	Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store

is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The method will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the method will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the method will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

A client application only needs to call this method if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** parameter should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was

created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are optional values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters can be NULL or omitted.

Example

```
pSocket->CreateSecurityCredentials(lpszCertName);

bConnected = pSocket->Connect(lpszHostName,
                              INET_PORT_HTTP,
                              INET_PROTOCOL_TCP,
                              INET_TIMEOUT,
                              INET_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Connect, DeleteSecurityCredentials, GetSecurityInformation, ValidateCertificate, SECURITYCREDENTIALS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current connection.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CreateSecurityCredentials, ValidateCertificate

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::DetachHandle Method

```
SOCKET DetachHandle();
```

The **DetachHandle** method detaches the socket handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active connection, the value INVALID_SOCKET will be returned.

Remarks

This method is used to detach a socket handle created by the class for use with the SocketWrench API. Once the socket handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly closed at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::DisableEvents Method

```
BOOL DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified socket handle. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the socket has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a socket handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

EnableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::DisableSecurity Method

```
INT DisableSecurity();
```

The **DisableSecurity** method disables a secure session with the remote host.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableSecurity** method disables a secure session, with subsequent calls to **Read** and **Write** sending and receiving unencrypted data. It is important to note that because this method sends a shutdown message to terminate the secure session, this may cause connection to be closed by the remote host.

This method does not close the socket. Use the **Disconnect** method to close the socket and release the resources allocated for the current session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CreateSecurityCredentials, DeleteSecurityCredentials, EnableSecurity

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::Disconnect Method

```
BOOL Disconnect();
```

Terminate the connection, closing the socket and releasing the memory allocated for the session.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

Once the connection has been terminated, the class instance socket handle is no longer valid and should no longer be used. Note that it is possible that the actual handle value may be re-used at a later point when a new connection is established. An application should always consider the socket handle to be opaque and never depend on it being a specific value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Abort, Accept, Connect, DisableEvents, EnableEvents, Listen

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::EnableEvents Method

```
BOOL EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the socket notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a network event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a network event occurs. This allows an application to monitor the status of different socket operations.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
INET_EVENT_CONNECT	The connection to the remote host has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
INET_EVENT_DISCONNECT	The remote host has closed the connection to the client. The client should read any remaining data and disconnect.
INET_EVENT_READ	Data is available to be read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
INET_EVENT_WRITE	The application can now send data to the remote host. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a

	blocking operation. This event is only generated if the client is in asynchronous mode.
INET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The application may attempt to retry the operation, or may disconnect from the remote host and report an error to the user.
INET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

DisableEvents, RegisterEvent

CSocketWrench::EnableSecurity Method

```
BOOL EnableSecurity();

BOOL EnableSecurity(
   LPCTSTR lpszCertName
);

BOOL EnableSecurity(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);
```

The **EnableSecurity** method enables a secure session with the remote host.

Parameters

lpszCertStore

A null-terminated string which specifies the name of certificate store.

lpszCertName

A null-terminated string which specifies the common name for the certificate that will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **EnableSecurity** method enables a secure communications session with the remote host, automatically negotiating the encryption algorithm and validating the certificate. If the socket was created using the **Connect** method to establish a client connection, then **EnableSecurity** will initiate the handshake with the remote host to establish a secure session. If the **Accept** method was used to accept a connection from a client, then the method will block and wait for the remote host to initiate the handshake.

This method is useful if the application needs to establish an initial, non-secure connection to the remote host and then negotiate a secure connection at a later point. If the method succeeds, all subsequent calls to **Read** and **Write** to receive and send data will be encrypted.

If no arguments are specified, then the security credentials established with a previous call to **CreateSecurityCredentials** will be used. If a certificate name is specified, then the current security credentials will be updated to use that certificate.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CreateSecurityCredentials, DeleteSecurityCredentials, DisableSecurity

CSocketWrench::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::EnumNetworkAddresses Method

```
INT EnumNetworkAddresses(
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddressList,
   INT nMaxAddresses
);

INT EnumNetworkAddresses(
   LPINTERNET_ADDRESS lpAddressList,
   INT nMaxAddresses
);
```

The **EnumNetworkAddresses** method returns the list of network addresses that are configured for the local host.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this method. It may be one of the following values:

Value	Description
INET_ADDRESS_ANY	Return both IPv4 or IPv6 addresses assigned to the local host, depending on how the system is configured and which network interfaces are enabled. This option is only recommended for applications that require support for IPv6 connections.
INET_ADDRESS_IPV4	Return only the IPv4 addresses assigned to the local host. The first four bytes of the *ipNumber* array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Return only the IPv6 addresses assigned to the local host. All bytes in the *ipNumber* array are significant. This option is only recommended for those applications that require support for IPv6 connections.

lpAddressList

A pointer to an array of INTERNET_ADDRESS structures that will contain the IP address of each local network interface. This parameter may be NULL, in which case the method will only return the number of available addresses.

nMaxAddresses

Maximum number of addresses to be returned. If the *lpAddressList* parameter is NULL, this value must be zero.

Return Value

If the method succeeds, the return value is the number of network addresses that are configured for the local host. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

If the *nAddressFamily* parameter is specified as INET_ADDRESS_ANY, the application must be prepared to accept IPv6 addresses returned by this method. On Windows Vista and later versions of the operating system, IPv6 support is enabled and the local network adapter will have IPv6 addresses assigned to them by default. For legacy applications that only recognize IPv4 addresses, the *nAddressFamily* parameter should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

This method will ignore addresses that are bound to a disabled interface, as well as those addresses bound to a virtual loopback interface. For example, although the loopback address 127.0.0.1 is a valid network address, it will not be included in list of addresses returned by this method.

The first IPv4 or IPv6 address returned by this method is typically the address assigned to the primary network adapter on the local system. However, your application should not depend on addresses being returned in any particular order. If the system has virtualization software installed, this method may also include the IP addresses assigned to any virtualized network adapters installed by that software.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetAdapterAddress, GetHostAddress, GetLocalAddress

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::Flush Method

```
BOOL Flush();
```

The **Flush** method flushes the internal send and receive buffers used by the socket.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Flush** method will flush any data waiting to be read or written to the remote host . It is important to note that this method is not similar to flushing data to a disk file; it does not ensure that a specific block of data has been written to the socket. For example, you should never call this function immediately after calling the **Write** method or prior to calling the **Disconnect** method.

An application never needs to use the **Flush** method under normal circumstances. This method is only to be used when the application needs to immediately return the socket to an inactive state with no pending data to be read or written. Calling this function may result in data loss and should only be used if you understand the implications of discarding any data which has been sent by the remote host.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsReadable, IsWritable, Read, Write

CSocketWrench::FormatAddress Method

```
INT FormatAddress(
   LPINTERNET_ADDRESS lpAddress,
   LPTSTR lpszAddress,
   INT cchAddress
);

INT FormatAddress(
   LPINTERNET_ADDRESS lpAddress,
   CString& strAddress
);
```

The **FormatAddress** method converts a numeric IP address to a printable string. The format of the string depends on whether an IPv4 or IPv6 address is specified.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure which specifies the numeric IP address that should be converted to a string.

lpszAddress

The buffer that will contain the formatted IP address. This buffer should be at least 46 characters in length. This may also reference a **CString** object which will contain the formatted address when the method returns.

cchAddress

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is the length of the IP address string. If the method fails, the return value is INET_ERROR, meaning that the IP address could not be converted into a string. Typically this indicates that the pointer to the INTERNET_ADDRESS structure is invalid, or the data does not specify a valid IP address family.

Remarks

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::FreezeEvents Method

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the application.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all socket events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the program has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetAdapterAddress Method

```
INT GetAdapterAddress(
   INT nAdapterIndex,
   INT nAddressType,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetAdapterAddress(
   INT nAdapterIndex,
   INT nAddressType,
   CString& strAddress
);
```

Return the IP or MAC assigned to the specified network adapter.

Parameters

nAdapterIndex

An integer value that identifies the network adapter.

nAddressType

An integer value which specifies the type of address that should be returned:

Value	Description
INET_ADAPTER_IPV4	The address string will contain the primary IPv4 unicast address assigned to the network adapter.
INET_ADAPTER_IPV6	The address string will contain the primary IPv6 unicast address assigned to the network adapter.
INET_ADAPTER_MAC	The address string will contain the media access control (MAC) address assigned to the network adapter.

lpszAddress

A string buffer that will contain the IP or MAC address assigned to the adapter. This parameter cannot be NULL and it is recommended that it be at least 64 characters in length to provide enough space for any address type. An alternate form of the method accepts a **CString** argument which will contain the hostname.

nMaxLength

The maximum number of characters that can be copied into the string buffer, including the terminating null character. If the buffer is too small to store the complete address, this method will fail.

Return Value

If the method succeeds, the return value is the number of characters copied to the string buffer, not including the terminating null character. A return value of zero indicates that the requested address type has not been assigned to the adapter. If the method fails, the return value is INET_ERROR and this typically indicates that either the adapter index is invalid or the string buffer is not large enough to store the complete address. To get extended error information, call **GetLastError**.

Remarks

The **GetAdapterAddress** method will return the IPv4, IPv6 or MAC address assigned to a specific network adapter. The primary network adapter has an index value of zero, and it increments for each adapter that is configured on the local system.

The media access control (MAC) address is a 48 bit or 64 bit value that is assigned to each network interface and is used for identification and access control. All network devices on the same subnet must be assigned their own unique MAC address. Unlike IP addresses which may be assigned dynamically and can be frequently changed, MAC addresses are considered to be more permanent because they are usually assigned by the device manufacturer and stored in firmware. Note that in some cases it is possible to change the address assigned to a device, and virtual network interfaces may have configurable MAC addresses.

This method returns the MAC address string as sequence of hexadecimal values separated by a colon. An example of a 48 bit MAC address would be "01:23:45:67:89:AB". Note that some virtual network adapters may not have a MAC address assigned to them, in which case this method would return zero.

This method will ignore network adapters that have been disabled, as well as those that are bound to a virtual loopback interface. If the system has dial-up networking or virtualization software installed, this method may also return IP addresses assigned to a virtualized network adapters installed by that software.

Example

```
// Display the IPv4 address assigned to each network adapter
for (INT nIndex = 0;; nIndex++)
{
    CString strAddress;

    if (pSocket->GetAdapterAddress(nIndex, INET_ADAPTER_IPV4, strAddress) ==
INET_ERROR)
        break;

    _tprintf(_T("Adapter %d: %s\n"), nIndex, szAddress);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::GetAddress Method

```
INT GetAddress(
   LPCTSTR lpszAddress,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);

INT GetAddress(
   LPCTSTR lpszAddress,
   LPINTERNET_ADDRESS lpAddress
);
```

The **GetAddress** method converts an IP address string to binary format.

Parameters

lpszAddress

A null-terminated string which specifies an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address specified by the ***lpszAddress*** parameter. It may be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on the value of the ***lpszAddress*** parameter.
INET_ADDRESS_IPV4	Specifies that the address should be in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero. If the ***lpszAddress*** parameter does not specify a valid IPv4 address string, this method will fail.
INET_ADDRESS_IPV6	Specifies that the address should be in IPv6 format. All bytes in the ***ipNumber*** array are significant. If the ***lpszAddress*** parameter does not specify a valid IPv6 address string, this method will fail.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

If the ***nAddressFamily*** parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible that an IPv6 address string has been specified. For legacy applications that only recognize IPv4 addresses, the ***nAddressFamily*** member

should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned and any attempt to specify an IPv6 address string would result in an error.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the ***lpszAddress*** parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSocketWrench::GetAddressFamily Method

```
INT GetAddressFamily(
   LPCTSTR lpszAddress,
);
```

Return the address family for the specified IP address.

Parameters

lpszAddress

A null-terminated string which specifies an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

Return Value

If the method succeeds, the return value is the address family for the specified IP address and may be one of the values listed below. If the method fails, the return value is INET_ADDRESS_UNKNOWN. To get extended error information, call the **GetLastError** method.

Value	Description
INET_ADDRESS_IPV4	The address passed to the method is a valid IPv4 address.
INET_ADDRESS_IPV6	The address passed to the method is a valid IPv6 address.

Remarks

The **GetAddressFamily** method returns the address family associated with the specified IP address string. This can be used to determine if a string specifies a valid IPv4 or IPv6 address that can be passed to other methods such as **Connect**. Note that this method will not attempt to resolve hostnames, it will only accept IP addresses.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *lpszAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSocketWrench::GetDefaultHostFile Method

```
INT GetDefaultHostFile(
   LPTSTR lpszFileName,
   INT nMaxLength
);

INT GetDefaultHostFile(
   CString& lpszFileName
);
```

The **GetDefaultHostFile** method returns the fully qualified path name of the host file on the local system. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **GetHostAddress** and **GetHostNames** method. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

The location of the default host file depends on the operating system. For Windows 95/98 and Windows Me the file is stored in C:\Windows\hosts and for Windows NT and later versions the file is stored in C:\Windows\system32\drivers\etc\hosts. Regardless of platform, there is no filename extension and this file may or may not exist on a given system.

Parameters

lpszFileName

Pointer to a string buffer that will contain the fully qualified file name to the default host file. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the method will return the length of the string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the method succeeds, the return value is length of the string. A return value of zero indicates that the default host file could not be determined for the current platform. To get extended error information, call **GetLastError**.

Remarks

This method only returns the default location of the host file and does not determine if the file actually exists. It is not required that a host file be present on the system.

The default host file is processed before performing a nameserver lookup when resolving a hostname into an IP address, or an IP address into a hostname.

To specify an alternate local host file, use the **SetHostFile** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSocketWrench::GetExternalAddress Method

```
INT GetExternalAddress(
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress,
   INT nMaxLength
);

INT GetExternalAddress(
   INT nAddressFamily,
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetExternalAddress(
   INT nAddressFamily,
   CString& strAddress
);
```

The **GetExternalAddress** method returns the external IP address for the local system.

Parameters

nAddressFamily

An integer which identifies the type of IP address that should be returned by this function. It may be one of the following values:

Value	Description
INET_ADDRESS_ANY	Return any external IP address available. IPv4 addresses will be preferred over IPv6 for backwards compatibilty.
INET_ADDRESS_IPV4	Specifies that the external address should be in IPv4 format.
INET_ADDRESS_IPV6	Specifies that the external address should be in IPv6 format. If the local system does not have IPv6 enabled, the method will fail.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the external IP address of the local host in binary form.

lpszAddress

A null-terminated string buffer that will contain the external IP address of the local host.

nMaxLength

The maximum length of the string that will contain the IP address when the method returns.

Return Value

If the method succeeds, the return value is zero. If the function fails, it will return INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **GetExternalAddress** method returns the IP address assigned to the router that connects the local host to the Internet. This is typically used by an application executing on a system in a local network that uses a router which performs Network Address Translation (NAT). In that network configuration, the **GetLocalAddress** method will only return the IP address for the local system on the

LAN side of the network unless a connection has already been established to a remote host. The **GetExternalAddress** method can be used to determine the IP address assigned to the router on the Internet side of the connection and can be particularly useful for servers running on a system behind a NAT router.

An application should always check the return value in case there is an error. Never assume that the return value is always a valid address. The method may be unable to determine the external IP address for the local system for a number of reasons, particularly if it is behind a firewall or uses a proxy server that restricts access to external sites on the Internet. If the method is able to obtain a valid external address for the local host, that address will be cached by the library. If you are using a VPN (Virtual Private Network), this method will return the external IP address for the VPN adapter and not your local network connection. The **GetVpnAdapter** method can be used to obtain information about the active VPN adapter.

Calling this method may cause the current thread to block until the external IP address can be resolved and should never be used in conjunction with asynchronous socket connections. If you need to call this method in an application which uses asynchronous sockets, it is recommended that you create a background worker thread and call this method from within that thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CSocketWrench::GetFirstAlias Method

```
BOOL GetFirstAlias(
   LPCTSTR lpszHostName,
   LPTSTR lpszHostAlias,
   INT nMaxLength
);

BOOL GetFirstAlias(
   LPCTSTR lpszHostName,
   CString& strHostAlias
);
```

The **GetFirstAlias** method returns the first alias for the specified host name.

Parameters

lpszHostName

A null-terminated string which specifies the host name that you wish to return aliases for. This should be complete domain name.

lpszHostAlias

A string buffer which will contain the first alias for the specified host name. This string should be at least 64 bytes in length. This argument may also reference a **CString** object which will contain the host alias when the method returns.

nMaxLength

Maximum number of characters that can be copied into the *lpszHostAlias* string buffer, including the terminating null byte.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
CSocketWrench sockClient;
CString strHostAlias;
BOOL bResult;

m_ctlListBox.ResetContent();

bResult = sockClient.GetFirstAlias(m_strHostName, strHostAlias);
if (bResult == FALSE)
{
    sockClient.ShowError();
    return;
}

while (bResult)
{
    m_ctlListBox.AddString(strHostAlias);
    bResult = sockClient.GetNextAlias(strHostAlias);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetHandle Method

```
SOCKET GetHandle();
```

The **GetHandle** method returns the socket handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the socket handle associated with the current instance of the class object. If there is no active connection, the value INVALID_SOCKET will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CSocketWrench::GetHostAddress Method

```
INT GetHostAddress(
   LPCTSTR lpszHostName,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);

INT GetHostAddress(
   LPCTSTR lpszHostName,
   LPINTERNET_ADDRESS lpAddress
);
```

The **InetGetHostAddress** method resolves the specified host name into an IP address in binary format.

Parameters

lpszHostName

The name of the host to resolve; this may be a fully-qualified domain name or an IP address. This method recognizes the format for both IPv4 and IPv6 format addresses.

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on how the host name can be resolved. By default, a preference will be given for returning an IPv4 address. However, if the host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the *ipNumber* array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the *ipNumber* array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address of the specified host.

Return Value

If the method succeeds, the return value is zero. If the function fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

This method can also be used to convert an address in dot notation to a binary format. If the method must perform a DNS lookup to resolve the hostname, the calling thread will block. To ensure future

compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the ***ipFamily*** member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

The ***nAddressFamily*** parameter is used to specify a preference for the type of address returned, however it is possible that a host may not have an IPv4 or IPv6 address record, in which case this function will fail. Although IPv4 is still the most common address used at this time, an application should not assume that because a given host name does not have an IPv4 address, that the host name is invalid.

If the ***nAddressFamily*** parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible for a host name to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the ***nAddressFamily*** member should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the ***lpszHostName*** parameter specifies an host that only has an IPv6 (AAAA) DNS record.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetHostName, GetLocalAddress, GetLocalName, GetPeerAddress, IsProtocolAvailable, INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::GetHostFile Method

```
INT GetHostFile(
   LPTSTR lpszFileName,
   INT nMaxLength
);

INT GetHostFile(
   CString& strFileName
);
```

The **GetHostFile** method returns the name of the host file previously set using the **SetHostFile** method. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **GetHostAddress** and **GetHostNames** method.

Parameters

lpszFileName

Pointer to a string buffer that will contain the host file name. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the method will return the length of the string, not including the terminating null character.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the method succeeds, the return value is length of the string. A return value of zero indicates that no host file has been specified or the method was unable to determine the file name. To get extended error information, call **GetLastError**. If the last error is zero, this indicates that no host file name has been specified for the current thread. If the last error is non-zero, this indicates the reason that the method failed.

Remarks

This method only returns the name of the host file that is cached in memory for the current thread. The contents of the file on the disk may have changed after the file was loaded into memory. To reload the host file or clear the cache, call the **SetHostFile** method.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

The host file returned by this method may be different than the default host file for the local system. To determine the file name for the default host file, use the **GetDefaultHostFile** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetDefaultHostFile, GetHostAddress, GetHostName, SetHostFile

CSocketWrench::GetHostName Method

```
INT GetHostName(
   LPINTERNET_ADDRESS lpAddress,
   LPTSTR lpszHostName,
   INT cchHostName
);

INT GetHostName(
   LPINTERNET_ADDRESS lpAddress,
   CString& strHostName
);
```

The **GetHostName** method performs a reverse lookup, returning the host name associated with a given IP address.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure which specifies the IP address that should be resolved into a host name.

lpszHostName

The buffer that will contain the host name. It is recommended that this buffer be at least 256 characters in length to accommodate the longest possible fully qualified domain name.

cchHostName

The maximum number of characters that can be copied into the buffer.

Return Value

If the method succeeds, the return value is the length of the hostname. If the method fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

If the method must perform a reverse DNS lookup to resolve the IP address into a host name, the calling thread will block. This method requires that the host have a PTR record, otherwise it will fail. Because many hosts do not have a PTR record, calling this method frequently may have a negative impact on the overall performance of the application.

To determine if the local system has an IPv6 TCP/IP stack installed and configured on the local system, use the **IsProtocolAvailable** method. If an IPv6 stack is not installed, this method will fail if the *lpAddress* parameter specifies an IPv6 address, even if the address itself is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetErrorString, SetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::GetLocalAddress Method

```
INT GetLocalAddress(
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress,
   UINT *lpnPort
);

INT GetLocalAddress(
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetLocalAddress(
   CString& strAddress,
   UINT *lpnPort
);
```

The **GetLocalAddress** method returns the local IP address and port number for the current socket.

Parameters

nAddressFamily

An integer which identifies the type of IP address to return. It may be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	Return the IP address for the specified host in either IPv4 or IPv6 format, depending on the type of connection that was established. If the ***hSocket*** parameter is INVALID_SOCKET, a preference will be given for returning an IPv4 address. However, if the local host only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the address should be returned in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address should be returned in IPv6 format. All bytes in the ***ipNumber*** array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address of the local host. If there is no active connection, this function will attempt to determine the IP address of the local host assigned by the system. If the address is not required, this parameter may be NULL.

lpszAddress

A null-terminated string that will contain the IP address of the local host. If this version of the method is used, the IP address is converted to a string format using the **FormatAddress** method. The string should be able to store at least 46 characters to ensure that both IPv4 and IPv6

formatted addresses can be returned without the possibility of a buffer overrun. An alternate form of the method accepts a **CString** argument which will contain the local address.

lpnPort

A pointer to an unsigned integer that will contain the local port number. If there is an active connection, this parameter will be set to the local port that the socket is bound to. If there is no active connection, this parameter is ignored. If the local port number is not required, this parameter may be NULL.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

To ensure future compatibility with IPv6 networks, it is important that the application does not make any assumptions about the format of the address. If the function returns successfully, the ***ipFamily*** member of the **INTERNET_ADDRESS** structure should always be checked to determine the type of address.

If the ***nAddressFamily*** parameter is specified as INET_ADDRESS_UNKNOWN, the application must be prepared to handle IPv6 addresses because it is possible for the local host to have an IPv6 address assigned to it and no IPv4 address. For legacy applications that only recognize IPv4 addresses, the ***nAddressFamily*** member should always be specified as INET_ADDRESS_IPV4 to ensure that only IPv4 addresses are returned.

If the system is connected to the Internet through a local network and/or uses a router that performs Network Address Translation (NAT), the **GetLocalAddress** method will return the local, non-routable IP address assigned to the local system. To determine the public IP address has been assigned to the system, you should use the **GetExternalAddress** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::GetLocalName Method

```
INT GetLocalName(
   LPTSTR lpszHostName,
   INT cchHostName
);

INT GetLocalName(
   CString& strHostName
);
```

The **GetLocalName** method returns the hostname assigned to the local system.

Parameters

lpszHostName

The buffer that will contain the hostname. This parameter cannot be NULL. An alternate form of the method accepts a **CString** argument which will contain the local hostname.

cchHostName

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is the length of the hostname. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetMemoryUsage Method

```
SIZE_T GetMemoryUsage();
```

Return the amount of memory allocated for the network connection.

Parameters

None.

Return Value

If the method succeeds, the return value is the number of bytes allocated. If the method fails, the return value is zero. Call the **GetLastError** method to determine the cause of the failure.

Remarks

This method returns the amount of memory allocated for the socket. It enumerates all heap allocations made by the process and returns the total number of bytes allocated for the current socket handle. This value only reflects the amount of memory explicitly allocated by this class library and does not reflect the total working set size of the process, or memory allocated by any other libraries. To determine the working set size for the process, refer to the Win32 **GetProcessWorkingSetSize** and **GetProcessMemoryInfo** functions.

This method forces the current thread into a locked state, and all network operations will block until the method returns. Because this method enumerates all heaps created for the process, it can be an expensive operation, particularly when a large number of connections have been established. Frequent use of this method can significantly degrade the performance of the application. It is primarily intended for use as a debugging tool to determine if memory usage is the result of an increase in active network connections. If the value returned by the method remains reasonably constant, but the amount of memory allocated for the process continues to grow, it could indicate a memory leak in some other area of the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::GetNextAlias Method

```
BOOL GetNextAlias(
   LPTSTR lpszHostAlias,
   INT nMaxLength
);

BOOL GetNextAlias(
   CString& strHostAlias
);
```

The **GetNextAlias** method returns the next alias for the host name specified in the call to **GetFirstAlias**.

Parameters

lpszHostAlias

A string buffer which will contain the next alias for the specified host name. This string should be at least 64 bytes in length. This argument may also reference a **CString** object which will contain the host alias when the method returns.

nMaxLength

Maximum number of characters that can be copied into the *lpszHostAlias* string buffer, including the terminating null byte.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Example

```
CSocketWrench sockClient;
CString strHostAlias;
BOOL bResult;

m_ctlListBox.ResetContent();

bResult = sockClient.GetFirstAlias(m_strHostName, strHostAlias);
if (bResult == FALSE)
{
    sockClient.ShowError();
    return;
}

while (bResult)
{
    m_ctlListBox.AddString(strHostAlias);
    bResult = sockClient.GetNextAlias(strHostAlias);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetOption Method

```
INT GetOption(
   DWORD dwOption,
   LPBOOL lpbEnabled
);
```

The **GetOption** method is used to determine if a specific socket option has been enabled.

Parameters

dwOption

An unsigned integer used to specify one of the socket options. These options cannot be combined. The following values are recognized:

Value	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.

lpbEnabled

A pointer to a boolean flag. If the option is enabled, the flag is set to a non-zero value, otherwise it is set to a value of zero.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Connect, SetOption

CSocketWrench::GetPeerAddress Method

```
INT GetPeerAddress(
   LPINTERNET_ADDRESS lpAddress,
   UINT *lpnRemotePort
);

INT GetPeerAddress(
   LPTSTR lpszAddress,
   INT nMaxLength
);

INT GetPeerAddress(
   CString& strAddress
);
```

The **GetPeerAddress** method returns the peer IP address and remote port number for the specified socket.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address of the remote host that is connected to the socket.

lpnRemotePort

A pointer to an unsigned integer that will contain the port number of the remote host that is connected to the socket.

lpszAddress

A null-terminated string buffer that will contain the formatted IP address, terminated with a null character. To accommodate both IPv4 and IPv6 addresses, this buffer should be at least 46 characters in length.

nMaxLength

The maximum number of characters that can be copied into the address buffer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

If this method is called by a server application in response to a INET_EVENT_ACCEPT event, it will return the IP address and port number for the client that is attempting to establish the connection. If the peer address is unavailable, the ***ipFamily*** member of the INTERNET_ADDRESS structure will be zero.

The format and length of IPv4 and IPv6 address strings are very different. An IPv4 address string looks like "192.168.0.20", while an IPv6 address string can look something like "fd7c:2f6a:4f4f:ba34::a32". If your application checks for the format of these address strings, it needs to be aware of the differences. You also need to make sure that you're providing enough space to display or store an address to avoid buffer overruns.

It is not recommended that you use the port number for anything other than informational and logging purposes. Server applications should not make any assumptions about the specific port

number or range of port numbers that a client is using when establishing a connection to the server. The ephemeral port number that a client is bound to can vary based on the client operating system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetHostAddress, GetHostName, GetLocalAddress, GetLocalName, GetPeerPort, INTERNET_ADDRESS

CSocketWrench::GetPhysicalAddress Method

```
BOOL GetPhysicalAddress(
   LPTSTR lpszAddress,
   UINT cchAddress
);

BOOL GetPhysicalAddress(
   CString& strAddress
);
```

Return the media access control (MAC) address for the primary network adapter.

Parameters

lpszAddress

A string buffer that will contain the address in a printable format when the function returns. This parameter cannot be NULL. An alternate form of the method accepts a **CString** argument which will contain the address.

cchAddress

The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetPhysicalAddress** method returns the media access control (MAC) address for the primary network adapter. This is a 48 bit or 64 bit address that is assigned to each network interface and is used for identification and access control. All network devices on the same subnet must be assigned their own unique MAC address. Unlike IP addresses which may be assigned dynamically and can be frequently changed, MAC addresses are considered to be more permanent because they are usually assigned by the device manufacturer and stored in firmware. Note that in some cases it is possible to change the address assigned to a device, and virtual network interfaces may have configurable MAC addresses.

This method returns the MAC address as a printable string, with each byte of the address as a two-digit hexadecimal value separated by a colon. The string buffer passed to the method should be at least 20 characters long to accommodate the address and terminating null character. An example of a 48 bit address would be "01:23:45:67:89:AB". If the local system is multi-homed (having more than one network adapter) then this method will return the MAC address for the primary network adapter.

This method is provided for backwards compatibility with previous versions of the library and it is recommended that new applications use the **GetAdapterAddress** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetSecurityInformation Method

```
BOOL GetSecurityInformation(
   LPSECURITYINFO lpSecurityInfo
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;
securityInfo.dwSize = sizeof(SECURITYINFO);

if (pSocket->GetSecurityInformation(&securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetServiceName Method

```
BOOL GetServiceName(
   UINT nServicePort,
   LPTSTR lpszServiceName,
   INT nMaxLength
);

BOOL GetServiceName(
   UINT nServicePort,
   CString& strServiceName
);
```

The **GetServiceName** method returns the service name associated with a specified port number.

Parameters

nServicePort

Port number associated with some network service.

lpszServiceName

A null-terminated string buffer that will contain the service name when the method returns. This may also reference a **CString** object that will contain the service name.

nMaxLength

An integer value which specifies the maximum number of characters that can be copied into the string buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetServicePort Method

```
UINT GetServicePort(
   LPCTSTR lpszServiceName
);
```

The **GetServicePort** method returns the port number associated with a service name.

Parameters

lpszServiceName

A null-terminated string which specifies the name of the service to return the port number for.

