, and strong general-purpose performance. Developers who are new to using large language models or want a reliable default should typically begin here.

To get started, developers create an API key, select a model name, and connect to the default OpenAI endpoint. The API is widely supported and serves as the baseline for compatibility with many other providers.

- OpenAI Platform

- OpenAI Documentation
- Manage API Keys

LLM_PROVIDER_ANTHROPIC

The Anthropic provider connects to Anthropic's Claude API, which focuses on conversational models designed for safety and structured reasoning. Developers must create an API key and select a supported Claude model. The API is similar in concept to OpenAI but uses its own endpoints and request formats.

- Anthropic
- Claude Documentation

LLM_PROVIDER_GOOGLE

The Google provider connects to Google's Gemini API, which provides access to multimodal models and integrates with the broader Google AI ecosystem. Developers typically obtain an API key through Google AI Studio and use it to authenticate requests to the Gemini service.

- Google AI
- Google Documentation

LLM_PROVIDER_MICROSOFT

The Microsoft provider connects to a Microsoft Foundary OpenAI-compatible deployment. This option is often used in enterprise environments where Azure integration, regional deployment, or Microsoft-managed infrastructure is required. Unlike the public OpenAI API, Microsoft requires a resource-specific endpoint, a deployment name instead of a direct model name, and an explicit API version. Authentication is typically performed using an API key.

- Microsoft Foundry
- Azure OpenAI Reference

LLM_PROVIDER_MISTRAL

The Mistral provider connects to Mistral AI's hosted API service. Mistral models are designed to provide strong general-purpose and reasoning performance while maintaining efficient resource usage and competitive pricing. Developers who want a balance between capability, response speed, and lower operational cost may find these models to be a good alternative to larger commercial providers. Some organizations may prefer Mistral AI due to regional deployment considerations or compatibility with European-based infrastructure and services.

Message History File Format

The Large Language Model client API uses a JSON-formatted message history file to support exporting and importing conversation state between application sessions. This format is used by the **LlmExportHistory** and **LlmImportHistory** functions and is intended to provide a simple, human-readable representation of the conversation history associated with a client session.

A message history file contains both the messages sent by the client application and the responses generated by the model. Together, these entries represent the conversational context for the session. The file does not contain information about the client session, aside from the provider type and model name. It does not contain user names, authorization tokens or any information related to the service account.

The history file may contain sensitive or private information, including user prompts, model responses or application-specific data. Applications should take reasonable precautions to protect these files, particularly if they are stored, transmitted or made available for users to download.

The following example shows a simplified message history file containing a single message turn:

```
{
  "version": 1,
  "provider": 1,
  "created": 1715000000,
  "messages": [
    {
      "message": {
        "role": 1,
        "reasoning": 0,
        "flags": 0,
        "id": 1,
        "timestamp": 1715000001,
        "maxTokens": 0,
        "inputTokens": 12,
        "content": "Hello"
      },
      "response": {
        "role": 2,
        "flags": 0,
        "messageId": 1,
        "status": 1,
        "elapsed": 812,
        "timestamp": 1715000002,
        "outputTokens": 24,
        "model": "gpt-5.4-nano",
        "content": "Hi there."
      }
    }
  ],
  "messageCount": 1,
  "model": "gpt-5.4-nano"
}
```

File Structure

A message history file consists of a root JSON object which contains session metadata and an array of message turns.

version

The format version number used by the exported history file.

provider

The numeric provider identifier associated with the session.

created

A Unix timestamp value which indicates when the history file was created.

messages

An array containing the exported message turns.

messageCount

The number of message turns stored in the history file.

model

The default model name associated with the exported session.

Message Turns

Each entry in the **`messages`** array represents a complete message turn consisting of two objects:

- A **`message`** object which contains the client input
- A **`response`** object which contains the model output

The fields within these objects closely correspond to members of the **`LLM_MESSAGE`** and **`LLM_RESPONSE`** structures used internally by the API.

Applications should not depend on undocumented fields or the exact formatting of exported history files. Future versions of the library may add additional fields or metadata while maintaining compatibility with previous versions where possible.

Remarks

The message history format is intended primarily for exporting, importing and persisting conversation state between application sessions. Although the file format is human-readable JSON text, applications should avoid modifying exported history files unless they fully understand the relationship between the stored values.

Changing values such as the provider identifier, model name, message role or status values may produce undefined or unexpected results when the history is imported. Applications should not modify role identifiers or assume that numeric values used internally by the API will remain unchanged in future versions.

Modifying the message or response content may also invalidate related metadata such as token usage values. For example, changing the **`content`** field may result in incorrect **`inputTokens`** or **`outputTokens`** values being associated with the imported conversation history.

Mail Message Library

Compose and parse standard MIME formatted email messages.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSMSGV12.DLL
Version	12.0.3024.1286
LibID	123A728A-D6CD-435F-A76D-0BA3C07DDFC1
Import Library	CSMSGV12.LIB
Dependencies	None
Standards	RFC 822, RFC 2045, RFC 2046, RFC 2047, RFC 2048

Overview

The Mail Message library provides an interface for composing and processing email messages and newsgroup articles which are structured according to the Multipurpose Internet Mail Extensions (MIME) standard. Using this library, an application can easily create complex messages which include multiple alternative content types, such as plain text and styled HTML text, file attachments and customized headers.

It is not required that the developer understand the complex MIME standard; a single function call can be used to create multipart message, complete with a styled HTML text body and support for international character sets. The Mail Message library can be easily integrated with the other mail related protocol libraries, making it extremely easy to create and process MIME formatted messages.

The library also includes an interface for managing a local message storage file that can be used to store and retrieve multiple messages. Functions are provided to open and create storage files, add, remove and extract messages from storage, and search the stored messages for specific header field values.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Mail Message Functions

Function	Description
MimeAddMessageHeaders	Add one or more header values to the current message
MimeAppendMessageText	Append text to the body of the current message part
MimeAttachData	Attach the contents of a buffer to the current message
MimeAttachFile	Attach a file to the current message
MimeAttachImage	Attach an inline image to the current message
MimeCheckAuthenticationResults	Check the authentication status for the current message
MimeClearMessageText	Clear the body of the current message part
MimeCloseMessage	Close the message handle and release the resources allocated for the message
MimeCloseMessageStore	Close the current message storage file
MimeCompareMessageText	Compare text in the body of the current message part
MimeComposeMessage	Compose a new message using the specified parameters
MimeCopyMessageStore	Duplicate the contents of the current message store in a new file
MimeCreateMessage	Create a new empty message
MimeCreateMessageEx	Create a new message from the contents of a file or a message in memory
MimeCreateMessagePart	Create a new message part for the current message
MimeCreateMessagePartEx	Create a new message part for the current message
MimeDecodeText	Decode a base64 or quoted-printable encoded string
MimeDecodeTextEx	Decode a base64 or quoted-printable encoded string using a specified character set
MimeDeleteMessageHeader	Delete the specified header field from the message
MimeDeleteMessagePart	Delete the current message part
MimeDeleteStoredMessage	Remove the current message from the message store
MimeEncodeText	Encode a string using base64 or quoted-printable encoding
MimeEncodeTextEx	Encode a string using base64 or quoted-printable encoding using a specified character set
MimeEnumAttachments	Enumerate all file attachments in the current message
MimeEnumMessageHeaders	Enumerate all header fields in the current message part
MimeEnumMessageRecipients	Enumerate addresses of all message recipients
MimeExportMessage	Export the current message to a text file
MimeExportMessageEx	Export the current message to a file, clipboard or memory buffer
MimeExtractAllFiles	Extract all file attachments in the message and store them in the specified directory
MimeExtractFile	Extract the file attachment from the current message part
MimeExtractFileEx	Extract a file attachment from the message with additional options
MimeFilterMessageText	Filter the contents of a HTML or plain text message
MimeFindAttachment	Search for a file attachment in the current message
MimeFindMessageText	Search for a regular expression or string literal in the current message text
MimeFindMessageTextEx	Saerch for a regular expression or string literal and return the offset and length into the message contents
MimeFindStoredMessage	Search for a message in the current message store
MimeFormatDate	Return a standard date and time string using a 32-bit time value
MimeFormatDate64	Return a standard date and time string using a 64-bit time value
MimeGetAllHeaders	Return the complete RFC 822 header values in a string buffer
MimeGetAllRecipients	Return a comma-separated list of recipient addresses in a string buffer
MimeGetAttachedFileName	Return the name of the file attachment for the current part

MimeGetAuthenticationResults	Return information about the authentication status of the message
MimeGetContentDigest	Return encoded digest of message's content
MimeGetContentLength	Return the length of the current message part content
MimeGetContentType	Return the content type identifier for the current message part
MimeGetContentTypeEx	Return information about the content type for the current message part
MimeGetErrorString	Return a description for the specified error code
MimeGetExportOptions	Return a bitmask that describes current message export options
MimeGetFileContentType	Return the content type for a specified file
MimeGetFirstMessageHeader	Return the first header field and value in the current message part
MimeGetLastError	Return the last error code
MimeGetMessageBoundary	Return the multipart message boundary string
MimeGetMessageDate	Return the date and time from the message header
MimeGetMessageDateEx	Return a localized message date and time to a string buffer
MimeGetMessageHeader	Return the value of a specified header from the message
MimeGetMessageHeaderEx	Copy the value of specified header to a string buffer
MimeGetMessageLinks	Returns the hyperlinks in the current message part
MimeGetMessagePart	Return the current message part index
MimeGetMessagePartCount	Return the total number of message parts
MimeGetMessageSender	Return the email address of the message sender
MimeGetMessageSize	Return the size of the complete message in bytes
MimeGetMessageText	Return the text of the current message part
MimeGetMessageVersion	Return the MIME version from the message header
MimeGetNextMessageHeader	Return the next header field and value in the current message part
MimeGetStoredMessage	Retrieve a message from the current message store
MimeGetStoredMessageCount	Return the number of messages in a message store
MimeImportMessage	Import a message from the specified text file
MimeImportMessageEx	Import a message from a file, clipboard or memory buffer
MimeInitialize	Initialize the library for use by the client
MimeIsContentType	Determine if the message part matches the specified content type
MimeLocalizeText	Localize Unicode text to ANSI using a specific character set
MimeNormalizeText	Normalize Unicode text, eliminating confusable homoglyphs and symbols
MimeOpenMessage	Open and parse the specified text file as a MIME formatted message
MimeOpenMessageStore	Open the current message storage file
MimeParseAddress	Parse the specified email address
MimeParseDate	Parse the specified date and time, returning a 32-bit time value
MimeParseDate64	Parse the specified date and time, returning a 64-bit time value
MimeParseHeader	Parse the specified text and add to message header
MimeParseText	Parse the specified text and add to the current message
MimePurgeMessageStore	Purge all deleted messages from the current message store
MimeReplaceStoredMessage	Replace the current message in the message store
MimeResetMessage	Clear the current message, deleting all message parts
MimeSetExportOptions	Specify a bitmask that describes current message export options
MimeSetFileContentType	Set the content type for a specific file name extension
MimeSetLastError	Set the last error code

MimeSetMessageDate	Set the current date in the header for the current message
MimeSetMessageHeader	Create or update a header field in the current message
MimeSetMessageHeaderEx	Create or update a header field, with additional options
MimeSetMessagePart	Set the current message part index for the current message
MimeSetMessageText	Create or update the current message body
MimeSetMessageVersion	Set the MIME version for the current message
MimeStoreMessage	Store the current message in a message store
MimeUninitialize	Terminate use of the library by the application

MimeAddMessageHeaders Function

```
BOOL WINAPI MimeAddMessageHeaders(
   HMESSAGE hMessage,
   LPCTSTR lpszHeaderList
);
```

The **MimeAddMessageHeaders** function adds one or more headers to the specified message.

Parameters

hMessage

Handle to the message.

lpszHeaderList

A null-terminated string which specifies one or more header values which should be set for the specified message. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the client handle is invalid, the function returns a value of zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeAddMessageHeaders** function enables your application to set one or more header values by providing a list of name/value pairs separated by a colon. Multiple header values may be provided by separating them with a newline character. This function is similar to calling the **MimeSetMessageHeader** function for each value. When the list of header values is parsed, extraneous whitespace is ignored; however, if the header list contains invalid text (for example, a missing colon separating a header name from its value) the function will fail and an error will be returned.

This function will only add or update header values in the main header block for the message. It cannot be used to update header values in a specific section of a multipart message. If you need to add or change a header value in a specific part of the message, use the **MimeSetMessageHeaderEx** function.

When adding custom, application-specific header values you should always prefix them with "X-" to avoid conflicting with standard headers.