Return Value

If the method succeeds, the return value is the port number associated with a service name. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method returns the current status of the socket.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value is one of the following values:

Value	Description
INET_STATUS_UNUSED	No connection has been established.
INET_STATUS_IDLE	The socket is idle and not in a blocked state
INET_STATUS_LISTEN	The socket is listening for inbound connections from a client
INET_STATUS_CONNECT	The socket is establishing a connection with a server
INET_STATUS_ACCEPT	The socket is accepting a connection from a client
INET_STATUS_READ	Data is being read from the socket
INET_STATUS_WRITE	Data is being written to the socket
INET_STATUS_FLUSH	The socket is being flushed; all data in the receive buffers is being discarded
INET_STATUS_DISCONNECT	The socket is disconnecting from the remote host

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified socket.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::GetStreamInfo Method

```
BOOL GetStreamInfo(
   LPINETSTREAMINFO lpStreamInfo
);
```

The **GetStreamInfo** function fills a structure with information about the current stream I/O operation.

Parameters

lpSecurityInfo

A pointer to an INETSTREAMINFO structure which contains information about the status of the network stream.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetStreamInfo** method returns information about the current streaming socket operation, including the average number of bytes transferred per second and the estimated amount of time until the operation completes. If there is no operation currently in progress, this method will return the status of the last successful streaming read or write performed by the client.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified socket.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the remote host. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

GetUrlHostName Method

```
INT GetUrlHostName(
   LPCTSTR lpszUrl,
   LPTSTR lpszHostName,
   INT nMaxLength,
   UINT *lpnHostPort,
   UINT *lpnProtocol,
   DWORD *lpdwOptions
);

INT GetUrlHostName(
   LPCTSTR lpszUrl,
   CString& strHostName,
   UINT *lpnHostPort,
   UINT *lpnProtocol,
   DWORD *lpdwOptions
);
```

The **GetUrlHostName** method returns the host name and port number specified in a URL.

Parameters

lpszUrl

A null-terminated string which specifies a URL. This parameter cannot be NULL or point to an empty string. If a non-standard URI scheme is used, the port number must be explicitly specified or the method will fail. See the remarks below for more information on the format supported by this method.

lpszHostName

Pointer to the string buffer that will contain the canonical form of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer and must be large enough to store the complete host name. An alternate version of this method accepts a reference to a **CString** object if MFC or ATL is used with the project.

nMaxLength

The maximum number of characters that can be copied to the ***lpszHostName*** string buffer. This parameter cannot be zero, and must include the terminating null character.

lpnHostPort

Pointer to an optional unsigned integer value which will contain the port number specified in the URL. This parameter value will always be initialized by the method with a value of zero. If this parameter is omitted or NULL, it will be ignored and no port information will be returned.

lpnProtocol

Pointer to an optional unsigned integer value which will contain the protocol associated with the URI scheme. This parameter value will always be initialized by the method with a value of zero. If this parameter is omitted or NULL, it will be ignored and no protocol information will be returned.

lpdwOptions

Pointer to an optional unsigned integer value which will contain any socket options required to establish a connection based on the URI scheme or specified port. This parameter value will always be initialized by the method with a value of zero. If this parameter is omitted or NULL, it will be ignored.

Return Value

If the method succeeds, the return value is the number of characters copied into the *lpszHostName* buffer. If the method fails, the return value is INET_ERROR. To get extended error information, call the **GetLastError** method.

Remarks

The **GetUrlHostName** method will extract the host name and port number from a URL and return the canonical form of the host name. If the *lpnHostPort*, *lpnProtocol* and *lpdwOptions* parameters have been specified, they will contain the port number, protocol and additional connection options associated with the URL scheme.

The general format of the URL should look like this:

```
[scheme]:// [[username : password] @] hostname [:port] / [path;parameters
...]
```

This method recognizes most standard URI schemes which use this format. The host name and port number specified in the URL will be used to establish a connection and the remaining information will be discarded. If the URL does not explicitly specify a port number, the default port number associated with the scheme will be used as the default value. For example, consider the following:

```
https://www.example.com/
```

In this example, there is no port number specified; instead, the default port for the **https://** scheme would be used, which is port 443. This method will also recognize a simpler format which only includes the host name and port number without a URI scheme, such as:

```
www.example.com:443
```

If the *lpszUrl* parameter only specifies a host name without a URI scheme or port number, this method will ignore the *lpnHostPort*, *lpnProtocol* and *lpdwOptions* parameters and return the canonical form of the host name in the *lpszHostName* string argument.

The host name portion of the URL can be specified as either a domain name or an IP address. Because an IPv6 address can contain colon characters, you must enclose the entire address in bracket [] characters. If this is not done, the method will return an error indicating the port number is invalid. For example, the URL `https://[2001:db8:0:0:1::128]/` uses an IPv6 host address and this would be considered valid. Without the brackets, this URL would not be accepted.

If the URL uses an IP address instead of a host name, this method will return a copy of that IP address in the *lpszHostName* string provided by the caller. The method will not attempt to resolve the IP address into a host name, however you can use the **GetHostName** method to perform a reverse DNS lookup if required.

The only URI schemes currently supported by this method use TCP stream connections. In practical terms, this means the *lpnProtocol* parameter will always return with the value INET_PROTOCOL_TCP when the method is successful. If the method fails, this value will be INET_PROTOCOL_NONE.

Although this method performs checks to ensure that the *lpszUrl* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the host name. To check if the host name exists and has a valid IP address, use the **ValidateHostName** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h

Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::GetVpnAdapter Method

```
BOOL GetVpnAdapter(
   LPTSTR lpszAdapterName,
   INT nMaxLength,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);

BOOL GetVpnAdapter(
   CString &strAdapterName,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);
```

The **GetVpnAdapter** method returns the name of the active VPN adapter.

Parameters

lpszAdapterName

A null-terminated string buffer which will contain the name of the active VPN adapter if one is found. If a VPN was not detected, the buffer will contain an empty string when the method returns. This parameter may be NULL if the adapter name is not required. An alternate version of this method accepts a reference to a **CString** object which will contain the adapter name when the method returns.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null character. If this value is zero, the ***lpszAdapterName*** parameter is ignored.

nAddressFamily

An optional integer value which identifies the type of IP address to return. It may be one of the following values:

Value	Description
INET_ADDRESS_ANY	Return the IP address for the adapter in either IPv4 or IPv6 format, depending on how the host name can be resolved. By default, a preference will be given for returning an IPv4 address. However, if the adapter only has an IPv6 address, that value will be returned.
INET_ADDRESS_IPV4	Specifies that the adapter address should be returned in IPv4 format. The first four bytes of the ***ipNumber*** member of the INTERNET_ADDRESS structure are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the adapter address should be returned in IPv6 format. All bytes in the ***ipNumber*** member of the INTERNET_ADDRESS structure are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the IP address assigned to the VPN adapter when the function returns. This parameter may be NULL or omitted if this information is not required. If this parameter is NULL, the value of the ***nAddressFamily*** parameter is ignored.

Return Value

If the method succeeds, the return value is non-zero if an active VPN adapter was found. If no VPN adapter was detected, this method will return zero.

Remarks

The **GetVpnAdapter** method provides a best-effort method to detect if the system is currently using a Virtual Private Network (VPN) connection. The detection logic is based on identifying active network adapters with names or descriptions that match known VPN software or common VPN adapter naming conventions, while explicitly excluding adapters associated with virtualization platforms (such as Hyper-V, VMware, and VirtualBox), loopback interfaces, and other non-VPN virtual adapters.

Because there is no industry standard for how VPN clients are identified at the network adapter level, this method uses a heuristic approach and cannot guarantee detection in every scenario. Some VPN clients may use custom adapter names or attempt to obscure their presence, and new VPN software may not be recognized until the internal detection list is updated. There is also a small chance that non-VPN software using similar naming conventions could result in a false positive.

The result of this method should be treated as a hint for diagnostic or troubleshooting purposes. It should not be used to restrict access to your application or deny service to users based solely on the possible presence of a VPN connection. If you specify an address family and the ***lpAddress*** parameter is not NULL, it will contain the first IP address bound to the adapter interface. It is possible for VPN adapters to be bound to multiple IP addresses. The **FormatAddress** method can be used to convert the INTERNET_ADDRESS value to a printable string.

The adapter name returned by this method is the description of the detected VPN adapter, encoded as a UTF-8 string in the ANSI version of this function. If you require more detailed network information, consider using the **EnumNetworkAddresses** method. You can use the **GetExternalAddress** method to obtain the public-facing IP address allocated for the client.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::HostNameToUnicode Method

```
INT HostNameToUnicode(
   LPCTSTR lpszHostName,
   LPTSTR lpszUnicodeName,
   INT nMaxLength
);

INT HostNameToUnicode(
   LPCTSTR lpszHostName,
   CString& strUnicodeName
);
```

The **HostNameToUnicode** method converts the canonical form of a host name to its Unicode version.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero-length string.

lpszUnicodeName

Pointer to the string buffer that will contain the original Unicode version of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer. An alternate version of this method accepts a reference to a **CString** object if MFC or ATL is used with the project.

nMaxLength

The maximum number of characters that can be copied to the *lpszUnicodeName* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **HostNameToUnicode** method will convert the encoded ASCII version of a host name to its Unicode version. Although any valid host name is accepted by this method, it is intended to convert a Punycode encoded host name to its original Unicode character encoding.

If the application is compiled using the Unicode character set, the value returned in *lpszUnicodeName* will be a Unicode string using UTF-16 encoding. If the ANSI character set is used, the value returned will be a Unicode string using UTF-8 encoding. To display a UTF-8 encoded host name, your application will need to convert it to UTF-16 using the **MultiByteToWideChar** function.

Although this method performs checks to ensure that the *lpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the GetHostAddress method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::IsAddressNull Method

```
BOOL IsAddressNull(
   LPCTSTR lpszAddress
);

BOOL IsAddressNull(
   LPINTERNET_ADDRESS lpAddress
);
```

The **IsAddressNull** method determines if the IP address is null.

Parameters

lpszAddress

A string that specifies the IP address.

lpAddress

A pointer to an INTERNET_ADDRESS structure that specifies the IP address.

Return Value

If the method succeeds and the IP address is null, or the parameter is a NULL pointer, the return value is non-zero. If the method fails or the address is not null, the return value is zero. If the address family is not supported, the last error code will be updated. If the address is valid but not null, the last error code will be set to NO_ERROR.

Remarks

A null IP address is one where all bits for the address (32 bits for IPv4 or 128 bits for IPv6) are zero. This is a special address that is typically used when creating a passive socket that should listen for connections on all available network interfaces.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetAddress, IsAddressRoutable, INTERNET_ADDRESS

CSocketWrench::IsAddressRoutable Method

```
BOOL IsAddressRoutable(
   LPCTSTR lpszAddress
);

BOOL IsAddressRoutable(
   LPINTERNET_ADDRESS lpAddress
);
```

The **IsAddressRoutable** method determines if the IP address is routable over the Internet.

Parameters

lpszAddress

A string that specifies the IP address.

lpAddress

A pointer to an INTERNET_ADDRESS structure that specifies the IP address.

Return Value

If the method succeeds and the IP address is routable over the Internet, the return value is non-zero. If the method fails or the address is not routable, the return value is zero. If the parameter is NULL, or the address family is not supported, the last error code will be updated. If the address is valid but not routable, the last error code will be set to NO_ERROR.

Remarks

A routable IP address is one that can be reached by anyone over the public Internet. These are also commonly referred to as "public addresses" which are typically assigned to networks and individual hosts by an Internet service provider. There are also certain addresses that are not routable over the Internet, and used to address systems over a local network or private intranet. This function can be used to determine if a given IP address is public (routable) or private.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the socket is performing a blocking operation.

Parameters

None.

Return Value

If the socket is currently performing a blocking operation, the method returns a non-zero value. If the socket is not performing a blocking operation, or the socket handle is invalid, the method returns zero.

Remarks

This method is typically used to determine if a socket that is being used by another thread is currently blocked. A socket may block when waiting to receive data from a remote host or while data is actively being exchanged. Because there can only be one blocking socket operation per thread, this method can be used to determine if a method such as **Read** or **Write** would fail because another thread is currently sending or receiving data on that socket.

It is important to note that if this method returns a non-zero value, it does not guarantee that a subsequent read or write on the socket will succeed. The application should always check the return value from methods such as **Read** and **Write** to ensure they were successful.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CSocketWrench::IsClosed Method

```
BOOL IsClosed();
```

The **IsClosed** method is used to determine if the remote host has closed its socket.

Parameters

None.

Return Value

If the remote host has closed its socket, the method returns a non-zero value. If the remote host has not closed its connection, or the socket handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the socket is currently connected to a remote host.

Parameters

None.

Return Value

If the client is connected to a remote host, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

GetStatus, IsBlocking, IsInitialized, IsReadable, IsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::IsListening Method

```
BOOL IsListening();
```

The **IsListening** method determines if the socket is listening for connection requests.

Parameters

None.

Return Value

If the socket is being used to listen for connection requests, the method returns a non-zero value. If the socket is not listening or the socket handle is invalid, the method returns zero.

Remarks

The **IsListening** method determines if the socket is being used in a server application to actively listen for incoming connection requests from client applications. A listening socket can be created using the **Listen** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::IsProtocolAvailable Method

```
BOOL IsProtocolAvailable(
   INT nAddressFamily,
   INT nProtocol
);
```

The **IsProtocolAvailable** method determines if the operating system supports creating a socket for the specified address family and protocol.

Parameters

nAddressFamily

An integer which identifies the address family that should be checked. It should be one of the following values:

Value	Description
INET_ADDRESS_IPV4	Specifies that the function should determine if it can create an Internet Protocol version 4 (IPv4) socket. This requires that the system have an IPv4 TCP/IP stack bound to at least one network adapter on the local system. All Windows systems include support for IPv4 by default.
INET_ADDRESS_IPV6	Specifies that the function should determine if it can create an Internet Protocol version 6 (IPv6) socket. This requires that the system have an IPv6 TCP/IP stack bound to at least one network adapter on the local system. Windows XP and Windows Server 2003 includes support for IPv6, however it is not installed by default. Windows Vista and later versions include support for IPv6 and enable it by default.

nProtocol

An integer which identifies the protocol that should be checked. It should be one of the following values:

Value	Description
INET_PROTOCOL_TCP	Specifies the Transmission Control Protocol. This protocol provides a reliable, bi-directional byte stream. This requires that the system be capable of creating a stream socket using the specified address family.
INET_PROTOCOL_UDP	Specifies the User Datagram Protocol. This protocol is message oriented, sending data in discrete packets. This requires that the system be capable of creating a datagram socket using the specified address family.

Return Value

If the system is capable of creating a socket using the specified address family and protocol, this method will return a non-zero value. If the combination of address family and protocol is not supported, this method will return a value of zero.

Remarks

The **IsProtocolAvailable** method is used to determine if the operating system supports creating a particular type of socket. Typically it is used by an application to determine if the system has an IPv6 TCP/IP stack installed and configured. By default, all Windows systems will have an IPv4 stack installed if the system has a network adapter. However, not all systems may have an IPv6 stack installed, particularly older Windows XP and Windows Server 2003 systems. Note that if an IPv6 stack is not installed, the library will not recognize IPv6 addresses and cannot resolve host names that only have an IPv6 (AAAA) record, even if the address or host name is valid.

Example

```
if (!pSocket->IsProtocolAvailable(INET_ADDRESS_IPV6, INET_PROTOCOL_TCP))
{
    AfxMessageBox(_T("This system does not support IPv6"), MB_ICONEXCLAMATION);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::IsReadable Method

```
BOOL IsReadable(
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the remote host.

Parameters

nTimeout

Timeout for remote host response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the current thread can read data from the socket without blocking, the method returns a non-zero value. If the current thread cannot read any data without blocking, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

If the connection is secure, the value returned in ***lpdwAvail*** will reflect the number of bytes available in the encrypted data stream. The actual amount of data available to the application after it has been decrypted will vary.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

IsWritable, Peek, Read, ReadLine, ReadStream

CSocketWrench::IsUrgent Method

```
BOOL IsUrgent();
```

The **IsUrgent** method determines if there is any out-of-band (OOB) data available to be read.

Parameters

None.

Return Value

If there is out-of-band data, the return value is non-zero. If there is no out-of-band data, or an error occurs the return value is zero. To determine if an error has occurred, use the **GetLastError** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

SetOption (INET_OPTION_INLINE)

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::IsWritable Method

```
BOOL IsWritable(
   INT nTimeout
);
```

The **IsWritable** method is used to determine if data can be written to the remote host.

Parameters

nTimeout

Timeout for remote host response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If data can be written to the socket within the specified timeout period, the method returns a non-zero value. The method will return zero if the socket send buffer is full.

Remarks

The **IsWritable** method cannot be used to determine the amount of data that can be sent to the remote host without blocking the current thread. A non-zero return value only indicates that the send buffer is not full and can accept some data. In most cases, it is recommended that larger blocks of data be broken into smaller logical blocks rather than attempting to send it all of the data at once. For very large streams of data, it is recommended that you use the **WriteStream** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CSocketWrench::Listen Method

```
SOCKET Listen(
   LPCTSTR lpszLocalAddress,
   UINT nLocalPort,
   UINT nBacklog,
   DWORD dwOptions
);
```

The **Listen** method creates a listening socket and specifies the maximum number of connection requests that will be queued.

This method has been deprecated and is included for backwards compatibility. Use the **CInternetServer** class to create a server application.

Parameters

lpszLocalAddress

A null-terminated string which specifies the local IP address that the socket should be bound to. If this parameter is NULL or points to an empty string, a client may establish a connection using any valid network interface configured on the local system. If an address is specified, then a client may only establish a connection with the system using that address.

nLocalPort

The local port number that the socket should be bound to. This value must be greater than zero. Port numbers less than 1024 are considered reserved ports and may require that the process execute with administrative privileges and/or require changes to the default firewall rules to permit inbound connections.

nBacklog

The maximum length of queue of pending connections. On Windows workstations, the maximum backlog value is 5. On Windows servers, the maximum value is 200.

dwOptions

An unsigned integer used to specify one or more socket options. The following values are recognized:

Value	Description
INET_OPTION_NONE	No option specified. If the address and port number are in use by another application or a closed socket which was listening on this port is still in the TIME_WAIT state, the function will fail.
INET_OPTION_REUSEADDRESS	This option enables a server application to listen for connections using the specified address and port number even if they were in use recently. This is typically used to enable an application to close the listening socket and immediately reopen it without getting an error that the address is in use.
INET_OPTION_EXCLUSIVE	This option specifies the local address and port number is for the exclusive use by the current process, preventing another application from forcibly binding to the same address. If another process has already bound a socket to

	the address provided by the caller, this function will fail.
INET_OPTION_NOINHERIT	This option prevents the socket handle from being inherited by child processes created by the application. Using this option can mitigate situations in which a child process does not close the handle, leaving it open after the parent process has disconnected from the server.

Return Value

If the method succeeds, the return value is a handle to the socket. If the method fails, the return value is INVALID_SOCKET. To get extended error information, call **GetLastError**.

Remarks

To listen for connections on any suitable IPv4 interface, specify the special dotted-quad address "0.0.0.0". You can accept connections from clients using either IPv4 or IPv6 on the same socket by specifying the special IPv6 address "::0", however this is only supported on Windows 7 and Windows Server 2008 R2 or later platforms. If no local address is specified, then the server will only listen for connections from clients using IPv4. This behavior is by design for backwards compatibility with systems that do not have an IPv6 TCP/IP stack installed.

If the INET_OPTION_REUSEADDRESS option is not specified, an error may be returned if a listening socket was recently created for the same local address and port number. By default, once a listening socket is closed there is a period of time that all applications must wait before the address can be reused (this is called the TIME_WAIT state). The actual amount of time depends on the operating system and configuration parameters, but is typically two to four minutes. Specifying this option enables an application to immediately re-use a local address and port number that was previously in use. Note that this does not permit more than one server to bind to the same address.

If the INET_OPTION_EXCLUSIVE option is specified, the local address and port number cannot be used by another process until the listening socket is closed. This can prevent another application from forcibly binding to the same listening address as your server. This option can be useful in determining whether or not another process is already bound to the address you wish to use, but it may also prevent your server application from restarting immediately, regardless if the INET_OPTION_REUSEADDRESS option has also been specified.

If an IPv6 address is specified as the local address, the system must have an IPv6 stack installed and configured, otherwise the method will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::MatchHostName Method

```
BOOL MatchHostName(
   LPCTSTR lpszHostName,
   LPCTSTR lpszHostMask
   BOOL bResolve
);
```

The **MatchHostName** method matches a host name against one more strings that may contain wildcards.

Parameters

lpszHostName

A null-terminated string which specifies the host name or IP address to match.

lpszHostMask

A null-terminated string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

bResolve

A boolean value which specifies if the host name or IP address should be resolved when matching the host against the mask string. If this parameter is non-zero, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is zero, then the match is made only against the host name string provided.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **MatchHostName** method provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the method would return a non-zero value indicating the host name matched the mask. However, if the mask string was "*.net" then the method would return zero, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

If an internationalized domain name (IDN) is specified, it will be converted internally to an ASCII string using Punycode encoding. The host mask will be matched against this encoded version of the host name, not its Unicode version.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetAddress, GetHostAddress, GetHostName, GetLocalAddress, GetPeerAddress

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NormalizeHostName Method

```
INT NormalizeHostName(
   LPCTSTR lpszHostName,
   LPTSTR lpszNormalized,
   INT nMaxLength
);

NormalizeHostName(
   LPCTSTR lpszHostName,
   CString& strNormalized
);
```

The **NormalizeHostName** method returns the canonical form of a host name in the specified buffer.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero-length string.

lpszNormalized

Pointer to the string buffer that will contain the canonical form of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer and must be large enough to store the complete host name. An alternate form of this method will accept a reference to a **CString** object if MFC or ATL is used with the project.

nMaxLength

The maximum number of characters that can be copied to the *lpszNormalized* string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the method succeeds, the return value is the number of characters copied into the string buffer. If the method fails, the return value is INET_ERROR. To get extended error information, call **InetGetLastError**.

Remarks

The **NormalizeHostName** method will remove all leading and trailing whitespace characters from the host name and fold all upper-case characters to lower-case. If an internationalized domain name (IDN) containing Unicode characters is passed to this method, it will be converted to an ASCII compatible format for domain names.

The *lpszHostName* parameter should only specify a host name or IP address. If you want to support the use of URLs to establish a connection, use the **GetUrlHostName** method which has extended support for extracting the host name and port number specified in a URL.

If the Unicode version of this method is used, the host name will be converted from UTF-16 to UTF-8 and then processed. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended you use the Unicode version.

Although this method performs checks to ensure that the *lpszHostName* parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the **ValidateHostName** method.

It is recommended that you use this method if your application needs to store the host name, and if accepts a host name as user input. It is not necessary to call this method prior to calling the other SocketWrench methods which accept a host name as a parameter. Those methods already normalize the host name and perform checks to ensure it is in the correct format.

If the *lpszHostName* parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this method will return a copy of that IP address in the buffer provided by the caller. This allows the method to be used in cases where a user may input either a host name or IP address. To determine if the IP address has a corresponding host name, use the **GetHostName** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::Peek Method

```
INT Peek(
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **Peek** method reads the specified number of bytes from the socket and copies them into the buffer, but it does not remove the data from the internal socket buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be stored. This argument may be NULL, in which case no data is copied from the socket buffers, however the function will return the number of bytes available to read.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. If the ***lpBuffer*** parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes available to read from the socket. A return value of zero indicates that there is no data available to read at that time. If the function fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Peek** method returns data that is available to read from the socket, up to the number of bytes specified. The data returned by this method is not removed from the socket buffers. It must be consumed by a subsequent call to the **Read** method. The return value indicates the number of bytes that can be read in a single operation, up to the specified buffer size. However, it is important to note that it may not indicate the total amount of data available to be read from the socket at that time.

If no data is available to be read, the method will return a value of zero. Using this method in a loop to poll a non-blocking socket may cause the application to become non-responsive. To determine if there is data available to be read, use the **IsReadable** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

EnableEvents, IsBlocking, IsReadable, IsWritable, Read, ReadLine, RegisterEvent, Write, WriteLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::Read Method

```
INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer,
   LPINTERNET_ADDRESS lpAddress,
   UINT *lpnRemotePort
);
```

The **Read** method reads the specified number of bytes from the socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be stored.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

lpAddress

Pointer to an INTERNET_ADDRESS structure that which will contain the IP address of the remote host that sent the data being read. If this information is not required, the parameter may be specified as NULL.

lpnRemotePort

Pointer to an unsigned integer which will contain the remote port number. If this information is not required, the parameter may be specified as NULL.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the remote host has closed the connection and there is no more data available to be read. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **Read** method will read up to the specified number of bytes and store the data in the buffer provided by the caller. If there is no data available to be read at the time this method is invoked, the session thread will block until at least one byte of data becomes available, the timeout period elapses or an error occurs. This method will return if any amount of data is sent by the remote host, and will not block until the entire buffer has been filled. To avoid blocking the current thread, either create an asynchronous socket or use the **IsReadable** method to determine if there is data available to be read prior to calling this function.

The application should never make an assumption about the amount of data that will be available to read. TCP considers all data to be an arbitrary stream of bytes and does not impose any structure on the data itself. For example, if the remote host is sending data to the server in fixed 512 byte blocks of data, it is possible that a single call to the **Read** method will return only a partial block of data, or it

may return multiple blocks combined together. It is the responsibility of the application to buffer and process this data appropriately.

For applications that are built using the Unicode character set, it is important to note that the buffer is an array of bytes, not characters. If the remote host is sending string data to the server, it must be read as a stream of bytes and converted using the **MultiByteToWideChar** function. If the remote host is sending lines of text terminated with a linefeed or carriage return and linefeed pair, the **ReadLine** method will return a line of text at a time and perform this conversion for you.

When **Read** is called and the socket is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CSocketWrench::ReadLine Method

```
BOOL ReadLine(
   LPTSTR lpszBuffer,
   LPINT lpnLength
);

BOOL ReadLine(
   LPTSTR lpszBuffer,
   INT nMaxLength
);

BOOL ReadLine(
   CString& strBuffer,
   INT nMaxLength
);
```

The **ReadLine** method reads up to a line of data from the socket and returns it in a string buffer.

Parameters

lpszBuffer

Pointer to the string buffer that will contain the data when the method returns. The string will be terminated with a null character, and will not contain the end-of-line characters. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the method returns, its value will updated with the actual length of the string.

nMaxLength

An integer value which specifies the maximum length of the buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadLine** method reads data from the socket and copies into a specified string buffer. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **ReadLine**. The method should only be used to read text, never binary data. In particular, the method will discard nulls, linefeed and carriage return control characters. The Unicode version of this method will return a Unicode string, however it does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the remote host closes its end of the socket connection. If this method is

called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **ReadLine** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **Read** and **ReadLine** method calls can be intermixed, however be aware that **Read** will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

Unlike the **Read** method, it is possible for data to be returned in the string buffer even if the return value is zero. Applications should check the length of the string to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the return value.

Example

```
CString strBuffer;
BOOL bResult;

do
{
    bResult = pSocket->ReadLine(strBuffer);

    if (strBuffer.GetLength() > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = pSocket->GetLastError();

if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The remote host has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::ReadStream Method

```
BOOL ReadStream(
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions,
   LPBYTE lpMarker,
   DWORD cbMarker
);
```

The **ReadStream** method reads the socket data stream and stores the contents in the specified buffer.

Parameters

lpvBuffer

Pointer to the buffer that will contain or reference the data when the method returns. The actual argument depends on the value of the ***dwOptions*** parameter which specifies how the data stream will be stored.

lpdwLength

A pointer to an unsigned integer value which specifies the maximum length of the buffer and contains the number of bytes read when the method returns. This argument should should always point to an initialized value. If the lpvBuffer argument specifies a memory buffer, then this argument cannot point to an initialized value of zero; if any other type of stream buffer is used and the initialized value is zero, that indicates that all available data from the socket should be returned until the end-of-stream marker is encountered or the remote host disconnects.

dwOptions

An unsigned integer value which specifies both the stream buffer type and any options to be used when reading the data stream. One of the following stream types may be specified:

Value	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the ***lpvBuffer*** parameter. If the argument specifies a pointer to a global memory handle initialized to NULL, then the method will return a handle which references the data; otherwise, the method will consider the parameter a pointer to a block of pre-allocated memory which will contain the stream data when the method returns. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The ***lpvBuffer*** argument specifies a pointer to a pre-allocated block of memory which will contain the data read from the socket when the method returns. If this stream buffer type is used, the ***lpdwLength*** argument must point to an unsigned integer which has been initialized with the maximum length of the buffer.
INET_STREAM_HGLOBAL	The ***lpvBuffer*** argument specifies a pointer to a global memory handle. When the method returns, the handle will reference a block of memory that contains the stream data. The application

	should take care to make sure that the handle passed to the method does not currently reference a valid block of memory; it is recommended that the handle be initialized to NULL prior to calling this method.
INET_STREAM_HANDLE	The ***lpvBuffer*** argument specifies a Windows handle to an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read from the socket will be written to this handle using the WriteFile function.
INET_STREAM_SOCKET	The ***lpvBuffer*** argument specifies a socket handle. The data read from the socket specified by the ***hSocket*** argument will be written to this socket. The socket handle passed to this method must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either create another instance of the class and attach the socket using the AttachHandle method or use the INET_STREAM_HANDLE stream buffer type instead.
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data returned in the buffer to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being returned as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the source data stream; if the application is using a pre-allocated memory buffer, this must be considered before calling this method.

lpMarker

A pointer to an array of bytes which marks the end of the data stream. When this byte sequence is encountered by the method, it will stop reading and return to the caller. The buffer will contain all of the data read from the socket up to and including the end-of-stream marker. If this argument is NULL, then the method will continue to read from the socket until the maximum buffer size is reached, the remote host closes its socket or an error is encountered.

cbMarker

An unsigned integer value which specifies the length of the end-of-stream marker in bytes. If the ***lpMarker*** parameter is NULL, then this value must be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To

get extended error information, call **GetLastError**.

Remarks

The **ReadStream** method enables an application to read an arbitrarily large stream of data and store it in memory, write it to a file or even another socket. Unlike the **Read** method, which will return immediately when any amount of data has been read, **ReadStream** will only return when the buffer is full as specified by the *lpdwLength* parameter, the logical end-of-stream marker has been read, the socket closed by the remote host or when an error occurs.

This method will force the thread to block until the operation completes. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **ReadStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for data to be returned in the buffer even if the method returns a value of zero. Applications should also check the value of the *lpdwLength* argument to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the method return value.

Because **ReadStream** can potentially cause the application to block for long periods of time as the data stream is being read, the method will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **RegisterEvent** method, and can obtain information about the current operation by calling the **GetStreamInfo** method.