Example

```
// Define a list of header values which should be included with the
// main header block for the message
LPCTSTR lpszHeaderList = _T("X-App-Sender: someuser@domain.tld\n") \
                         _T("X-App-Version: 1.5\n") \
                         _T("X-App-Mailer: AppMail (Win64)\n")

if (!MimeAddMessageHeaders(hMessage, lpszHeaderList))
{
    // Unable to add headers for this message
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeEnumMessageHeaders, MimeGetMessageHeader, MimeSetMessageHeader, MimeSetMessageHeaderEx

MimeAppendMessageText Function

```
LONG WINAPI MimeAppendMessageText(
    HMESSAGE hMessage,
    LPCTSTR lpszText
);
```

The **MimeAppendMessageText** function appends the specified text to the body of the current message part.

Parameters

hMessage

Handle to the message.

lpszText

A null-terminated string which specifies the text to be appended to the current message part.

Return Value

If the function succeeds, the return value is the number of bytes copied into the message. A return value of zero indicates that no text could be appended to the current message part. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeClearMessageText, MimeCompareMessageText, MimeGetMessageText, MimeSetMessageText

MimeAttachData Function

```
BOOL WINAPI MimeAttachData(
   HMESSAGE hMessage,
   LPBYTE lpBuffer,
   LONG cbBuffer,
   LPCTSTR lpszContentName,
   LPCTSTR lpszContentType,
   DWORD dwOptions
);
```

The **MimeAttachData** function attaches the contents of the buffer to the message.

Parameters

hMessage

Handle to the message.

lpBuffer

Pointer to a byte buffer which contains the data to be attached to the message. This parameter may be NULL, in which case no data is attached, but an additional empty message part will be created.

cbBuffer

An unsigned integer which specifies the number of bytes of data in the buffer pointed to by the *lpBuffer* parameter. If the *lpBuffer* parameter is NULL, this value must be zero.

lpszContentName

Pointer to a string which specifies a name for the data being attached to the message. This typically is used as a file name by the mail client to store the data in. If this parameter is NULL or an empty string then no name is defined and the data is attached as inline content. Note that if a file name is specified with a path, only the base name will be used.

lpszContentType

Pointer to a string which specifies the type of data being attached. The value must be a valid MIME content type. If this parameter is NULL or an empty string, then the buffer will be examined to determine what kind of data it contains. If there is only text characters, then the content type will be specified as "text/plain". If the buffer contains binary data, then the content type will be specified as "application/octet-stream", which is appropriate for any type of data.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
MIME_ATTACH_DEFAULT	The data encoding is based on the content type. Text data is not encoded, and binary data is encoded using the standard base64 encoding algorithm.
MIME_ATTACH_BASE64	The data is always encoded using the standard base64 algorithm, even if the buffer only contains printable text characters.
MIME_ATTACH_UUCODE	The data is always encoded using the uuencode algorithm, even if the buffer only contains printable text characters.

MIME_ATTACH_QUOTED	The data is always encoded using the quoted-printable algorithm. This encoding should only be used if the data contains 8-bit text characters.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeAttachData** function allows an application to attach data to the message as either a file attachment or as inline content. The recipient of the message will see the attached data in the same way that they would see a file attached to the message using the **MimeAttachFile** function.

If the specified message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeAttachFile Function

```
BOOL WINAPI MimeAttachFile(
   HMESSAGE hMessage,
   LPCTSTR lpszFileName,
   DWORD dwOptions
);
```

The **MimeAttachFile** function attaches the specified file to the message.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string which specifies the name of the file to be attached to the message.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
MIME_ATTACH_DEFAULT	The file attachment encoding is based on the file content type. Text files are not encoded, and binary files are encoded using the standard base64 encoding algorithm. This is the default option for file attachments.
MIME_ATTACH_BASE64	The file attachment is always encoded using the standard base64 algorithm, even if the attached file is a plain text file.
MIME_ATTACH_UUCODE	The file attachment is always encoded using the uuencode algorithm, even if the attached file is a plain text file.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

If the specified message is not a multipart message, it is marked as multipart and the attached file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

To attach data that is stored in a memory buffer rather than a file, use the **MimeAttachData** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeAttachImage Function

```
BOOL WINAPI MimeAttachImage(
   HMESSAGE hMessage,
   LPCTSTR lpszImageFile,
   LPCTSTR lpszContentId
);
```

The **MimeAttachImage** function attaches the specified file to the message as an inline image.

Parameters

hMessage

Handle to the message.

lpszImageFile

Pointer to a string which specifies the name of the image file to be attached to the message. This parameter cannot be NULL and must specify the name of an existing file.

lpszContentId

A null-terminated string which specifies the content ID associated with the inline image. If this parameter is NULL, a random content ID string will be automatically generated.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeAttachImage** function enables an application to attach an inline image to the message. Unlike a normal file attachment, this function is designed to be used with HTML formatted email messages that display images attached to the message. The ***lpszContentId*** parameter specifies the content ID string that is used with the HTML image tag to reference that image.

If the specified message is not a multipart message, it is marked as multipart and the attached image file is appended to the message. If the message is already a multipart message, an additional part is created and the attachment is added to the message.

To attach regular files to the message, use the **MimeAttachFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeCheckAuthenticationResults Function

```
BOOL WINAPI MimeCheckAuthenticationResults(
    HMESSAGE hMessage,
    DWORD dwAuthFlags
);
```

The **MimeCheckAuthenticationResults** function checks if the authentication status in the message matches one or more values.

Parameters

hMessage

A handle to the message.

dwAuthFlags

A bitmask that specifies one or more authentication flags to check for. These can be any combination of the values listed below.

Value	Description
MIME_AUTH_SPF_PASSED	The message passed the Sender Policy Framework (SPF) check. The sender's IP address was authorized to send mail for the domain in the envelope sender address.
MIME_AUTH_SPF_FAILED	The message failed the SPF check. The sending mail server is not authorized by the domain's SPF record to send mail on its behalf.
MIME_AUTH_DKIM_PASSED	The message passed the DomainKeys Identified Mail (DKIM) check. The signature applied by the sender was successfully verified using the domain's public key.
MIME_AUTH_DKIM_FAILED	The message failed the DKIM check. The signature could not be verified or did not match the message content, suggesting it may have been altered.
MIME_AUTH_DMARC_PASSED	The message passed DMARC evaluation. The message aligned with a valid SPF or DKIM result based on the sender domain's policy.
MIME_AUTH_DMARC_FAILED	The message failed DMARC evaluation. It did not pass SPF or DKIM checks in a way that aligns with the domain's published policy.
MIME_AUTH_TEMP_ERROR	A temporary error occurred while evaluating one or more authentication mechanisms. This may indicate a DNS lookup timeout or other transient failure.
MIME_AUTH_PERM_ERROR	A permanent error occurred during authentication checks. This may indicate a malformed DNS record or invalid message structure that prevents proper evaluation.

Return Value

This function returns a non-zero value if one or more of the specified flags match the values found in the message's `Authentication-Results` header. If there is no match, the function returns zero. This

function explicitly clears the last error code to assist in differentiating between an actual error condition (such as an invalid message handle) and a case where no authentication data matched.

Remarks

This function provides a convenient way to check if the authentication status of the message matches one or more values. In addition to the flags specified above, the following predefined flag combinations are also available:

- MIME_AUTH_PASSED is a combination of all passing results (SPF, DKIM, DMARC).
- MIME_AUTH_FAILED is a combination of all failing results.
- MIME_AUTH_ERROR is a combination of temporary or permanent errors.

This function was included as a convenience for languages other than C/C++, where unpacking bitfields returned by **MimeGetAuthenticationResults** may be more cumbersome. It allows for quick checks against common authentication outcomes using predefined flags. For example, to check whether the message failed authentication or encountered a temporary error, you could specify `MIME_AUTH_FAILED | MIME_AUTH_TEMP_ERROR`.

For more information about SPF, DKIM and DMARC, please refer to the **MimeGetAuthenticationResults** function.

Example

```
HMESSAGE hMessage = MimeOpenMessage(lpszFileName, MIME_OPEN_DEFAULT);

if (hMessage != INVALID_MESSAGE)
{
    // Check if any of the SPF, DKIM, or DMARC checks failed
    if (MimeCheckAuthenticationResults(hMessage, MIME_AUTH_FAILED))
        _tprintf(_T("This message has failed one or more authentication
checks\n"));

    MimeCloseMessage(hMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeGetAuthenticationResults, MimeGetMessageHeader, MimeGetMessageHeaderEx

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeClearMessageText Function

```
BOOL WINAPI MimeClearMessageText(
    HMESSAGE hMessage
);
```

The **MimeClearMessageText** function deletes the text from the body of the current message part.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeAppendMessageText, MimeCompareMessageText, MimeGetMessageText, MimeSetMessageText

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeCloseMessage Function

```
BOOL WINAPI MimeCloseMessage(
   HMESSAGE hMessage
);
```

The **MimeCloseMessage** function closes the specified message and releases the memory allocated for the header and body.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeCloseMessage** function closes the handle returned by the **MimeComposeMessage**, **MimeCreateMessage** or **MimeOpenMessage** functions. Once the message has been closed, the handle is invalid and should not be referenced. When your application no longer needs to access the contents of the message, this function must be called to release the HMESSAGE handle otherwise there will be a memory leak.

It is important to note that a message handle is not a kernel object and should never be closed with the **CloseHandle** function in the Windows API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeComposeMessage, MimeCreateMessage, MimeDeleteMessagePart, MimeOpenMessage, MimeResetMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeCloseMessageStore Function

```
BOOL WINAPI MimeCloseMessageStore(
   HMESSAGESTORE hStorage,
   BOOL bPurgeMessages
);
```

The **MimeCloseMessageStore** function closes the specified message store.

Parameters

hStorage

Handle to the message store.

bPurgeMessages

An integer value which specifies if deleted messages are purged from the message store. A non-zero value specifies that all messages marked for deletion will be removed from the message store. A value of zero specifies that deleted messages will not be removed from the store.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeCloseMessageStore** function closes the storage file that was previously opened, releasing all of the memory allocated for the message store and optionally purging all deleted messages. This function must be called when the application has finished accessing the messages in the message store. Failure to call this function will leave the storage file open and potentially locked by the process.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeCopyMessageStore, MimeOpenMessageStore, MimePurgeMessageStore

MimeCompareMessageText Function

```
BOOL WINAPI MimeCompareMessageText(
    HMESSAGE hMessage,
    LONG *lpnOffset,
    LPCTSTR lpszText,
    LONG cchText,
    BOOL bCaseSensitive
);
```

The **MimeCompareMessageText** function compares a text string against the contents of the current message part.

Parameters

hMessage

Handle to the message.

lpnOffset

Pointer to a long integer which specifies the offset in the message at which to begin the comparison. This value will be updated when the function returns to indicate the offset position in the message where the comparison ended.

lpszText

Pointer to a string buffer which contains the text that is to be compared against the body of the message.

cchText

The number of characters in the buffer that should be compared against the body of the message.

bCaseSensitive

Boolean flag which specifies that the comparison should be case sensitive.

Return Value

If the text buffer matches the contents of the current message body, the function will return a non-zero value, and the *lpnOffset* argument will be set to position in the buffer where the match terminated. If the text buffer does not match, the function will return a value of zero, and the *lpnOffset* argument will be set to the position of the first non-matching character. The function will also return zero if one of the arguments is invalid. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeComposeMessage Function

```
HMESSAGE WINAPI MimeComposeMessage(
   LPCTSTR lpszFrom,
   LPCTSTR lpszTo,
   LPCTSTR lpszCc,
   LPCTSTR lpszSubject,
   LPCTSTR lpszMessageText,
   LPCTSTR lpszMessageHTML,
   UINT nCharacterSet,
   UINT nEncodingType
);
```

The **MimeComposeMessage** function creates a new message using the specified parameters.

Parameters

lpszFrom

A null-terminated string which specifies the sender's email address. This parameter may be NULL, in which case no sender address will be included in the message header.

lpszTo

A null-terminated string which specifies one or more recipient addresses. If multiple addresses are specified, each address must be separated by a comma. This parameter may be NULL, in which case no recipient addresses will be included in the message header.

lpszCc

A null-terminated string which specifies one or more addresses that will receive a copy of the message in addition to the listed recipients. If multiple addresses are specified, each address must be separated by a comma. This parameter may be NULL, in which case no carbon-copy addresses will be included in the message header.

lpszSubject

A null-terminated string which specifies the subject of the message. This parameter may be NULL, in which case no subject will be included in the message.

lpszMessageText

A null-terminated string which contains the body of the message as plain text. Each line of text contained in the string should be terminated with a carriage-return and linefeed (CRLF) pair, which is recognized as the end-of-line. If this parameter is NULL or points to an empty string, then the message will have an empty body unless the ***lpszMessageHTML*** parameter is not NULL.

lpszMessageHTML

A null-terminated string which contains the message using HTML formatting. If the ***lpszMessageText*** parameter is not NULL, then a multipart message will be created with both plain text and HTML text as the alternative. This allows mail clients to select which message body they wish to display. If the ***lpszMessageText*** argument is NULL or points to an empty string, then the message will only contain HTML. Although this is supported, it is not recommended because older mail clients may be unable to display the message correctly.

nCharacterSet

A numeric identifier which specifies the character set to use when composing the message. A value of zero specifies that the default UTF-8 character set should be used. It is recommended that you always use UTF-8 when composing a new message or creating a new message part.

nEncodingType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Value	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

Return Value

If the function succeeds, the return value is a handle to the message. If the function fails, the return value is INVALID_MESSAGE. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeComposeMessage** function composes a new message and returns a handle which can be used to further modify or export the message. To create an empty message without any predefined header values, call the **MimeCreateMessage** function.

email addresses may be specified as simple addresses, or as commented addresses that include the sender's name or other information. For example, any one of these address formats are acceptable:

```
user@domain.tld
User Name <user@domain.tld>
user@domain.tld (User Name)
```

To specify multiple addresses, you should separate each address by a comma or semi-colon. Note that the *lpszFrom* parameter cannot specify multiple addresses, however it is permitted with the *lpszTo* and *lpszCc* parameters.

To send a message that contains HTML, it is recommended that you provide both a plain text version of the message body and an HTML formatted version. While it is permitted to send a message that only contains HTML, some older mail clients may not be capable of displaying the message correctly. In some cases, anti-spam software will increase the spam score of messages that do not contain a plain text message body. This can result in your message being rejected or quarantined by the mail server.

Call the **MimeCloseMessage** function to free the memory allocated for this message when it is no longer needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeCloseMessage, MimeCreateMessage, MimeCreateMessagePart, MimeExportMessage, MimeImportMessage, MimeInitialize, MimeOpenMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeCopyMessageStore Function

```
BOOL WINAPI MimeCopyMessageStore(
   HMESSAGESTORE hStorage,
   LPCTSTR lpszFileName
);
```

The **MimeCopyMessageStore** function duplicates the contents of the specified message store in a new file.