Example

```
HGLOBAL hgblBuffer = NULL; // Return data in a global memory buffer
DWORD cbBuffer = 102400;   // Read up to 100K bytes
BOOL bResult;

bResult = pSocket->ReadStream(&hgblBuffer, &cbBuffer,
                              INET_STREAM_HGLOBAL | INET_STREAM_CONVERT);

if (bResult && cbBuffer > 0)
{
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // Use data in the stream buffer

    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

CSocketWrench::RegisterEvent Method

```
INT RegisterEvent(
   UINT nEventId,
   INETEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
INET_EVENT_CONNECT	The connection to the remote host has completed.
INET_EVENT_DISCONNECT	The remote host has closed the connection to the client. The client should read any remaining data and disconnect.
INET_EVENT_READ	A network event which indicates data is available to read. No additional messages will be posted until the process has read at least some of the data from the socket. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_WRITE	A network event which indicates the application can send data to the remote host. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the socket is in asynchronous mode.
INET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The application may attempt to retry the operation, or may disconnect from the remote host and report an error to the user.
INET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **InetEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR.

To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **InetEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::Reject Method

```
BOOL Reject();
```

The **Reject** method is used to reject a client connection request.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Reject** method rejects a pending client connection and the remote host will see this as the connection being aborted. If there are no pending client connections at the time, this method will immediately return with an error indicating that the operation would cause the thread to block.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::SetHostFile Method

```
INT SetHostFile(
   LPCTSTR lpszFileName
);
```

The **SetHostFile** method specifies the name of an alternate file to use when resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **GetHostAddress** and **GetHostNames** method. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

lpszFileName

Pointer to a string that specifies the name of the file. If the parameter is NULL, then the current host file is cleared from the cache and only the default host file will be used to resolve hostnames and addresses.

Return Value

If the method succeeds, the return value is the number of entries in the host file. A return value of INET_ERROR indicates failure. To get extended error information, call **GetLastError**.

Remarks

This method loads the file into memory allocated for the current thread. If the contents of the file have changed after the method has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, call this method again with the same file name. To remove the alternate host file from memory, specify a NULL pointer as the parameter.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

To determine if an alternate host file has been specified, use the **GetHostFile** method. A return value of zero indicates that no alternate host file has been cached for the current thread.

A system may have a default host file, which is used to resolve hostnames before performing a nameserver lookup. To determine the name of this file, use the **GetDefaultHostFile** method. It is not necessary to specify this default host file, since it is always used to resolve host names and addresses.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h

Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_SOCKET or INET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::SetOption Method

```
INT SetOption(
   DWORD dwOption,
   BOOL bEnabled
);
```

The **SetOption** method is used to enable or disable a specific socket option.

Parameters

dwOption

An unsigned integer used to specify one of the socket options. These options cannot be combined. The following values are recognized:

Value	Description
INET_OPTION_BROADCAST	This option specifies that broadcasting should be enabled for datagrams. This option is invalid for stream sockets.
INET_OPTION_KEEPALIVE	This option specifies that packets are to be sent to the remote system when no data is being exchanged to keep the connection active. This is only valid for stream sockets.
INET_OPTION_REUSEADDRESS	This option specifies the local address can be reused. This option is commonly used by server applications.
INET_OPTION_NODELAY	This option disables the Nagle algorithm, which buffers unacknowledged data and insures that a full-size packet can be sent to the remote host.

bEnabled

A boolean flag. If the flag is set to a non-zero value, the option is enabled. Otherwise the socket option is disabled.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

It is not recommend that you disable the Nagle algorithm by specifying the INET_OPTION_NODELAY flag unless it is absolutely required. Doing so can have a significant, negative impact on the performance of the application and network.

If if the INET_OPTION_KEEPALIVE option is enabled, keep-alive packets will start being generated five seconds after the socket has become idle with no data being sent or received. Enabling this option can be used by applications to detect when a physical network connection has been lost. However, it is recommended that most applications query the remote host directly to determine if the connection is still active. This is typically accomplished by sending specific commands to the server to query its status, or checking the elapsed time since the last response from the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

Connect, GetOption

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the remote host. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

See Also

CSocketWrench::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetErrorString, GetLastError, SetLastError

CSocketWrench::Shutdown Method

```
INT Shutdown(
   DWORD dwOption
);
```

The **Shutdown** method is used to disable reception or transmission of data, or both.

Parameters

dwOption

An unsigned integer used to specify one of the shutdown options. These options cannot be combined. The following values are recognized:

Value	Description
INET_SHUTDOWN_READ	Disable reception of data.
INET_SHUTDOWN_WRITE	Disable transmission of data.
INET_SHUTDOWN_BOTH	Disable both reception and transmission of data.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method is rarely needed. It is provided as an interface to the Windows Sockets **shutdown** method.

In some asynchronous applications, it may be desirable for a client to inform the server that no further communication is wanted, while allowing the client to read any residual data that may reside in internal buffers on the client side. **Shutdown** accomplishes this because the socket handle is still valid after it has been called, although some or all communication with the remote host has ceased.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib

CSocketWrench::StoreStream Method

```
BOOL StoreStream(
   LPCTSTR lpszFileName,
   DWORD dwLength,
   LPDWORD lpdwCopied
   DWORD dwOffset,
   DWORD dwOptions
);
```

The **StoreStream** method reads the socket data stream and stores the contents in the specified file.

Parameters

lpszFileName

Pointer to a string which specifies the name of the file to create or overwrite.

dwLength

An unsigned integer which specifies the maximum number of bytes to read from the socket and write to the file. If this value is zero, then the method will continue to read data from the socket until the remote host disconnects or an error occurs.

lpdwCopied

A pointer to an unsigned integer value which will contain the number of bytes written to the file when the method returns.

dwOffset

An unsigned integer which specifies the byte offset into the file where the method will start storing data read from the socket. Note that all data after this offset will be truncated. A value of zero specifies that the file should be completely overwritten if it already exists.

dwOptions

An unsigned integer value which specifies one or more options. Programs can use a bitwise operator to combine any of the following values:

Value	Description
INET_STREAM_CONVERT	The data stream is considered to be textual and will be modified so that end-of-line character sequences are converted to follow standard Windows conventions. This will ensure that all lines of text are terminated with a carriage-return and linefeed sequence. Because this option modifies the data stream, it should never be used with binary data. Using this option may result in the amount of data written to the file to be larger than the source data. For example, if the source data only terminates a line of text with a single linefeed, this option will have the effect of inserting a carriage-return character before each linefeed.
INET_STREAM_UNICODE	The data stream should be converted to Unicode. This option should only be used with text data, and will result in the stream data being written as 16-bit wide characters rather than 8-bit bytes. The amount of data returned will be twice the amount read from the

	source data stream. If the *dwOffset* parameter has a value of zero, the Unicode byte order mark (BOM) will be written to the beginning of the file.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **StoreStream** method enables an application to read an arbitrarily large stream of data and store it in a file. This method is essentially a simplified version of the **ReadStream** method, designed specifically to be used with files rather than memory buffers or handles.

This method will force the thread to block until the operation completes. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **StoreStream** is blocked waiting for data from the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

Because **StoreStream** can potentially cause the application to block for long periods of time as the data stream is being read, the method will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **RegisterEvent** method, and can obtain information about the current operation by calling the **GetStreamInfo** method.

Example

```
DWORD dwCopied;
BOOL bResult;

bResult = pSocket->StoreStream(lpszFileName, 0, &dwCopied, 0,
                               INET_STREAM_CONVERT);

if (bResult && dwCopied > 0)
{
    // The data has been written to the file
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::ValidateCertificate Method

```
BOOL ValidateCertificate(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertPassword,
   LPCTSTR lpszCertName
);
```

The **ValidateCertificate** method determines if the specified security certificate is installed on the local system.

Parameters

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the personal certificate store will be used as the default. This parameter may also specify the name of a certificate file in PKCS #12 (PFX) format.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertPassword

A null-terminated string which specifies the password associated with a certificate file. This parameter is only used if the ***lpszCertStore*** parameter specifies a certificate file, otherwise it is ignored. If the certificate file is not protected with a password, this parameter should be a NULL pointer or empty string.

lpszCertName

A null-terminated string which specifies the name of the certificate to validate. The method will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the method will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the method will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

If you are checking the validity of a certificate installed in the local certificate store, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user.

It is possible to validate a certificate file rather than one stored in the local certificate store. The *lpszCertStore* member should specify the name of a file in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate file was created, it must be provided in with the *lpszCertPassword* parameter or this method will be unable to access the certificate.

This method can only validate certificate files in PFX format and cannot be used to validate a certificate file in another format, such as PEM (base64 encoded) or DER (binary).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

ValidateHostName Method

```
BOOL ValidateHostName(
   LPCTSTR lpszHostName,
   LPTSTR lpszAddress,
   INT nMaxLength
);

BOOL ValidateHostName(
   LPCTSTR lpszHostName,
   CString& strAddress
);
```

The **ValidateHostName** method determines if the specified host name is valid and returns its IP address.

Parameters

lpszHostName

A null-terminated string which specifies the host name. The method will fail If this parameter is NULL or an empty string.

lpszAddress

A null-terminated string buffer which will contain the IP address of the host. If specified, this string must be large enough to store the complete IP address, including the terminating null character. If this parameter is NULL or the ***nMaxLength*** parameter is zero, it will be ignored and the IP address will not be returned. An alternate version of this method accepts a reference to a **CString** object if MFC or ATL is used with the project.

nMaxLength

An integer value that specifies the maximum number of characters which can be copied into the ***lpszAddress*** string buffer. The buffer must be large enough to store the complete address. Because this method can return either an IPv4 or IPv6 address, it is recommended the minimum length for the buffer to be 46 characters. If this parameter is zero, the ***lpszAddress*** parameter will be ignored.

Return Value

If the method succeeds, the host name is valid and the return value will be non-zero. If the method fails, the host name could not be resolved to an IP address and the return value will be zero. To get extended error information, call the **GetLastError** method.

Remarks

The **ValidateHostName** method provides a convenient way to determine if a host name is valid by attempting to resolve the name into an IP address. It is similar to calling the **NormalizeHostName** method to obtain the canonical form of the host name, calling **GetAddress** to obtain the IP address and then calling **FormatAddress** to return the string representation of the host's IP address.

If the Unicode version of this method is used, any non-ASCII characters in the host name will be automatically encoded into a compatible format and then resolved to an IP address. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended you use the Unicode version.

The ***lpszHostName*** parameter can only specify a host name or IP address and cannot be a URL. If you want your application to support providing a URL in addition to a host name, use the **GetUrlHostName** method to extract the host name from the URL. You can then provide the host

name to this method to obtain its IP address.

If the *lpszHostName* parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this method will return a copy of that IP address in the buffer provided by the caller. This allows the method to be used in cases where a user may input either a host name or IP address. To determine if the IP address has a corresponding host name, use the **GetHostName** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

CSocketWrench::Write Method

```
INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer,
   LPINTERNET_ADDRESS lpAddress,
   UINT nRemotePort
);
```

The **Write** method sends the specified number of bytes to the remote host.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the remote host.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero.

lpAddress

Pointer to an INTERNET_ADDRESS structure that specifies the address of the remote host that is to receive the data being written. For TCP stream sockets, this parameter must always be NULL or specify the same address that was used to establish the connection. For UDP datagram sockets, this may specify any valid IP address.

nRemotePort

The port number of the remote host that is to receive the data being written. For TCP stream sockets, this value must always be zero, or specify the same port number that was used to establish the connection. For UDP datagram sockets, this may specify any valid port number.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is INET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking sockets, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

EnableEvents, IsBlocking, IsReadable, IsWritable, Read, ReadLine, RegisterEvent, WriteLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::WriteLine Method

```
BOOL WriteLine(
   LPCTSTR lpszBuffer,
   LPINT lpnLength
);
```

The **WriteLine** function sends a line of text to the remote host, terminated by a carriage-return and linefeed.

Parameters

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the remote host. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WriteLine** method writes a line of text to the remote host and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a null-terminated string.

If the ***lpszBuffer*** string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the ***lpnLength*** parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **WriteLine**. This method should only be used to send text, never binary data. In particular, it will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this method will accept a Unicode string, however it does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

This method will force the thread to block until the complete line of text has been written, the write operation times out or the remote host aborts the connection. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **WriteLine** is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application

needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **Write** and **WriteLine** methods can be safely intermixed.

Unlike the **Write** function, it is possible for data to have been written to the socket if the return value is zero. For example, if a timeout occurs while the method is waiting to send more data to the remote host, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the ***lpnLength*** argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

IsWritable, Read, ReadLine, ReadStream, Write, WriteStream

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CSocketWrench::WriteStream Method

```
BOOL WriteStream(
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwOptions
);
```

The **WriteStream** method writes data from the stream buffer to the specified socket.

Parameters

lpvBuffer

Pointer to the buffer that contains or references the data to be written to the socket. The actual argument depends on the value of the ***dwOptions*** parameter which specifies how the data stream will be accessed.

lpdwLength

A pointer to an unsigned integer value which specifies the size of the buffer and contains the number of bytes written when the method returns. This argument should should always point to an initialized value. If the ***lpvBuffer*** argument specifies a memory buffer or global memory handle, then this argument cannot point to an initialized value of zero.

dwOptions

An unsigned integer value which specifies the stream buffer type to be used when writing the data stream to the socket. One of the following stream types may be specified:

Value	Description
INET_STREAM_DEFAULT	The default stream buffer type is determined by the value passed as the ***lpvBuffer*** parameter. If the argument specifies a a global memory handle, then the method will write the data referenced by that handle; otherwise, the method will consider the parameter a pointer to a block of memory which contains data to be written. In most cases, it is recommended that an application explicitly specify the stream buffer type rather than using the default value.
INET_STREAM_MEMORY	The ***lpvBuffer*** argument specifies a pointer to a block of memory which contains the data to be written to the socket. If this stream buffer type is used, the ***lpdwLength*** argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HGLOBAL	The ***lpvBuffer*** argument specifies a global memory handle that references the data to be written to the socket. The handle must have been created by a call to the GlobalAlloc or GlobalReAlloc function. If this stream buffer type is used, the ***lpdwLength*** argument must point to an unsigned integer which has been initialized with the size of the buffer.
INET_STREAM_HANDLE	The ***lpvBuffer*** argument specifies a Windows handle to

	an open file, console or pipe. This should be the same handle value returned by the CreateFile function in the Windows API. The data read using the ReadFile function with this handle will be written to the socket.
INET_STREAM_SOCKET	The ***lpvBuffer*** argument specifies a socket handle. The data read from the socket specified by this handle will be written to the socket specified by the ***hSocket*** parameter. The socket handle passed to this method must have been created by this library; if it is a socket created by an third-party library or directly by the Windows Sockets API, you should either create another instance of the class and attach the socket using the AttachHandle method or use the INET_STREAM_HANDLE stream buffer type instead.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **InetGetLastError**.

Remarks

The **WriteStream** method enables an application to write an arbitrarily large stream of data from memory or a file to the specified socket. Unlike the **Write** method, which may not write all of the data in a single method call, **WriteStream** will only return when all of the data has been written or an error occurs.

This method will force the thread to block until the operation completes. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, write the data stream and then restore the socket to asynchronous operation when it has finished. If another socket operation is attempted while **WriteStream** is blocked sending data to the remote host, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

It is possible for some data to have been written even if the method returns a value of zero. Applications should also check the value of the ***lpdwLength*** argument to determine if any data was sent. For example, if a timeout occurs while the method is waiting to write more data, it will return zero; however, some data may have already been written to the socket prior to the error condition.

Because **WriteStream** can potentially cause the application to block for long periods of time as the data stream is being written, the method will periodically generate INET_EVENT_PROGRESS events. An application can register an event handler using the **RegisterEvent** method, and can obtain information about the current operation by calling the **GetStreamInfo** method.

Example

```
CFile *pFile = new CFile();
DWORD dwLength = 0;

if (!pFile->Open(strFileName, CFile::modeRead | CFile::shareDenyWrite))
    return;
```

```
dwLength = pFile->GetLength();

if (dwLength > 0)
{
    BOOL bResult = pSocket->WriteStream(
                      pFile->m_hFile,
                      &dwLength,
                      INET_STREAM_HANDLE);
}

delete pFile;
```

INETSTREAMINFO

The INETSTREAMINFO structure contains information about the data stream being currently read or written.

```
typedef struct _INETSTREAMINFO
{
    DWORD   dwStreamThread;
    DWORD   dwStreamSize;
    DWORD   dwStreamCopied;
    DWORD   dwStreamMode;
    DWORD   dwStreamError;
    DWORD   dwBytesPerSecond;
    DWORD   dwTimeElapsed;
    DWORD   dwTimeEstimated;
} INETSTREAMINFO, *LPINETSTREAMINFO;
```

Members

dwStreamThread

Specifies the numeric ID for the thread that created the socket.

dwStreamSize

The maximum number of bytes that will be read or written. This is the same value as the buffer length specified by the caller, and may be zero which indicates that no maximum size was specified. Note that if this value is zero, the application will be unable to calculate a completion percentage or estimate the amount of time for the operation to complete.

dwStreamCopied

The total number of bytes that have been copied to or from the stream buffer.

dwStreamMode

A numeric value which specifies the stream operation that is current being performed. It may be one of the following values:

Value	Description
INET_STREAM_READ	Data is being read from the socket and stored in the specified stream buffer.
INET_STREAM_WRITE	Data is being written from the specified stream buffer to the socket.

dwStreamError

The last error that occurred when reading or writing the data stream. If no error has occurred, this value will be zero.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the operation is completed. This is based on the average number of bytes transferred per second and requires that a maximum stream buffer size be specified by the caller.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h

INTERNET_ADDRESS

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
    INT    ipFamily;
    BYTE   ipNumber[16];
} INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the ***ipNumber*** array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the ***ipNumber*** array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the ***ipNumber*** array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the ***ipFamily*** member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cswsock12.h

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SocketWrench Class Error Codes

Value	Constant	Description
0x80042711	ST_ERROR_NOT_HANDLE_OWNER	Handle not owned by the current thread
0x80042712	ST_ERROR_FILE_NOT_FOUND	The specified file or directory does not exist
0x80042713	ST_ERROR_FILE_NOT_CREATED	The specified file could not be created
0x80042714	ST_ERROR_OPERATION_CANCELED	The blocking operation has been canceled
0x80042715	ST_ERROR_INVALID_FILE_TYPE	The specified file is a block or character device, not a regular file
0x80042716	ST_ERROR_INVALID_DEVICE	The specified device or address does not exist
0x80042717	ST_ERROR_TOO_MANY_PARAMETERS	The maximum number of method parameters has been exceeded
0x80042718	ST_ERROR_INVALID_FILE_NAME	The specified file name contains invalid characters or is too long
0x80042719	ST_ERROR_INVALID_FILE_HANDLE	Invalid file handle passed to method
0x8004271A	ST_ERROR_FILE_READ_FAILED	Unable to read data from the specified file
0x8004271B	ST_ERROR_FILE_WRITE_FAILED	Unable to write data to the specified file
0x8004271C	ST_ERROR_OUT_OF_MEMORY	Out of memory
0x8004271D	ST_ERROR_ACCESS_DENIED	Access denied
0x8004271E	ST_ERROR_INVALID_PARAMETER	Invalid argument passed to method
0x8004271F	ST_ERROR_CLIPBOARD_UNAVAILABLE	The system clipboard is currently unavailable
0x80042720	ST_ERROR_CLIPBOARD_EMPTY	The system clipboard is empty or does not contain any text data
0x80042721	ST_ERROR_FILE_EMPTY	The specified file does not contain any data
0x80042722	ST_ERROR_FILE_EXISTS	The specified file already exists
0x80042723	ST_ERROR_END_OF_FILE	End of file
0x80042724	ST_ERROR_DEVICE_NOT_FOUND	The specified device could not be found
0x80042725	ST_ERROR_DIRECTORY_NOT_FOUND	The specified directory could not be found
0x80042726	ST_ERROR_INVALID_BUFFER	Invalid memory address passed to method
0x80042728	ST_ERROR_NO_HANDLES	No more handles available to this process
0x80042733	ST_ERROR_OPERATION_WOULD_BLOCK	The specified operation would block the current thread
0x80042734	ST_ERROR_OPERATION_IN_PROGRESS	A blocking operation is currently in progress
0x80042735	ST_ERROR_ALREADY_IN_PROGRESS	The specified operation is already in progress
0x80042736	ST_ERROR_INVALID_HANDLE	Invalid handle passed to method
0x80042737	ST_ERROR_INVALID_ADDRESS	Invalid network address specified

0x80042738	ST_ERROR_INVALID_SIZE	Datagram is too large to fit in specified buffer
0x80042739	ST_ERROR_INVALID_PROTOCOL	Invalid network protocol specified
0x8004273A	ST_ERROR_PROTOCOL_NOT_AVAILABLE	The specified network protocol is not available
0x8004273B	ST_ERROR_PROTOCOL_NOT_SUPPORTED	The specified protocol is not supported
0x8004273C	ST_ERROR_SOCKET_NOT_SUPPORTED	The specified socket type is not supported
0x8004273D	ST_ERROR_INVALID_OPTION	The specified option is invalid
0x8004273E	ST_ERROR_PROTOCOL_FAMILY	Specified protocol family is not supported
0x8004273F	ST_ERROR_PROTOCOL_ADDRESS	The specified address is invalid for this protocol family
0x80042740	ST_ERROR_ADDRESS_IN_USE	The specified address is in use by another process
0x80042741	ST_ERROR_ADDRESS_UNAVAILABLE	The specified address cannot be assigned
0x80042742	ST_ERROR_NETWORK_UNAVAILABLE	The networking subsystem is unavailable
0x80042743	ST_ERROR_NETWORK_UNREACHABLE	The specified network is unreachable
0x80042744	ST_ERROR_NETWORK_RESET	Network dropped connection on remote reset
0x80042745	ST_ERROR_CONNECTION_ABORTED	Connection was aborted due to timeout or other failure
0x80042746	ST_ERROR_CONNECTION_RESET	Connection was reset by remote network
0x80042747	ST_ERROR_OUT_OF_BUFFERS	No buffer space is available
0x80042748	ST_ERROR_ALREADY_CONNECTED	Connection already established with remote host
0x80042749	ST_ERROR_NOT_CONNECTED	No connection established with remote host
0x8004274A	ST_ERROR_CONNECTION_SHUTDOWN	Unable to send or receive data after connection shutdown
0x8004274C	ST_ERROR_OPERATION_TIMEOUT	The specified operation has timed out
0x8004274D	ST_ERROR_CONNECTION_REFUSED	The connection has been refused by the remote host
0x80042750	ST_ERROR_HOST_UNAVAILABLE	The specified host is unavailable
0x80042751	ST_ERROR_HOST_UNREACHABLE	Remote host is unreachable
0x80042753	ST_ERROR_TOO_MANY_PROCESSES	Too many processes are using the networking subsystem
0x8004276B	ST_ERROR_NETWORK_NOT_READY	Network subsystem is not ready for communication
0x8004276C	ST_ERROR_INVALID_VERSION	This version of the operating system is not supported
0x8004276D	ST_ERROR_NETWORK_NOT_INITIALIZED	The networking subsystem has not been initialized
0x80042775	ST_ERROR_REMOTE_SHUTDOWN	The remote host has initiated a graceful shutdown sequence

0x80042AF9	ST_ERROR_INVALID_HOSTNAME	The specified hostname is invalid or could not be resolved
0x80042AFA	ST_ERROR_HOSTNAME_NOT_FOUND	The specified hostname could not be found
0x80042AFB	ST_ERROR_HOSTNAME_REFUSED	Unable to resolve hostname, request refused
0x80042AFC	ST_ERROR_HOSTNAME_NOT_RESOLVED	Unable to resolve hostname, no address for specified host
0x80042EE1	ST_ERROR_INVALID_LICENSE	The license for this product is invalid
0x80042EE2	ST_ERROR_PRODUCT_NOT_LICENSED	This product is not licensed to perform this operation
0x80042EE3	ST_ERROR_NOT_IMPLEMENTED	This method has not been implemented on this platform
0x80042EE4	ST_ERROR_UNKNOWN_LOCALHOST	Unable to determine local host name
0x80042EE5	ST_ERROR_INVALID_HOSTADDRESS	Invalid host address specified
0x80042EE6	ST_ERROR_INVALID_SERVICE_PORT	Invalid service port number specified
0x80042EE7	ST_ERROR_INVALID_SERVICE_NAME	Invalid or unknown service name specified
0x80042EE8	ST_ERROR_INVALID_EVENTID	Invalid event identifier specified
0x80042EE9	ST_ERROR_OPERATION_NOT_BLOCKING	No blocking operation in progress on this socket
0x80042F45	ST_ERROR_SECURITY_NOT_INITIALIZED	Unable to initialize security interface for this process
0x80042F46	ST_ERROR_SECURITY_CONTEXT	Unable to establish security context for this session
0x80042F47	ST_ERROR_SECURITY_CREDENTIALS	Unable to open client certificate store or establish client credentials
0x80042F48	ST_ERROR_SECURITY_CERTIFICATE	Unable to validate the certificate chain for this session
0x80042F49	ST_ERROR_SECURITY_DECRYPTION	Unable to decrypt data stream
0x80042F4A	ST_ERROR_SECURITY_ENCRYPTION	Unable to encrypt data stream
0x80043031	ST_ERROR_MAXIMUM_CONNECTIONS	The maximum number of client connections exceeded
0x80043032	ST_ERROR_THREAD_CREATION_FAILED	Unable to create a new thread for the current process
0x80043033	ST_ERROR_INVALID_THREAD_HANDLE	The specified thread handle is no longer valid
0x80043034	ST_ERROR_THREAD_TERMINATED	The specified thread has been terminated
0x80043035	ST_ERROR_THREAD_DEADLOCK	The operation would result in the current thread becoming deadlocked
0x80043036	ST_ERROR_INVALID_CLIENT_MONIKER	The specified moniker is not associated with any client session
0x80043037	ST_ERROR_CLIENT_MONIKER_EXISTS	The specified moniker has been assigned to another client session

0x80043038	ST_ERROR_SERVER_INACTIVE	The specified server is not listening for client connections
0x80043039	ST_ERROR_SERVER_SUSPENDED	The specified server is suspended and not accepting client connections

Telnet Protocol Class Library

Establish an interactive terminal session with a server.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CTelnetClient
File Name	CSTNTV12.DLL
Version	12.0.3024.1286
LibID	552A583F-46C0-4A66-8BC5-B75B468763EE
Import Library	CSTNTV12.LIB
Dependencies	None
Standards	RFC 854

Overview

The Telnet protocol is used to establish a connection with a server which provides a virtual terminal session for a user. Its functionality is similar to how character based consoles and serial terminals work, enabling a user to login to the server, execute commands and interact with applications running on the server. The class provides an interface for establishing the connection, negotiating certain options (such as whether characters will be echoed back to the client) and handling the standard I/O functions needed by the program.

The class also provides methods that enable a program to easily scan the data stream for specific sequences of characters, making it very simple to write light-weight client interfaces to applications running on the server. The CTelnetClient class can be combined with the CTerminalEmulator class to provide complete terminal emulation services for a standard ANSI or DEC-VT220 terminal.

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this library supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the CSshClient class.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Telnet Protocol Class Methods

Class	Description
CTelnetClient	Constructor which initializes the current instance of the class
~CTelnetClient	Destructor which releases resources allocated by the class
Method	Description
Abort	Abort the current session and close the connection with the server
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Break	Send a break signal to the server
Cancel	Cancel the current blocking operation
Connect	Connect to the specified server
CreateSecurityCredentials	Create a new security credentials structure
DeleteSecurityCredentials	Delete a previously created security credentials structure
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of network function calls to a file
FreezeEvents	Suspend asynchronous event processing
GetErrorString	Return a description for the specified error code
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetMode	Return the current client mode
GetSecurityInformation	Return security information about the current client connection
GetStatus	Return the current client status
GetTerminalType	Return the current terminal type
GetTimeout	Return the number of seconds until an operation times out
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if data can be read from the server
IsThere	Determine if the server is available
IsWritable	Determine if data can be written to the server

Login	Login to the server using the specified username and password
Read	Read data returned by the server
ReadLine	Read a line of text from the server and return it in a string buffer
RegisterEvent	Register an event callback function
Search	Search for a specific character sequence in the data stream
SetLastError	Set the last error code
SetMode	Set the current client mode
SetTerminalType	Set the current terminal type
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
TelnetEventProc	Callback function that processes events generated by the client
Write	Write data to the server
WriteLine	Write a line of text to the server

CTelnetClient::CTelnetClient Method

```
CTelnetClient();
```

The **CTelnetClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **TelnetInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CTelnetClient, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::~CTelnetClient

```
~CTelnetClient();
```

The **CTelnetClient** destructor releases resources allocated by the current instance of the **CTelnetClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CTelnetClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CTelnetClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::Abort Method

```
INT Abort();
```

The **Abort** method aborts the current session and terminates the connection.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Abort** method is called, the abort sequence is sent to the server and the connection to the server is terminated. Once this method returns, the client handle is no longer valid. If a program is currently executing on the server at the time this method is called, that program may be terminated as a result of the session being aborted. Applications should normally call **Disconnect** to gracefully disconnect from the server and should only use this method when the connection must be aborted immediately.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

Break, Cancel, IsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::AttachHandle Method

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

AttachHandle, Cancel, Connect, DetachHandle, Disconnect, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::Break Method

```
INT Break();
```

The **Break** method sends a signal to the server which may terminate an application that is currently running. The actual response to the break signal depends on the application.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Abort, Cancel, Read, Write

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

CTelnetClient::Connect Method

```
BOOL Connect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions
);
```

The **Connect** method establishes a connection with the specified server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 23. For secure connections, the default port number is 992.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TELNET_OPTION_NONE	No connection options specified. A standard connection to the server will be established using the specified host name and port number.
TELNET_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established.
TELNET_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
TELNET_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
TELNET_OPTION_SECURE_EXPLICIT	This option specifies the client should attempt to establish a secure connection with the server using the START_TLS option. The client initiates a

	standard connection with the server, then requests a secure connection during the option negotiation process.
TELNET_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
TELNET_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
TELNET_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur. If this argument is NULL, then the client session will be blocking and no network events will be sent to the client.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files. If the ***hEventWnd*** argument is NULL, this argument should be specified as WM_NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this library supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the CSshClient class.

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a

worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the class instance is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call methods using that instance of the class. The ownership of the class instance may be transferred from one thread to another using the **AttachThread** method.

Specifying the TELNET_OPTION_FREETHREAD option enables any thread to call any method in that instance of the class, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the class instance is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same instance.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CreateSecurityCredentials, Disconnect, GetSecurityInformation

CTelnetClient::CreateSecurityCredentials Method

```
BOOL CreateSecurityCredentials(
   DWORD dwProtocol,
   DWORD dwOptions,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertStore,
   LPCTSTR lpszCertName
);

BOOL CreateSecurityCredentials(
   LPCTSTR lpszCertName
);
```

The **CreateSecurityCredentials** method creates security credentials for the client session.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows

	Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or more options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store

is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The method will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the method will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the method will return an error indicating that the certificate could not be found.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

A client application only needs to call this method if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** parameter should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was

created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are optional values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters can be NULL or omitted.

Example

```
pClient->CreateSecurityCredentials(
            SECURITY_PROTOCOL_DEFAULT,
            0,
            NULL,
            NULL,
            lpszCertStore,
            lpszCertName);

bConnected = pClient->Connect(lpszHostName,
                              TELNET_PORT_SECURE,
                              TELNET_TIMEOUT,
                              TELNET_OPTION_SECURE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CTelnetClient::DeleteSecurityCredentials Method

```
VOID DeleteSecurityCredentials();
```

The **DeleteSecurityCredentials** method releases the security credentials for the current session.

Parameters

None.

Return Value

None.

Remarks

This method can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated. The security credentials are released when the class destructor is called, so it is normally not required that the application explicitly call this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CreateSecurityCredentials

CTelnetClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

AttachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

EnableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::Disconnect Method

```
VOID Disconnect();
```

The **Disconnect** method terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

None.

Return Value

None.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

Connect, IsConnected

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::EnableEvents Method

```
INT EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
TELNET_EVENT_CONNECT	The connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking

	operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

DisableEvents, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTelnetClient::FreezeEvents Method

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DisableEvents, EnableEvents, RegisterEvent

CTelnetClient::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetLastError, SetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

CTelnetClient::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TELNET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

CTelnetClient::GetMode Method

```
UINT GetMode();
```

The **GetMode** method returns the current client mode.

Parameters

None.

Return Value

If the method succeeds, the return value is the current client mode. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The client mode is a combination of one or more flags which determines how the client handles local character echo and character processing. The following values are recognized:

Value	Description
TELNET_MODE_LOCALECHO	The local client is responsible for echoing data entered by the user. By default, this mode is not set which means that the server is responsible for echoing back each character written to it.
TELNET_MODE_BINARY	Data exchanged between the client and server should not be converted or line buffered. If this option is not specified, the high-bit will be cleared on all characters and single linefeeds will be automatically converted to carriage-return/linefeed sequences.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTelnetClient::GetSecurityInformation Method

```
BOOL GetSecurityInformation(
   LPSECURITYINFO lpSecurityInfo
);
```

The **GetSecurityInformation** method returns security protocol, encryption and certificate information about the current client connection.

Parameters

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

```
// Notifies the user if the connection is secure or not
SECURITYINFO securityInfo;
securityInfo.dwSize = sizeof(SECURITYINFO);

if (pClient->GetSecurityInformation(&securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTelnetClient::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
TELNET_STATUS_UNUSED	No connection has been established.
TELNET_STATUS_IDLE	The client is current idle and not sending or receiving data.
TELNET_STATUS_CONNECT	The client is establishing a connection with the server.
TELNET_STATUS_READ	The client is reading data from the server.
TELNET_STATUS_WRITE	The client is writing data to the server.
TELNET_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

CTelnetClient::GetTerminalType Method

```
INT GetTerminalType(
   LPCTSTR lpszTermType,
   INT nMaxLength
);

INT GetTerminalType(
   CString& strTermType
);
```

The **GetTerminalType** method returns the terminal type for the current client session.

Parameters

lpszTermType

Points to a buffer which the current terminal type is copied into. This buffer should be at least 32 characters in length, including the terminating null character. This argument may also be a **CString** object which will contain the terminal type when the method returns.

nMaxLength

Maximum number of characters that may be copied to the buffer, including the terminating null character.

Return Value

If the method succeeds, the return value is the length of the terminal type name. A value of zero indicates that no terminal type has been specified. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

SetTerminalType

CTelnetClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

Connect, IsReadable, IsWritable, Read, SetTimeout, Write

CTelnetClient::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTelnetClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

GetStatus, IsBlocking, IsInitialized, IsReadable, IsWritable

CTelnetClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

CTelnetClient::IsReadable Method

```
BOOL IsReadable(
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

CTelnetClient::IsThere Method

```
BOOL IsThere();
```

The **IsThere** method reports the response of the client to a "Are you there" command to the telnet server.

Parameters

None.

Return Value

The method returns a non-zero value if the server acknowledges a specific control sequence used to determine if a server is responsive. If the server does not respond, the method will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

CTelnetClient::IsWritable Method

```
BOOL IsWritable(
   INT nTimeout
);
```

The **IsWritable** method is used to determine if data can be written to the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the method returns a non-zero value. If the client cannot write any data, the method returns zero.

Remarks

Although this method can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

CTelnetClient::Login Method

```
BOOL Login(
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword
);
```

The **Login** method attempts to authenticate the user and log them in to the current session.

Parameters

lpszUserName

A null-terminated string which specifies the name of the user to authenticate.

lpszPassword

A null-terminated string which specifies the password to be used when authenticating the user. If the user does not require a password, this parameter may be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

Caution: The Telnet protocol transmits all data, including login credentials, in plaintext and does not provide any inherent encryption. While this library supports optional TLS connections for Telnet, secure Telnet servers are rare in practice. This protocol is still supported for compatibility with legacy systems, but it is strongly recommended that you use secure protocols such as SSH whenever possible, especially when connecting over public or untrusted networks. To establish a secure connection to the server using the Secure Shell (SSH) protocol, use the CSshClient class.

This method is used to authenticate a user, logging them into the server. This method is specifically designed to work with most UNIX based servers, and may work with other servers that use a similar login process. The method works by scanning the data stream for a username prompt and then replying with the specified username. If that is successful, it will then scan for a password prompt and provide the specified password. If no recognized prompt is found, or if the server responds with an error indicating that the username or password is invalid, the method will fail.

If the **Login** method succeeds, the next call to **Read** by the client will return any welcome message to the user. This is typically followed by a command prompt where the user can enter commands to be executed on the server. The data sent by the server during the login process is discarded and not available when the method returns. If the client requires this information, use the **Search** method to automate the login process instead.

Because the **Login** method is designed for UNIX based systems, it may not work with servers running on other operating system platforms such as Windows or VMS. In this case, applications should use the **Search** method to search for the appropriate login prompts in the data stream.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTelnetClient::Read Method

```
INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   CString& strBuffer,
   INT cbBuffer
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

CTelnetClient::ReadLine Method

```
BOOL ReadLine(
   LPTSTR lpszBuffer,
   LPINT lpnLength
);

BOOL ReadLine(
   LPTSTR lpszBuffer,
   INT nMaxLength
);

BOOL ReadLine(
   CString& strBuffer,
   INT nMaxLength
);
```

The **ReadLine** method reads up to a line of data from the server and returns it in a string buffer.

Parameters

lpszBuffer

Pointer to the string buffer that will contain the data when the method returns. The string will be terminated with a null character, and will not contain the end-of-line characters. An alternate form of the method accepts a **CString** argument which will contain the line of text returned by the server.

lpnLength

A pointer to an integer value which specifies the length of the buffer. The value should be initialized to the maximum number of characters that can be copied into the string buffer, including the terminating null character. When the method returns, its value will updated with the actual length of the string.

nMaxLength

An integer value which specifies the maximum length of the buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **ReadLine** method reads data from the server and copies into a specified string buffer. Unlike the **Read** method which reads arbitrary bytes of data, this method is specifically designed to return a single line of text data in a string. When an end-of-line character sequence is encountered, the method will stop and return the data up to that point. The string buffer is guaranteed to be null-terminated and will not contain the end-of-line characters.

There are some limitations when using **ReadLine**. The method should only be used to read text, never binary data. In particular, the method will discard nulls, linefeed and carriage return control characters. The Unicode version of this method will return a Unicode string, however it does not support reading raw Unicode data from the socket. Any data read from the socket is internally buffered as octets (eight-bit bytes) and converted to Unicode using the **MultiByteToWideChar** function.

This method will force the thread to block until an end-of-line character sequence is processed, the read operation times out or the server closes its end of the socket connection. If this method is called

with asynchronous events enabled, it will automatically switch the socket into a blocking mode, read the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **ReadLine** is blocked waiting for data from the server, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **Read** and **ReadLine** method calls can be intermixed, however be aware that **Read** will consume any data that has already been buffered by the **ReadLine** method and this may have unexpected results.

Unlike the **Read** method, it is possible for data to be returned in the string buffer even if the return value is zero. Applications should check the length of the string to determine if any data was copied into the buffer. For example, if a timeout occurs while the method is waiting for more data to arrive on the socket, it will return zero; however, data may have already been copied into the string buffer prior to the error condition. It is the responsibility of the application to process that data, regardless of the return value.

Example

```
CString strBuffer;
BOOL bResult;

do
{
    bResult = pClient->ReadLine(strBuffer);

    if (strBuffer.GetLength() > 0)
    {
        // Process the line of data returned in the string
        // buffer; the string is always null-terminated
    }
} while (bResult);

DWORD dwError = pClient->GetLastError();

if (dwError == ST_ERROR_CONNECTION_CLOSED)
{
    // The server has closed its side of the connection and
    // there is no more data available to be read
}
else if (dwError != 0)
{
    // An error has occurred while reading a line of data
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTelnetClient::RegisterEvent Method

```
INT RegisterEvent(
   UINT nEventId,
   TELNETEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
TELNET_EVENT_CONNECT	The connection to the server has completed.
TELNET_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
TELNET_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
TELNET_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
TELNET_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **TelnetEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **TelnetEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

See Also

CTelnetClient::Search Method

```
BOOL Search(
   LPCTSTR lpszString
);

BOOL Search(
   LPCTSTR lpszString,
   LPBYTE lpBuffer,
   LPDWORD lpdwLength
);

BOOL Search(
   LPCTSTR lpszString,
   HGLOBAL *lpBuffer,
   LPDWORD lpdwLength
);

BOOL Search(
   LPCTSTR lpszString,
   CString& strBuffer
);
```

The **Search** method searches for a specific character sequence in the data stream and stops reading if the sequence is encountered.

Parameters

lpszString

A null-terminated string which specifies the sequence of characters to search for in the data stream. This parameter cannot be NULL or point to an empty string.

lpBuffer

A buffer which will contain the output from the server, or a pointer to a global memory handle which will reference the output when the method returns. If the output from the server is not required, this parameter may be NULL.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpBuffer*** parameter. If the ***lpBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual number of bytes of output stored in the buffer. If the ***lpBuffer*** parameter is NULL, this parameter should also be NULL.

Return Value

If the method succeeds and the character sequences was found in the data stream, the return value is non-zero. If the method fails or a timeout occurs before the sequence is found, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Search** method searches for a character sequence in the data stream and stops reading when it is found. This is useful when the client wants to automate responses to the server, such as logging in a user and executing a command. The method collects the output from the server and stores it in the buffer specified by the ***lpBuffer*** parameter. When the method returns, the buffer will contain everything sent by the server up to and including the search string.

The *lpBuffer* parameter may be specified in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the a fixed amount of output. In this case, the *lpBuffer* parameter will point to the buffer that was allocated, the value that the *lpdwLength* parameter points to should be initialized to the size of that buffer. If the server sends more output than can be stored in the buffer, the remaining output will be discarded.

The second method that can be used is have the *lpBuffer* parameter point to a global memory handle which will contain the output when the method returns. In this case, the value that the *lpdwLength* parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. This method is preferred if the client application does not have a general idea of how much output will be generated until the search string is found.

Example

```
CString strOutput;
BOOL bResult;

// Search for the login prompt issued by the server

bResult = pClient->Search(T("ogin: ");

// If the Login: prompt was found, then write out the
// username and search for the Password: prompt; note
// that the username, password and command strings are
// terminated with a carriage-return/linefeed sequence
// which the server will see as the user pressing the
// Enter or Return key on the keyboard

if (bResult)
{
    pClient->Write(lpszUserName);
    bResult = pClient->Search(_T("word: "));
}

// If the Password: prompt was found, write out the
// password and then search for the shell prompt;
// the prompt may be different, depending on what
// operating system and shell is being used

if (bResult)
{
    pClient->Write(lpszPassword);
    bResult = Search(hClient, _T("$ "));
}

// If the shell prompt was found, issue the command
// and capture the output into the strOutput string
// and then write it to standard output

if (bResult)
{
    pClient->Write(lpszCommand);

    if (pClient->Search(_T("$ "), strOutput))
        cout << (LPCTSTR)strOutput << endl;
}
```

Requirements

CTelnetClient::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or TELNET_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

CTelnetClient::SetMode Method

```
UINT SetMode(
   UINT nMode,
   BOOL bEnable
);
```

The **SetMode** method sets one or more client modes for the specified session.

Parameters

nMode

The client mode. This value is a combination of one or more flags which determines how the client handles local character echo and character processing. The following values are recognized:

Value	Description
TELNET_MODE_LOCALECHO	The local client is responsible for echoing data entered by the user. By default, this mode is not set which means that the server is responsible for echoing back each character written to it.
TELNET_MODE_BINARY	Data exchanged between the client and server should not be converted or line buffered. If this option is not specified, the high-bit will be cleared on all characters, and single linefeed characters will be converted to carriage-return/linefeed sequences.

bEnable

This boolean flag specifies if the specified mode is to be enabled or disabled.

Return Value

If the method succeeds, the return value is the previous mode. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

CTelnetClient::SetTerminalType Method

```
INT SetTerminalType(
   LPCTSTR lpszTermType
);
```

The **SetTerminalType** method sets the terminal type for the current client session.

Parameters

lpszTermType

Points to a string which specifies the terminal type.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetTerminalType

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTelnetClient::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib

CTelnetClient::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTelnetClient::Write Method

```
INT Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Write(
   LPCTSTR lpszBuffer
   INT cbBuffer
);
```

The **Write** method sends the specified number of bytes to the server.

Parameters

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server. In an alternate form of the method, the pointer is to a string.

cbBuffer

The number of bytes to send from the specified buffer. This value must be greater than zero, unless a pointer to a string buffer is passed as the parameter. In that case, if the value is -1, all of the characters in the string, up to but not including the terminating null character, will be sent to the server.

Return Value

If the method succeeds, the return value is the number of bytes actually written. If the method fails, the return value is TELNET_ERROR. To get extended error information, call **GetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstntv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTelnetClient::WriteLine Method

```
BOOL WriteLine(
   LPCTSTR lpszBuffer,
   LPINT lpnLength
);
```

The **WriteLine** function sends a line of text to the server, terminated by a carriage-return and linefeed.

Parameters

lpszBuffer

The pointer to a string buffer which contains the data that will be sent to the server. All characters up to, but not including, the terminating null character will be written to the socket. The data will always be terminated with a carriage-return and linefeed control character sequence. If this parameter points to an empty string or NULL pointer, then a only a carriage-return and linefeed are written to the socket.

lpnLength

A pointer to an integer value which will contain the number of characters written to the socket, including the carriage-return and linefeed sequence. If this information is not required, a NULL pointer may be specified.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WriteLine** method writes a line of text to the server and terminates the line with a carriage-return and linefeed control character sequence. Unlike the **Write** method which writes arbitrary bytes of data to the socket, this method is specifically designed to write a single line of text data from a null-terminated string.

If the ***lpszBuffer*** string is terminated with a linefeed (LF) or carriage return (CR) character, it will be automatically converted to a standard CRLF end-of-line sequence. Because the string will be sent with a terminating CRLF sequence, the value returned in the ***lpnLength*** parameter will typically be larger than the original string length (reflecting the additional CR and LF characters), unless the string was already terminated with CRLF.

There are some limitations when using **WriteLine**. This method should only be used to send text, never binary data. In particular, it will discard nulls and append linefeed and carriage return control characters to the data stream. The Unicode version of this method will accept a Unicode string, however it does not support writing raw Unicode data to the socket. Unicode strings will be automatically converted to UTF-8 encoding using the **WideCharToMultiByte** function and then written to the socket as a stream of bytes.

This method will force the thread to block until the complete line of text has been written, the write operation times out or the server aborts the connection. If this method is called with asynchronous events enabled, it will automatically switch the socket into a blocking mode, send the data and then restore the socket to asynchronous operation. If another socket operation is attempted while **WriteLine** is blocked sending data to the server, an error will occur. It is recommended that this method only be used with blocking (synchronous) socket connections; if the application needs to

establish multiple simultaneous connections, it should create worker threads to manage each connection.

The **Write** and **WriteLine** methods can be safely intermixed.

Unlike the **Write** function, it is possible for data to have been written to the socket if the return value is zero. For example, if a timeout occurs while the method is waiting to send more data to the server, it will return zero; however, some data may have already been written prior to the error condition. If this is the case, the ***lpnLength*** argument will specify the number of characters actually written up to that point.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Telnet Protocol Data Structures

- SECURITYCREDENTIALS
- SECURITYINFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing

	a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH protocol has been specified, this member should be NULL.

lpszKeyFile

This member is not used and should always be NULL. The private key cannot be specified separately and must be associated with the certificate.

Remarks

An application only needs to create this structure if the server requires the client to provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is

specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description
SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be

	cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Terminal Emulation Class Library

Emulate an ANSI or DEC VT-220 character mode display terminal.

Reference

- Class Methods
- Data Structures
- Control Sequences
- Error Codes

Library Information

Class Name	CTerminalEmulator
File Name	CSNVTV12.DLL
Version	12.0.3024.1286
LibID	9A302CB9-6BEE-4D11-9785-76E7624BD130
Import Library	CSNVTV12.LIB
Dependencies	None

Remarks

The Terminal Emulation library provides a comprehensive API for emulating an ANSI or DEC-VT220 terminal, with full support for all standard escape and control sequences, color mapping and other advanced features. The library methods provide both a high level interface for parsing escape sequences and updating a display, as well as lower level primitives for directly managing the virtual display, such as controlling the individual display cells, moving the cursor position and specifying display attributes.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing

applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Terminal Emulation Class Methods

Class	Description
CTerminalEmulator	Constructor which initializes the current instance of the class
~CTerminalEmulator	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified display handle to this instance of the class
Clear	Clear the virtual display
ConvertPos	Convert between pixel and screen coordinates
CopySelectedText	Copy the selected text to the clipboard
Create	Create a new virtual terminal emulation display
DeleteChar	Delete the specified number of characters
DeleteLine	Delete the current line, shifting remaining lines up
DetachHandle	Detach the handle for the current instance of this class
EraseChar	Erase the specified number of characters
EraseLine	Erase the current line
GetAttributes	Return the current display attributes
GetBackColor	Return the current background color
GetCell	Return information about the specified cell in the virtual display
GetCellSize	Return the size of the display character cells
GetColor	Get the current virtual display colors
GetColorMap	Return the virtual display color table
GetCursorPos	Return the current cursor position
GetDisplayInfo	Return information about the virtual display
GetDC	Get the current virtual display device context
GetEmulation	Get the current terminal emulation type
GetFont	Get the current virtual display font
GetForeColor	Return the current foreground color
GetLine	Return a line of text from the virtual display
GetMode	Get the current virtual display mode
GetRect	Return the rectangle for the display window client area
GetScrollPos	Get the display scroll box position
GetSize	Return the current size of the virtual display
GetText	Get the specified block of text from the virtual display

GetWindow	Get the current virtual display window
GetHandle	Return the display handle used by this instance of the class
GetMappedKey	Return the escape sequence for the mapped key
GetScrollRegion	Return the current scrolling region
GetSelectedText	Return the currently selected text
GetTextColor	Return the current text foreground or background color
InsertChar	Insert the specified number of characters
InsertLine	Insert a line, shifting the remaining lines down
IsInitialized	Determine if the class has been successfully initialized
Refresh	Refresh the specified display
Reset	Reset the virtual display
ResetMappedKeys	Reset the mapped key table to default values
Resize	Resize the virtual display
RestoreCursor	Restore the saved cursor position and text attributes
SaveCursor	Save the current cursor position and text attributes
Scroll	Scroll the virtual display
SelectText	Select a region of the virtual display
SetAttributes	Set the current display attributes
SetBackColor	Set the background color for the virtual display
SetBoldColor	Set the bold color for the virtual display
SetCell	Set the value of a character cell in the virtual display
SetColor	Set the virtual display colors
SetColorMap	Set the virtual display color table
SetCursorPos	Set the current cursor position
SetDC	Set the current virtual display device context
SetEmulation	Set the current terminal emulation type
SetFocus	Set the focus on the virtual display
SetFont	Set the current virtual display font
SetForeColor	Set the foreground color for the virtual display
SetMode	Set the current virtual display mode
SetScrollPos	Set the display scroll box position
SetSize	Set the size of the virtual display
SetWindow	Set the current virtual display window
SetMappedKey	Set the escape sequence for the specified key
SetScrollRegion	Set the current scrolling region

SetTextColor	Set the current text foreground or background color
TranslateMappedKey	Translate the keypress to a mapped key escape sequence
Update	Update the window attached to the virtual display
UpdateCaret	Update the display window caret
Write	Write the specified buffer to the virtual display

CTerminalEmulator::CTerminalEmulator Method

```
CTerminalEmulator();
```

The **CTerminalEmulator** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **NvtInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CTerminalEmulator, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::~CTerminalEmulator

```
~CTerminalEmulator();
```

The **CTerminalEmulator** destructor releases resources allocated by the current instance of the **CTerminalEmulator** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CTerminalEmulator** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the emulator are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTerminalEmulator::AttachHandle Method

```
VOID AttachHandle(
   HDISPLAY hDisplay
);
```

The **AttachHandle** method attaches the specified display handle to the current instance of the class.

Parameters

hDisplay

The handle to the virtual display that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a display handle created outside of the class using the SocketTools API. Once the handle is attached to the class, the other class member functions may be used with that virtual display.

The virtual display for the current instance of the class will be destroyed when the new handle is attached to the class object. If you want to prevent the display handle from being released, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hDisplay*** parameter is presumed to be a valid display handle and no checks are performed to ensure that the handle is valid. Specifying an invalid handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

DetachHandle, GetHandle

CTerminalEmulator::Clear Method

```
BOOL Clear(
   UINT nMode
);
```

The **Clear** method clears the specified display, erasing the text and clearing any attributes.

Parameters

nMode

Mode which specifies how the display will be cleared. The following values may be used:

Value	Description
NVT_CLEAR_EOS	The display is cleared from the current cursor position to the end of the display. The cursor position is not changed.
NVT_CLEAR_TOS	The display is cleared from the beginning of the display to the current cursor position. The cursor position is not changed.
NVT_CLEAR_ALL	The entire display is cleared and the cursor is repositioned to the upper left corner of the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::ConvertPos Method

```
BOOL ConvertPos(
   INT nMethod,
   INT xPos,
   INT yPos,
   LPPOINT lppt
);

BOOL ConvertPos(
   INT xPos,
   INT yPos,
   LPPOINT lppt
);
```

The **ConvertPos** method converts the specified X,Y position and stores the result in the POINT structure provided by the caller.

Parameters

nMethod

An integer value which specifies the conversion method to use. This may be one of the following values:

Value	Description
NVT_CURSOR_TO_PIXELS	Convert cursor X,Y coordinates to the current window X,Y pixel coordinates. An error is returned if the coordinates are out of bounds for the current display.
NVT_PIXELS_TO_CURSOR	Convert window X,Y pixel coordinates to cursor X,Y coordinates. If the point is outside of the bounds of the display, it is normalized to account for mouse capture.

xPos

An integer value which specifies the X position in the virtual display. This may either be the cursor position or a pixel position, based on the value of the ***nMethod*** parameter.

yPos

An integer value which specifies the Y position in the virtual display. This may either be the cursor position or a pixel position, based on the value of the ***nMethod*** parameter.

lppt

A pointer to a POINT structure which will contain the converted coordinates.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::CopySelectedText Method

```
BOOL CopySelectedText();
```

The **CopySelectedText** method copies any selected text to the system clipboard.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

CTerminalEmulator::Create Method

```
BOOL Create(
   HWND hWnd,
   HFONT hFont,
   UINT nEmulation,
   UINT nColumns,
   UINT nRows
);
```

The **Create** method creates a new virtual terminal emulation display using the specified window and font.

Parameters

hWnd

Handle to the window that will be used to display the virtual terminal.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case a default fixed-width font will be used. If a font is specified, it must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

nEmulation

Identifies the virtual terminal emulation type. The following emulation types are currently supported.

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process escape sequences.
NVT_EMULATION_ANSI	The virtual display processes ANSI escape sequences for screen management and cursor positioning. This emulation also supports escape sequences to control the foreground and background color. The default keymap for ANSI function key escape sequences will be selected.
NVT_EMULATION_VT100	The virtual display processes DEC VT-100 escape sequences for screen management and cursor positioning. The default keymap for a DEC VT-100 terminal will be selected.
NVT_EMULATION_VT220	The virtual display processes DEC VT-220 escape sequences for screen management and cursor positioning. This emulation also supports DEC VT-320 escape sequences to control the foreground and background color. The default keymap for a DEC VT-220 terminal will be selected.

nColumns

The maximum number of columns used by the virtual display. This value must be at least 5, and no greater than 255.

nRows

The maximum number of rows used by the virtual display. This value must be at least 5, and no greater than 127.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

Remarks

The default colors for the display is a black background and white foreground. If ANSI terminal emulation is selected, bold characters will be displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

AttachHandle, DetachHandle, GetDisplayInfo

CTerminalEmulator::DeleteChar Method

```
BOOL DeleteChar(
   INT nChars
);
```

The **DeleteChar** method deletes the specified number of characters from the display, shifting the characters that follow to the left. The characters are deleted from the current cursor position.

Parameters

nChars

Number of characters to delete from the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. To erase characters from the display without affecting the characters that follow, use the **EraseChar** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

Clear, DeleteLine, EraseChar, EraseLine

CTerminalEmulator::DeleteLine Method

```
BOOL DeleteLine();
```

The **DeleteLine** method deletes the current line, shifting up the lines that follow.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. To erase a line from the display without affecting the lines that follow, use the **EraseLine** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

CTerminalEmulator::DetachHandle Method

```
HDISPLAY DetachHandle();
```

The **DetachHandle** method detaches the display handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the display handle associated with the current instance of the class object. If there is no virtual display associated with that instance of the class, the value INVALID_DISPLAY will be returned.

Remarks

This method is used to detach a display handle created by the class for use with the SocketTools API. Once the handle is detached from the class, no other class methods may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

AttachHandle, GetHandle

CTerminalEmulator::EraseChar Method

```
BOOL EraseChar(
   INT nChars
);
```

The **EraseChar** method erases the specified number of characters from the display, without affecting the position of the characters that follow. The characters are erased from the current cursor position.

Parameters

nChars

Number of characters to erase from the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. To delete characters from the display and shift the remaining characters to the left, use the **DeleteChar** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

Clear, DeleteChar, DeleteLine, EraseLine

CTerminalEmulator::EraseLine Method

```
BOOL EraseLine(
   UINT nMode
);
```

The **EraseLine** method erases the current line without affecting the lines that follow.

Parameters

nMode

Mode which specifies how the line will be erased. The following values may be used:

Value	Description
The line is erased from the current cursor position to the end of the line.	
The line is cleared from the beginning of the line to the current cursor position.	
The entire line is cleared.	

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. To delete a line from the display and shift the remaining lines up, use the **DeleteLine** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTerminalEmulator::GetAttributes Method

```
UINT GetAttributes();
```

The **GetAttributes** method returns the current display attributes which have been set, either explicitly by the client or as the result of an escape sequence parsed by the emulator.

Parameters

None.

Return Value

If the method succeeds, the return value the current display attributes. If the method fails, the return value is NVT_ERROR.

The following table lists the valid attributes:

Value	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

GetCell, SetAttributes

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::GetBackColor Method

```
COLORREF GetBackColor();
```

The **GetColor** method returns the background color used by the current display.

Parameters

None.

Return Value

If the method succeeds, the return value is the RGB value of the background color. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::GetCell Method

```
BOOL GetCell(
   INT xPos,
   INT yPos
   TCHAR *pChar
   UINT *pAttributes
);

BOOL GetCell(
   TCHAR *pChar
   UINT *pAttributes
);
```

The **GetCell** method returns information about the specified character cell in the virtual display.

Parameters

xPos

An integer value which specifies the X cursor position in the display. If this argument is omitted or has the value -1, then the current position in the display is used.

yPos

An integer value which specifies the Y cursor position in the display. If this argument is omitted or has the value -1, then the current position in the display is used.

pChar

A buffer that will contain the character in the specified cell when the method returns. If this argument is NULL, then no character is returned.

pAttributes

A pointer to an unsigned integer value which specifies the attributes for the specified character cell. If this argument is NULL, then no attribute information is returned.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero. Failure typically indicates that the X or Y position is invalid, or that a virtual display has not been created.

Remarks

The attribute value returned by the **GetCell** method may be one or more of the following values:

Value	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

One or more attributes may be combined using a bitwise Or operator. Certain attributes, such as

NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::GetCellSize Method

```
BOOL GetCellSize(
   LPSIZE lpCellSize
);
```

```
BOOL GetCellSize(
   LPINT lpnWidth
   LPINT lpnHeight
);
```

The **GetCellSize** method returns the size of a character cell in pixels.

Parameters

lpCellSize

A pointer to a SIZE structure which will contain the size of a character cell in pixels when the method returns.

lpnWidth

A pointer to an integer which will contain the width of a character cell in pixels when the method returns.

lpnHeight

A pointer to an integer which will contain the height of a character cell in pixels when the method returns.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero. Failure typically indicates that the virtual display has not been created.

Remarks

The **GetCellSize** method is used to determine the size of a character cell in the display. This can be useful when the application needs to determine where a display cell is physically located within the virtual display window.

To convert between display and window coordinates, use the **ConvertPos** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::GetColor Method

```
COLORREF GetColor(
   UINT nColorIndex,
   BOOL bForeground
);
```

The **GetColor** method returns the color used by the virtual display to display text with a specific attribute.

Parameters

nColorIndex

The index into the virtual display color table. It may be one of the following values.

Value	Description
NVT_COLOR_NORMAL	The colors displayed for normal text. These are the default colors used with the display.
NVT_COLOR_REVERSE	The colors displayed for text with the reverse attribute set. This is only used when emulation is enabled.
NVT_COLOR_BOLD	The colors displayed for text with the bold attribute set. This is only used when emulation is enabled.
NVT_COLOR_REVERSEBOLD	The colors displayed for text with the reverse and bold attributes set. This is only used when emulation is enabled.

bForeground

A boolean flag which specifies if the color is a foreground color, used when displaying text, or a background color.

Return Value

If the method succeeds, the return value is the RGB value of the specified color. If the method fails, it returns zero.