Parameters

hStorage

Handle to the message store.

lpszFileName

A null-terminated string which specifies the name of the file that the messages will be copied to. This parameter cannot be NULL and must specify a valid file path and name.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeCopyMessageStore** function is used to create a copy of the specified message store in a new file. If the file does not exist, it will be created. If the file already exists, then the contents will be overwritten with the contents of the message store.

Messages that have been marked for deletion are not copied to the new message store file.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeCloseMessageStore, MimeOpenMessageStore, MimePurgeMessageStore

MimeCreateMessage Function

```
HMESSAGE MimeCreateMessage();
```

The **MimeCreateMessage** function creates a new empty message.

Parameters

There are no parameters.

Return Value

If the function succeeds, the return value is a handle to the message. If the function fails, the return value is INVALID_MESSAGE. To get extended error information, call **MimeGetLastError**.

Remarks

To create a message with defined values for the sender, recipient, subject and body it is recommended that you use the **MimeComposeMessage** function.

Call the **MimeCloseMessage** function to free the memory allocated for this message when it is no longer needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeCloseMessage, MimeComposeMessage, MimeCreateMessageEx, MimeCreateMessagePart, MimeExportMessage, MimeImportMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeCreateMessageEx Function

```
HMESSAGE WINAPI MimeCreateMessageEx(
    DWORD dwImportMode,
    DWORD dwImportOptions,
    LPVOID lpvMessage,
    DWORD dwMessageSize
);
```

The **MimeCreateMessageEx** function creates a new message and imports the contents from a file or memory.

Parameters

dwImportMode

An unsigned integer which specifies how the message contents will be imported. It may be one of the following values:

Value	Description
MIME_IMPORT_DEFAULT	The default import mode. If the ***lpvMessage*** parameter is NULL, the function will return a handle to an empty message. Otherwise, the ***lpvMessage*** parameter is a pointer to a string which specifies the name of a file that contains the message. The ***dwMessageSize*** parameter is ignored.
MIME_IMPORT_FILE	The ***lpvMessage*** parameter is a pointer to a string which specifies the name of a file that contains the message. If the file does not exist, or is not a regular text file, an error will occur. The ***dwMessageSize*** parameter is ignored.
MIME_IMPORT_CLIPBOARD	The contents of the message is imported from the system clipboard. The ***lpvMessage*** parameter is ignored. The ***dwMessageSize*** parameter is ignored.
MIME_IMPORT_MEMORY	The contents of the message is imported from a local buffer. The ***lpvMessage*** parameter must point to a byte array which contains the message to be imported. The ***dwMessageSize*** parameter specifies the number of bytes to copy from the buffer. If this value is zero, it is assumed that the end of the message data in the buffer is terminated with a null character and the length is calculated automatically.
MIME_IMPORT_HGLOBAL	The contents of the message is imported from a global memory buffer. The ***lpvMessage*** parameter must be a global memory handle which contains the message. The ***dwMessageSize*** parameter specifies the number of bytes to copy from the buffer. If this value is zero, it is assumed that the end of the message data in the buffer is terminated with a null character and the length is calculated automatically.

dwImportOptions

An unsigned integer which specifies how the message will be imported:

Value	Description

MIME_OPTION_DEFAULT	The default import options. Currently this is the only valid value for this parameter and applications should always specify this constant.

lpvMessage

A null-terminated string, a byte buffer or a global memory handle. The ***dwImportMode*** parameter determines how this pointer is used by the function.

dwMessageSize

An unsigned integer value which specifies the size of the message to import. This parameter is only used when importing a message from a memory buffer. The message size is determined automatically when the message is imported from a file or the system clipboard.

Return Value

If the function succeeds, the return value is a handle to the message. If the function fails, the return value is INVALID_MESSAGE. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeCreateMessageEx** function creates a new message from the contents of a file or memory, and returns a handle to the parsed message. When the message is no longer needed by the application, it should call **MimeCloseMessage** to free the memory allocated for the message and release the handle.

To create a new message with predefined header values and content, use the **MimeComposeMessage** function.

Example

```
// Creates a message using an HGLOBAL handle which references
// a block of memory containing an email message
hMessage = MimeCreateMessageEx(MIME_IMPORT_HGLOBAL,
                               MIME_OPTION_DEFAULT,
                               (LPVOID)hgblMessage,
                               0);

if (hMessage != INVALID_MESSAGE)
{
    // The message has been successfully created
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeCloseMessage, MimeComposeMessage, MimeCreateMessage, MimeExportMessage, MimeImportMessage

MimeCreateMessagePart Function

```
INT WINAPI MimeCreateMessagePart(
    HMESSAGE hMessage
);
```

The **MimeCreateMessagePart** function creates a new part for the specified message. If this the first part created for a message that does not have the multipart content type specified, the message is marked as multipart and the header fields are updated.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is the new message part number. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeCreateMessagePartEx Function

```
INT WINAPI MimeCreateMessagePartEx(
    HMESSAGE hMessage,
    UINT nCharacterSet,
    UINT nEncodingType,
    LPCTSTR lpszText
);
```

The **MimeCreateMessagePartEx** function creates a new part for the specified message. If this the first part created for a message that does not have the multipart content type specified, the message is marked as multipart and the header fields are updated.

Parameters

hMessage

Handle to the message.

nCharacterSet

A numeric identifier which specifies the character set to use when composing the message. A value of zero specifies the character set should be the same character set used to initially compose the message. It is recommended that you always use UTF-8 when composing a new message or creating a new message part.

nEncodingType

A numeric identifier which specifies the encoding type to use when composing the message. A value of zero specifies that default 7bit encoding should be used. The following values may also be used:

Value	Description
MIME_ENCODING_7BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long, with the most significant bit cleared. This encoding is most commonly used with plain text using the US-ASCII character set, where each character is represented by a single byte in the range of 20h to 7Eh.
MIME_ENCODING_8BIT	Each character is encoded in one or more bytes, with each byte being 8 bits long and all bits are used. 8-bit encoding is typically used with multibyte character sets and is the default encoding used with Unicode text.
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use Latin character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or

	when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

lpszText

A null-terminated string which specifies the text to be included in the body of the new message part. If this parameter is NULL or points to an empty string, no text is added to the message part.

Return Value

If the function succeeds, the return value is the new message part number. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeDecodeText Function

```
LONG WINAPI MimeDecodeText(
   UINT nEncodingType,
   LPCTSTR lpszInput,
   LONG cchInput,
   LPTSTR lpszOutput,
   LONG cchOutput
);
```

The **MimeDecodeText** function decodes a string which was previously encoded using base64 or quoted-printable encoding.

Parameters

nEncodingType

An integer value that specifies the encoding method used. It may be zero or one of the following values:

Value	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this function.

lpszInput

A null-terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be decoded. If this value is -1, the entire length of the string up to the terminating null will be decoded.

lpszOutput

A null-terminated string buffer that will contain the decoded text. This buffer must be large enough to store all of the characters in the decoded text, including the terminating null character. This parameter cannot be NULL.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the decoded text and

terminating null character. This value must be greater than zero.

Return Value

If the input buffer can be successfully decoded, the return value is the length of the decoded output string. If the function returns zero, then no text was decoded and the output string buffer will be empty. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function provides a means to decode text that was previously encoded using either base64 or quoted-printable encoding. In most cases, it is not necessary to use this function because the message parser will automatically decode the message text if necessary.

This function and the **MimeEncodeText** function use the UTF-8 character set. If the Unicode version of this function is called, the output text will be decoded as UTF-8, then converted to UTF-16 and returned to the caller. If the ANSI version of this function is used, the decoded output will always be returned to the caller using the UTF-8 character set.

If an unsupported encoding type is specified, this function will return MIME_ERROR and the output text string will be empty. In most cases, it is preferable to use MIME_ENCODING_BASE64 as the encoding method, with quoted-printable encoding only used for legacy support.

If the original text was encoded using a different character set, use the **MimeDecodeTextEx** function, which enables you to specify an alternate character set.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeDecodeTextEx, MimeEncodeText, MimeEncodeTextEx, MimeGetMessageText, MimeLocalizeText, MimeSetMessageText

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeDecodeTextEx Function

```
LONG WINAPI MimeDecodeTextEx(
   UINT nCharacterSet,
   UINT nEncodingType,
   DWORD dwReserved,
   LPCTSTR lpszInput,
   LONG cchInput,
   LPTSTR lpszOutput,
   LONG cchOutput
);
```

The **MimeDecodeTextEx** function decodes a string which was previously encoded using base64 or quoted-printable encoding. This extended version of the function enables the caller to specify the character set for the original text.

Parameters

nCharacterSet

A numeric identifier which specifies the character set to use when decoding the input text. A value of zero specifies the character set is undefined and no Unicode text conversion is performed when the input string is decoded. If this value does not match the character set used when the text was originally encoded, the resulting output text may be invalid.

nEncodingType

An integer value that specifies the encoding method used. It may be zero or one of the following values:

Value	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this function.

dwReserved

An integer value reserved for internal use. This value must always be zero.

lpszInput

A null-terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be decoded. If this value is -1, the entire length of the string up to the terminating null will be decoded.

lpszOutput

A null-terminated string buffer that will contain the decoded text. This buffer must be large enough to store all of the characters in the decoded text, including the terminating null character. This parameter cannot be NULL.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the decoded text and terminating null character. This value must be greater than zero.

Return Value

If the input buffer can be successfully decoded, the return value is the length of the decoded output string. If the function returns zero, then no text was decoded and the output string buffer will be empty. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function provides a means to decode text that was previously encoded using either base64 or quoted-printable encoding. In most cases, it is not necessary to use this function because the message parser will detect which character set and encoding was used, then automatically decode the message text if necessary.

The value of the ***nCharacterSet*** parameter does not affect the resulting output text, it is only used when decoding the input text. If the Unicode version of this function is called, the output text will be converted to UTF-16 and returned to the caller. If the ANSI version of this function is used, the decoded output will always be returned to the caller using the UTF-8 character set.

If the ***nCharacterSet*** parameter is specified as MIME_CHARSET_UTF16, the encoding type must be MIME_ENCODING_BASE64. Other encoding methods are not supported for Unicode strings and will cause the function to fail. In most cases, it is preferable to use MIME_ENCODING_BASE64 as the encoding method, with quoted-printable encoding only used for legacy support.

If an unsupported encoding type is specified, this function will return MIME_ERROR and the output text string will be empty. This function cannot be used to decode uuencoded text.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeDeleteMessageHeader Function

```
BOOL WINAPI MimeDeleteMessageHeader(
    HMESSAGE hMessage,
    LPCTSTR lpszHeader
);
```

The **MimeDeleteMessageHeader** function deletes the specified header field from the message.

Parameters

hMessage

Handle to the message.

lpszHeader

Pointer to a string which specifies the header field that will be deleted.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeGetMessageHeader, MimeSetMessageHeader

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeDeleteMessagePart Function

```
BOOL WINAPI MimeDeleteMessagePart(
    HMESSAGE hMessage,
    INT nMessagePart
);
```

The **MimeDeleteMessagePart** function deletes the specified message part from the multipart message. The memory allocated for the message part is released.

Parameters

hMessage

Handle to the message.

nMessagePart

The message part index to delete.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function cannot be used to delete part zero, which is the main body of the message. Instead use the **MimeResetMessage** function to clear the entire message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeCreateMessagePart, MimeCreateMessagePartEx, MimeGetMessagePart, MimeGetMessagePartCount, MimeResetMessage, MimeSetMessagePart

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeDeleteStoredMessage Function

```
BOOL WINAPI MimeDeleteStoredMessage(
   HMESSAGESTORE hStorage,
   LONG nMessageId
);
```

The **MimeDeleteStoredMessage** function removes the specified message from the message store.

Parameters

hStorage

Handle to the message store.

nMessageId

An integer value which identifies the message that is to be removed from the message store. Message numbers begin at one and increment for each message in the store.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeDeleteStoredMessage** function marks the specified message for deletion from the storage file. When the message store is closed or purged, the message is removed from the file. Once a message has been marked for deletion, it may no longer be referenced by the application. For example, you cannot access the contents of a message that has been deleted.

The message store must be opened with write access. This function will fail if you attempt to delete a message from a storage file that has been opened for read-only access. If the application needs to delete messages in the message store, it is recommended that the file be opened for exclusive access using the MIME_STORAGE_LOCK option.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeCloseMessageStore, MimeFindStoredMessage, MimeGetStoredMessage, MimeGetStoredMessageCount, MimePurgeMessageStore

MimeEncodeText Function

```
LONG WINAPI MimeEncodeText(
   UINT nEncodingType,
   LPCTSTR lpszInput,
   LONG cchInput,
   LPTSTR lpszOutput,
   LONG cchOutput
);
```

The **MimeEncodeText** function encodes a string using base64 or quoted-printable encoding.

Parameters

nEncodingType

An integer value that specifies the encoding method used. It may be zero or one of the following values:

Value	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text. This is the default encoding type used by this function.

lpszInput

A null-terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be encoded. If this value is -1, the entire length of the string up to the terminating null will be encoded.

lpszOutput

A null-terminated string buffer that will contain the encoded text. This buffer must be large enough to store all of the characters in the encoded text, including the terminating null character. This parameter cannot be NULL.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the encoded text and terminating null character. This value must be greater than zero.

Return Value

If the input buffer can be successfully encoded, the return value is the length of the encoded output string. If the function returns zero, then no text was encoded and the output string buffer will be empty. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function provides a means to encode text using either base64 or quoted-printable encoding. It is not necessary to use this function to encode text when using the **MimeSetMessageText** function. The library will automatically encode message text which contains non-ASCII characters using the character set specified when the message is created.

This function and the **MimeDecodeText** function use the UTF-8 character set. If the Unicode version of this function is called, the input text will be converted to UTF-8 and then encoded. If the ANSI version of this function is used, the input text is expected to be UTF-8 or ASCII text. If you are encoding text which uses non-ASCII characters, it is recommended that you use the Unicode version of this function.

If an unsupported encoding type is specified, this function will return MIME_ERROR and the output text string will be empty. This function cannot be used to create uuencoded text. In most cases, it is preferable to use MIME_ENCODING_BASE64 as the encoding method, with quoted-printable encoding only used for legacy support.

If you want the text to be encoded using a different character set, you can use the **MimeEncodeTextEx** function. In most cases, your application should use the default UTF-8 character set when encoding and decoding text which contains non-ASCII characters, rather than using specific character sets.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeDecodeText, MimeDecodeTextEx, MimeEncodeTextEx, MimeGetMessageText, MimeSetMessageText

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeEncodeTextEx Function

```
LONG WINAPI MimeEncodeTextEx(
   UINT nCharacterSet,
   UINT nEncodingType,
   DWORD dwReserved,
   LPCTSTR lpszInput,
   LONG cchInput,
   LPTSTR lpszOutput,
   LONG cchOutput
);
```

The **MimeEncodeTextEx** function encodes a string using base64 or quoted-printable encoding. This extended version of the function enables the caller to specify the character set for the input text.

Parameters

nCharacterSet

A numeric identifier which specifies the character set to use when encoding the input text. A value of zero specifies the character set is undefined and no Unicode text conversion is performed when the input string is encoded.

nEncodingType

An integer value that specifies the encoding method used. It may be one of the following values:

Value	Description
MIME_ENCODING_QUOTED	Quoted-printable encoding is designed for textual messages where most of the characters are represented by the ASCII character set and is generally human-readable. Non-printable characters or 8-bit characters with the high bit set are encoded as hexadecimal values and represented as 7-bit text. Quoted-printable encoding is typically used for messages which use character sets such as ISO-8859-1, as well as those which use HTML.
MIME_ENCODING_BASE64	Base64 encoding converts binary or text data to ASCII by translating it so each base64 digit represents 6 bits of data. This encoding method is commonly used with messages that contain binary data (such as binary file attachments), or when text uses extended characters that cannot be represented by 7-bit ASCII. It is recommended that you use base64 encoding with Unicode text.

dwReserved

An integer value reserved for internal use. This value must always be zero.

lpszInput

A null-terminated string which contains the encoded text. This parameter cannot be a NULL pointer.

cchInput

An integer value which specifies the number of characters of text in the input string which should be encoded. If this value is -1, the entire length of the string up to the terminating null will be encoded.

lpszOutput

A null-terminated string buffer that will contain the encoded text. This buffer must be large enough to store all of the characters in the encoded text, including the terminating null character. This parameter cannot be NULL.

cchOutput

An integer value which specifies the maximum number of characters which can be copied into the output string buffer. The buffer must be large enough to store all of the encoded text and terminating null character. This value must be greater than zero.

Return Value

If the input buffer can be successfully encoded, the return value is the length of the encoded output string. If the function returns zero, then no text was encoded and the output string buffer will be empty. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function provides a means to encode text using either base64 or quoted-printable encoding. It is not necessary to use this function to encode text when using the **MimeSetMessageText** function. The library will automatically encode message text which contains non-ASCII characters using the character set specified when the message is created.

If the ***nCharacterSet*** parameter parameter is non-zero, the function will encode the text using the specified character set. If the Unicode version of this function is called, the input text is converted to ANSI using the code page associated with the character set. If the ANSI version of this function is called, the input text is converted to Unicode using the system default code page, and then back to ANSI using the specified character set.

If the ***nCharacterSet*** parameter specifies the MIME_CHARSET_UTF16 character set, you must specify MIME_ENCODING_BASE64 as the encoding method. Other encoding methods are not supported for Unicode strings and will cause the function to fail. It is not recommended you encode text as UTF-16 unless there is a specific requirement to use that character set.

It is recommended that you use the MIME_CHARSET_UTF8 character set whenever possible. It is capable of encoding all Unicode code points, and is a standard for virtually all modern Internet applications. In most cases, it is preferable to use MIME_ENCODING_BASE64 as the encoding method, with quoted-printable encoding only used for legacy support.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

MimeEnumAttachments Function

```
INT WINAPI MimeEnumAttachments(
   HMESSAGE hMessage,
   LPCTSTR* lpFileNames,
   INT nMaxFiles
);
```

The **MimeEnumAttachments** function enumerates all of the file attachments in the specified message.

Parameters

hMessage

Handle to the message.

lpFileNames

A pointer to a an array of null-terminated strings that contain the names of the files attached to the message. If this parameter is NULL, the function will only return the number of files attached to the message.

nMaxFiles

An integer value that specifies the maximum size of the array of string pointers specified by the *lpFileNames* parameter. If this value is zero, the *lpFileNames* parameter is ignored and the function will only return the number of files attached to the message.

Return Value

If the function succeeds, the return value is the number of files attached to the message. If the message does not contain any file attachments, this function will return a value of zero. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function can be used to obtain the names of the files attached to the message. If this function is used with languages other than C/C++, it is important to note that the *lpFileNames* parameter is not a pointer to a string, but rather a pointer to an array of pointers to null-terminated strings. It is not recommended that you use this function with languages that do not support C-style arrays. For example, Visual Basic represents arrays as SAFEARRAY structures and is not compatible with this function.

Example

```
LPCTSTR lpszFiles[MAXFILES];

INT nFiles = MimeEnumAttachments(hMessage, lpszFiles, MAXFILES);
if (nFiles == MIME_ERROR)
{
    DWORD dwError = MimeGetLastError();
    _tprintf(_T("Unable to enumerate attachments, error 0x%08lx\n"), dwError);
    return;
}

_tprintf(_T("There are %d files attached to the message\n"), nFiles);
for (INT nIndex = 0; nIndex < nFiles; nIndex++)
{
    BOOL bResult = MimeExtractFileEx(hMessage, -1, lpszFiles[nIndex], NULL, 0);
```

```
    if (bResult)
        _tprintf(_T("%d: extracted attachment \"%s\"\n"), nIndex,
lpszFiles[nIndex]);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeEnumMessageHeaders Function

```
INT WINAPI MimeEnumMessageHeaders(
   HMESSAGE hMessage,
   LPCTSTR *lpHeaderList,
   INT nMaxHeaders
);
```

The **MimeEnumMessageHeaders** function returns a list of pointers to all header field names in the current message part. This can be used in conjunction with the **MimeGetMessageHeader** function to retrieve the values for every header in the message.

Parameters

hMessage

Handle to the message.

lpHeaderList

Pointer to an array of pointers to null-terminated header field names. If this parameter is NULL, the function only returns the number of headers in the current message part.

nMaxHeaders

The maximum number of header fields which may be returned in the ***lpHeaderList*** parameter.

Return Value

If the function succeeds, the return value is the total number of headers that are defined in the current message part. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The values returned in the header list array must not be directly modified by the application. There is no specific order in which the header fields are enumerated by this function. The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined.

Example

```
// Determine the total number of headers in the current
// message part

nHeaders = MimeEnumMessageHeaders(hMessage, NULL, 0);
if (nHeaders > 0)
{

    // Allocate memory for the list of headers

    lpHeaderList = (LPCTSTR *)LocalAlloc(LPTR, nHeaders * sizeof(LPCTSTR));
    assert(lpHeaderList != NULL);

    // Retrieve the list of headers in the current
    // message part, and get their values

    MimeEnumMessageHeaders(hMessage, lpHeaderList, nHeaders);
    for (nIndex = 0; nIndex < nHeaders; nIndex++)
```

```
    {

        LPCTSTR lpszValue;
        lpszValue = MimeGetMessageHeader(hMessage, lpHeaderList[nIndex]);
        assert(lpszValue != NULL);

        printf("%s: %s\n", lpHeaderList[nIndex], lpszValue);

    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeEnumMessageRecipients Function

```
INT WINAPI MimeEnumMessageRecipients(
   HMESSAGE hMessage,
   LPCTSTR lpszExtraAddress,
   LPTSTR lpBuffer,
   LPDWORD lpcchBuffer
);
```

The **MimeEnumMessageRecipients** function returns a null-terminated list of strings which contain the email address of each recipient for the specified message.

Parameters

hMessage

Handle to the message.

lpszExtraAddress

A null-terminated string which contains one or more additional email addresses that should be included in the list, in addition to those found in the message. If more than one address is specified, each address should be separated by a comma. This parameter may be NULL if there are no extra addresses to include in the recipient list.

lpBuffer

Pointer to buffer which will contain zero or more null-terminated strings. The end of the string list is indicated by an additional terminating null. If this parameter is NULL, the function will calculate the minimum number of bytes required to store the addresses and return the value in the ***lpcbBuffer*** parameter.

lpcchBuffer

A pointer to an unsigned integer which should be initialized to the maximum number of characters that can be copied into the buffer specified by the ***lpBuffer*** parameter. When the function returns, it will be updated to contain the actual number of characters copied into the buffer. If the ***lpBuffer*** parameter is NULL, then this value will contain the minimum number of characters required to store all of the recipient addresses in the current message.

Return Value

If the function succeeds, the return value is the total number of recipients for the current message. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeEnumMessageRecipients** function returns a list of recipient email addresses for the specified message, with each address being terminated by a null character. The end of the list is indicated by an additional null character. To determine the size of the buffer you should pass to this function, you can specify the ***lpBuffer*** parameter as NULL and initialize the value of the ***lpcchBuffer*** parameter to zero.

This function is primarily designed for use with C/C++ and languages that can easily use C-style strings and pointers to string values. In many cases, it may be preferable to use the **MimeGetAllRecipients** function which returns a comma-separated list of recipient addresses in a string buffer.

If you are using the Unicode version of this function, keep in mind that the ***lpcchBuffer*** parameter

returns the number of characters in the output buffer, not the number of bytes. If you are dynamically allocating the buffer, make sure you allocate enough memory to store Unicode strings, which are two bytes per character.

Example

```
LPTSTR lpRecipients = NULL;
DWORD cchRecipients = 0;
INT nRecipients = 0;

// Determine the number of characters that should be allocated to store
// all of the recipient addresses in the current message

nRecipients = MimeEnumMessageRecipients(hMessage,
                                        NULL,
                                        NULL,
                                        &cchRecipients);

// Allocate the memory for the string buffer that will contain all
// of the recipient addresses and call MimeEnumMessageRecipients
// again to store those addresses in the buffer

if (nRecipients > 0 && cchRecipients > 0)
{
    lpRecipients = (LPTSTR)LocalAlloc(LPTR, cchRecipients * sizeof(TCHAR));
    if (lpRecipients == NULL)
        return; // Virtual memory exhausted

    nRecipients = MimeEnumMessageRecipients(hMessage,
                                            NULL,
                                            lpRecipients,
                                            &cchRecipients);
}

// Move through the buffer, processing each recipient address
// that was returned

if (nRecipients > 0)
{
    LPTSTR lpszAddress = lpRecipients;
    INT cchAddress;

    while (lpszAddress != NULL)
    {
        if ((cchAddress = lstrlen(lpszAddress)) == 0)
            break;

        // lpszAddress specifies a recipient address
        // Advance to the next address string in the buffer
        lpszAddress += cchAddress + 1;
    }
}

if (lpRecipients)
{
    LocalFree((HLOCAL)lpRecipients);
    lpRecipients = NULL;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

MimeExportMessage Function

```
BOOL WINAPI MimeExportMessage(
   HMESSAGE hMessage,
   LPCTSTR lpszFileName
);
```

The **MimeExportMessage** function writes the specified message to a file. If the file does not exist, it will be created. If it does exist, it will be overwritten with the contents of the message.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string which specifies the name of the file to be created from the message. If this parameter is NULL, the contents of the message will be copied to the system clipboard.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function is provided for backwards compatibility with previous versions of the API. To export the contents of the message to a buffer in memory, use the **MimeExportMessageEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeCreateMessage, MimeExportMessageEx, MimeImportMessage, MimeImportMessageEx, MimeSetExportOptions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeExportMessageEx Function

```
BOOL WINAPI MimeExportMessageEx(
   HMESSAGE hMessage,
   DWORD dwExportMode,
   DWORD dwExportOptions,
   LPVOID lpvMessage,
   LPDWORD lpdwMessageSize
);
```

The **MimeExportMessageEx** function exports the message to a file, the system clipboard or global memory buffer.

Parameters

hMessage

Handle to the message.

dwExportMode

An unsigned integer which specifies how the message contents will be exported. It may be one of the following values:

Value	Description
MIME_EXPORT_DEFAULT	The default export mode. If the ***lpvMessage*** parameter is NULL, then the contents of the message will be copied to the system clipboard. Otherwise, the ***lpvMessage*** parameter is a pointer to a string which specifies the name of a file to store the message in.
MIME_EXPORT_FILE	The ***lpvMessage*** parameter is a pointer to a null-terminated string which specifies the name of a file to store the message in. If the file does not exist, it will be created. Otherwise the file will be overwritten with the contents of the message.
MIME_EXPORT_CLIPBOARD	The contents of the message is copied to the system clipboard. The ***lpvMessage*** parameter is ignored.
MIME_EXPORT_MEMORY	The contents of the message is copied to a local buffer. The ***lpvMessage*** parameter must point to a byte array which will contain the message contents when the function returns. The ***lpdwMessageSize*** parameter must be initialized to the maximum size of the buffer and will contain the number of bytes copied to the buffer when the function returns.
MIME_EXPORT_HGLOBAL	The contents of the message is stored in a global memory buffer. The ***lpvMessage*** parameter must point to a global memory handle which will reference the message buffer when the function returns. The ***lpdwMessageSize*** parameter will contain the number of bytes allocated for the message. The client application is responsible for releasing the memory handle when the message contents are no longer needed.

dwExportOptions

An unsigned integer which specifies how the message will be exported. The following values may be combined using a bitwise Or operator:

Value	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

lpvMessage

A null-terminated string, a byte buffer or a global memory handle. The ***dwExportMode*** parameter determines how this pointer is used by the function.

lpdwMessageSize

A pointer to an unsigned integer value which will contain the size of the message when the function exits. This parameter may be NULL if you do not require this information, except if the ***dwExportMode*** parameter is MIME_EXPORT_MEMORY. In this case, the parameter must point to a value initialized with the maximum size of the byte buffer that has been passed to the function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

If the MIME_EXPORT_MEMORY mode is used to export the message to a pre-allocated buffer, the ***lpdwMessageSize*** parameter must be initialized to the size of the buffer before being passed to the function by reference. If this value is not properly initialized by the application, it can result in an error or a general protection exception. If the function succeeds, the message will be copied to the buffer. If the function fails, the previous contents of the buffer will not be preserved. It is not guaranteed that the buffer will be terminated with a null byte. If the buffer is not large enough to store the entire message, the function will fail. The **MimeGetMessageSize** function can be used to determine the

minimum size of the buffer required to store the message.