Remarks

The default colors for the display is a black background and white foreground. Bold characters are displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::GetColorMap Method

```
BOOL GetColorMap(
   COLORREF *lpColor,
   INT nMaxColors
);
```

The **GetColorMap** method returns the virtual display color table which determines what RGB values are used to display foreground and background text color attributes.

Parameters

lpColor

A pointer to an array of COLORREF values which will contain the color values currently being used in the virtual display.

nMaxColors

The maximum number of colors which may be stored in the color array. The minimum value for this parameter is 1, and the maximum value is 16.

Return Value

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. Failure indicates that the handle to the virtual display is invalid, the pointer to the color table is NULL or the maximum number of color values is invalid.

Remarks

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **GetColorMap** method is useful for determining what values are being used when a color attribute is set. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals:

Index	Color	Default (Hex)	Default (Integer)	Default (RGB)
Black	RGB(0,0,0)			
Red	000000A0h	RGB(160,0,0)		
Green	0000A000h	RGB(0,160,0)		
Yellow	0000A0A0h	RGB(160,160,0)		
Blue	00A00000h	RGB(0,0,160)		
Magenta	00A000A0h	RGB(160,0,160)		
Cyan	00A0A000h	RGB(0,160,160)		
White	00E0E0E0h	RGB(224,224,224)		
Gray	00C0C0C0h	RGB(192,192,192)		
Light Red	008080FFh	RGB(255,128,128)		
Light Green	0090EE90h	RGB(144,238,144)		
Light Yellow	00C0FFFFh	RGB(255,255,192)		
Light Blue	00E6D8ADh	RGB(173,216,230)		

Light Magenta	00FFC0FFh	RGB(255,192,255)
Light Cyan	00FFFFE0h	RGB(224,255,255)
High White	00FFFFFFh	RGB(255,255,255)

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

```
ESC [ 37;44 m
```

Note that if you wanted to set the foreground color to a bold version of standard yellow, you would first set the bold attribute, and then use the index value of 3, such as:

```
ESC [ 1;33m
```

GetColorMap is typically used in conjunction with the **SetColorMap** method to load the current color values and then make selective changes to the actual RGB color value that is used when a color attribute is set. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters.

Example

The following example will load the current color table for the virtual display and change the standard white color attribute to use the same value as the high-intensity white:

```
COLORREF rgbColor[16];

if (pDisplay->GetColorMap(rgbColor, 16) )
{
     rgbColor[7] = rgbColor[15];
     pDisplay->SetColorMap(rgbColor, 16);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTerminalEmulator::GetCursorPos Method

```
BOOL GetCursorPos(
   LPINT lpnCursorX,
   LPINT lpnCursorY
);
```

The **GetCursorPos** method returns the current cursor column and row position on the virtual display.

Parameters

lpnCursorX

Address of the variable that will be set to the column of the current cursor position. If this argument is a NULL pointer, the argument is ignored.

lpnCursorY

Address of the variable that will be set to the row of the current cursor position. If this argument is a NULL pointer, the argument is ignored.

Return Value

If the method succeeds, the return value is a non-zero value. If the handle to the virtual display is invalid, the method will return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::GetDC Method

```
HDC GetDC();
```

The **GetDC** returns the device context that has been specified for the virtual display.

Parameters

None.

Return Value

If the method succeeds, the return value is a handle to the device context. If the method fails, or no device context has been specified, the return value is NULL.

Remarks

Normally there is no device context explicitly set for the display. Instead, the device context is dynamically created and released when the virtual display is updated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CTerminalEmulator::GetDisplayInfo Method

```
BOOL GetDisplayInfo(
   LPNVTDISPLAYINFO lpvdi
);
```

The **GetDisplayInfo** method returns information about the specified virtual display.

Parameters

lpvdi

Pointer to a NVTDISPLAYINFO structure which contains information about the virtual display, including the display window, font, cursor and scrolling position.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

UINT GetEmulation();
```

The **GetEmulation** method returns the current virtual terminal emulation type.

Parameters

None.

Return Value

If the method succeeds, the return value is the terminal emulation type and may contain one of the following values:

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
NVT_EMULATION_ANSI	The virtual display will process ANSI escape sequences. The default keymap for an ANSI console is loaded.
NVT_EMULATION_VT100	The virtual display will process DEC VT100 escape sequences. The default keymap for a VT100 terminal is loaded.
NVT_EMULATION_VT220	The virtual display will process DEC VT220 escape sequences. The default keymap for a VT220 terminal is loaded.

If the method fails, because an invalid display handle was specified, the return value will be NVT_ERROR.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

CTerminalEmulator::GetFont Method

```
HFONT GetFont();
```

The **GetFont** method returns the current font handle being used by the virtual display.

Parameters

None.

Return Value

If the method succeeds, the return value is a handle to the font. If the method fails, it returns NULL.

Remarks

The handle returned by this method should not be released, and the font object should never be directly modified by the application. Functions that return information about the font, such as **GetTextMetrics**, may be safely called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

Create, SetFont

CTerminalEmulator::GetForeColor Method

```
COLORREF GetForeColor();
```

The **GetColor** method returns the foreground color used by the current display.

Parameters

None.

Return Value

If the method succeeds, the return value is the RGB value of the foreground color. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

GetBackColor, SetBackColor, SetBoldColor, SetColor, SetForeColor

CTerminalEmulator::GetHandle Method

```
HDISPLAY GetHandle();
```

The **GetHandle** method returns the display handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the display handle associated with the current instance of the class object. If there is no virtual display associated with that instance of the class, the value INVALID_DISPLAY will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

AttachHandle, DetachHandle, IsInitialized

CTerminalEmulator::GetLine Method

```
INT GetLine(
   INT nRow,
   LPTSTR lpszText,
   INT nMaxLength
);

INT GetLine(
   INT nRow,
   CString& strText
);
```

The **GetLine** method copies a block of text from the specified virtual display into a string buffer.

Parameters

nRow

The row in the virtual display to return the line of text from. The first row in the display is zero. If the value -1 is specified, the row where the cursor is currently located will be used.

lpszText

Pointer to the buffer that the display text will be copied to, terminated with a null character character. An alternate version of this method accepts a reference to a **CString** object which will contain the display text when the method returns.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the method fails, it returns zero.

Remarks

The **GetLine** method allows the application to copy the contents of the display at a specific row. Note that the buffer must be large enough to accommodate the text and the null character terminator. Unlike the **GetText** method, any trailing whitespace in the specified row is not copied to the buffer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTerminalEmulator::GetMappedKey Method

```
BOOL GetMappedKey(
   UINT nMappedKey,
   LPTSTR lpszKeyBuffer,
   UINT cchKeyBuffer
);
```

```
BOOL GetMappedKey(
   UINT nMappedKey,
   CString& strKeyBuffer
);
```

The **GetMappedKey** method returns the escape sequence mapped to the specified key.

Parameters

nMappedKey

The key which is an index into the display key mapping table. This defines the values returned by special (method) keys for the current emulation.

lpszKeyBuffer

Address of the buffer which will receive the escape sequence mapped to the specified key. This argument may also be a **CString** object which will contain the mapped key string when the method returns.

cchKeyBuffer

The maximum number of characters that may be copied into the key buffer string, including the terminating null character.

Return Value

If the method succeeds, the return value is non-zero and the escape sequence for the mapped key is copied into the specified buffer. If the key has not been mapped, and there is no default escape sequence defined, then the method will return zero.

Remarks

The **GetMappedKey** method returns the escape sequence that has been mapped to a special key. This method can be used to determine what sequence of characters should be sent in response to a keypress (for example, what sequence should be sent to a server when the user presses the F1 method key). If a sequence has not been explicitly mapped through a call to **SetMappedKey**, the default sequence for the current emulation will be returned.

Note that the current display mode, such as whether or not the emulator is in application mode or not, should be considered when determining which mapped key to use. For example, if the emulator is not in application mode and the user presses the up-arrow key, the sequence mapped to the NVT_UP key should be sent to the server. However, if the emulator is in application mode, the sequence mapped to the NVT_APPUP key should be sent instead. This is automatically handled by the **TranslateMappedKey** method, so it is recommended that it be used when mapping a virtual keypress to the appropriate escape sequence.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetMode, ResetMappedKeys, SetMode, SetMappedKey, TranslateMappedKey

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::GetMode Method

```
UINT GetMode();
```

The **GetMode** method returns the current virtual display modes.

Parameters

None.

Return Value

If the method succeeds, the return value is the display mode for the virtual display. If the method fails, it returns zero.

Remarks

The display mode is a combination of one or more flags which determines how the emulator handles automatic line wrapping, caret display, and other methods. The following values are recognized.

Value	Description
NVT_MODE_AUTOWRAP	The emulator will automatically wrap to the next line when a character is written to the last column on the virtual display.
NVT_MODE_SHOWCARET	The emulator will display a caret when the display receives the focus.
NVT_MODE_BLOCKCARET	The emulator will display a block carat that is the height of the selected font characters. If this mode is not set, the caret is displayed as an underline.
NVT_MODE_BELL	The emulator will beep when a BEL character is processed.
NVT_MODE_CRLF	The cursor will automatically be positioned at the first column when a linefeed character is processed.
NVT_MODE_CRNL	The cursor will automatically advance to the next row when a carriage return character is processed.
NVT_MODE_APPCURSOR	The emulator cursor keys are placed in application mode. This mode changes the default key mappings used when the cursor (arrow) keys are translated. This corresponds to the application mode supported by DEC VT terminals.
NVT_MODE_APPKEYPAD	The emulator keypad keys are placed in application mode. This mode changes the default key mappings used when the keypad keys are translated. This corresponds to the application keypad mode supported by DEC VT terminals.
NVT_MODE_ORIGIN	The emulator is in origin mode. If enabled, the cursor cannot be positioned outside of the current scrolling region. Otherwise, the cursor can be positioned at any valid location on the virtual display.
NVT_MODE_COLOR	The emulator supports the use of escape sequences to change the foreground and background colors. This option is enabled by default if emulating an ANSI console or DEC VT220 terminal.
NVT_MODE_TABOVER	The emulator will clear the character cells between the current cursor position and the next tab stop when the HT (horizontal tab) control

	sequence is processed. By default this mode is disabled, and the cursor is simply positioned at the next tab stop.
NVT_MODE_HSCROLL	The emulator will display a horizontal scroll bar if the number of visible columns are less then that total number of columns in the virtual display. Disabling this mode prevents a horizontal scrollbar from being displayed, regardless of the number of visible columns. By default, this mode is enabled.
NVT_MODE_VSCROLL	The emulator will display a vertical scroll bar if the number of visible rows are less then that total number of rows in the virtual display. Disabling this mode prevents a vertical scrollbar from being displayed, regardless of the number of visible rows. By default, this mode is enabled.
NVT_MODE_NOREFRESH	The emulator will not automatically refresh the window after any change has been made to the virtual display, including changes in the cursor position or display mode. This allows the caller to make a sequence of changes, and then update the display all at one time to prevent a flicker effect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

GetEmulation, GetDisplayInfo, SetMode

CTerminalEmulator::GetRect Method

```
BOOL GetRect(
   LPRECT lpRect
);
```

The **GetRect** returns the client rectangle for the virtual display window.

Parameters

lpRect

Pointer to a RECT structure which will contain the client rectangle values when the method returns.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

GetDisplayInfo, GetSize, Resize, SetSize

CTerminalEmulator::GetScrollPos Method

```
INT GetScrollPos(
   INT nScrollBar
);
```

The **GetScrollPos** method gets the position of the scroll box for the specified scroll bar.

Parameters

nScrollBar

Specifies the scroll bar to return the position for. This parameter can be one of the following values:

Value	Description
SB_HORZ	Gets the position of the scroll box in the display's standard horizontal scroll bar.
SB_VERT	Gets the position of the scroll box in the display's standard vertical scroll bar.

Return Value

If the method succeeds, the return value is the position of the scroll box. If the method fails, it returns -1.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

SetScrollPos

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::GetScrollRegion Method

```
BOOL GetScrollRegion(
   LPINT lpnTop,
   LPINT lpnBottom
);
```

The **GetScrollRegion** method returns the top and bottom rows of the current scrolling region.

Parameters

lpnTop

Address of the variable that will be set to the top row of the current scrolling region. If no scrolling region has been defined, the value will be 0, the first row in the virtual display. If a NULL pointer is passed as the value, this argument will be ignored.

lpnBottom

Address of the variable that will be set to the bottom row of the current scrolling region. If no scrolling region has been defined, the value will be one less than the maximum number of rows in the virtual display. If a NULL pointer is passed as the value, this argument will be ignored.

Return Value

If the method succeeds, it will return zero. If the handle to the display is invalid, the method will return zero.

Remarks

The **GetScrollRegion** method allows an application to determine the top and bottom rows of the current scrolling region. By default, the scrolling region is the entire virtual display, however this may be changed through a call to **SetScrollRegion** or an ANSI escape sequence. If the display is in origin mode, note that the cursor cannot be positioned outside of the current scrolling region.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

CTerminalEmulator::GetSelectedText Method

```
INT GetSelectedText(
   LPTSTR lpszBuffer,
   INT nMaxLength
);

INT GetSelectedText(
   CString& strBuffer
);
```

The **GetSelectedText** method copies the currently selected text into the specified buffer.

Parameters

lpszBuffer

Pointer to the buffer that the selected text will be copied to, terminated with a null character character. This argument may also be a **CString** object which will contain the selected text when the method returns.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CTerminalEmulator::GetSize Method

```
BOOL GetSize(
   LPSIZE lpSize
);

BOOL GetSize(
   LPINT lpnWidth,
   LPINT lpnHeight
);
```

The **GetSize** returns the size of the virtual display in columns and rows.

Parameters

lpSize

Pointer to a SIZE structure which will contain the size of the virtual display.

lpnWidth

Pointer to an integer which will contain the number of columns in the virtual display when the method returns. If a NULL pointer is passed as the argument, this value is ignored.

lpnHeight

Pointer to an integer which will contain the number of rows in the virtual display when the method returns. If a NULL pointer is passed as the argument, this value is ignored.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

The **GetSize** method returns the number of columns and rows in the virtual display. To convert this to pixels, use the **GetCellSize** method to determine the size of a character cell and multiply that by the number of columns and/or rows.

Example

```
// Calculate the size of the client area in pixels
// for the virtual display

INT cxCell = 0, cyCell = 0;
INT cxDisplay = 0, cyDisplay = 0;

if (pDisplay->GetCellSize(&cxCell, &cyCell))
{
    INT nColumns, nRows;
    if (pDisplay->GetSize(&nColumns, &nRows))
    {
        cxDisplay = nColumns * cxCell;
        cyDisplay = nRows * cyCell;
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csnvtv12.lib

See Also

GetCellSize, GetDisplayInfo, GetRect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::GetText Method

```
INT GetText(
   INT xPos,
   INT yPos,
   LPTSTR lpszText,
   INT nLength
);

INT GetText(
   INT xPos,
   INT yPos,
   CString& strText,
   INT nLength
);

INT GetText(
   LPTSTR lpszText,
   INT nLength
);

INT GetText(
   CString& strText,
   INT nLength
);
```

The **GetText** method copies a block of text from the specified virtual display into a string buffer.

Parameters

xPos

The starting column where the display text will be copied from. If the method is called where this argument is omitted, the text will be copied from the current cursor position.

yPos

The starting row where the display text will be copied from. If the method is called where this argument is omitted, the text will be copied from the current cursor position.

lpszText

Pointer to the buffer that the display text will be copied to, terminated with a null character character. An alternate version of this method accepts a reference to a **CString** object which will contain the display text when the method returns.

nLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator. If a CString object is passed to the method, this value may be -1 which specifies that all of the text from the specified position to the last column and row should be copied to the buffer.

Return Value

If the method succeeds, the return value is the number of characters copied into the buffer, not including the null character terminator. If the method fails, it returns zero.

Remarks

The **GetText** method allows the application to copy the contents of the display at a specific location. Note that the buffer must be large enough to accommodate the text and the null character

terminator. To copy an entire row of text in the display, use the **GetLine** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTerminalEmulator::GetTextColor Method

```
BOOL GetTextColor(
   COLORREF *lprgbColor,
   BOOL bForeground
);
```

The **GetTextColor** method returns the current foreground or background text color.

Parameters

lprgbColor

A pointer to a COLORREF variable which will contain the current foreground or background text color.

bForeground

A boolean value which determines if the foreground or background color is returned. A value of TRUE indicates that the foreground color should be returned, otherwise the background color is returned.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. Failure indicates that the handle to the display is invalid, the display does not support text color attributes, or the pointer to the color value is NULL.

Remarks

This method is used to return the current foreground or background color, as determined by the text attribute. The RGB color value for a color attribute is determined by the virtual display's color table.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::GetWindow Method

```
HWND GetWindow();
```

The **GetWindow** returns the handle to the window being used by the virtual display.

Parameters

None.

Return Value

If the method succeeds, the return value is a handle to the virtual display window. If the method fails, it returns NULL.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

GetDisplayInfo

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::InsertChar Method

```
BOOL InsertChar(
   INT nChars
);
```

The **InsertChar** method inserts one or more space characters at the current cursor position.

Parameters

nChars

Number of space characters to insert at the current cursor position.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the cursor position. Inserting space characters may cause the virtual display to scroll.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

DeleteChar, EraseChar, InsertLine

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::InsertLine Method

```
BOOL InsertLine();
```

The **InsertLine** method inserts an empty line at the current row, shifting the remaining lines down.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the cursor position. Inserting a line may cause the virtual display to scroll.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

DeleteLine, EraseLine, InsertChar

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::Refresh Method

```
BOOL Refresh(
   BOOL bUpdate
);
```

The **Refresh** method refreshes the specified virtual display, updating the current scroll position and caret.

Parameters

bUpdate

Boolean flags which specifies if the display window is to be updated. If set, the window client area is invalidated and the virtual display is redrawn.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::Reset Method

```
BOOL Reset(
   HWND hWnd,
   HFONT hFont,
   UINT nColumns,
   UINT nRows
);

BOOL Reset(
   UINT nColumns,
   UINT nRows
);
```

The **Reset** resets the virtual terminal display, using the new window, font, columns and rows. This method should be used when the virtual display must be attached to a different window, or the number of rows or columns must be changed.

Parameters

hWnd

Handle to the window that will be used to display the virtual terminal. This parameter may be NULL, in which case the current window will be used.

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case the current font will be used. If a font is specified, it must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

nColumns

The maximum number of columns used by the virtual display. A value of zero specifies that the same number of columns should be used. If a non-zero value is specified, it must be at least 5, and no greater than 255.

nRows

The maximum number of rows used by the virtual display. A value of zero specifies that the same number of columns should be used. If a non-zero value is specified, it must be at least 5, and no greater than 127.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero.

Remarks

This method will clear the display and reset the current text attributes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::ResetMappedKeys Method

```
BOOL ResetMappedKeys();
```

The **ResetMappedKeys** method resets all mapped method keys to their default values, based on the current emulation.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the handle to the display is invalid, the method will return zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::Resize Method

```
BOOL Resize(
   INT cxClient,
   INT cyClient
);
```

The **Resize** method resizes the virtual display to the specified width and height.

Parameters

cxClient

New width of the display window in pixels. If this value is zero, the width of the virtual display remains unchanged.

cyClient

New height of the display window in pixels. If this value is zero, the height of the virtual display remains unchanged.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method resizes the virtual display and updates the scrolling information. Typically this method is called when the display window receives a WM_SIZE message, causing the virtual display to match the size of the window's client area.

This method will not change the size of the display window. To change the size of the display window, use the **SetWindowPos** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

CTerminalEmulator::RestoreCursor Method

```
BOOL RestoreCursor();
```

The **RestoreCursor** method restores the cursor position and text attributes to their previous values.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

Use the **SaveCursor** method to save the current cursor position and text attributes. This method may only be called once for each time that the cursor position is saved.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CTerminalEmulator::Scroll Method

```
BOOL Scroll(
   BOOL bScrollUp
);
```

The **Scroll** method scrolls the virtual display up or down and updates the scroll box position if necessary.

Parameters

bScrollUp

Boolean flag which specifies if the virtual display is scrolled up or down.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method does not change the current cursor position. The **Refresh** method should be called to update the window attached to the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::SelectText Method

```
BOOL SelectText(
   LPRECT lpRect,
   DWORD dwOptions
);
```

The **SelectText** method selects or unselects a region of the virtual display.

Parameters

lpRect

A pointer to a region of the display to select. The coordinates must be in display cursor coordinates, not pixels. If this parameter is NULL, any selected text in the display is unselected.

dwOptions

One or more options which specifies how the region will be selected. These options may be combined using a bitwise Or operator. The following values may be used:

Value	Description
NVT_SELECT_DEFAULT	The default selection option. If there is a region of the display already selected, it will be cleared and the new region is selected.
NVT_SELECT_CLIPBOARD	Copy the selected text to the clipboard. If this option is not specified, the selected text is buffered and may be copied at a later point.
NVT_SELECT_NOREFRESH	The display is not refreshed when the region is selected. This is useful if the application is going to be selecting multiple regions of the display, or combining more than one region, in order to minimize output to the window.
NVT_SELECT_NOBUFFER	Do not buffer the text in the selected region of the display. The display will show any text as being selected, but it will not be available to be copied by the application. This can be useful if the application is going to select multiple regions and combine them.
NVT_SELECT_COMBINE	If there is already a region of the display that has been selected, the new region is combined with the previous region, selecting all of the text.
NVT_SELECT_UNSELECT	Unselect the specified region of the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

CTerminalEmulator::SetAttributes Method

```
UINT SetAttributes(
   UINT nAttributes
);
```

The **SetAttributes** method sets the current display attributes.

Parameters

nAttributes

An unsigned integer value which specifies the new display attributes. This may be one or more of the following values:

Value	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

Return Value

If the method succeeds, the return value is the previous display attributes. If the method fails, the return value is 0xFFFFFFFF.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

CTerminalEmulator::SetBackColor Method

```
BOOL SetBackColor(
   COLORREF rgbBackground
);
```

The **SetBackColor** sets the background color used by the virtual display.

Parameters

rgbBackground

The background color specified as a 32-bit RGB value.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method sets the background color for normal, reverse, bold and reverse-bold text attributes. To set the background color for a specific attribute, use the **SetColor** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

GetBackColor, GetColor, GetForeColor, SetBoldColor, SetColor, SetForeColor

CTerminalEmulator::SetBoldColor Method

```
BOOL SetBoldColor(
   COLORREF rgbBold
);
```

The **SetBoldColor** sets the color used by the virtual display to display text with the bold attribute enabled.

Parameters

rgbBold

The bold attribute color specified as a 32-bit RGB value.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method sets the foreground color for the bold and reverse-bold text attributes. To set the color for a specific attribute, use the **SetColor** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

GetColor, SetBackColor, SetColor, SetForeColor

CTerminalEmulator::SetCell Method

```
BOOL SetCell(
   INT xPos,
   INT yPos,
   TCHAR nChar
   UINT nAttributes
);

BOOL SetCell(
   TCHAR nChar
   UINT nAttributes
);
```

The **SetCell** method sets the value of the specified cell in the virtual display.

Parameters

xPos

An integer value which specifies the cell column in the virtual display. If this argument is omitted or a value of -1 is specified, the cell at the current cursor position will be used.

yPos

An integer value which specifies the cell row in the virtual display. If this argument is omitted or a value of -1 is specified, the cell at the current cursor position will be used.

nChar

The character that should be displayed at the specified location in the virtual display

nAttributes

An unsigned integer which specifies the attributes for the character in the virtual display. The attributes may be one or more of the following values, combined using a bitwise Or operator:

Value	Description
NVT_ATTRIBUTE_NORMAL	Normal, default attributes.
NVT_ATTRIBUTE_REVERSE	Foreground and background cell colors are reversed.
NVT_ATTRIBUTE_BOLD	The character is displayed using a higher intensity color.
NVT_ATTRIBUTE_DIM	The character is displayed using a lower intensity color.
NVT_ATTRIBUTE_UNDERLINE	The character is displayed with an underline.
NVT_ATTRIBUTE_HIDDEN	The character is stored in display memory, but not shown.
NVT_ATTRIBUTE_PROTECT	The character is protected and cannot be cleared.

Note that certain attributes, such as NVT_ATTRIBUTE_BOLD and NVT_ATTRIBUTE_DIM are mutually exclusive.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it returns zero. Failure typically indicates that the virtual display has not been created, or that the row and/or column values are outside of the bounds of the display.

Remarks

The **SetCell** method is used to modify a specific character cell in the virtual display, changing both the character and the attributes for that cell. Unlike the higher level methods such as **Write** which process character strings and escape sequences, the **GetCell** and **SetCell** methods allow direct, low-level access to the virtual display in memory. After one or more cells are modified using this function, you should call the **Refresh** method to redraw the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

CTerminalEmulator::SetColor Method

```
BOOL SetColor(
   UINT nColorIndex,
   COLORREF dwColor,
   BOOL bForeground
);
```

The **SetColor** method sets the colors used by the virtual display. Each display has a color table which specifies the foreground and background colors used when displaying text with a specific attribute.

Parameters

nColorIndex

The index into the virtual display color table. It may be one of the following values.

Value	Description
NVT_COLOR_NORMAL	The colors displayed for normal text. These are the default colors used with the display.
NVT_COLOR_REVERSE	The colors displayed for text with the reverse attribute set. This is only used when emulation is enabled.
NVT_COLOR_BOLD	The colors displayed for text with the bold attribute set. This is only used when emulation is enabled.
NVT_COLOR_REVERSEBOLD	The colors displayed for text with the reverse and bold attributes set. This is only used when emulation is enabled.

dwColor

The RGB color value that will be used.

bForeground

A boolean flag which specifies if the color is a foreground color, used when displaying text, or a background color.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

The default colors for the display is a black background and white foreground. Bold characters are displayed on a white background and blue foreground.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTerminalEmulator::SetColorMap Method

```
BOOL SetColorMap(
   COLORREF *lpColor,
   INT nColors
);
```

The **SetColorMap** method modifies the virtual display color table which determines what RGB values are used to display foreground and background text color attributes.

Parameters

lpColor

A pointer to an array of COLORREF values which specifies the values to be used by the emulator when setting a color attribute. If this value is NULL, the default color table will be loaded.

nColors

The number of colors which are stored in the array. The minimum value for this parameter is 1, and the maximum value is 16.

Return Value

If the method succeeds, the return value is a non-zero value. If the method fails, the return value is zero. Failure indicates that the handle to the virtual display is invalid or the number of color values is invalid.

Remarks

When the emulator processes an escape sequence that changes the current foreground or background color, the actual RGB color value is determined by looking up the value in the virtual display's color table. The **SetColorMap** method is useful for changing what values are being used when a color attribute it set. The emulator currently supports a maximum of sixteen (16) color values, and the index into the table corresponds to the color as defined by the standard for ANSI terminals:

Index	Color	Default (Hex)	Default (Integer)	Default (RGB)
Black	RGB(0,0,0)			
Red	000000A0h	RGB(160,0,0)		
Green	0000A000h	RGB(0,160,0)		
Yellow	0000A0A0h	RGB(160,160,0)		
Blue	00A00000h	RGB(0,0,160)		
Magenta	00A000A0h	RGB(160,0,160)		
Cyan	00A0A000h	RGB(0,160,160)		
White	00E0E0E0h	RGB(224,224,224)		
Gray	00C0C0C0h	RGB(192,192,192)		
Light Red	008080FFh	RGB(255,128,128)		
Light Green	0090EE90h	RGB(144,238,144)		
Light Yellow	00C0FFFFh	RGB(255,255,192)		
Light Blue	00E6D8ADh	RGB(173,216,230)		

Light Magenta	00FFC0FFh	RGB(255,192,255)
Light Cyan	00FFFFE0h	RGB(224,255,255)
High White	00FFFFFFh	RGB(255,255,255)

A standard ANSI color terminal supports eight standard colors (0-7). To select a foreground color, you add 30 to the color index and pass that value as a parameter to the SGR (select graphic rendition) escape sequence. To select a background color, you add 40 to the color index. For example, to set the current foreground color to white and the background color to blue, you could send the following escape sequence:

```
ESC [ 37;44 m
```

Note that if you wanted to set the foreground color to a bold version of standard yellow, you would first set the bold attribute, and then use the index value of 3, such as:

```
ESC [ 1;33m
```

The **SetColorMap** method is used to modify the actual color displayed by the emulator. For example, if the emulator processes an escape sequence which sets the current foreground color to white, the actual color displayed could be changed to light green. Passing a NULL pointer as the second parameter restores the original color map back to the default values. Note that changes to the color map will only affect new characters as they are displayed, not any previously displayed characters.

Example

The following example will load the current color table for the virtual display and change the standard white color attribute to use the same value as the high-intensity white:

```
COLORREF rgbColor[16];

if (pDisplay->GetColorMap(rgbColor, 16) )
{
     rgbColor[7] = rgbColor[15];
     pDisplay->SetColorMap(rgbColor, 16);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::SetCursorPos Method

```
BOOL SetCursorPos(
   INT nCursorX,
   INT nCursorY
);
```

The **SetCursorPos** method sets the current cursor column and row position on the virtual display.

Parameters

nCursorX

New cursor column position. If this value is greater than the maximum number of columns, the current position is set to the last column on the display. The first column on the display is zero.

nCursorY

New cursor row position. If this value is greater than the maximum number of rows, the current position is set to the last row on the display. The first row on the display is zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it will return a value of zero. Typically this would indicate that the virtual display has not been created.

Remarks

The **SetCursorPos** method sets the current cursor position on the virtual display. If the display is in origin mode (a scrolling region has been set), then the cursor row position is bound by the current region.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CTerminalEmulator::SetDC Method

```
BOOL SetDC(
   HDC hDC
);
```

The **SetDC** method sets the device context to be used by the virtual display when updating the window.

Parameters

hDC

Handle to the device context. This parameter may be NULL, any device context that is currently associated with the virtual display will be removed. Note that the application still has the responsibility for deleting the device context, otherwise a handle leak will occur.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

It is not required that the device context be explicitly set by the application. By default, the class will use a device context created using the window attached to the virtual display. If a device context is specified by the application, it must be released when it is no longer needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::SetEmulation Method

```
BOOL SetEmulation(
   UINT nEmulation
);
```

The **SetEmulation** method specifies the type of terminal emulation to be performed by the virtual display.

Parameters

nEmulation

Identifies the virtual terminal emulation type. The following emulation types are currently supported.

Value	Description
NVT_EMULATION_NONE	The virtual display does not emulate any specific terminal type, and does not process any escape sequences.
NVT_EMULATION_ANSI	The virtual display will process ANSI escape sequences. The default keymap for an ANSI console is loaded.
NVT_EMULATION_VT100	The virtual display will process DEC VT100 escape sequences. The default keymap for a VT100 terminal is loaded.
NVT_EMULATION_VT220	The virtual display will process DEC VT220 escape sequences. The default keymap for a VT220 terminal is loaded.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

Changing the emulation type will not affect the current display.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

CTerminalEmulator::SetFocus Method

```
BOOL SetFocus(
   BOOL bFocus
);
```

The **SetFocus** method sets or removes the focus from the virtual display. This method should be called when the display window receives or loses focus.