If the MIME_EXPORT_HGLOBAL mode is used, a global memory handle will be returned to the caller which contains the message contents. This handle must be dereferenced using the **GlobalLock** function. No changes should be made to this copy of the message. If you wish to modify the contents of the message, allocate a local buffer and copy the message contents, or use the MIME_EXPORT_MEMORY option instead. Your application is responsible for calling **GlobalUnlock** and **GlobalFree** to unlock and free the handle when it is no longer needed.

Example

```
// Exports the message contents to a global buffer
HGLOBAL hgblMessage = NULL;
DWORD dwMessageSize = 0;

bResult = MimeExportMessageEx(hMessage,
                              MIME_EXPORT_HGLOBAL,
                              MIME_OPTION_DEFAULT,
                              &hgblMessage,
                              &dwMessageSize);

if (bResult)
{
    LPBYTE lpMessage = (LPBYTE)GlobalLock(hgblMessage);

    if (lpMessage != NULL)
    {
        // Process the contents of the message
    }

    GlobalUnlock(hgblMessage);
    GlobalFree(hgblMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeExtractAllFiles Function

```
INT WINAPI MimeExtractAllFiles(
   HMESSAGE hMessage,
   LPCTSTR lpszDirectory,
   DWORD dwReserved
);
```

The **MimeExtractAllFiles** function extracts all of the file attachments in a message and stores them in the specified directory.

Parameters

hMessage

Handle to the message.

lpszDirectory

A null-terminated string which specifies the name of the directory where the file attachments should be stored. If this parameter is NULL or points to an empty string, the attached files will be stored in the current working directory on the local system.

dwReserved

An unsigned integer value that is reserved for future use. This parameter must always have a value of zero.

Return Value

If the function succeeds, the return value is the number of file attachments which were extracted from the message. If the message does not contain any file attachments, this function will return a value of zero. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function will extract all of the files that are attached to the message and store them in the specified directory. The directory must exist and the current user must have the appropriate permissions to create files there. If a file with the same name as the attachment already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this function will automatically decode the contents of the attachment.

To determine the file names for each of the attachments in a message, use the **MimeEnumAttachments** function. To store a file attachment on the local system using a name that is different than the file name of the attachment, use the **MimeExtractFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeExtractFile Function

```
BOOL WINAPI MimeExtractFile(
   HMESSAGE hMessage,
   LPCTSTR lpszFileName
);
```

The **MimeExtractFile** function extracts a file attachment from the current message part and stores it on the local system.

Parameters

hMessage

Handle to the message.

lpszFileName

A null-terminated string which specifies the name of a file on the local system.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function will store the contents of a file attachment in the current message part to the specified file on the local system. If a path is specified as part of the file name, it must exist and the current user must have the appropriate permissions to create the file. If a file with the same name already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this function will automatically decode the contents of the attachment.

To determine if the current message part contains a file attachment, use the **MimeGetAttachedFileName** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeAttachFile, MimeExportMessage, MimeExtractFileEx, MimeGetAttachedFileName, MimeImportMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeExtractFileEx Function

```
BOOL WINAPI MimeExtractFileEx(
   HMESSAGE hMessage,
   INT nMessagePart,
   LPCTSTR lpszAttachment,
   LPCTSTR lpszFileName,
   DWORD dwReserved
);
```

The **MimeExtractFileEx** function extracts a file attachment from the message and stores it on the local system.

Parameters

hMessage

Handle to the message.

nMessagePart

An integer value that specifies the message part that contains the file attachment. This value may be -1, in which case the current message part will be used, or the function will search for an attachment with a file name that matches the value of the ***lpszAttachment*** parameter.

lpszAttachment

A null-terminated string that specifies the file name for the attachment in the message. If the file name of the attachment is not known, this parameter can be NULL or point to an empty string. This parameter is ignored if the ***nMessagePart*** parameter has a value greater than -1.

lpszFileName

A null-terminated string that specifies the name of a file on the local system. If this parameter is NULL or points to an empty string, the value of the ***lpszAttachment*** parameter will specify the name of the file in the current working directory. If both the ***lpszAttachment*** and ***lpszFileName*** parameters are NULL, the function will fail.

dwReserved

An unsigned integer value that is reserved for future use. This parameter must always have a value of zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

This function will store the contents of a file attachment in the current message part to the specified file on the local system. If a path is specified as part of the file name, it must exist and the current user must have the appropriate permissions to create the file. If a file with the same name already exists, it will be overwritten with the contents of the attachment. If the file attachment was encoded using base64 or uuencode, this function will automatically decode the contents of the attachment.

If the ***nMessagePart*** parameter has a value of -1 and the ***lpszAttachment*** parameter specifies a file name, this function will search the entire message for an attachment with the same file name. The search is not case-sensitive, however it must match the attachment file name completely. This function will not match partial file names or names that include wildcard characters. If a match is found, the contents of that attachment will be stored in the file specified by the ***lpszFileName*** parameter.

If the *nMessagePart* parameter has a value of -1 and the *lpszAttachment* parameter is NULL or points to an empty string, then the attachment in the current message part will be stored in the specified file. If the current message part does not contain a file attachment, this function will fail. Calling this function in this manner is effectively the same as calling the **MimeExtractFile** function.

To extract all of the files attached to a message in a single function call, use the **MimeExtractAllFiles** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeFilterMessageText Function

```
LONG WINAPI MimeFilterMessageText(
   HMESSAGE hMessage,
   LPTSTR lpszFilteredText,
   LONG nMaxLength,
   DWORD dwOptions
);
```

The **MimeFilterMessageText** function filters the contents of a HTML or plain text message.

Parameters

hMessage

Handle to the message.

lpszFilteredText

A null-terminated string buffer which will contain the filtered text when the function returns. This buffer must be large enough to contain all of the filtered content and a terminating null character. If this parameter is NULL, the filtered text will not be copied. This can be used to determine the amount of filtered text that would be returned. This can be used to determine how much memory should be allocated for the filtered text; however, remember to allocate additional space for the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the maximum length is not large enough to store all of the filtered text and a terminating null character, the function will return an error. This value may be zero which indicates you want determine the length of the filtered text without copying any characters.

dwOptions

An unsigned integer which specifies one or more bit flags. which controls what content is filtered from the message. It may be one or more of the following values.

Value	Description
MIME_FILTER_DEFAULT	Perform default filtering which removes HTML markup and decodes HTML entities. No additional filtering of URLs or text is performed.
MIME_FILTER_REMOVE_QUERY	Remove query parameters from hyperlinks such as `?id=123`. Useful for stripping tracking information or session data.
MIME_FILTER_REMOVE_CREDENTIALS	Remove embedded user credentials in URLs such as `user:pass@example.com`, preventing obfuscation or accidental disclosure.
MIME_FILTER_REMOVE_LINKS	Remove all hyperlinks from the message content. This includes both anchor tags in HTML and plain text URLs.
MIME_FILTER_REMOVE_UNICODE	Strip all non-ASCII (Unicode) characters from the message. Use this when only 7-bit clean output is required.

MIME_FILTER_REJECT_LOCAL	Reject any link that refers to internal or local domains, including **.local**, **.lan**, and **localhost**.
MIME_FILTER_REJECT_IP	Reject links that use raw IP addresses instead of hostnames, such as **http://192.168.1.1**.
MIME_FILTER_REJECT_PUNYCODE	Reject hyperlinks using Punycode-encoded domain names, such as those with the **xn--** prefix. This helps prevent spoofing using visually similar characters.
MIME_FILTER_REJECT_HTTP	Reject any hyperlinks that use **http://** instead of the secure **https://** protocol.
MIME_FILTER_REJECT_UNSAFE	Reject links using unsafe schemes such as **file:**, **data:**, or **javascript:**. These links are excluded by default unless overridden.
MIME_FILTER_ALLOW_PUNYCODE	Explicitly permit Punycode domain names in URLs even when **MIME_FILTER_REMOVE_UNICODE** is specified. Use when legitimate IDN domains are expected.
MIME_FILTER_ALLOW_UNSAFE	Allow potentially unsafe schemes such as **file:** or **javascript:** in message content. Use with caution and only when the message source is fully trusted.
MIME_FILTER_ALLOW_SYMBOLS	Allow Unicode symbols such as emojis and pictographs in the filtered text.
MIME_FILTER_ALLOW_CONFUSABLES	Allow Unicode characters which can be confused with normal ASCII characters. Use only when the message source is fully trusted.

Return Value

The function will return the number of characters of filtered text copied to the string buffer, not including the terminating null character. If the ***lpszFilteredText*** parameter is NULL, the function will return the length of the filtered text without copying any characters. A return value of zero indicates the message part does not contain any message text. If the function fails it will return MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeFilterMessageText** function filters MIME-encoded message parts by removing HTML tags and other potentially unsafe or undesired content. It handles both HTML and plain text content types. For HTML, the function converts the markup to plain text and decodes HTML entities. For plain text, it scans for embedded URLs and applies filtering based on the specified options.

When filtering HTML markup and text from message content, this function can:

- Remove script, style, and other non-visible or unsafe elements.
- Convert common tag structures, such as lists and headers, into readable plain text.
- Extract and optionally filter or remove hyperlinks and image alt text.
- Decode common HTML entities such as **&trade** and **&copy**, as well as numeric entites like

`&#x20.`

- Normalize Unicode characters to their canonical values (NKFD normalization).
- Replace confusable homoglyhs with their ASCII counterparts.
- Remove symbols such as emojis and pictographs which can confuse pattern matching.

The function is designed to produce clean, human-readable output suitable for previewing message contents in text-only environments, logging, or performing further analysis. It ensures that embedded credentials, tracking links, or insecure resources are removed or sanitized based on caller preferences.

By default, the function does not remove Unicode characters or strip links unless explicitly instructed via flags. The `MIME_FILTER_STRICT` constant is a recommended combination for maximum safety and removes potentially malicious or misleading elements from messages. Characters that are visually indistinguishable from standard Latin letters, such as the Cyrillic "a" (U+0430) and Latin "a" (U+0061), will be converted to their ASCII equivalent, preventing homoglyhph attacks and attempts to obsfucate links or defeat pattern matching.

To obtain the original message content, use the **MimeGetMessageText** function. If you want to perform generalized normalization on the contents of a message, you can also use the **MimeNormalizeText** function. However, this function already performs equivalent normalization on the message text, so it is not necessary to use either **MimeNormalizeText** or the **NormalizeString** function on the output from this function.

Example

```
// Search a multipart message for the HTML version of the message
// and write the filtered content to standard output

HMESSAGE hMessage = MimeOpenMessage(pszFileName, MIME_OPEN_DEFAULT);

if (hMessage == INVALID_MESSAGE)
{
    _tprintf(_T("Unable to open message %s\n"), pszFileName);
    return;
}

// Get the number of parts in the message
INT nPartCount = MimeGetMessagePartCount(hMessage);

for (INT nMessagePart = 0; nMessagePart < nPartCount; nMessagePart++)
{
    // Set the current message part
    MimeSetMessagePart(hMessage, nMessagePart);

    if (MimeIsContentType(hMessage, MIME_CURRENT_PART, _T("text/html")))
    {
        DWORD dwOptions = MIME_FILTER_STRICT;

        // Determine the amount of memory we need to allocate
        LPTSTR pszFiltered = NULL;
        LONG cchFiltered = MimeFilterMessageText(hMessage, NULL, 0, dwOptions);

        if (cchFiltered < 1)
        {
            // Unable to filter this message part even though its identified
            // as containing HTML or it does not contain any text
            break;
        }
```

```
        else
        {
            // Allocate memory for the filtered text; note the extra space is
            // included for the terminating null character
            pszFiltered = (LPTSTR)malloc((cchFiltered + 1) * sizeof(TCHAR));

            if (pszFiltered == NULL)
            {
                // Unable to allocate memory for the filtered text
                break;
            }

            // Return the filtered message contents in pszFiltered
            cchFiltered = MimeFilterMessageText(
                                hMessage,
                                pszFiltered,
                                cchFiltered + 1,
                                dwOptions);

            if (cchFiltered > 0)
            {
                // Write the filtered text to standard output on the console
                fwrite(pszFiltered, sizeof(TCHAR), cchFiltered, stdout);
            }

            // Free the memory we allocated for the filtered text
            free(pszFiltered);
            break;
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeFindAttachment Function

```
INT WINAPI MimeFindAttachment(
   HMESSAGE hMessage,
   LPCTSTR lpszFileName
);
```

The **MimeFindAttachment** function searches the message for an attachment with the specified file name.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string that specifies the name of the file attachment to search for. This parameter should only specify a base file name; it should not include a file path and cannot be NULL.

Return Value

If the function succeeds, the return value is the message part number that contains an attachment that matches the specified file name. If the message does not contain an attachment with the specified file name, the function will return MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function will search the message for a attachment that matches the specified file name. The search is not case-sensitive, however it must match the attachment file name completely. This function will not match partial file names or names that include wildcard characters. To obtain a list of all of the files attached to a message, use the **MimeEnumAttachments** function.

Example

```
// The name of the file attachment to search for
LPCTSTR lpszFileName = _T("MyProject.docx");

// Search for the attached file and store it on the local system
INT nMessagePart = MimeFindAttachment(hMessage, lpszFileName);
if (nMessagePart != MIME_ERROR)
{
    MimeSetMessagePart(hMessage, nMessagePart);

    if (MimeExtractFile(hMessage, lpszFileName) != MIME_ERROR)
        _tprintf(_T("Saved file attachment %s\n"), lpszFileName);
    else
    {
        _tprintf(_T("Unable to save file attachment %s\n"), lpszFileName);
        return;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeFindStoredMessage Function

```
LONG WINAPI MimeFindStoredMessage(
   HMESSAGESTORE hStorage,
   LONG nMessageId,
   LPCTSTR lpszHeaderName,
   LPCTSTR lpszHeaderValue,
   DWORD dwOptions
);
```

The **MimeFindStoredMessage** function searches for a message in the specified message store.

Parameters

hStorage

Handle to the message store.

nMessageId

An integer value which specifies the message number that should be used when starting the search. The first message in the message store has a value of one.

lpszHeaderName

The string which specifies the name of the header field that should be searched. The header field name is not case sensitive. This parameter cannot be NULL.

lpszHeaderValue

The string which specifies the header value that should be searched for. This may be a literal string or it may specify a regular expression. The search options can be used to specify if the search is case-sensitive, and whether the search should return partial matches to the string. This parameter cannot be NULL.

dwOptions

A value which specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
MIME_SEARCH_DEFAULT	Perform a complete match against the specified header value. The comparison is not case-sensitive.
MIME_SEARCH_CASE_SENSITIVE	The header field value comparison will be case-sensitive. Note that this does not affect header field names. Matches for header names are always case-insensitive.
MIME_SEARCH_PARTIAL_MATCH	Perform a partial match against the specified header value. It recommended that this option be used when searching for matches to email addresses.
MIME_SEARCH_DECODE_HEADERS	Decode any encoded message headers before comparing them to the specified value.
MIME_SEARCH_ANCHORED_MATCH	Perform a complete match against the specified header value. This is the default behavior if a partial match is not specified.

MIME_SEARCH_LITERAL_MATCH	Perform a literal match against the specified header value, even if it may include a regular expression.

Return Value

If the function succeeds, the return value is the number for the message which matches the search criteria. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeFindStoredMessage** function is used to search the message store for a message which matches a specific header field value. For example, it can be used to find every message which is addressed to a specific recipient or has a subject which matches a particular string value.

If the *lpszHeaderValue* parameter does not contain any regular expression constructs (such as **^**, **$**, **[ ]**, or quantifiers like ***** and **+**), the search is performed using a simple substring comparison. If a regular expression pattern is specified, the function compiles the pattern and searches the message headers for a match. The regular expression matching uses a simplified version which only supports anchors, wildcards, match classes (enclosed in brackets) and a limited number of escape sequences such as **\d** to match any digit or **\s** to match any space character. It does not support grouping or replacement.

If you want to search for a message where the header value may contain characters typically used in regular expressions such as **[** or **$**, you can either escape them using a backslash, or you can use the MIME_SEARCH_LITERAL_MATCH option which forces the function to only perform a substring search.

Example

```
HMESSAGE hMessage = INVALID_MESSAGE;
LPCTSTR lpszHeader = _T("From");
LPCTSTR lpszAddress = _T("jsmith@example.com");
LONG nMessageId = 1;

// Begin searching for messages from the specified sender
while (nMessageId != MIME_ERROR)
{
    nMessageId = MimeFindStoredMessage(hStorage,
                                       nMessageId,
                                       lpszHeader,
                                       lpszAddress,
                                       MIME_SEARCH_PARTIAL_MATCH);

    if (nMessageId != MIME_ERROR)
    {
        // Get a handle to the message that was found
        hMessage = MimeGetStoredMessage(hStorage, nMessageId, 0);

        if (hMessage != INVALID_MESSAGE)
        {
            // Store the message in a file
            TCHAR szFileName[MAX_PATH];
            BOOL bExported;

            // Create a filename based on the message number
            wsprintf(szFileName, _T("msg%05ld.tmp"), nMessageId);

            // Export the message to a file
            bExported = MimeExportMessage(hMessage, szFileName);
```

```
        }

        // Increase the message ID to resume the search at the next message
        nMessageId++;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeFormatDate Function

```
LPTSTR WINAPI MimeFormatDate(
    LONG nSeconds,
    LONG nTimezone,
    LPTSTR lpszDate,
    INT cchMaxDate
);
```

The **MimeFormatDate** converts the specified date, expressed as the number of seconds since 1 January 1970, into a string compatible with the RFC 822 standard format for email messages.

Parameters

nSeconds

An integer which specifies the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C/C++ time functions. If the value of this parameter is zero, the current date and time is used.

nTimezone

An integer which is set to the difference in seconds between the specified date's timezone and Coordinated Universal Time. A value of zero specifies Coordinated Universal Time (UTC), while a positive value specifies a timezone west of UTC and a negative value specifies a timezone east of UTC. For example, Eastern Standard Time would be specified as 18000 and Pacific Standard Time would be 28800.

lpszDate

A null-terminated string buffer which will contain the formatted date. This parameter cannot be a NULL pointer.

cchMaxDate

The maximum number of characters, including the terminating null character, which may be copied into the date string buffer.

Return Value

If the function succeeds, a pointer to the date string buffer is returned. If the function fails, a NULL pointer is returned. To get extended error information, call **MimeGetLastError**.

Remarks

The date string is returned in a standard format as outlined in RFC 822, the document which describes the basic structure of Internet email messages. This format is as follows:

```
www, dd mmm yyyy hh:mm:ss [-]zzzz
```

Each part of the date string is defined as follows:

Format	Description
www	Weekday
dd	Day
mmm	Month
yyyy	Year
hh	Hour (24-hour clock)

mm	Minutes
ss	Seconds
zzzz	Timezone

The weekday and month are displayed using standard three-character English abbreviations. The timezone is displayed as the difference (in hours and minutes) between the specified timezone and Coordinated Universal Time. For example, if the timezone is eight hours west of Coordinated Universal Time, the ***nTimezone*** value would be 28800. This would be displayed as -0800 in the formatted date string.

Note that the format of the date string is defined by the RFC 822 standard, and is not affected by localization settings on the host system.

Developers are strongly encouraged to use the **MimeFormatDate64** function for all new development. This function represents date and time values as 32-bit integers, which limits the representable range to dates before 19 January 2038 (the so-called "Year 2038 problem"). After this date, 32-bit time values will overflow, resulting in incorrect date calculations and potential failures in software that processes email message dates. By contrast, the 64-bit versions use 64-bit integer values, matching the standard **`time_t`** type used by modern C/C++ libraries. This not only eliminates the Year 2038 limitation but also ensures compatibility with current and future systems, allowing correct handling of dates both far in the past and well into the future. Whenever possible, applications should transition to these 64-bit functions to ensure long-term reliability and portability.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeFormatDate64 Function

```
LPTSTR WINAPI MimeFormatDate64(
    LONGLONG nSeconds,
    LONG nTimezone,
    LPTSTR lpszDate,
    INT nMaxLength
);
```

The **MimeFormatDate** converts the specified date, expressed as the number of seconds since 1 January 1970, into a string compatible with the RFC 822 standard format for email messages.

Parameters

nSeconds

A 64-bit integer which specifies the number of seconds since 1 January 1970 00:00:00 UTC. This date is commonly called the epoch, and is the base date used by the standard C/C++ time functions. If the value of this parameter is zero, the current date and time is used.

nTimezone

A 32-bit integer which is set to the difference in seconds between the specified date's timezone and Coordinated Universal Time. A value of zero specifies Coordinated Universal Time (UTC), while a positive value specifies a timezone west of UTC and a negative value specifies a timezone east of UTC. For example, Eastern Standard Time would be specified as 18000 and Pacific Standard Time would be 28800.

lpszDate

A null-terminated string buffer which will contain the formatted date. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters, including the terminating null character, which may be copied into the date string buffer.

Return Value

If the function succeeds, a pointer to the date string buffer is returned. If the function fails, a NULL pointer is returned. To get extended error information, call **MimeGetLastError**.

Remarks

The date string is returned in a standard format as outlined in RFC 822, the document which describes the basic structure of Internet email messages. This format is as follows:

```
www, dd mmm yyyy hh:mm:ss [-]zzzz
```

Each part of the date string is defined as follows:

Format	Description
www	Weekday
dd	Day
mmm	Month
yyyy	Year
hh	Hour (24-hour clock)

mm	Minutes
ss	Seconds
zzzz	Timezone

The weekday and month are displayed using standard three-character English abbreviations. The timezone is displayed as the difference (in hours and minutes) between the specified timezone and Coordinated Universal Time. For example, if the timezone is eight hours west of Coordinated Universal Time, the ***nTimezone*** value would be 28800. This would be displayed as -0800 in the formatted date string.

Note that the format of the date string is defined by the RFC 822 standard, and is not affected by localization settings on the host system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

MimeGetAllHeaders Function

```
INT WINAPI MimeGetAllHeaders(
   HMESSAGE hMessage,
   LPTSTR lpszHeaders,
   INT nMaxLength
);
```

The **MimeGetAllHeaders** function returns the complete RFC 822 header values in a string buffer.

Parameters

hMessage

Handle to the message.

lpszHeaders

Pointer to string buffer which will contain the header values for the specified message. This parameter may be NULL, in which case the function will calculate the number of characters needed to store the complete header block.

nMaxLength

An integer value which specifies the maximum number of characters that can be stored in the *lpszHeaders* string. If the *lpszHeaders* parameter is NULL, this value must be zero. If the *lpszHeaders* parameter is not NULL, this value must be large enough to store the entire list of addresses.

Return Value

If the function succeeds and the *lpszHeaders* parameter is NULL, the return value is the minimum number of characters that should be allocated to store all of the header values, including the terminating null character. If the *lpszHeaders* parameter is not NULL, then the return value is the number of characters copied into the string, not including the terminating null character. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetAllHeaders** function will return all of the RFC 822 header values in a string buffer. This includes the message headers that are most commonly referred to, such as the To, From and Subject headers. Each header and its value are separated by a colon, and terminated with a carriage return and linefeed (CRLF) pair.

The headers and their values returned by this function will not be identical to the header block in the original message. If a header value is split across multiple lines, this function will fold the text, returning the complete header value on a single line of text and removing any extraneous whitespace. If the header value has been encoded by the mail client, this function will return the decoded value, not the original encoded value.

Example

```
LPTSTR lpszHeaders = NULL;
INT nLength;

// Determine the number of characters that should be allocated to store
// the RFC822 headers
```

```
nLength = MimeGetAllHeaders(hMessage, NULL, 0);

// Allocate the memory for the string buffer that is large enough and
// call MimeGetAllHeaders again

if (nLength > 0)
{
    lpszHeaders = (LPTSTR)LocalAlloc(LPTR, nLength * sizeof(TCHAR));
    if (lpszHeaders == NULL)
        return; // Virtual memory exhausted

    nLength = MimeGetAllHeaders(hMessage, lpszHeaders, nLength);
}

// The lpszHeaders string now contains all of the RFC822 headers for the
// message, with each header terminated by a CRLF sequence

if (lpszHeaders != NULL)
{
    LocalFree((HLOCAL)lpszHeaders);
    lpszHeaders = NULL;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetAllRecipients Function

```
INT WINAPI MimeGetAllRecipients(
   HMESSAGE hMessage,
   LPCTSTR lpszExtraAddress,
   LPTSTR lpszRecipients,
   INT nMaxLength
);
```

The **MimeGetAllRecipients** function returns a comma-separated list of recipient addresses in a string buffer.

Parameters

hMessage

Handle to the message.

lpszExtraAddress

A null-terminated string which contains one or more additional email addresses that should be included in the list, in addition to those found in the message. If more than one address is specified, each address should be separated by a comma. This parameter may be NULL if there are no extra addresses to include in the recipient list.

lpszRecipients

Pointer to string buffer which will contain a comma-separated list of email addresses when the function returns. This parameter may be NULL, in which case the function will calculate the number of characters needed to store the complete list.

nMaxLength

An integer value which specifies the maximum number of characters that can be stored in the ***lpszRecipients*** string. If the ***lpszRecipients*** parameter is NULL, this value must be zero. If the ***lpszRecipients*** parameter is not NULL, this value must be large enough to store the entire list of addresses.

Return Value

If the function succeeds and the ***lpszRecipients*** parameter is NULL, the return value is the minimum number of characters that should be allocated to store the list recipient addresses, including the terminating null character. If the ***lpszRecipients*** parameter is not NULL, then the return value is the number of characters copied into the buffer, not including the terminating null character. If the function returns a value of zero, then the specified message has no recipients. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetAllRecipients** function is useful for creating a list of message recipients that can be passed to functions like **SmtpSendMessage**. If you wish to dynamically allocate the string buffer that will contain the list of recipients, then the ***lpszRecipients*** parameter should be NULL and the ***nMaxLength*** parameter should have a value of zero. The function will then return the recommended size of the buffer that should be allocated. This value is guaranteed to be large enough to store the entire list of message recipients, including the terminating null character.

Example

```
LPTSTR lpszRecipients = NULL;
INT nLength;
```

```
// Determine the number of characters that should be allocated to store
// a list of the recipient addresses in the message

nLength = MimeGetAllRecipients(hMessage, NULL, NULL, 0);

// Allocate the memory for the string buffer that is large enough and
// call MimeGetAllRecipients again

if (nLength > 0)
{
    lpszRecipients = (LPTSTR)LocalAlloc(LPTR, nLength * sizeof(TCHAR));
    if (lpRecipients == NULL)
        return; // Virtual memory exhausted

    nLength = MimeGetAllRecipients(hMessage, NULL, lpszRecipients, nLength);
}

// The lpszRecipients string now contains a comma-separated list of
// each recipient address in the message

if (lpszRecipients != NULL)
{
    LocalFree((HLOCAL)lpszRecipients);
    lpszRecipients = NULL;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetAttachedFileName Function

```
BOOL WINAPI MimeGetAttachedFileName(
    HMESSAGE hMessage,
    LPTSTR lpszFileName,
    INT cchFileName
);
```

The **MimeGetAttachedFileName** function returns the file name for the attachment to the current message part.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a buffer that will contain the current attachment file name as a string.

cchFileName

The maximum number of characters that may be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **MimeGetLastError**.