Parameters

bFocus

A boolean flag which specifies that the display should receive or lose focus.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

When the virtual display receives focus, it updates the current cursor position and displays the caret. When the display loses focus, the caret is hidden. This method should be called in response to the display window receiving the WM_SETFOCUS and WM_KILLFOCUS messages.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::SetFont Method

```
BOOL SetFont(
   HFONT hFont
);

BOOL SetFont(
   LPTSTR lpszFontName,
   INT nFontSize
);
```

The **SetFont** sets the font that will be used when updating the display. The specified font must be fixed-width, otherwise the virtual cursor positioning will be incorrect in some cases.

Parameters

hFont

Handle to the font that will be used with the virtual terminal. This parameter may be NULL, in which case a default fixed-width font will be used.

lpszFontName

A null-terminated string which specifies the name of the font that will be loaded. If a NULL pointer or an empty string is passed as the value, the default **Terminal** font will be used.

nFontSize

The point size of the font that will be loaded. If this value is zero, a default point size will be used.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

If the previous font was a default font created by the library as the result of a NULL font handle being passed to a method, it will be released. However, if the previous font was created by the application, the **DeleteObject** method must be called to release it.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

GetFont

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::SetForeColor Method

```
BOOL SetForeColor(
   COLORREF rgbForeground
);
```

The **SetForeColor** sets the foreground color used by the virtual display.

Parameters

rgbForeground

The foreground color specified as a 32-bit RGB value.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method sets the foreground color for the normal and reverse text attributes. To set the foreground color for a specific attribute, use the **SetColor** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

CTerminalEmulator::SetMappedKey Method

```
BOOL SetMappedKey(
   UINT nMappedKey,
   LPCTSTR lpszKeyBuffer
);
```

The **SetMappedKey** method maps an escape sequence to the specified key.

Parameters

nMappedKey

The key which is an index into the display key mapping table. This defines the values returned by special (method) keys for the current emulation.

lpszKeyBuffer

Pointer to a string which defines the sequence of characters that are to be mapped to the specified key. Passing an empty string or NULL pointer will delete the current sequence mapped to the key and restore the default value, if one has been defined.

Return Value

If the method succeeds, the return value is non-zero and the escape sequence is mapped to the specified key. If the key value is invalid or could not be mapped, then the method will return zero.

Remarks

The **SetMappedKey** method maps an escape sequence to a special key. This method can be used to specify what sequence of characters should be sent in response to a keypress (for example, what sequence should be sent to a server when the user presses the F1 method key). There are a number of default sequences that are mapped to the method and cursor keys, based on the current emulation. Calling this method will override the default sequence for a key, if one has been defined.

The following special keys are defined:

Value	Description
NVT_F1	F1 method key
NVT_F2	F2 method key
NVT_F3	F3 method key
NVT_F4	F4 method key
NVT_F5	F5 method key
NVT_F6	F6 method key
NVT_F7	F7 method key
NVT_F8	F8 method key
NVT_F9	F9 method key
NVT_F10	F10 method key
NVT_F11	F11 method key
NVT_F12	F12 method key
NVT_SF1	Shift F1 method key

NVT_SF2	Shift F2 method key
NVT_SF3	Shift F3 method key
NVT_SF4	Shift F4 method key
NVT_SF5	Shift F5 method key
NVT_SF6	Shift F6 method key
NVT_SF7	Shift F7 method key
NVT_SF8	Shift F8 method key
NVT_SF9	Shift F9 method key
NVT_SF10	Shift F10 method key
NVT_SF11	Shift F11 method key
NVT_SF12	Shift F12 method key
NVT_ENTER	Enter key
NVT_ERASE	Backspace key
NVT_UP	Cursor up key
NVT_DOWN	Cursor down key
NVT_LEFT	Cursor left key
NVT_RIGHT	Cursor right key
NVT_INSERT	Insert key
NVT_DELETE	Delete key
NVT_HOME	Home key
NVT_END	End key
NVT_PGUP	Page up key
NVT_PGDN	Page down key
NVT_APPUP	Up arrow key
NVT_APPDOWN	Down arrow key
NVT_APPLEFT	Left arrow key
NVT_APPRIGHT	Right arrow key
NVT_APPENTER	Keypad enter key
NVT_KEYPAD0	Numeric keypad 0
NVT_KEYPAD1	Numeric keypad 1
NVT_KEYPAD2	Numeric keypad 2
NVT_KEYPAD3	Numeric keypad 3
NVT_KEYPAD4	Numeric keypad 4
NVT_KEYPAD5	Numeric keypad 5

NVT_KEYPAD6	Numeric keypad 6
NVT_KEYPAD7	Numeric keypad 7
NVT_KEYPAD8	Numeric keypad 8
NVT_KEYPAD9	Numeric keypad 9

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::SetMode Method

```
BOOL SetMode(
   UINT nMode,
   BOOL bEnable
);
```

The **SetMode** method sets one or more display modes for the specified virtual display.

Parameters

nMode

The virtual display mode bitmask. This value is a combination of one or more flags which determines how the emulator handles automatic line wrapping, caret display, and other methods. The following values may be specified.

NVT_MODE_AUTOWRAP	The emulator will automatically wrap to the next line when a character is written to the last column on the virtual display.
NVT_MODE_SHOWCARET	The emulator will display a caret when the display receives the focus.
NVT_MODE_BLOCKCARET	The emulator will display a block carat that is the height of the selected font characters. If this mode is not set, the caret is displayed as an underline.
NVT_MODE_BELL	The emulator will beep when a BEL character is processed.
NVT_MODE_CRLF	The cursor will automatically be positioned at the first column when a linefeed character is processed.
NVT_MODE_CRNL	The cursor will automatically advance to the next row when a carriage return character is processed.
NVT_MODE_APPCURSOR	The emulator cursor keys are placed in application mode. This mode changes the default key mappings used when the cursor (arrow) keys are translated. This corresponds to the application mode supported by DEC VT terminals.
NVT_MODE_APPKEYPAD	The emulator keypad keys are placed in application mode. This mode changes the default key mappings used when the keypad keys are translated. This corresponds to the application keypad mode supported by DEC VT terminals.
NVT_MODE_ORIGIN	The emulator is in origin mode. If enabled, the cursor cannot be positioned outside of the current scrolling region. Otherwise, the cursor can be positioned at any valid location on the virtual display.
NVT_MODE_COLOR	The emulator supports the use of escape sequences to change the foreground and background colors. This option is enabled by default if emulating an ANSI console or DEC VT220 terminal.
NVT_MODE_TABOVER	The emulator will clear the character cells between the current cursor position and the next tab stop when the HT (horizontal tab) control sequence is processed. By default this mode is

	disabled, and the cursor is simply positioned at the next tab stop.
NVT_MODE_HSCROLL	The emulator will display a horizontal scroll bar if the number of visible columns are less then the total number of columns in the virtual display. Disabling this mode prevents a horizontal scroll bar from being displayed, regardless of the number of visible columns. By default, this mode is enabled.
NVT_MODE_VSCROLL	The emulator will display a vertical scroll bar if the number of visible rows are less then the total number of rows in the virtual display. Disabling this mode prevents a vertical scroll bar from being displayed, regardless of the number of visible rows. By default, this mode is enabled.
NVT_MODE_NOREFRESH	The emulator will not automatically refresh the window after any change has been made to the virtual display, including changes in the cursor position or display mode. This allows the caller to make a sequence of changes, and then update the display all at one time to prevent a flicker effect.

bEnable

This boolean flag specifies if the specified mode is to be enabled or disabled.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::SetScrollPos Method

```
BOOL SetScrollPos(
   INT nScrollBar,
   INT nScrollPos
);
```

The **SetScrollPos** method sets the position of the scroll box for the specified scroll bar and redraws the scroll bar to reflect the new position of the scroll box.

Parameters

nScrollBar

Specifies the scroll bar to be set. This parameter can be one of the following values:

Value	Description
SB_HORZ	Sets the position of the scroll box in the display's standard horizontal scroll bar.
SB_VERT	Sets the position of the scroll box in the display's standard vertical scroll bar.

nScrollPos

Specifies the new row or column of the scroll box. The position must be within the scrolling range.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method should always be used to change the scroll box position. The **SetScrollPos** method will result in unpredictable behavior if used on the virtual display window.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

GetScrollPos, Scroll, Update

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::SetScrollRegion Method

```
BOOL SetScrollRegion(
   INT nTop,
   INT nBottom
);
```

The **SetScrollRegion** method sets the top and bottom rows of the current scrolling region.

Parameters

nTop

The top row of the current scrolling region. If this value is greater than the bottom scrolling region row or the total number of rows in the display, it will be silently adjusted.

nBottom

The bottom row of the current scrolling region. If this value is less than zero or the top scrolling region row, it will be silently adjusted.

Return Value

If the method succeeds, it will return zero. If the handle to the display is invalid, the method will return zero.

Remarks

The **SetScrollRegion** method allows an application to set the current scrolling region for the virtual display. This specifies the region (between the top and bottom rows) in which text will normally scroll. If the display is in origin mode, the cursor cannot be positioned outside of the scrolling region.

The minimum scrolling region that may be defined is two rows. If a scrolling region is specified that is less than two rows, the method will fail and the current scrolling region will remain unchanged. Specifying values of -1 for both arguments will reset the scrolling region to the default values (the full display).

The DEC STBM escape sequence is used to set or clear the scrolling region of the virtual display.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::SetSize Method

```
BOOL SetSize(
   LPSIZE lpSize
);
```

```
BOOL SetSize(
   INT nColumns,
   INT nRows
);
```

The **SetSize** sets the size of the virtual display.

Parameters

lpSize

Pointer to a SIZE structure which specifies the new size of the virtual display. The width should be specified in columns and the height should be specified in rows.

nColumns

The number of columns in the virtual display.

nRows

The number of rows in the virtual display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::SetTextColor Method

```
BOOL SetTextColor(
   COLORREF rgbColor,
   BOOL bForeground
);
```

The **SetTextColor** method changes the current foreground or background text color.

Parameters

rgbColor

A color value which specifies the current foreground or background text color. The RGB macro can be used to specify the red, green and blue values for the color.

bForeground

A boolean value which determines if the foreground or background color is changed. A value of TRUE indicates that the foreground color should be changed, otherwise the background color is changed.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. Failure indicates that the handle to the display is invalid or that the current display does not support color text attributes.

Remarks

This method is used to change the current foreground or background color, as determined by the text attribute. Note that changing the current foreground or background text color does not affect the virtual display color table. To change how color attributes are mapped to an RGB color value, use the **SetColorMap** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

GetColorMap, GetTextColor, SetColorMap

CTerminalEmulator::SetWindow Method

```
BOOL SetWindow(
   HWND hWnd
);
```

The **SetWindow** method sets the window used by the virtual display.

Parameters

hWnd

Handle to the window that will be used by the virtual display. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method will clear the display and reset the current text attributes.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

CTerminalEmulator::TranslateMappedKey Method

```
BOOL TranslateMappedKey(
   UINT nKey,
   UINT nFlags,
   UINT *lpnMappedKey,
   LPTSTR lpszKeyBuffer,
   UINT cchBuffer
);

BOOL TranslateMappedKey(
   UINT nKey,
   UINT nFlags,
   UINT *lpnMappedKey,
   CString& strKeyBuffer
);
```

The **TranslateMappedKey** method translates a virtual key press to an escape sequence based on the current terminal emulation that has been selected.

Parameters

nKey

The virtual key code for the specified key.

nFlags

The scan code, key-transition code, previous key state, and context code for the specified key.

lpnMappedKey

A pointer to an unsigned integer which will contain the index into the keymap table when the method returns. This is the same value used with the **GetMappedKey** and **SetMappedKey** method. If the index into the keymap is not required, this parameter can be NULL.

lpszKeyBuffer

Address of the buffer to receive the escape sequence mapped to the specified key. If the mapped key string is not required, this parameter can be NULL.

cchBuffer

The maximum number of characters that can be copied into the key buffer, including the terminating null character. If the ***lpszKeyBuffer*** parameter is NULL, this value must be zero.

Return Value

If the virtual key can be mapped to an escape sequence, the method will return a non-zero value. If the key is not mapped, or one of the arguments is invalid, the method will return zero.

Remarks

The **TranslateMappedKey** method allows an application to map a virtual key code to an escape sequence that is appropriate for the type of terminal that is being emulated. For example, it will return the escape sequence for the F1 method key when passed the VK_F1 key value. This method should be called when the WM_KEYDOWN message is processed by an application so that it may send the correct sequence to the server.

This method should only be called in response to a keyboard message such as WM_KEYDOWN. To determine if a specific key has been mapped to an escape sequence, use the **GetMappedKey** method.

Example

```
case WM_KEYDOWN:
    /*
     * If the Num Lock key is pressed, then set the terminal into application
     * keypad mode. This will change how the TranslateMappedKey method will
     * translate the keypad keys.
     *
     * Note that the terminal may also be placed into application keypad mode
     * if emulating a DEC VT terminal and the DECNKM escape sequence is sent
     * by the host.
     */
    if (wParam == VK_NUMLOCK)
        pDisplay->SetMode(NVT_MODE_APPKEYPAD, !(GetKeyState(VK_NUMLOCK) & 1));
    else
    {
        BOOL bMapped;
        UINT nMappedKey;
        TCHAR szKey[128];

        bMapped = pDisplay->TranslateMappedKey(wParam, HIWORD(lParam),
                                               &nMappedKey, szKey, 128);

        if (bMapped)
            pTelnet->Write(szKey);
    }
    break;
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTerminalEmulator::Update Method

```
BOOL Update();
```

The **Update** method updates the window attached to the virtual display.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method should be called when the display window receives a WM_PAINT message. If the **SetDC** method has not been called to explicitly set the display device context, this method will acquire one for the display window. In this case, the application should not create device context for the window or call the **BeginPaint** and **EndPaint** methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

Refresh, Resize, SetDC, SetScrollPos, SetWindow

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTerminalEmulator::UpdateCaret Method

```
BOOL UpdateCaret();
```

The **UpdateCaret** method updates the position of the caret in the display window to the current cursor position.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

See Also

SetCursorPos, SetMode, Update

CTerminalEmulator::Write Method

```
BOOL Write(
   LPBYTE lpBuffer,
   INT cbBuffer
);

BOOL Write(
   LPCTSTR lpszBuffer,
   INT cbBuffer
);

BOOL Write(
   TCHAR nChar,
   INT nCount
);
```

The **Write** method writes the contents of the specified buffer to the virtual display.

Parameters

lpBuffer

Pointer to the buffer which contains the data to be written to the virtual display. This may also specify a string which contains the characters to be written to the display.

cbBuffer

Number of bytes to write to the display. If the buffer is a string, this value may be -1, in which case all characters up to the terminating null character will be written to the display.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, it returns zero.

Remarks

This method writes the data at the current cursor location. Control characters are recognized by this method and processed accordingly. If ANSI emulation is enabled, embedded escape sequences will also be parsed and processed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csnvtv12.lib

Terminal Emulation Data Structures

- NVTDISPLAYINFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

NVTDISPLAYINFO

The **NVTDISPLAYINFO** structure contains information about the virtual terminal display.

```
typedef struct _NVTDISPLAYINFO {
   HWND    hWnd;
   HFONT   hFont;
   INT     xPos;
   INT     yPos;
   INT     cxClient;
   INT     cyClient;
   INT     cxChar;
   INT     cyChar;
   INT     nScrollCol;
   INT     nScrollRow;
   INT     nMaxScrollCol;
   INT     nMaxScrollRow;
} NVTDISPLAYINFO, *LPNVTDISPLAYINFO;
```

Members

hWnd

The handle to the terminal emulation display window.

hFont

The handle to the current font.

xPos

The current display x coordinate.

yPos

The current display y coordinate.

cxClient

The width of the client window in pixels.

cyClient

The height of the client window in pixels.

cxChar

The width of the current font in pixels.

cyChar

The height of the current font in pixels.

nScrollCol

The current horizontal scrolling column.

nScrollRow

The current vertical scrolling row.

nMaxScrollCol

The maximum horizontal scrolling column.

nMaxScrollRow

The maximum vertical scrolling row.

Remarks

This structure is populated by the **GetDisplayInfo** method to provide information about the current state of the virtual terminal. Member of this structure should be modified directly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

<ESC>(0	Assign graphics character set to font bank G0
<ESC>)A	Assign ISO Latin 1 character set to font bank G1
<ESC>)B	Assign United States ASCII character set to font bank G1
<ESC>)0	Assign graphics character set to font bank G1

Erase Sequences

<ESC>[*n*@ Insert ***n*** blank spaces

Erase all or part of the display

<ESC>[*n*J

n Value	Description
0	From current position to end of display
1	From beginning of display to current position
2	Erase the entire display

Erase all or part of a line

<ESC>[*n*K

n Value	Description
0	From current position to end of line
1	From beginning of line to current position
2	Erase the entire line

<ESC>[*n*L Insert ***n*** new blank lines

<ESC>[*n*M	Delete *n* lines from current cursor position
<ESC>[*n*P	Delete *n* characters from current cursor position

Scrolling Sequences

<ESC>[*n*S	Scroll display up *n* lines
<ESC>[*n*T	Scroll display down *n* lines
<ESC>[*n*X	Erase *n* characters from the current position
<ESC>[*y1*;*y2*r	Set scrolling region from lines *y1* to *y2*

Keypad Sequences

<ESC>=	Place keypad into applications mode
<ESC>>	Place keypad into numeric mode

Emulation Option Sequences

<ESC>[?*n*h

Set emulation option

n Value	Description
1	Enable cursor key application mode
2	Enable ANSI escape sequences
5	Reverse foreground and background colors
6	Enable origin mode
7	Enable auto-wrap mode
20	Enable linefeed/newline mode
25	Display caret
66	Place keypad in applications mode

<ESC>[?*n*1

Set emulation option

n Value	Description
1	Disable cursor key application mode
2	Enable VT52 escape sequences
5	Restore foreground and background colors
6	Disable origin mode
7	Disable auto-wrap mode
20	Disable linefeed/newline mode
25	Hide caret
66	Place keypad in numeric mode

Console Escape Sequences

<ESC>[=*n*A	Set the overscan color (ignored)
<ESC>[=*n1*;*n2*B	Set bell sound (parameters ignored)
<ESC>[=*n1*;*n2*C	Set the caret size

<ESC>[=*n*D

Set background color intensity

n Value	Description
0	Decrease background color intensity

	1	Increase background color intensity
<ESC>[=*n*E	Set blink vs. bold attribute (ignored)	
<ESC>[=*n*F	Set normal foreground color	
<ESC>[=*n*G	Set normal background color	
<ESC>[=*n*H	Set reverse foreground color	
<ESC>[=*n*I	Set reverse background color	
<ESC>[=*n*J	Set graphics foreground color	
<ESC>[=*n*K	Set graphics background color	

n Value	Description
0	Black
1	Blue
2	Green
3	Cyan
4	Red
5	Magenta
6	Brown
7	White
8	Gray
9	Light blue
10	Light green
11	Light cyan
12	Light red
13	Light magenta
14	Yellow
15	High White

Control Character Sequences

<CTL>G	Ring audible bell, if enabled
<CTL>H	Move cursor one character backwards
<CTL>I	Move cursor forward to next tabstop
<CTL>J	Move cursor down to next line
<CTL>M	Move cursor to beginning of line
<CTL>N	Select G1 character set
<CTL>O	Select G0 character set
<CTL>Z	Abort current escape sequence
<DEL>	Erase and move cursor one character backwards

Text Message Class Library

Send text messages to a mobile communications device using a gateway service.

Reference

- Class Methods
- Data Structures
- Error Codes

Library Information

Class Name	CTextMessage
File Name	CSTXTV12.DLL
Version	12.0.3024.1286
LibID	B8830D80-2618-4202-9C9C-9C3AD511E9D0
Import Library	CSTXTV12.LIB
Dependencies	None

Overview

Short Message Service (SMS) is a text messaging service used by mobile communication devices to exchange brief text messages. Most service providers also provide gateway servers that can be used to send messages to a wireless device on their network using standard email protocols. The **CTextMessage** class provides methods that can be used to determine the provider associated with a specific telephone number and send a text message to the device using the provider's mail gateway.

This class has been designed to assist developers in sending text message notifications as part of their application. For example, it can be used to enable your software to automatically send notifications when a specific event occurs, such as an error condition. This class is not designed to be used with software that will send out a large number of text messages to many users, and there are limitations on the number of messages that may be sent to different phone numbers over a short period of time. Because many recipients must pay a fee for each text message they receive, text messages should only be sent to those who explicitly request them.

Applications should use an alternate method for sending text messages. Most mobile carriers have shut down their email-to-SMS gateways, making this method of sending text messages unreliable or unavailable. It is recommended that you transition to dedicated SMS service providers, which deliver messages over HTTPS-based APIs instead of email.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop

and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Text Message Class Methods

Class	Description
CTextMessage	Constructor which initializes the current instance of the class
~CTextMessage	Destructor which releases resources allocated by the class
Method	Description
DisableRelay	Disable the relaying of messages through another mail server
DisableTrace	Disable logging of network function calls
EnableRelay	Enable the relaying of messages through another mail server
EnableTrace	Enable logging of network function calls to a text file
EnumProviders	Enumerate the available wireless service providers
GetAddress	Return the email address associated with the specified phone number.
GetErrorString	Return a description for the specified error code
GetFirstProvider	Return information about the first supported wireless service provider
GetGateway	Return information about the gateway server for the specified phone number
GetLastError	Return the last error code
GetNextProvider	Return information about the next supported wireless service provider
GetProvider	Return information about the wireless service provider for the specified phone number
GetTimeout	Return the amount of time until an operation times out
IsInitialized	Determine if the class has been successfully initialized
IsRelaying	Determine if relaying through another mail server has been enabled
SendMessage	Send a text message to the specified mobile device
SetLastError	Set the last error code
SetTimeout	Set the amount of time to wait before an operation times out
ShowError	Display a message box with a description of the specified error

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTextMessage::CTextMessage Method

```
CTextMessage();
```

The **CTextMessage** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **SmsInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CTextMessage, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTextMessage::~CTextMessage

```
~CTextMessage();
```

The **CTextMessage** destructor releases resources allocated by the current instance of the **CTextMessage** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CTextMessage** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

See Also

CTextMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTextMessage::DisableRelay Method

```
VOID DisableRelay();
```

The **DisableRelay** method disables the relaying of text messages through another mail server.

Parameters

None.

Return Value

None.

Remarks

The **DisableRelay** method sets an internal flag that specifies that messages should not be relayed through another mail server. When using the default SMTP service, this means that the library will attempt to send the message directly to the gateway used by the wireless service provider. Relaying is only enabled when the **EnableRelay** method is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

EnableRelay, IsRelaying, SendMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTextMessage::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

See Also

EnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTextMessage::EnableRelay Method

```
BOOL EnableRelay(
   LPCTSTR lpszHostName,
   UINT nHostPort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   DWORD dwOptions,
);

BOOL EnableRelay(
   LPCTSTR lpszHostName,
   UINT nHostPort,
);

BOOL EnableRelay();
```

The **EnableRelay** method enables the relaying of messages through another mail server.

Parameters

lpszHostName

A null-terminated string that specifies the hostname or IP address of the mail server that the messages will be relayed through. If this parameter is NULL or an empty string, then message relaying will be disabled.

nHostPort

An integer value that specifies the port number that should be used to establish the connection with the mail server. If this value is zero, then the default SMTP port will be used.

lpszUserName

A null-terminated string that specifies the user name that will be used to authenticate the session with the mail server. If the server does not require authentication, this parameter can be NULL or an empty string.

lpszPassword

A null-terminated string that specifies the password that will be used to authenticate the session with the mail server. If the server does not require authentication, this parameter can be NULL or an empty string.

dwOptions

An integer value which specifies one or more options.

Value	Description
SMS_OPTION_NONE	No additional options specified. This is the default value.
SMS_OPTION_SECURE	This option specifies that TLS will be used to establish a secure, encrypted connection with the mail server. For some servers, it may be required to connect to them securely and this option will be enabled automatically.

Return Value

If the method succeeds and relaying is enabled, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

When a text message is sent using the SMTP service, the default action is to attempt to connect directly to the wireless service provider's gateway server. However, many residential Internet service providers (ISPs) do not permit their customers to connect to third-party mail servers and will block the outbound connection. Some wireless service providers may also reject messages that originate from residential IP addresses.

To resolve this issue, the developer should allow the user to specify an alternate mail server that will relay the message to the wireless service provider. For residential users, this will typically be the mail server provided by their ISP. For business users, this will usually be their corporate mail server. The **EnableRelay** method is used to specify the connection information for the mail server and the **SendMessage** method will relay messages through that server.

Calling the **EnableRelay** method without any arguments will enable relaying through the mail server specified by a previous call to the method. The **EnableRelay** method must be called at least once with arguments to enable relaying. To temporarily disable relaying, call the **DisableRelay** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CTextMessage::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTextMessage::EnumProviders Method

```
INT EnumProviders(
   LPSMSPROVIDER lpProviders,
   INT nMaxProviders,
);
```

The **EnumProviders** method enumerates the supported wireless service providers and populates an array of **SMSPROVIDER** structures.

Parameters

lpProviders

A pointer to an array of SMSPROVIDER structures that will be populated with information about each service provider. If this parameter is NULL, the method will return the number of service providers that are known.

nMaxProviders

An integer value which specifies the maximum number of service providers that may be enumerated by this method. If this parameter is zero, the method will return the number of service providers that are known. If the *lpProviders* parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of known service providers. If the method fails, the return value is SMS_ERROR. To get extended error information, call **GetLastError**. If the *lpProviders* parameter is not NULL and the *nMaxProviders* parameter indicates the array is not large enough to store all of the provider information, this method will fail with an error indicating that the buffer is too small.

Remarks

The **EnumProviders** method is used to enumerate all of the supported wireless service providers, populating an array of **SMSPROVIDER** structures that contains information about each provider, such as their name, domain, region of the country they service and the maximum message size they will accept. Typically this would be used to update a user interface control such as a listbox or drop-down combobox, enabling a user to select a preferred service provider.

The **GetFirstProvider** and **GetNextProvider** methods offer an alternative way to enumerate the available service providers.

To obtain information about a single service provider, use the **GetProvider** method.

Example

```
SMSPROVIDER smsProviders[MAXPROVIDERS];

INT nProviders = pTextMessage->EnumProviders(smsProviders, MAXPROVIDERS);
if (nProviders == SMS_ERROR)
{
    pTextMessage->ShowError();
}
else
{
    for (INT nIndex = 0; nIndex < nProviders; nIndex++)
        pComboBox->AddString(smsProviders[nIndex].szName));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetFirstProvider, GetGateway, GetNextProvider, GetProvider, SMSPROVIDER

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTextMessage::GetAddress Method

```
BOOL GetAddress(
   LPCTSTR lpszPhoneNumber,
   LPTSTR lpszAddress,
   INT nMaxLength,
);

BOOL GetAddress(
   LPCTSTR lpszPhoneNumber,
   CString& strAddress
);
```

The **GetAddress** method returns the email address associated with the specified phone number.

Parameters

lpszPhoneNumber

A null-terminated string that specifies the phone number of the mobile device.

lpszAddress

A null-terminated string that will contain the email address associated with the specified phone number when the method returns. If MFC or ATL is being used, an alternate version of this function will return the address in a **CString** type variable.

nMaxLength

The maximum number of characters that may be copied into the string buffer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetAddress** method is used to determine the email address associated with a mobile device. Sending an email message to this address will forward that message to the device as a text message. Internally, this method calls **GetGateway** and returns the address specified in the SMSGATEWAY structure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTextMessage::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetLastError, SetLastError, ShowError

CTextMessage::GetFirstProvider Method

```
BOOL GetFirstProvider(
   LPSMSPROVIDER lpProvider
);
```

The **GetFirstProvider** method returns information about the first supported wireless service provider.

Parameters

lpProvider

A pointer to an SMSPROVIDER structure that will contain information about the service provider. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **SmsGetLastError**.

Remarks

The **GetFirstProvider** method is used in conjunction with **GetNextProvider** to enumerate all of the supported wireless providers available to the client. These two methods can be used as an alternative to the **EnumProviders** method.

Example

```
SMSPROVIDER smsProvider;

BOOL bResult = pTextMessage->GetFirstProvider(&smsProvider);
while (bResult)
{
    pListBox->AddString(smsProvider.szName);
    bResult = pTextMessage->GetNextProvider(&smsProvider);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

EnumProviders, GetGateway, GetNextProvider, SMSPROVIDER

CTextMessage::GetGateway Method

```
BOOL GetGateway(
   LPCTSTR lpszPhoneNumber,
   LPCTSTR lpszProvider,
   LPSMSGATEWAY lpGateway
);

BOOL GetGateway(
   LPCTSTR lpszPhoneNumber,
   LPSMSGATEWAY lpGateway
);
```

The **GetGateway** method returns text message service information for a phone number.

Parameters

lpszPhoneNumber

A null-terminated string which specifies the telephone number that you wish to obtain information about. Any whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpszProvider

A null-terminated string which specifies the preferred service provider for this telephone number. If the preferred service provider is unknown, this parameter can be omitted or specify a NULL pointer and the default provider will be selected.

lpGateway

A pointer to an SMSGATEWAY structure that will contain information about the text message gateway when the method returns. This includes information such as the name of the provider, the server that will accept text messages for this phone number, and the recipient address that should be used. This parameter cannot be NULL.

Return Value

If the method succeeds and relaying is enabled, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetGateway** method returns information about the service provider and mail gateway for a specific phone number, and can be used to determine if a given phone number is assigned to a mobile device capable of receiving text messages. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices. If the phone number is valid, information will be returned about the provider that is responsible for that number along with information about its text message gateway service.

If the ***lpszProvider*** parameter is not NULL, this will identify a preferred provider for the phone number specified. In the United States and Canada, most wireless common carriers are required to provide wireless number portability (WNP) which allows a customer to continue to use their current phone number even if they switch to another service provider. This can result in a situation where a specific phone number is shown as allocated to one provider, but in actuality that user has switched to a different provider. For example, a user may have originally purchased a phone and service with AT&T and then later switched to Verizon, but decided to keep their phone number. In this case, if Verizon was not specified as the preferred provider, the library would attempt to send the message to the

AT&T gateway, since that was the original provider who allocated the phone number.

For most applications, the correct way to handle the situation in which a user may have switched to a different service provider is to allow them to select an alternate service provider in your user interface. For example, you could display a drop-down list of available service providers, populated using the **EnumProviders** method. If they select a preferred provider, then you would pass that value to this method. If they do not, then specify a NULL pointer and the default provider will be selected.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTextMessage::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

See Also

CTextMessage::GetNextProvider Method

```
BOOL GetNextProvider(
   LPSMSPROVIDER lpProvider,
);
```

The **GetNextProvider** method returns information about the next supported wireless service provider.

Parameters

lpProvider

A pointer to an SMSPROVIDER structure that will contain information about the service provider. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the last service provider has been enumerated or the method fails, the return value is zero. To get extended error information, call **SmsGetLastError**.

Remarks

The **GetNextProvider** method is used in conjunction with **GetFirstProvider** to enumerate all of the supported wireless providers available to the client. These two methods can be used as an alternative to the **EnumProviders** method.

Example

```
SMSPROVIDER smsProvider;

BOOL bResult = pTextMessage->GetFirstProvider(&smsProvider);
while (bResult)
{
    pListBox->AddString(smsProvider.szName);
    bResult = pTextMessage->GetNextProvider(&smsProvider);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

EnumProviders, GetGateway, GetNextProvider, SMSPROVIDER

CTextMessage::GetProvider Method

```
BOOL GetProvider(
   LPCTSTR lpszPhoneNumber,
   LPSMSPROVIDER lpProvider
);

BOOL GetProvider(
   LPCTSTR lpszPhoneNumber,
   LPTSTR lpszProvider,
   INT nMaxLength
);

BOOL GetProvider(
   LPCTSTR lpszPhoneNumber,
   CString& strProvider
);
```

The **GetProvider** method returns information about the service provider for the specified phone number.