Remarks

The function will first try to get the filename from the Content-Disposition header field. If this field does not exist, it then attempts to get the name from the Content-Type header field. If neither field exists, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetAuthenticationResults Function

```
DWORD WINAPI MimeGetAuthenticationResults(
    HMESSAGE hMessage
);
```

The **MimeGetAuthenticationResults** function returns information about the authentication status of the message.

Parameters

hMessage

A handle to the message.

Return Value

This function returns one or more flags based on the value of the `Authentication-Results` header in the message. This function explicitly clears the last error code to assist in differentiating between an error condidition, such as an invalid message handle, and when no authentication information was available. The following flags are defined:

Value	Description
MIME_AUTH_NONE	The message does not contain an Authentication-Results header or does not include any recognizable authentication types and their associated results.
MIME_AUTH_SPF_PASSED	The message passed the Sender Policy Framework (SPF) check. The sender's IP address was authorized to send mail for the domain in the envelope sender address.
MIME_AUTH_SPF_FAILED	The message failed the SPF check. The sending mail server is not authorized by the domain's SPF record to send mail on its behalf.
MIME_AUTH_DKIM_PASSED	The message passed the DomainKeys Identified Mail (DKIM) check. The signature applied by the sender was successfully verified using the domain's public key.
MIME_AUTH_DKIM_FAILED	The message failed the DKIM check. The signature could not be verified or did not match the message content, suggesting it may have been altered.
MIME_AUTH_DMARC_PASSED	The message passed DMARC evaluation. The message aligned with a valid SPF or DKIM result based on the sender domain's policy.
MIME_AUTH_DMARC_FAILED	The message failed DMARC evaluation. It did not pass SPF or DKIM checks in a way that aligns with the domain's published policy.
MIME_AUTH_TEMP_ERROR	A temporary error occurred while evaluating one or more authentication mechanisms. This may indicate a DNS lookup timeout or other transient failure.
MIME_AUTH_PERM_ERROR	A permanent error occurred during authentication checks. This may indicate a malformed DNS record or invalid

	message structure that prevents proper evaluation.

Remarks

Modern email systems use a set of authentication mechanisms to help verify that a message was sent from a legitimate source and not forged by a spammer or attacker. The **MimeGetAuthenticationResults** function enables you to easily determine which of these mechanisms have passed a check and which of them have failed. It evaluates the following authentication information reported by the mail server:

SPF
Sender Policy Framework allows the owner of a domain to specify which mail servers are authorized to send email on its behalf. If the sending server is not listed in the domain's SPF record, the message may be marked as suspicious. SPF helps prevent spoofing of the envelope sender address, which is often used in phishing attacks.

DKIM
DomainKeys Identified Mail uses public-key cryptography to sign specific parts of the email, such as headers and body content. The signature is added by the sending mail server, and receiving systems use DNS to retrieve the sender's public key to verify that the message has not been tampered with. A valid DKIM signature helps confirm that the message was truly sent by the claimed domain.

DMARC
Domain-based Message Authentication, Reporting, and Conformance builds on SPF and DKIM by defining a policy for how a domain wants email receivers to handle messages that fail authentication checks. It also ensures that the visible From: address matches the domain that passed SPF or DKIM (a concept called alignment). DMARC allows domain owners to monitor abuse and enforce stronger protection against spoofing.

Checking these authentication results can help identify spoofed or forged messages, improve filtering decisions, and increase overall mail security. While not every legitimate message will have all three, failure of all mechanisms, especially from domains that publish strict DMARC policies, should be treated as suspicious.

While these authentication methods are useful signals, failing one of them does not necessarily mean a message is malicious. Many legitimate messages, even from well-known companies, may have misconfigured SPF records, missing DKIM signatures, or inconsistent DMARC policies. Conversely, a message that passes all checks could still be unwanted or deceptive. These results should be treated as advisory signals rather than absolute indicators of legitimacy. Developers are encouraged to consider authentication status alongside other factors, such as message content, sender reputation, and user reporting.

To simplify checking authentication outcomes, the following predefined flag combinations are also available:

- MIME_AUTH_PASSED is a combination of all passing results (SPF, DKIM, DMARC).
- MIME_AUTH_FAILED is a combination of all failing results.
- MIME_AUTH_ERROR is a combination of temporary or permanent errors.

For a simplified boolean check using these flags, see the **MimeCheckAuthenticationResults** function.

Example

```
HMESSAGE hMessage = MimeOpenMessage(lpszFileName, MIME_OPEN_DEFAULT);

if (hMessage != INVALID_MESSAGE)
{
    // Get the authentication results for the message
    DWORD dwAuthFlags = MimeGetAuthenticationResults(hMessage);

    // Check if any of the SPF, DKIM, or DMARC checks failed
    if (dwAuthFlags & MIME_AUTH_FAILED)
        _tprintf(_T("This message has failed one or more authentication
checks\n"));

    MimeCloseMessage(hMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeGetContentDigest Function

```
INT WINAPI MimeGetContentDigest(
    HMESSAGE hMessage,
    LPTSTR lpszDigest,
    INT cchDigest
);
```

The **MimeGetContentDigest** function returns an encoded digest of the message.

Parameters

hMessage

Message handle.

lpszDigest

Pointer to a string buffer to contain the MD5 digest for the specified message.

cchDigest

Maximum length of the digest string, in bytes.

Return Value

If the function succeeds, the return value is the length of the message digest string. A value of zero specifies that there is no MD5 digest for the current message. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function returns the value of the Content-MD5 header field in the main body of the message. If the header exists, it contains the MD5 digest for the message as defined in RFC 1864.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeGetContentLength Function

```
LONG WINAPI MimeGetContentLength(
    HMESSAGE hMessage
);
```

The **MimeGetContentLength** function returns the size of the current message part content in bytes.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is the content length. If the function fails, the return value is MIME_ERROR. To get extended error information, call **MimeGetLastError**.

Remarks

This function will return the size of the content in the current message part as the number of bytes and does not account for any Unicode conversion of text. Exercise caution when using this function to determine the size of the buffer that should be allocated for a function like **MimeGetMessageText**. You should always allocate enough memory to accommodate any potential text conversion and decoding which may occur.

It is important to note that this function does not return the number of characters of text in the message. The number of characters and bytes would only be the same when working with messages which contain plain, unencoded ASCII text. Messages which are encoded and/or multibyte character sets can represent a single character with multiple byte sequences. In this case, the content length will not accurately represent the number of characters copied to a string buffer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

MimeGetContentType Function

```
INT WINAPI MimeGetContentType(
    HMESSAGE hMessage
);
```

Parameters

hMessage

Handle to the message whose content type should be retrieved. The current message part is used.

Return Value

The function returns an integer value that identifies the top-level media type for the current message part. This value may be one of the following predefined constants:

Value	Description
MIME_CONTENT_TEXT	Textual content (e.g.: text/plain, text/html)
MIME_CONTENT_IMAGE	Image content (e.g.: image/jpeg, image/png)
MIME_CONTENT_AUDIO	Audio content (e.g.: audio/mpeg)
MIME_CONTENT_VIDEO	Video content (e.g.: video/mp4)
MIME_CONTENT_APPLICATION	Application-specific data (e.g.: application/pdf)
MIME_CONTENT_MESSAGE	Embedded message (e.g.: message/rfc822)
MIME_CONTENT_MULTIPART	Multipart content (e.g.: multipart/alternative)
MIME_CONTENT_WIDETEXT	Extended text using wide character encoding
MIME_CONTENT_UNKNOWN	The content type is unknown or could not be determined

If the function fails, it returns **MIME_ERROR**. To retrieve extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetContentType** function parses the `Content-Type` header of the current message part and returns the content type in a normalized form. This function eliminates the need for manual parsing of MIME headers and is useful for determining how message parts should be processed based on their media type. For example, consider a current message part with:

```
Content-Type: text/html; charset=utf-8
```

In this case, the function will return `MIME_CONTENT_TEXT`. This function always returns the content type for the current message part set by the **MimeSetMessagePart** function.

Example

```
if (MimeGetContentType(hMessage) == MIME_CONTENT_TEXT)
{
    // Get the size of the decoded/converted message text
    LONG cchMessage = MimeGetMessageText(hMessage, 0, NULL, 0);
    if (cchMessage < 1)
    {
        _tprintf(_T("Message part %d does not contain any text\n"), nMessagePart);
```

```
        return;
    }

    // Allocate a buffer for the message text on the heap
    LPTSTR pszMessage = (LPTSTR)malloc((cchMessage + 1) * sizeof(TCHAR));
    if (pszMessage == NULL) // Virtual memory exhausted
        return;

    // Copy the message contents to the buffer
    cchMessage = MimeGetMessageText(hMessage, 0, pszMessage, cchMessage + 1);
    if (cchMessage > 0)
    {
        // Write the contents of the message part to the console
        fwrite(pszMessage, sizeof(TCHAR), cchMessage, stdout);
        fflush(stdout);
    }

    // Free the memory allocated for our text buffer
    free(pszMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeGetContentTypeEx Function

```
INT WINAPI MimeGetContentTypeEx(
    HMESSAGE hMessage,
    INT nMessagePart,
    LPTSTR lpszSubType,
    INT cchSubType,
    LPTSTR lpszParams,
    INT cchParams
);
```

Parameters

hMessage

Handle to the message whose content type should be retrieved.

nMessagePart

An integer value which specifies the message part. Message parts are zero-based with the part zero being the primary content and additional parts typically containing message content and file attachments. A value of MIME_CURRENT_PART (-1) specifies the content type for the current message part should be returned.

lpszSubType

A null-terminated string buffer that will receive the content subtype, such as "html" or "plain". This parameter may be NULL if the subtype is not required.

cchSubType

The maximum number of characters that can be copied into the ***lpszSubType*** buffer, including the terminating null character. If the buffer is too small, the function will return an error.

lpszParams

A null-terminated string buffer that will receive any parameters associated with the content type, such as `charset=utf-8`. This parameter may be NULL if parameters are not needed.

cchParams

The maximum number of characters that can be copied into the ***lpszParams*** buffer, including the terminating null character. If the buffer is too small, the function will return an error.

Return Value

The function returns an integer value that identifies the top-level media type for the current message part. This value may be one of the following predefined constants:

Value	Description
MIME_CONTENT_TEXT	Textual content (e.g.: text/plain, text/html)
MIME_CONTENT_IMAGE	Image content (e.g.: image/jpeg, image/png)
MIME_CONTENT_AUDIO	Audio content (e.g.: audio/mpeg)
MIME_CONTENT_VIDEO	Video content (e.g.: video/mp4)
MIME_CONTENT_APPLICATION	Application-specific data (e.g.: application/pdf)
MIME_CONTENT_MESSAGE	Embedded message (e.g.: message/rfc822)
MIME_CONTENT_MULTIPART	Multipart content (e.g.: multipart/alternative)

MIME_CONTENT_WIDETEXT	Extended text using wide character encoding
MIME_CONTENT_UNKNOWN	The content type is unknown or could not be determined

If the function fails, it returns MIME_ERROR. To retrieve extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetContentTypeEx** function parses the `Content-Type` header of the current message part and returns the content type information in a normalized form. If requested, the subtype name and any optional parameters are copied to the caller-supplied buffers. This function eliminates the need for manual parsing of MIME headers and is useful for determining how message parts should be processed based on their media type. For example, consider a message part with:

```
Content-Type: text/html; charset=utf-8
```

This function will return `MIME_CONTENT_TEXT`, a subtype of `"html"`, and the parameter string `"charset=utf-8"`. If only the numeric media type is required for use in a `switch` or `if-then-else` statement, the content type and parameters buffers may be passed as `NULL`.

If you wish to determine if the content type for a message part matches a specific value, you can use the **MimeIsContentType** function.

Example

```
TCHAR szSubType[32] = {0};
TCHAR szParams[64] = {0};

// Check if the current message part is plain text; szParams may
// contain the original character set used
INT nContentType = MimeGetContentTypeEx(
                        hMessage,
                        MIME_CURRENT_PART,
                        szSubType, _countof(szSubType),
                        szParams, _countof(szParams));

if (nContentType == MIME_CONTENT_TEXT && lstrcmpiA(szSubType, "plain") == 0)
{
    // Get the size of the decoded/converted message text
    LONG cchMessage = MimeGetMessageText(hMessage, 0, NULL, 0);
    if (cchMessage < 1)
    {
        _tprintf(_T("Message part %d does not contain any text\n"), nMessagePart);
        return;
    }

    // Allocate a buffer for the message text on the heap
    LPTSTR pszMessage = (LPTSTR)malloc((cchMessage + 1) * sizeof(TCHAR));
    if (pszMessage == NULL) // Virtual memory exhausted
        return;

    // Copy the message contents to the buffer
    cchMessage = MimeGetMessageText(hMessage, 0, pszMessage, cchMessage + 1);
    if (cchMessage > 0)
    {
        // Write the contents of the message part to the console
        fwrite(pszMessage, sizeof(TCHAR), cchMessage, stdout);
```

```
        fflush(stdout);
    }

    // Free the memory allocated for our text buffer
    free(pszMessage);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetErrorString Function

```
INT WINAPI MimeGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **MimeGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **MimeGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetExportOptions Function

```
BOOL WINAPI MimeGetExportOptions(
    HMESSAGE hMessage
    LPDWORD lpdwOptions
);
```

The **MimeGetExportOptions** function returns a bitmask that describes current message export options.