Parameters

lpszPhoneNumber

A null-terminated string which specifies the telephone number that you wish to obtain information about. Any whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpProvider

A pointer to an SMSPROVIDER structure that will contain information about the service provider for the specified phone number.

lpszProvider

A null-terminated string that will contain the name of the wireless service provider associated with the specified phone number when the method returns. If MFC or ATL is being used, an alternate version of this function will return the address in a **CString** type variable.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string.

Return Value

If the method succeeds and relaying is enabled, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetProvider** method returns information about the service provider associated with a phone number. This is done by sending an query to a server that will check the phone number against a database of known providers and the phone numbers that have been allocated for wireless devices. If the phone number is valid, information will be returned about the provider that is responsible for that number.

Because most wireless carriers in the United States and Canada must provide for wireless number portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify

an alternate preferred provider to use when sending the text message. For more information, refer to the **GetGateway** method.

This method sends an HTTP query to the server **api.sockettools.com** to obtain information about the wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the method will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

For a list of all supported wireless service providers, use the **EnumProviders** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTextMessage::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is SMS_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

See Also

EnableRelay, SendMessage, SetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTextMessage::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

CTextMessage::IsRelaying Method

```
BOOL IsRelaying();
```

The **IsRelaying** method returns whether or not messages will be relayed through another mail server.

Parameters

None.

Return Value

This method returns a non-zero value if relaying has been enabled, otherwise this method will return zero.

Remarks

For more information about relaying text messages, refer to the **EnableRelay** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

See Also

DisableRelay, EnableRelay, SendMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CTextMessage::SendMessage Method

```
BOOL SendMessage(
   DWORD dwServiceType,
   LPCTSTR lpszProvider,
   LPCTSTR lpszPhoneNumber,
   LPCTSTR lpszSender,
   LPCTSTR lpszMessage
);

BOOL SendMessage(
   LPSMSSERVICE lpService,
   LPSMSMESSAGE lpMessage
);
```

The **SendMessage** method sends a text message to the specified mobile device.

Parameters

dwServiceType

An unsigned integer value which identifies the type of service being used to send the message. Currently there is only one valid service type, **SMS_SERVICE_SMTP** which sends the message to a mail gateway provided by the wireless service provider. This parameter is included for future expansion when multiple alternative services may be used to send the message.

lpszProvider

A null-terminated string that identifies the wireless service provider that is responsible for the specified phone number. If the service provider is unknown, this parameter can be NULL or an empty string. In that case, the default provider for the phone number will be used.

lpszPhoneNumber

A null-terminated string that specifies the phone number for the mobile device. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored. This parameter cannot be NULL.

lpszSender

A null-terminated string which identifies the sender of the message and should specify a valid email address. If the recipient replies to the message, the reply will be sent to this address. This parameter cannot be NULL.

lpszMessage

A null-terminated string that contains the message to be sent to the recipient. In most cases, a message should not exceed 160 characters in length, although some service providers may accept longer messages. If a message exceeds the maximum number of characters accepted by a service provider, the message may be ignored or it may be split into multiple messages.

lpService

A pointer to an SMSSERVICE structure that identifies the messaging service that will be used to send the text message. The default service sends the message through the mail server gateway for the wireless service provider associated with the recipient's phone number. This parameter cannot be NULL.

lpMessage

A pointer to an SMSMESSAGE structure that contains information about the message to be sent,

including the sender, the recipient and the text message itself. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SendMessage** method is used to send a text message to a mobile device. This API is designed to support multiple methods of sending text messages, with the default method sending the message through a server gateway established by the wireless service provider.

SMS_SERVICE_SMTP

This message service sends the message through the wireless service provider's mail gateway using the SMTP protocol. However, it is important to note that many of these gateways will not accept messages from a client that is connected to them using a residential Internet service provider. If the application is being run on a system that uses a residential provider, that service provider may also block outbound connections to all mail servers other than their own. These anti-spam measures typically require that most end-user applications specify a relay mail server rather than submitting the message directly to the wireless provider's gateway.

Because most wireless carriers in the United States and Canada must provide for wireless number portability, there is the possibility that the provider information returned may no longer correspond to the telephone number. It is recommended that you provide your end-user with the ability to specify an alternate preferred provider to use when sending the text message. For more information, refer to the **GetGateway** method.

This service also sends an HTTP query to the server **api.sockettools.com** to obtain information about the phone number and wireless service provider. This requires that the local system can establish a standard network connection over port 80. If the client cannot connect to the server, the function will fail and an appropriate error will be returned. The server imposes a limit on the maximum number of connections that can be established and the maximum number of requests that can be issued per minute. If this method is called multiple times over a short period, the library may also force the application to block briefly. Server responses are cached per session, so calling this method multiple times using the same phone number will not increase the request count.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

CTextMessage::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or SMS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the blocking method will fail and return to the caller.

Parameters

nTimeout

The number of seconds until a blocking operation fails. Setting this parameter to zero will use the default timeout period.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is SMS_ERROR. To get extended error information, call **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib

CTextMessage::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cstxtv12.lib
Unicode: Implemented as Unicode and ANSI versions

Text Message Data Structures

- SMSGATEWAY
- SMSMESSAGE
- SMSPROVIDER
- SMSSERVICE

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SMSGATEWAY

This structure contains information about a text message gateway server and the recipient.

```
typedef struct _SMSGATEWAY
{
    INT     nGatewayId;
    INT     nCountryCode;
    INT     nAreaCode;
    INT     nExchange;
    INT     nMessageLength;
    DWORD   dwReserved;
    TCHAR   szProvider[SMS_MAXPROVIDERNAMELEN];
    TCHAR   szDomain[SMS_MAXDOMAINNAMELEN];
    TCHAR   szServer[SMS_MAXMAILSERVERLEN];
    TCHAR   szAddress[SMS_MAXMAILADDRESSLEN];
}  SMSCHANNEL, *LPSMSCHANNEL;
```

Members

nGatewayId

An integer value which identifies the gateway record. This value is used internally and an application should not depend on the value not changing over time for a specific telephone number. As new area codes are introduced, the provider database will be updated to reflect these changes and that can result in a change to the gateway ID associated with a specific telephone number.

nCountryCode

An integer value which specifies the ITU country calling code associated with the service provider. Currently this value will always be 1, which is the country code used by North American service providers. If the service provider database is expanded to include additional countries in the future, this value will identify the country of origin.

nAreaCode

An integer value which specifies the Numbering Plan Area (NPA) code, commonly known as the area code. For the United States and Canada, area codes are assigned by the North American Numbering Plan Administration (NANPA). In North America, the area code is digits 1-3 for a 10-digit telephone number. This value, along with the exchange, is used to determine which company provides wireless service for a specific telephone number.

nExchange

An integer value which specifies the exchange area. In North America, the exchange is digits 4-6 for a 10-digit telephone number. This value, along with the area code, is used to determine which company provides wireless service for a specific telephone number.

nMessageLength

An integer value which specifies the maximum number of characters that the service provider will accept for a single text message. If the message exceeds this number of characters, the service provider may reject the message, or it may split the message into multiple messages.

dwReserved

A value reserved for internal use.

szProvider

A null-terminated string which identifies the name of the service provider that is associated with the specified telephone number. Note that this value may not represent the actual company that is providing the wireless service.

szDomain

A null-terminated string which identifies the gateway domain name used by the service provider to accept text messages for their customer. This domain name is used to determine the actual name of the gateway mail server that is responsible for accepting messages.

szServer

A null-terminated string which identifies the host name or IP address of the mail server used to accept text messages for the specified service provider. In some cases, a provider may have multiple gateway servers and this value will represent the preferred mail server for the domain.

szAddress

A null-terminated string which contains the complete email address that should be used when sending the text message through the gateway mail server. Different service providers can have slightly different rules about how the address is formatted, but it typically is a combination of the telephone number and the gateway domain name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SMSMESSAGE

This structure provides information about a text message.

```
typedef struct _SMSMESSAGE
{
    DWORD dwFormat;
    DWORD dwLength;
    DWORD dwFlags;
    DWORD dwReserved;
    LPCTSTR lpszProvider;
    LPCTSTR lpszPhoneNumber;
    LPCTSTR lpszSender;
    LPCTSTR lpszMessage;
}  SMSMESSAGE, *LPSMSMESSAGE;
```

Members

dwFormat

An integer value which specifies the format of the message message. This member is included for future use where a service provider supports multiple message formats based on different versions of the protocol. The default value for this member is SMS_FORMAT_TEXT.

dwLength

An integer value which specifies the length of the message. If this member is zero, the length will be automatically calculated based on the length of the ***lpszMessage*** text that is terminated by a null character. If this value is larger than the actual length of the message text, it will be ignored.

dwFlags

An integer value which specifies one or more message options.

Value	Description
SMS_MESSAGE_DEFAULT	The default value used with standard text messages.
SMS_MESSAGE_URGENT	The text message should be flagged as urgent. For messages that are sent through a mail gateway, this will set the header to indicate that it is a high priority message. Note that service providers handle urgent messages differently and some may ignore the message priority.

dwReserved

Reserved for future use. This value should always be zero.

lpszProvider

A null-terminated string which specifies the name of the preferred wireless service provider responsible for handling the message. If this member is NULL or an empty string, the default provider assigned to the recipient's phone number will be used. This structure member is only used with SMS_SERVICE_SMTP messages and is ignored for other message services.

lpszPhoneNumber

A null-terminated string which specifies the recipient's phone number. This can be a standard E.164 formatted number or an unformatted number. Any extraneous whitespace, punctuation or other non-numeric characters in the string will be ignored. This structure member cannot be NULL.

lpszSender

A null-terminated string which identifies the sender of the message. For SMS_SERVICE_SMTP messages, this string should be a valid email address. For other services, this string may specify a phone number or shortcode. This structure member cannot be NULL.

lpszMessage

A null-terminated string that contains the message to be sent to the recipient. In most cases, a message should not exceed 160 characters in length, although some service providers may accept longer messages. If a message exceeds the maximum number of characters accepted by a service provider, the message may be ignored or it may be split into multiple messages.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

SMSPROVIDER

This structure contains information about a wireless service provider.

```
typedef struct _SMSPROVIDER
{
    INT     nProviderId;
    INT     nCountryCode;
    INT     nRegionCode;
    INT     nMessageLength;
    DWORD   dwFlags;
    DWORD   dwReserved;
    TCHAR   szGuid[SMS_MAXPROVIDERGUIDLEN];
    TCHAR   szName[SMS_MAXPROVIDERNAMELEN];
    TCHAR   szCompany[SMS_MAXCOMPANYNAMELEN];
    TCHAR   szDomain[SMS_MAXDOMAINNAMELEN];
}  SMSPROVIDER, *LPSMSPROVIDER;
```

Members

nProviderId

An integer value which identifies the provider record. This value is used internally and an application should not depend on the value not changing over time for a specific service provider. To uniquely identify a provider, use the ***szGuid*** member of the structure, which is guaranteed not to change as providers are added and removed from the database.

nCountryCode

An integer value which specifies the ITU country calling code associated with the service provider. Currently this value will always be 1, which is the country code used by North American service providers. If the service provider database is expanded to include additional countries in the future, this value will identify the country of origin.

nRegionCode

An integer value which identifies the region that the service provider covers. In North America, each region consists of multiple states and/or provinces. If a provider services multiple regions, this will identify the primary region where they provide coverage.

Value	Description
SMS_REGION_NATIONAL 0	All regions. This region code is used for service providers that have national coverage and do not exclusively provide service within one or more specific geographical regions.
SMS_REGION_NORTH_EAST_ATLANTIC 1	Northeastern Atlantic region which includes Connecticut, Maine, Massachusetts, New Hampshire, New Brunswick, Newfoundland, Nova Scotia, Rhode Island and Vermont.
SMS_REGION_MIDDLE_ATLANTIC 2	Middle Atlantic region which includes New Jersey, New York, Delaware, District of Columbia, Maryland, Pennsylvania, Quebec, Virginia and West Virginia.
SMS_REGION_EAST_NORTH_CENTRAL 3	Northeastern central region which includes Illinois, Indiana, Michigan, Ohio and Wisconsin.

SMS_REGION_SOUTH_ATLANTIC 4	Southern Atlantic region which includes Florida, Georgia, North Carolina and South Carolina.
SMS_REGION_EAST_SOUTH_CENTRAL 5	Southeastern central region which includes Alabama, Kentucky, Mississippi and Tennessee.
SMS_REGION_WEST_NORTH_CENTRAL 6	Northwestern central region which includes Iowa, Kansas, Manitoba, Minnesota, Missouri, Nebraska, North Dakota, Ontario and South Dakota.
SMS_REGION_WEST_SOUTH_CENTRAL 7	Southwestern central region which includes Arkansas, Louisiana, Oklahoma and Texas.
SMS_REGION_MOUNTAIN 8	Mountain region which includes Alberta, Arizona, Colorado, Idaho, Montana, Nevada, New Mexico, Northwest Territories, Saskatchewan, Utah and Wyoming.
SMS_REGION_PACIFIC 9	Pacific region which includes Alaska, British Columbia, California, Hawaii, Oregon, Washington and Yukon.

nMessageLength

An integer value which specifies the maximum number of characters that the service provider will accept for a single text message. If the message exceeds this number of characters, the service provider may reject the message, or it may split the message into multiple messages.

dwFlags

An unsigned integer value which specifies one or more flags that provides additional information about the service provider. This value is constructed by using a bitwise operator with any of the following constants:

Value	Description
SMS_PROVIDER_DEFAULT 0	A standard service provider. Typically this means that customers have a service contract for their mobile device and pay monthly access and service charges.
SMS_PROVIDER_PREPAID 1	A service provider that offers pre-paid calling cards or fixed month-to-month payments that do not require long-term service contracts.

dwReserved

A value reserved for internal use.

szGuid

A null-terminated string which uniquely identifies the service provider. The string is in a standard format used for globally unique identifiers (GUIDs) and is guaranteed to not change for the service provider it has been assigned to.

szName

A null-terminated string which specifies the name of service provider. Note that this value may not represent the actual company that is providing the wireless service.

szCompany

A null-terminated string which specifies the name of the company associated with the service provider. This may be the same as name of the service provider itself or it may be the name of a parent company that owns the service provider.

szDomain

A null-terminated string which identifies the gateway domain name used by the service provider to accept text messages for their customer. This domain name is used to determine the actual name of the gateway mail server that is responsible for accepting messages.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SMSSERVICE

This structure provides information about the service used to send a text message.

```
typedef struct _SMSSERVICE
{
    DWORD dwServiceType;
    DWORD dwAuthType;
    DWORD dwVersion;
    DWORD dwTimeout;
    DWORD dwOptions;
    DWORD dwReserved;
    LPCTSTR lpszResource;
    LPCTSTR lpszAccount;
    LPCTSTR lpszUserName;
    LPCTSTR lpszPassword;
}  SMSSERVICE, *LPSMSSERVICE;
```

Members

dwServiceType

An integer value which identifies the type of service that will be used to send the message. This member can be one of the following values:

Value	Description
SMS_SERVICE_SMTP	The text message will be sent through the mail gateway for the specified service provider. This service uses SMTP to submit the message for delivery, either directly to the server provider's mail gateway server or through a relay server. This is the default service type.

dwAuthType

An integer value which identifies the type of authentication used with the service. This member can be one of the following values:

Value	Description
SMS_AUTH_DEFAULT	The default authentication method for this service type should be used. Most applications should use this value unless a service type provides multiple authentication methods.
SMS_AUTH_USERNAME	The service requires authentication using a username and password. This value can be used with an SMTP service that requires user authentication and is typically needed when using a mail server relay. For the SMS_SERVICE_SMTP service, this is the default authentication method.

dwVersion

An integer value which identifies the interface version for the service being used. This member is included for future use where a service may support multiple versions of their interface and should normally be set to the value SMS_VERSION_DEFAULT.

dwTimeout

An integer value which specifies the amount of time in seconds that a function will wait for a response from the service. If this value is zero, a default timeout period of 20 seconds will be used.

If the service does not respond within this time period, the function will fail.

dwOptions

An integer value which specifies one or more options.

Value	Description
SMS_OPTION_NONE	No additional options for the service.
SMS_OPTION_SECURE	This option specifies that TLS will be used to establish a secure, encrypted connection with the service. For some services, it may be required to connect to them securely and this option will be enabled automatically.

dwReserved

Reserved for future use. This value should always be zero.

lpszResource

A null-terminated string that specifies a resource for the service. Typically this will be either a fully qualified domain name or a URL. For gateways using SMTP, this string should identify the mail server. An alternate port number can also be specified by appending it to the hostname, separated by a colon. For example, **smtp.company.com:587** would connect to the server on port 587. If you are specifying an IPv6 address with an alternate port number, the address must be enclosed in brackets. For services where a domain name or resource URL is not required, this member will be ignored and can be NULL.

lpszAccount

A null-terminated string that specifies an account name or identifier. Some service providers may require a unique account name or a token (application ID) in conjunction with other credentials. This member is not used with mail gateways and ignored if the service type is SMS_SERVICE_SMTP. If no account name is required for session authentication, this member can be NULL.

lpszUserName

A null-terminated string that specifies a user name to authenticate the session. If the authentication type is SMS_AUTH_USERNAME this member must specify a valid user name. If no authentication is required, this member may be NULL. Note that some service providers may use terminology other than "username" with their documentation; this member will always specify the first of a pair of authentication tokens.

lpszPassword

A null-terminated string that specifies the password used to authenticate the session. If the authentication type is SMS_AUTH_USERNAME this member must specify a valid password. If no authentication is required, this member may be NULL. Note that some service providers may use terminology other than "password" with their documentation; this member will always specify the second of a pair of authentication tokens.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebStorage Application Storage Class Library

The CWebStorage class provides data storage for applications.

Reference

- Class Methods
- Constants
- Data Structures
- Error Codes

Library Information

Class Name	CWebStorage
File Name	CSWEBV12.DLL
Version	12.0.3024.1286
LibID	ECC96063-0D95-4378-A747-E0040B8618F1
Import Library	CSWEBV12.LIB
Dependencies	None

Overview

The CWebStorage class enables an application to store and manage data remotely. These methods use secure services provided by SocketTools API servers and do not require third-party party APIs or accounts with other cloud service providers.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most

commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage Class Methods

Class	Description
CWebStorage	Constructor which initializes the current instance of the class
~CWebStorage	Destructor which releases resources allocated by the class
Method	Description
Cancel	Cancel a storage operation that is currently in progress
CloseStorage	Close the storage container and release resources allocated for the client session
CompareFile	Compare the contents of a stored object with a local file
CompareData	Compare the contents of a stored object with a memory buffer
CompareText	Compare the contents of a stored object with a string
CopyObject	Copy a storage object to a new location and optionally rename the object label
DeleteObject	Delete an existing storage object
DownloadFile	Download the contents of a stored object to a local file
DisableTrace	Disable logging of method calls to the trace log file
EnableTrace	Enable logging of method calls to a log file
EnumObjects	Enumerate all storage objects that match the specified label or content type
GetAccountId	Return the current web services account identifier
GetData	Download the contents of a storage object to a memory buffer
GetErrorString	Return a description for the specified error code
GetFile	Download the contents of a storage object to a local file
GetFirstApplication	Return information about the first registered application
GetFirstObject	Return information about the first object that matches search criteria
GetHandle	Return the storage handle used by this instance of the class
GetLastError	Return the last error code
GetNextApplication	Return information about the next registered application
GetNextObject	Return information about the next object that matches search criteria
GetObjectInformation	Retrieve the metadata for the specified storage object
GetObjectSize	Return the size of the specified storage object
GetObjectTime	Return the creation and last modification time for the specified storage object
GetStorageQuota	Return quota limits assigned to your storage account
GetStorageId	Return the returns the current storage container ID
GetTimeout	Get the number of seconds until a storage operation times out
GetTransferStatus	Return status information about the progress of a data transfer
IsBlocking	Determine if the session waiting for a response from the storage server

IsConnected	Determine if the client is connected to the storage server
IsInitialized	Determine if the class has been successfully initialized
MoveObject	Move a storage object to a new location and optionally rename the object label
OpenStorage	Open a storage container and return a handle for the client session
PutData	Upload the contents of a memory buffer and return information about the new object
PutFile	Upload the contents of a local file and return information about the new object
RegisterAppId	Register a new application identifier used to store and retrieve data
RegisterEvent	Register an event handler to receive notifications for the session
RenameObject	Change the label associated with a storage object
ResetStorage	Resets the application storage container and deletes all stored objects
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until a storage operation times out
ShowError	Display a message box with a description of the specified error
UnregisterAppId	Unregister the application identifier and delete all associated storage objects
UnregisterEvent	Unregister an event handler and stop receiving notifications for the session
UploadFile	Upload the contents of a local file
ValidateAppId	Validate the specified application identifier
ValidateLabel	Check the specified string to ensure it is a valid object label

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::CWebStorage

```
CWebStorage();
```

The **CWebStorage** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only method on the development system and cannot be redistributed.

The constructor calls the **WebInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors.

You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CWebStorage, IsInitialized, WebInitialize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::~CWebStorage

```
~CWebStorage();
```

The **CWebStorage** destructor releases resources allocated by the current instance of the **CWebStorage** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CWebStorage** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CWebStorage, IsConnected, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::Cancel Method

```
BOOL Cancel();
```

The **Cancel** method cancels the current data transfer in progress.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **Cancel** method will cancel the current data transfer and abort the connection to the storage server. This method will fail if an active data transfer (either an upload or download) is not in progress.

This would typically be used within an event handler to cancel an operation as the contents of an object are being read or written. There is no mechanism to resume a canceled data transfer and this method should only be used when absolutely necessary.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)
Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

GetTransferStatus, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::CloseStorage Method

```
BOOL CloseStorage();
```

The **CloseStorage** method closes the open storage container.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CloseStorage** method must be called after all operations using the storage container have completed. The access token granted to the application will be released and the memory allocated for the session cache will be freed.

Requirements

Minimum Desktop Platform: Windows 7 (Service Pack 1)
Minimum Server Platform: Windows Server 2008 R2 (Service Pack 1)
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

GetHandle, OpenStorage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::CompareData Method

```
BOOL CompareData(
   LPCTSTR lpszObjectLabel,
   LPCVOID lpvBuffer,
   DWORD dwLength
);
```

The **CompareData** method compares the contents of a stored object with the data provided by the caller.

Parameters

lpszObjectLabel

A null-terminated string which specifies the label of the object to be compared.

lpvBuffer

A buffer that contains the data to be compared against the storage object.

dwLength

An unsigned integer which specifies the length of the data buffer to be compared.

Return Value

If the method succeeds, the return value is a non-zero and the data matches the contents of the stored object. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CompareData** method performs a binary comparison of the data in the specified buffer with the contents of the storage object on the server. The *dwLength* parameter must match the size of the stored object exactly, or this method will fail. Partial comparisons are not supported by this method.

If you wish to compare the contents of a text object, it is recommended that you use **CompareText**. This method ensures that Unicode text is compared correctly.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CompareFile, CompareText, GetObjectInformation

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::CompareFile Method

```
BOOL CompareFile(
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszLocalFile
);
```

The **CompareFile** method compares the contents of a stored object with a local file.

Parameters

lpszObjectLabel

A null-terminated string which specifies the label of the object to be compared.

lpszLocalFile

A null-terminated string that specifies the name of the local file. If a path is not specified, the file will be created in the current working directory.

Return Value

If the method succeeds, the return value is a non-zero and the contents of the file matches the stored object. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CompareFile** method performs a binary comparison of the contents of a local file with a stored object on the server. The contents of the file must be identical to the contents of the stored object or the method will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CompareData, CompareText, GetObjectInformation

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::CompareText Method

```
BOOL CompareText(
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszObjectText,
   INT cchObjectText
);
```

The **CompareText** method compares the contents of a stored object with the string provided by the caller.

Parameters

lpszObjectLabel

A null-terminated string which specifies the label of the object to be compared.

lpszObjectText

A null-terminated string which contains the text to be compared with the stored object.

cchObjectText

The number of characters in the ***lpszObjectText*** string to be compared. This value may be -1, in which case the string length will be determined by counting the number of characters up to the terminating null.

Return Value

If the method succeeds, the return value is a non-zero and the data matches the contents of the stored object. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CompareText** method performs a text comparison of the characters in the string with the contents of the storage object on the server. The string length must match the amount of text in the stored object exactly, or this function will fail. Partial comparisons are not supported by this function.

Unicode strings will be automatically converted from UTF-16 to UTF-8 encoding in the same way the **PutData** method does when storing text objects.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::CopyObject Method

```
BOOL CopyObject(
   LPCTSTR lpszOldLabel,
   LPCTSTR lpszNewLabel,
   DWORD dwStorageType,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **CopyObject** method creates a copy of an existing storage object using a new label.

Parameters

lpszOldLabel

A null-terminated string which specifies the label of the existing storage object to be copied. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A null-terminated string which specifies the name of the new storage object that will be created. This parameter may be NULL or point to an empty string, in which case the label name is not changed. In this case, the ***dwStorageType*** parameter cannot be WEB_STORAGE_DEFAULT.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, the value WEB_STORAGE_DEFAULT will be used. One of the following values can be specified:

Value	Description
WEB_STORAGE_DEFAULT	The default storage type. If this value is specified, the new object will be created using the same storage type as the original storage object.
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type

	are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain information about the new storage object. If this information is not required, this parameter may be omitted or a NULL pointer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **CopyObject** method is used to create a copy of an existing storage object. It may be used to duplicate an object with a different label, or it may be used to copy the object to a new storage container type. For example, it can copy an object originally created using WEB_STORAGE_USER to a new object stored using WEB_STORAGE_MACHINE.

Copied objects are assigned their own unique ID and are not linked to one another. Any subsequent changes made to the original object will not affect the copied object. Attempting to copy an object to itself or another existing object will result in an error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::DeleteObject Method

```
BOOL DeleteObject(
   LPCTSTR lpszObjectLabel
);
```

The **DeleteObject** method deletes an object from the storage container.

Parameters

lpszObjectLabel

A null-terminated string which specifies the label of the object to be deleted.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **DeleteObject** method permanently deletes the storage object and its associated data from the server. Deleted objects cannot be recovered by the application. To remove all objects stored in the container, use the **ResetStorage** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

CWebStorage::DownloadFile Method

```
BOOL DownloadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPWEB_STORAGE_OBJECT lpObject
);

BOOL DownloadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszAppId,
   DWORD dwStorageType,
   DWORD dwTimeout,
   LPWEB_STORAGE_OBJECT lpObject,
   WEBEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **DownloadFile** method downloads the contents of a storage object and copies it to a local file.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

lpszAppId

A null-terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is NULL or an empty string, the default identifier `SocketTools.Storage.Default` will be used.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, WEB_STORAGE_GLOBAL will be used as the default. One of the following values can be specified:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to

	the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwTimeout

An integer value that specifies a timeout period in seconds. If this value is zero, a default timeout period will be used.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object that has been downloaded. This parameter may be omitted or NULL if the information is not required.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback method, see the description of the **WebEventProc** callback method. If this parameter is omitted or NULL, no callback function will be invoked during the data transfer.

dwParam

A user-defined integer value that is passed to the callback method specified by ***lpEventProc***. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **DownloadFile** method downloads the contents of the storage object and stores it in a local file. Unlike the **GetFile** method, it is not required that you explicitly open a storage container using the **OpenStorage** method prior to calling this method.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are downloading a large object and want your application to receive progress updates during the data transfer, provide a pointer to a static callback function as the ***lpEventProc*** parameter. That function will receive event notifications as the data is being downloaded.