Parameters

hMessage

Handle to the message.

lpdwOptions

Pointer to mask of attribute options. The mask is a combination of the following values:

Value	Description
MIME_OPTION_DEFAULT	The default export options. The headers for the message are written out in a specific consistent order, with custom headers written to the end of the header block regardless of the order in which they were set or imported from another message. If the message contains Bcc, Received, Return-Path, Status or X400-Received header fields, they will not be exported.
MIME_OPTION_KEEPORDER	The original order in which the message header fields were set or imported are preserved when the message is exported.
MIME_OPTION_ALLHEADERS	All headers, including the Bcc, Received, Return-Path, Status and X400-Received header fields will be exported. Normally these headers are not exported because they are only used by the mail transport system. This option can be useful when exporting a message to be stored on the local system, but should not be used when exporting a message to be delivered to another user.
MIME_OPTION_NOHEADERS	When exporting a message, the main header block will not be included. This can be useful when creating a multipart message for services which expect MIME formatted data, such as HTTP POST requests. This option should never be used for email messages being submitted using SMTP.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is 0. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csmsgv12.lib

See Also

MimeGetFileContentType Function

```
UINT WINAPI MimeGetFileContentType(
   HMESSAGE hMessage,
   LPCTSTR lpszFileName,
   LPTSTR lpszContentType,
   INT cchContentType
);
```

The **MimeGetFileContentType** function returns the content type for the specified file.

Parameters

hMessage

Handle to the message.

lpszFileName

Pointer to a string which specifies the name of the file for which content type information is returned.

lpszContentType

Pointer to a string buffer that will contain the MIME type for the specified file. This may be a NULL pointer, in which case this parameter is ignored. If a buffer is provided, it is recommended that it be at least 64 characters in length.

cchContentType

An integer which specifies the maximum number of characters, including the terminating null character, which may be copied into the string buffer.

Return Value

If the function succeeds, the return value is the content type of the specified file. If the function fails, the return value is MIME_CONTENT_UNKNOWN. To get extended error information, call **MimeGetLastError**.

The following values may be returned by this function:

Value	Description
MIME_CONTENT_UNKNOWN	The file content type is unknown. This value may be returned if the message handle is invalid, or if the file extension is unknown and the file could not be opened for read access.
MIME_CONTENT_APPLICATION	The file content is application specific. Examples of this type of file would be a Microsoft Word document or an executable program. This is also the default type for files which have an unrecognized file name extension and contain binary data.
MIME_CONTENT_AUDIO	The file is an audio file in one of several standard formats. Examples of this type of file would be a Windows (.wav) file or MPEG3 (.mp3) file.
MIME_CONTENT_IMAGE	The file is an image file in one of several standard formats. Examples of this type of file would be a GIF or JPEG image file.
MIME_CONTENT_TEXT	The file is a text file. This is also the default type for files which have an unrecognized file name extension and contain only

	printable text data.
MIME_CONTENT_VIDEO	The file is a video file in one of several standard formats. Examples of this type of file would be a Windows (.avi) or Quicktime (.mov) video file.

Remarks

The content type for a given file is determined based on the file name extension, or if the extension is not recognized, the actual contents of the file. On 32-bit platforms, the system registry is used to determine the default content type values for a given extension. In all cases, file types that are explicitly set using the **MimeSetFileContentType** function will override the default system values.

The content type string which is copied to the string buffer is the standard MIME content type description, which specifies a primary type and a subtype, separated by a slash. For example, a plain text file would have a content type of text/plain, while an HTML document would have a content type of text/html. Binary files may be associated with a specific application. For example, the content type for a Microsoft Word document is application/msword. Those binary files which are not associated with a specific application, or have an unrecognized file name extension, have a content type of application/octet-stream.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeGetFirstMessageHeader Function

```
BOOL WINAPI MimeGetFirstMessageHeader(
    HMESSAGE hMessage,
    LPTSTR lpszHeader,
    INT cchMaxHeader,
    LPTSTR lpszValue,
    INT cchMaxValue
);
```

The **MimeGetFirstMessageHeader** function returns the header field name and value for the first header in the current message part. This function is typically used in conjunction with **MimeGetNextMessageHeader** to enumerate all of the message header fields and their values in the current message part.

Parameters

hMessage

Handle to the message.

lpszHeader

A null-terminated string buffer that will contain the name of the first header in the current message part. This parameter cannot be a NULL pointer.

cchMaxHeader

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. This parameter must have a value greater than zero.

lpszValue

A null-terminated string buffer that will contain the value of the first header in the current message part. This parameter may be a NULL pointer, in which case the value of the header field is ignored.

cchMaxValue

An integer which specifies the maximum number of characters which may be copied into the buffer, including the terminating null character. If the ***lpszValue*** parameter is NULL, this parameter should have a value of zero.

Return Value

If the function succeeds, the return value is non-zero. If no headers exist for the current message part, or the handle to the message is invalid, the function will return zero. To get extended error information, call **MimeGetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **MimeSetMessagePart** function.

The header fields from an imported message may not be returned in the same order as which they appear in the message. An application should never make an assumption about the order in which one or more header fields are defined.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeGetLastError Function

```
DWORD WINAPI MimeGetLastError();
```

Parameters

None.

Return Value

The return value is the calling thread's last error code value. Functions set this value by calling the **MimeSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last-error code.

Remarks

You should call the **MimeGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **MimeSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_MESSAGE or MIME_ERROR. Those functions which call **MimeSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib

See Also

MimeGetErrorString, MimeSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeGetMessageBoundary Function

```
LPCTSTR WINAPI MimeGetMessageBoundary(
    HMESSAGE hMessage
);
```

The **MimeGetMessageBoundary** function returns a pointer to the boundary string used to separate the parts of a multipart message.

Parameters

hMessage

Handle to the message.

Return Value

If the function succeeds, the return value is a pointer to the boundary string. If the function fails, a NULL pointer is returned. To get extended error information, call **MimeGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeCreateMessagePart, MimeGetMessageHeader, MimeGetMessagePart

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeGetMessageDate Function

```
LPCTSTR WINAPI MimeGetMessageDate(
    HMESSAGE hMessage,
    BOOL bLocalize
);
```

The **MimeGetMessageDate** function returns a pointer to a string that contains the message date and time.

Parameters

hMessage

Handle to the message.

bLocalize

Boolean flag which specifies if the date and time should be localized for the current timezone.

Return Value

If the function succeeds, the return value is a pointer to the date and time string. If the function fails, it will return a NULL pointer. To get extended error information, call **MimeGetLastError**.

Remarks

If no date has been specified in the message, the Date header field will be set to the current date and time, and that value will be returned. The date string returned by this function should never be directly modified by the application. Each call to this function will invalidate the previous value that was returned, so if you wish to save or modify the value, you should first make a private copy of the string.

To convert this date string to a long integer value that can be used with the standard C/C++ time functions, use the **MimeParseDate64** function. Refer to the **MimeFormatDate64** function for information on the format of the date string.

Developers are encouraged to use the **MimeGetMessageDateEx** function for all new development. This function returns a pointer to a string managed by the internal message context, which may become invalid or be overwritten by subsequent operations. In addition, if the message does not contain a `Date` header, this function will automatically generate and insert a current date value, modifying the message content as a side effect. By contrast, **MimeGetMessageDateEx** copies the date string directly into a caller-supplied buffer and does not alter the message if the header is missing. This results in more predictable and thread-safe behavior, with no risk of unintentional modifications to the message.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

MimeFormatDate, MimeFormatDate64, MimeGetMessageDateEx, MimeGetMessageHeader, MimeParseDate, MimeParseDate64, MimeSetMessageDate

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

MimeGetMessageDateEx Function

```
INT WINAPI MimeGetMessageDateEx(
    HMESSAGE hMessage,
    LPTSTR lpszDate,
    INT nMaxLength,
    BOOL bLocalize
);
```

The **MimeGetMessageDateEx** function copies the current message date to the specified string buffer.

Parameters

hMessage

Handle to the message.

lpszDate

A null-terminated string buffer which will contain the message date. This parameter cannot be NULL.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character. This parameter cannot be zero.

bLocalize

A boolean flag which specifies if the date and time should be localized for the current time zone.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer., not including the terminating null character A return value of zero indicates the message does not have a valid `Date` header or an error has occurred. To get extended error information, call **MimeGetLastError**.

Remarks

The **MimeGetMessageDateEx** function copies the formatted date string directly into the buffer provided by the caller. This ensures the date string remains valid for the lifetime of the caller's buffer, avoiding issues with internal pointer reuse or invalidation that could occur in multithreaded or reentrant scenarios. If the message contains a valid `Date` or `Sent` header, the function retrieves and, if requested, localizes the date and time string before copying it to the specified buffer. The returned string always conforms to the standard format described in RFC 822. To convert this date string into a numeric value suitable for time calculations, use the **MimeParseDate64** function.

A key difference between this function and the behavior of the **MimeGetMessageDate** function is that this function will not automatically create or set a `Date` header if it is missing from the message. If neither a `Date` nor `Sent` header is present, the function simply fails and returns zero, rather than inserting the current date and time into the message. This change eliminates side effects and ensures that calling this function does not modify the underlying message content.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetMessageHeader Function

```
LPCTSTR WINAPI MimeGetMessageHeader(
    HMESSAGE hMessage,
    LPCTSTR lpszHeader
);
```

The **MimeGetMessageHeader** function returns a pointer to the value associated with the specified header field in the current message part.

Parameters

hMessage

Handle to the message.

lpszHeader

A null-terminated string which specifies the message header. This parameter cannot be a NULL pointer.

Return Value

If the function succeeds, the return value is a pointer to the header value. If the header field does not exist, a NULL pointer is returned. To get extended error information, call **MimeGetLastError**.

Remarks

Each part in a multipart message has one or more header fields. To obtain header values for the main message, rather than the message attachments, the current part number must be set to zero using the **MimeSetMessagePart** function. For languages other than C/C++, it may be preferable to use the **MimeGetMessageHeaderEx** function which copies the header value into a string buffer rather than returning a pointer to the header value itself.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetMessageHeaderEx Function

```
INT WINAPI MimeGetMessageHeaderEx(
    HMESSAGE hMessage,
    INT nMessagePart,
    LPCTSTR lpszHeader,
    LPTSTR lpszValue,
    INT nMaxValue,
    DWORD dwReserved
);
```

The **MimeGetMessageHeaderEx** copies the value of the specified header into a string buffer.

Parameters

hMessage

Handle to the message.

nMessagePart

An integer value which specifies which part of the message to return the header value from. A value of zero returns a header value from the main message header, while a value greater than zero returns the header value from that specific part of a multipart message. A value of -1 specifies that the header value should be returned from the current message part.

lpszHeader

A null-terminated string which specifies the message header. This parameter cannot be a NULL pointer.

lpszValue

A null-terminated string buffer which will contain the value of the specified header when the function returns. If this parameter is NULL, the function will return the length of the header value without copying the data. This is useful for determining the length of a header value so that a string buffer can be allocated and passed to a subsequent call to the function.

nMaxValue

An integer value which specifies the maximum number of characters that can be copied to the string buffer, including the terminating null character. If the ***lpszValue*** parameter is NULL, this value should be zero.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the number of bytes copied into the string buffer, not including the terminating null byte. If the ***lpszValue*** parameter is NULL, the return value is the length of the header value. If the header field does not exist, a value of zero is returned. If an invalid pointer or message part is specified, a value of MIME_ERROR is returned. To get extended error information, call **MimeGetLastError**.

Example

```
LPTSTR lpszValue = NULL;
INT cchValue = 0;

// Determine the length of the To header field
```

```
cchValue = MimeGetMessageHeaderEx(hMessage, 0, _T("To"), NULL, 0);

// If the header field exists, allocate a string buffer
// and copy the value into the buffer
if (cchValue > 0)
{
    lpszValue = (LPTSTR)LocalAlloc(LPTR, cchValue + 1);
    MimeGetMessageHeaderEx(hMessage,
                           0,
                           _T("To"),
                           lpszValue,
                           cchValue + 1);
}

// After the string buffer has been used, release the
// memory that was allocated for it
if (lpszValue)
{
    LocalFree((HLOCAL)lpszValue);
    lpszValue = NULL;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csmsgv12.lib
Unicode: Implemented as Unicode and ANSI versions

MimeGetMessageLinks Function

```
LONG WINAPI MimeGetMessageLinks(
   HMESSAGE hMessage,
   DWORD dwLinkTypes,
   LPTSTR lpszLinkList,
   LONG nMaxLength,
   LONG *lpnLinkCount
);
```

The **MimeGetMessageLinks** function returns the hyperlinks in the current message part.

Parameters

hMessage

Handle to the message.

dwLinkTypes

An unsigned integer value which specifies one or more bitflags which identify what types of links you would like to extract. To extract all supported link types, use a value of zero.

Value	Description
MIME_LINK_HTTP	Return standard **http://** links in the current message part.
MIME_LINK_HTTPS	Return secure **https://** links in the current message part.
MIME_LINK_FTP	Return standard **ftp://** links in the current message part.
MIME_LINK_FTPS	Return secure **ftps://** and **ftpes://** links in the current message part.
MIME_LINK_SFTP	Return secure **sftp://** links in the current message part.
MIME_LINK_FILE	Return local **file://** links in the current message part.

lpszLinkList