Example

```
WEB_STORAGE_OBJECT webObject;

// Download the object from global storage to a local file
if (pStorage->DownloadFile(lpszObjectLabel, lpszLocalFile, &webObject))
{
    // The object was downloaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be retrieved, display the error
    CString strError;

    pStorage->GetLastError(strError);
    _tprintf(_T("Unable to retrieve \"%s\" (%s)\n"), lpszObjectLabel,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::EnumObjects Method

```
BOOL EnumObjects(
   LPCTSTR lpszMatchLabel,
   LPCTSTR lpszContentType,
   LPWEB_STORAGE_OBJECT& lpObjects,
   DWORD& dwObjects
);

DWORD EnumObjects(
   LPCTSTR lpszMatchLabel,
   LPCTSTR lpszContentType
);
```

The **EnumObjects** method enumerates all storage objects that match the specified label or content type.

Parameters

lpszMatchLabel

A null-terminated string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this value is a NULL pointer or an empty string, all objects in the container will be matched.

lpszContentType

A null-terminated string which specifies the content type of the objects to be enumerated. If this value is a NULL pointer or an empty string, the content type is ignored and all matching objects are returned.

lpObjects

A pointer to an array of WEB_STORAGE_OBJECT structures that will contain information about the enumerated objects. If this parameter is NULL, then no object information is returned.

lpdwObjects

A pointer to an unsigned integer that will contain the number of objects enumerated by this method. If the *lpObjects* parameter points to an array of WEB_STORAGE_OBJECT structures, this parameter must be initialized to the maximum size of the array being passed to the method. If the *lpObjects* parameter is NULL, this value must be initialized to zero, and when the method returns it will contain the number of matching objects.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **EnumObjects** method can be used to enumerate the number of objects that match a given label, content type or both. If a content type is specified, it must be a valid MIME media content type designated using the type/subtype nomenclature. For example, "text/plain" or "image/jpeg". An invalid MIME type will cause the method to fail.

This method can be used in two ways. If the *lpObjects* parameter is NULL and the value passed by reference in the *lpdwObjects* parameter is initialized to zero, the method will return the number of

matching objects in *lpdwObjects*. This can be used to dynamically determine the size of the lpObjects array instead of declaring a fixed-size array in your application.

If the *lpObjects* parameter is not NULL, then the value referenced by *lpdwObjects* must be initialized to the maximum size of the array that *lpObjects* points to. It is important to note that if either parameter is not initialized correctly, it can result in memory corruption and/or an unhandled exception.

There is an alternative version of **EnumObjects** which only returns a count of objects that match the specified content type and/or object label name, without returning information about the objects. This can be used to determine how many objects match the given criteria prior to requesting the object metadata.

The **GetFirstObject** and **GetNextObject** methods can be used to iterate through all matching storage objects without allocating memory to store all of the matching objects. Using **GetFirstObject** and **GetNextObject** is more efficient when the container contains a large number of objects that match the specified label and/or content type.

Example

```
DWORD dwObjects = 0;
LPWEB_STORAGE_OBJECT lpObjects = NULL;

if (pStorage->EnumObjects(_T("*.pdf"), NULL, lpObjects, dwObjects))
{
    // Print information about each object
    for (DWORD dwIndex = 0; dwIndex < dwObjects; dwIndex++)
    {
        _tprintf(_T("Object: %s\n"), lpObjects[dwIndex].szObjectId);
        _tprintf(_T("Label: %s\n"), lpObjects[dwIndex].szLabel);
        _tprintf(_T("Size: %lu\n"), lpObjects[dwIndex].dwObjectSize);
        _tprintf(_T("Digest: %s\n"), lpObjects[dwIndex].szDigest);
        _tprintf(_T("Content: %s\n"), lpObjects[dwIndex].szContent);

        if (dwObjects > 1 && dwIndex < dwObjects - 1)
            _tprintf(_T("\n"));
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::GetAccountId Method

```
BOOL GetAccountId(
   LPCTSTR lpszAccountId,
   INT nMaxLength
);

BOOL GetAccountId(
   CString& strAccountId
);
```

The **GetAccountId** method returns the web services account ID associated with the current session.

Parameters

lpszAccountId

A null-terminated string that will contain the account ID when the method returns. This parameter cannot be NULL and must be at least 35 characters in length. An alternate form of the method accepts a **CString** variable which will contain the account ID.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the *lpszAccountId* string parameter, including the terminating null character.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The account ID is a string that uniquely identifies the web services account that is associated with the session. The account ID corresponds with your product serial number and runtime license key, but it is not identical to either of those values.

If you are using an evaluation license, the account ID is temporary and only valid during the evaluation period. After the evaluation period has expired, the account ID is revoked and objects stored using this ID will be deleted. It is not recommended that you store critical application data using an evaluation license.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::GetData Method

```
BOOL GetData(
   LPCTSTR lpszObjectLabel,
   LPBYTE lpBuffer,
   LPDWORD lpdwLength,
   LPWEB_STORAGE_OBJECT lpObject,
);

BOOL GetData(
   LPCTSTR lpszObjectLabel,
   HGLOBAL *lphgblBuffer,
   LPDWORD lpdwLength,
   LPWEB_STORAGE_OBJECT lpObject,
);

BOOL GetData(
   LPCTSTR lpszObjectLabel,
   LPTSTR lpszBuffer,
   INT nMaxLength,
   LPWEB_STORAGE_OBJECT lpObject,
);

BOOL GetData(
   LPCTSTR lpszObjectLabel,
   CString& strBuffer,
   LPWEB_STORAGE_OBJECT lpObject,
);
```

The **GetData** method retrieves the contents of a storage object and copies it to the memory buffer that is provided. Additional information about the object is optionally returned to the caller.

Parameters

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

lpBuffer

A pointer to a byte array which will contain the object's data. When this version of the method is called, the buffer must be pre-allocated by the application and large enough to store all of the data or the method will fail. The ***lpdwLength*** parameter must be initialized with the maximum size of the byte array, and will be updated with the actual number of bytes copied into the buffer when the method returns.

lphgblBuffer

A pointer to a HGLOBAL memory handle. When this version of the method returns, the handle will reference a block of memory allocated by the **GlobalAlloc** function and the ***lpdwLength*** parameter will contain the number of bytes copied. To obtain a pointer to the data, the application must call the **GlobalLock** function. It is the responsibility of the application to free the global memory handle when it is no longer needed.

lpszBuffer

A null-terminated string buffer which will contain the object's text when the method returns. When this version of the method is called, the string will be populated with the object contents and terminated with a null character. The ***nMaxLength*** parameter must specify the maximum number of

characters that can be copied into the string, including the terminating null. This version of the function should only be used with text and must never be used with binary data.

strBuffer

A **CString** which will contain the object's text when the method returns. This version of the method requires the application be compiled with MFC or ATL support. This version of the function should only be used with text and must never be used with binary data.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpBuffer*** parameter. If the ***lpBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the method returns, this value will be updated with the actual length of the file that was downloaded.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the ***lpszBuffer*** string buffer provided by the caller. This value must be large enough to contain the entire contents of the object, including the terminating null character.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter may be omitted or NULL if the information is not required.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetData** method is used to retrieve a stored object from the server and copy it into a local buffer. The method may be used in one of several ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the object. In this case, the ***lpBuffer*** parameter will point to the buffer that was allocated and the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is to provide a pointer to an HGLOBAL global memory handle which will contain the file data when the method returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the method must be freed by the application, otherwise a memory leak will occur. See the example code below.

The third method is to provide a string buffer which will contain the contents of a text object. The ***nMaxLength*** parameter must specify a size large enough to contain the entire object text, including a terminating null character. If the **PutData** method was previously used to store UTF-16 encoded text, you must use a byte array to retrieve that data. This method only recognizes UTF-8 encoded text and considers UTF-16 encoded text to be binary data. This version of the method should never be used to retrieve data from an object that does not contain text.

If you wish to retrieve the contents of an object and store it in a file, use the **GetFile** method.

Additional metadata about the object can be returned in a WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
DWORD dwLength = 0;
LPCTSTR lpszObjectLabel = _T("MyAppData");

// Open the default global storage container
if (!pStorage->OpenStorage(WEB_STORAGE_GLOBAL))
{
    _tprintf(_T("Unable to open global storage\n"));
    return;
}

// Return the file data into block of global memory allocated by
// the GlobalAlloc method; the handle to this memory will be
// returned in the hgblBuffer parameter
if (pStorage->GetData(lpszObjectLabel, &hgblBuffer, &dwLength))
{
    // Lock the global memory handle, returning a pointer to the
    // resource data
    LPBYTE lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
else
{
    // The GetData method failed
    _tprintf(_T("Unable to retrieve object \"%s\"\n"), lpszObjectLabel);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::GetFile Method

```
BOOL GetFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **GetFile** method downloads the contents of a storage object and copies it to a local file.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter may be omitted or NULL if the information is not required.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

If you are downloading a large object and want your application to receive progress updates during the data transfer, use the **RegisterEvent** method and provide a pointer to a static callback function that will receive event notifications.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetFirstApplication Method

```
BOOL GetFirstApplication(
   LPWEB_STORAGE_APPLICATION lpAppInfo
);
```

The **GetFirstApplication** method returns information about the first registered application for the current storage account.

Parameters

lpAppInfo

A pointer to a WEB_STORAGE_APPLICATION structure that will contain information about the registered application when the function returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFirstApplication** method returns information about the first registered application. It is used in conjunction with the **GetNextApplication** method to enumerate all of the registered application IDs associated with your storage account.

The cached application ID information used by this method is shared by the entire process. Attempting to enumerate all registered application IDs in multiple threads at the same time can yield unexpected results. It is recommended that multithreaded clients use a critical section to ensure that only a single thread is enumerating the AppIDs at any one time.

Example

```
WEB_STORAGE_APPLICATION webApp;

if (pStorage->GetFirstApplication(&webApp))
{
    do
    {
        // Print information for each registered application
        _tprintf(_T("AppId: %s\n"), webApp.szAppId);
        _tprintf(_T("Key: %s\n"), webApp.szApiKey);
        _tprintf(_T("LUID: %s\n"), webApp.szLuid);
        _tprintf(_T("Tokens: %lu\n"), webApp.dwTokens);
        _tprintf(_T("\n"));
    }
    while (pStorage->GetNextApplication(&webApp));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetFirstObject Method

```
BOOL GetFirstObject(
   LPWEB_STORAGE_OBJECT lpObject
);

BOOL GetFirstObject(
   LPCTSTR lpszMatchLabel,
   LPWEB_STORAGE_OBJECT lpObject
);

BOOL GetFirstObject(
   LPCTSTR lpszMatchLabel,
   LPCTSTR lpszContentType,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **GetFirstObject** method returns information about the first storage object that matches the specified label or content type.

Parameters

lpszMatchLabel

A null-terminated string which specifies the value to match against the object labels in the container. The string may contain wildcard characters similar to those use with the Windows filesystem. A "?" character matches any single character, and "*" matches any number of characters in the label. If this parameter is omitted, a NULL pointer or an empty string, all objects in the container will be matched.

lpszContentType

A null-terminated string which specifies the content type of the objects to be enumerated. If this parameter is omitted, a NULL pointer or an empty string, the content type is ignored and all matching objects are returned. If a content type is specified, it must be a valid MIME media content type designated using the type/subtype nomenclature.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain information about the storage object when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **WebGetLastError**.

Remarks

The **GetFirstObject** method returns information about the first object that matches a given label, content type or both. It is used in conjunction with the **GetNextObject** method to enumerate all of the matching objects in the storage container.

This method provides an alternative to the **EnumObjects** method, which populates an array of WEB_STORAGE_OBJECT structures. In some cases, iterating over each object in a loop may be preferred to preallocating memory for an array to store every matching object. Using **GetFirstObject** and **GetNextObject** is more efficient when the container contains a large number of objects that match the specified label and/or content type.

You cannot intermix calls between **GetFirstObject** and **EnumObjects**. The **EnumObjects** method will

reset the internal object cache for the client session and subsequent calls to **GetNextObject** will fail.

Example

```
WEB_STORAGE_OBJECT webObject;

if (pStorage->GetFirstObject(&webObject))
{
    do
    {
        // Print information about each object
        _tprintf(_T("Object: %s\n"), webObject.szObjectId);
        _tprintf(_T("Label: %s\n"), webObject.szLabel);
        _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
        _tprintf(_T("Digest: %s\n"), webObject.szDigest);
        _tprintf(_T("Content: %s\n"), webObject.szContent);
        _tprintf(_T("\n"));
    }
    while (pStorage->GetNextObject(&webObject));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CWebStorage::GetHandle Method

```
HSTORAGE GetHandle();
```

The **GetHandle** method returns the storage handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_HANDLE will be returned.

Remarks

This method is used to obtain the storage handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

CWebStorage::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Methods set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Method failure is typically indicated by a return value such as FALSE, NULL, INVALID_HANDLE or WEBAPI_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

GetNextApplication Function

```
BOOL GetNextApplication(
   LPWEB_STORAGE_APPLICATION lpAppInfo
);
```

The **GetNextApplication** method returns information about the next registered application for the current storage account.

Parameters

lpAppInfo

A pointer to a WEB_STORAGE_APPLICATION structure that will contain information about the registered application when the function returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextApplication** method returns information about the next registered application after initially calling the **GetFirstApplication** method. It is used to enumerate all of the registered application IDs associated with your storage account.

The cached application ID information used by this method is shared by the entire process. Attempting to enumerate all registered application IDs in multiple threads at the same time can yield unexpected results. It is recommended that multithreaded clients use a critical section to ensure that only a single thread is enumerating the AppIDs at any one time.

Example

```
WEB_STORAGE_APPLICATION webApp;

if (pStorage->GetFirstApplication(&webApp))
{
    do
    {
        // Print information for each registered application
        _tprintf(_T("AppId: %s\n"), webApp.szAppId);
        _tprintf(_T("Key: %s\n"), webApp.szApiKey);
        _tprintf(_T("LUID: %s\n"), webApp.szLuid);
        _tprintf(_T("Tokens: %lu\n"), webApp.dwTokens);
        _tprintf(_T("\n"));
    }
    while (pStorage->GetNextApplication(&webApp));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetNextObject Method

```
BOOL GetNextObject(
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **GetNextObject** method returns information about the next storage object that matches the specified label or content type.

Parameters

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain information about the storage object when the function returns. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNextObject** method returns information about the next object that matches the label and/or content type that was specified by the **GetFirstObject** method. This method may only be called after **GetFirstObject** has been called, otherwise it will fail.

When all matching objects have been returned to the caller, this method will return zero (FALSE) and the **GetLastError** method will return NO_ERROR. Any other error code indicates an underlying problem with the request, such as an invalid parameter passed to the function.

You cannot intermix calls between **GetNextObject** and **EnumObjects**. The **EnumObjects** method will reset the internal object cache for the client session and subsequent calls to **GetNextObject** will fail.

Example

```
WEB_STORAGE_OBJECT webObject;

if (pStorage->GetFirstObject(&webObject))
{
    do
    {
        // Print information about each object
        _tprintf(_T("Object: %s\n"), webObject.szObjectId);
        _tprintf(_T("Label: %s\n"), webObject.szLabel);
        _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
        _tprintf(_T("Digest: %s\n"), webObject.szDigest);
        _tprintf(_T("Content: %s\n"), webObject.szContent);
        _tprintf(_T("\n"));
    }
    while (pStorage->GetNextObject(&webObject));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::GetObjectInformation Method

```
BOOL GetObjectInformation(
   LPCTSTR lpszObjectLabel,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **GetObjectInformation** method retrieves the metadata for a storage object.

Parameters

lpszObjectLabel

A null-terminated string that specifies the label of the storage object.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter cannot be a NULL pointer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetObjectInformation** method is used to retrieve the metadata for a stored object on the server, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents. This method can also be used as a simple method to determine if the specified object exists without the overhead of requesting the server attempt to retrieve the contents of an object.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting information about an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

If you are only interested in obtaining the size of a stored object, you can use the **GetObjectSize** method.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **GetStorageQuota** method.

Example

```
WEB_STORAGE_OBJECT webObject;

// Get information about the object
if (pStorage->GetObjectInformation(lpszObjectLabel, &webObject))
{
    // The object exists, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object does not exist, display the error
```

```
    CString strError;

    pStorage->GetLastError(strError);
    _tprintf(_T("Unable to get information on \"%s\" (%s)\n"), lpszObjectLabel,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetFile, GetData, GetObjectSize, GetObjectTime, GetStorageQuota, PutFile, PutData

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::GetObjectSize Method

```
DWORD GetObjectSize(
   LPCTSTR lpszObjectLabel
);

BOOL GetObjectSize(
   LPCTSTR lpszObjectLabel,
   LPDWORD lpdwObjectSize
);
```

The **GetObjectSize** method returns the size of the stored object.

Parameters

lpszObjectLabel

A null-terminated string that specifies the label of the storage object. This parameter cannot be a NULL pointer.

lpdwObjectSize

A pointer to an unsigned integer value that will contain the size of the object. If this parameter is NULL, the parameter is ignored and the method only checks for the existence of an object that matches the specified label.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetObjectSize** method is used to retrieve the size of a stored object on the server. This method can also be used as a simple method to determine if the specified object exists. An object size of zero means the object exists, but currently has no data associated with it.

If the first version of this method is called, where the object size is a return value, you can distinguish between an error and an empty object by calling the **GetLastError** method. If the last error code is NO_ERROR then the object exists, but it has no data associated with it. Any other error code value indicates the reason the object size could not be returned.

If the second version of this method is used and the *lpObjectSize* parameter is not NULL, its value is initialized to zero when the method is called, and updated with the object size when the method returns.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting the size of an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

The **GetObjectInformation** method can be used to obtain the metadata associated with the storage object, including the size, content type, creation date and a SHA-256 digest of the data.

To obtain information about how much storage your applications are using and the total number of stored objects, use the **GetStorageQuota** method.

Example

```
// Check if the object exists
DWORD dwObjectSize = 0;
```

```
if (pStorage->GetObjectSize(lpszObjectLabel, &dwObjectSize))
{
    // The object exists, display the size in bytes
    _tprintf(_T("The size of \"%s\" is %lu bytes\n"), lpszObjectLabel,
dwObjectSize);
}
else
{
    // The object size could not be determined, display the error
    CString strError;

    pStorage->GetErrorString(strError);
    _tprintf(_T("Unable to get the size of \"%s\" (%s)\n"), lpszObjectLabel,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

GetData, GetObjectInformation, GetObjectTime, GetStorageQuota, PutData

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::GetObjectTime Method

```
BOOL GetObjectTime(
   LPCTSTR lpszObjectLabel,
   LPFILETIME lpTimeCreated,
   LPFILETIME lpTimeModified
);

BOOL GetObjectTime(
   LPCTSTR lpszObjectLabel,
   LPSYSTEMTIME lpTimeCreated,
   LPSYSTEMTIME lpTimeModified
);
```

The **GetObjectTime** method returns the creation and last modification time of the stored object.

Parameters

lpszObjectLabel

A null-terminated string that specifies the label of the storage object. This parameter cannot be a NULL pointer.

lpTimeCreated

A pointer to a FILETIME structure which will contain the time the storage object was created when the method returns. If this information is not required, the parameter may be NULL. An alternate version of this method accepts a pointer to a SYSTEMTIME structure instead of a FILETIME structure.

lpTimeModified

A pointer to a FILETIME structure which will contain the time the storage object was last modified when the method returns. If this information is not required, the parameter may be NULL. An alternate version of this method accepts a pointer to a SYSTEMTIME structure instead of a FILETIME structure.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetObjectTime** method is used to retrieve the creation and modification times for a stored object on the server. This method can also be used as a simple method to determine if the specified object exists. Each of the LPFILETIME or LPSYSTEMTIME parameters are optional and may be NULL if either the creation or modification times are not needed. If a pointer to a structure is provided, its members will be initialized to zero and then updated with the creation and/or modification time if the method succeeds.

Although storage object labels are similar to Windows file names, they are case-sensitive. When requesting the size of an object, your application must specify the label name exactly as it was created. The object label cannot contain wildcard characters.

If you wish to obtain all of the metadata associated with a specific object with a single method call, including the size, content type, creation and modification times, use the **GetObjectInformation** method.

Example

```
// Check if the object exists
FILETIME ftCreated;
FILETIME ftModified;

if (pStorage->GetObjectTime(lpszObjectLabel, &ftCreated, &ftModified))
{
    // The object exists, display the last modification time
    TCHAR szLocalDate[128];
    TCHAR szLocalTime[128];
    FILETIME ftLocalTime;
    SYSTEMTIME stLocalTime;

    FileTimeToLocalFileTime(&ftModified, &ftLocalTime);
    FileTimeToSystemTime(&ftLocalTime, &stLocalTime);

    GetDateFormat(LOCALE_USER_DEFAULT,
                  DATE_SHORTDATE,
                  &stLocalTime,
                  NULL,
                  szLocalDate, 128);

    GetTimeFormat(LOCALE_USER_DEFAULT,
                  TIME_FORCE24HOURFORMAT,
                  &stLocalTime,
                  NULL,
                  szLocalTime, 128);

    _tprintf(_T("The object \"%s\" was lasted modified on %s %s\n"),
lpszObjectLabel, szLocalDate, szLocalTime);
}
else
{
    // The object times could not be determined, display an error
    CString strError;

    pStorage->GetErrorString(strError);
    _tprintf(_T("Unable to get the size of \"%s\" (%s)\n"), lpszObjectLabel,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::GetStorageId Method

```
BOOL GetStorageId(
   LPCTSTR lpszStorageId,
   INT nMaxLength
);

BOOL GetStorageId(
   CString & strStorageId
);
```

The **GetStorageId** method returns the current storage container ID.

Parameters

lpszStorageId

A null-terminated string that will contain the storage ID when the method returns. This parameter cannot be NULL and must be at least 35 characters in length. An alternate version of this method accepts a **CString** parameter if the application is compiled with support for MFC or ATL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the *lpszStorageId* string parameter, including the terminating null character.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The storage ID is a string that identifies the storage container that was opened with the **OpenStorage** method. The storage ID is associated with your account ID and development license and is guaranteed to be a unique value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::GetStorageQuota Method

```
BOOL GetStorageQuota(
   LPWEB_STORAGE_QUOTA lpQuota
);
```

The **GetStorageQuota** method returns quota limits assigned to your development account.

Parameters

lpQuota

A pointer to a WEB_STORAGE_QUOTA structure that will contain information the quota limits for your account when the method returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetStorageQuota** method can be used to determine how much storage space is available to your application. The *ulBytesFree* structure member will tell you how many bytes of storage you have available, and the *dwObjectSize* member will tell you the maximum size of any individual storage object. In addition to the bytes allocated for storage, there is also a limit on the total number of objects that your application may create which is specified by the *dwObjectLimit* member.

Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

Example

```
CWebStorage appStorage;
WEB_STORAGE_QUOTA appQuota;

// Display storage account usage and limits
if (appStorage.GetStorageQuota(&appQuota))
{
     _tprintf(_T("Objects Used:  %lu\n"), appQuota.dwObjects);
     _tprintf(_T("Object Limit:  %lu\n"), appQuota.dwObjectLimit);
     _tprintf(_T("Object Size:   %lu\n"), appQuota.dwObjectSize);
     _tprintf(_T("Bytes Used:    %I64u\n"), appQuota.ulBytesUsed);
     _tprintf(_T("Bytes Free:    %I64u\n"), appQuota.ulBytesFree);
     _tprintf(_T("Storage Limit: %I64u\n"), appQuota.ulStorageLimit);
}
else
{
    // Unable to get the quota information for this account
    CString strError;

    appStorage.GetErrorString(strError);
    _tprintf(_T("Unable to get the account quota (%s)\n"), (LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CWebStorage::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the storage server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The default timeout period is 10 seconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

CWebStorage::GetTransferStatus Method

```
    LPWEB_STORAGE_TRANSFER lpStatus
);
```

The **GetTransferStatus** method returns information about the current data transfer in progress.

Parameters

lpStatus

A pointer to a WEB_STORAGE_TRANSFER structure which contains information about the status of the current data transfer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **GetTransferStatus** method returns information about the current data transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no data currently being transferred, this method will return the status of the last successful data transfer.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the storage session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can potentially allow the application to be re-entered, it is possible that another blocking method may be called while it is in progress. Because only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the storage client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

If your application attempts to perform multiple operations simultaneously, such as downloading multiple stored objects to the local system, each client session should be isolated in its own thread. This will avoid potential situations where a request is refused because a blocking data transfer is already in progress on the current thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Cancel, GetFile, GetData, IsConnected, IsInitialized, PutFile, PutData

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if a connection has been established with the storage server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero. To get extended error information, call the **GetLastError** method.

Remarks

The client does not maintain a continuous, persistent connection with the storage server. The connection may be closed and reopened internally as needed. If the client session has been idle for a period of time, this method can return zero.

If the **GetLastError** method returns ST_ERROR_NOT_CONNECTED it means the client session is valid, however it not currently connected to the storage server. The next call to store or retrieve an object will the cause the client to reconnect automatically.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

IsBlocking, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on a different system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

CWebStorage::MoveObject Method

```
BOOL MoveObject(
   LPCTSTR lpszOldLabel,
   LPCTSTR lpszNewLabel,
   DWORD dwStorageType,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **MoveObject** method moves an existing object to a different storage container.

Parameters

lpszOldLabel

A null-terminated string which specifies the name of the existing storage object to be moved. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A null-terminated string which specifies a new label for the storage object being moved. This parameter may be NULL or point to an empty string, in which case the label name is not changed.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, the object is renamed and not moved to another container. One of the following values may be specified:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain information about the new storage object. If this information is not required, this parameter may be omitted or a NULL pointer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **MoveObject** method is used to move an existing storage object to a new container. For example, it can move an object originally created using WEB_STORAGE_USER to the WEB_STORAGE_MACHINE container. The *dwStorageType* parameter must specify a valid storage container type and cannot be WEB_STORAGE_DEFAULT.

If the *dwStorageType* parameter specifies the same container that the object is currently in, and the *lpszNewLabel* parameter specifies a new label name, this method will simply rename the existing object and is effectively the same as calling the **RenameObject** method.

To duplicate an existing storage object, use the **CopyObject** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CWebStorage::OpenStorage Method

```
BOOL OpenStorage(
   DWORD dwStorageType
);

BOOL OpenStorage(
   LPCTSTR lpszAppId,
   DWORD dwStorageType
);
```

The **OpenStorage** method establishes a connection with the server and opens the storage container associated with the specified storage type.

Parameters

lpszAppId

A null-terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is omitted, NULL or an empty string, the default identifier `SocketTools.Storage.Default` will be used.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, the WEB_STORAGE_GLOBAL container will be opened. One of the following values may be specified:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this

	storage type will not be available to the application.

Return Value

If the method succeeds, the return value is a handle to the storage container. If the method fails, the return value is INVALID_HANDLE. To get extended error information, call the **GetLastError** method.

Remarks

The **OpenStorage** method opens the specified storage container and requests an access token for the application. This is the first method that must be called prior to accessing any stored objects.

The application ID is a string that uniquely identifies the application requesting the access and must have been previously registered with the server by calling the **RegisterAppId** method. If the *lpszAppId* parameter is NULL or an empty string, the method will use a default internal ID that is allocated for each storage account. You can use this default ID if you wish to share data between all of the applications you create.

The storage type specifies the type of container that objects will be stored in. In most cases, we recommend using WEB_STORAGE_GLOBAL which means that stored objects will be accessible to all users of your application. However, you can limit access to the stored objects based on the local domain, local machine ID or the current user SID.

If you specify anything other than global storage, objects can be orphaned if the system configuration changes. For example, if WEB_STORAGE_MACHINE is specified the objects that are stored can only be accessed from that system. If the system is reconfigured (for example, the boot volume formatted and Windows is reinstalled) the unique identifier for that system will change and the previous objects that were stored by your application can no longer be accessed.

It is advisable is to store critical application data and configuration information using WEB_STORAGE_GLOBAL and use other non-global storage containers for configuration information that is unique to that system and/or user which is not critical and can be easily recreated.

If a storage container was previously opened, calling this method will automatically close the current container and open the new container specified by the *dwStorageType* parameter. This can change the internal handle value used to reference the container and the old handle will no longer be valid.

Example

```
CWebStorage appStorage;
LPCTSTR lpszAppId = _T("MyCompany.WebTest.1");
LPCTSTR lpszLocalFile = _T("TestDocument.pdf");
LPCTSTR lpszObjectLabel = _T("TestDocument.pdf");
WEB_STORAGE_OBJECT webObject = { 0, };

// Register the application ID which identifies the application
if (!appStorage.RegisterAppId(lpszAppId))
{
    tprintf(_T("Unable to register the application ID"));
    _exit(0);
}

// Open the application storage container
if (!appStorage.OpenStorage(lpszAppId, WEB_STORAGE_GLOBAL);
{
    tprintf(_T("Unable to open global storage for this application"));
    _exit(0);
}
```

```
// Upload a local file to the storage server and return information
// about the stored object when it completes
if (appStorage.PutFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // Print information about the object that was created
    _tprintf(_T("Object: %s\n"), webObject.szObjectId);
    _tprintf(_T("Label: %s\n"), webObject.szLabel);
    _tprintf(_T("Size: %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest: %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The upload failed, display error information
    CString strError;

    appStorage.GetLastError(strError);
    _tprintf(_T("Cannot store \"%s\" (%s)\n"), lpszLocalFile, (LPCTSTR)strError);
}

// Release the handle allocated for this storage session
appStorage.CloseStorage();
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::PutData Method

```
BOOL PutData(
   LPCTSTR lpszObjectLabel,
   LPCVOID lpvBuffer,
   DWORD dwLength,
   LPWEB_STORAGE_OBJECT lpObject
);

BOOL PutData(
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszObjectText,
   INT cchObjectText,
   LPWEB_STORAGE_OBJECT lpObject
);

BOOL PutData(
   LPCTSTR lpszObjectLabel,
   LPCVOID lpvBuffer,
   DWORD dwLength,
   LPCTSTR lpszContentType,
   DWORD dwAttributes,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **PutData** method stores the contents of buffer to a container and returns information about the new object.

Parameters

lpszObjectLabel

A null-terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The method will fail if the label contains any illegal characters.

lpvBuffer

A buffer that contains the data to be stored. If this parameter is NULL, the ***dwLength*** parameter must have a value of zero and a storage object will be created which has no data associated with it.

dwLength

An unsigned integer value that specifies the number of bytes that will be copied from the ***lpvBuffer*** parameter and stored in the object. If the ***lpvBuffer*** parameter is NULL, this value must be zero or the method will fail.

lpszObjectText

A null-terminated string which is used with an alternate version of this method. The string will be stored as a text object and the ***cchObjectText*** parameter will specify the number of characters to be stored.

cchObjectText

An integer value that specifies the number of characters that will be copied from the ***lpszObjectText*** string and stored in the object. If the ***lpszObjectText*** parameter is NULL, this value must be zero or the method will fail. If this parameter is omitted, the length of the string will be calculated by counting the number of characters up to the terminating null.

lpszContentType

A null-terminated string that identifies the contents of the buffer being stored. If this parameter is omitted, a NULL pointer, or specifies a zero-length string, the method will attempt to automatically determine the content type based on the object label and the contents of the buffer.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. If this parameter is omitted, the default value WEB_OBJECT_NORMAL will be used. This value can be a combination of one or more of the following bit flags using a bitwise OR operation:

Value	Description
WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the **EnumObjects** method. The object can only be accessed directly when specifying its label.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object that was created or replaced. This parameter may be omitted or NULL if the information is not required.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **PutData** method uploads the contents of a buffer to the current storage container. The content type, which identifies the type of data stored in the object, and its attributes may be specified by the caller or default values may be used.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text files have a content type of **text/plain** while an XML-formatted text file would have a content type of **text/xml**. Files that contain unstructured binary data are typically identified as **application/octet-stream**.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

If **PutData** method is used to store the contents of a string as a text object, the string should be terminated with a null character and cannot contain embedded nulls. If the Unicode version of this function is called, the contents of the string will be normalized prior to being converted to UTF-8 using canonical composition, where decomposed characters are combined to create their canonical precomposed equivalent.

The size of the text object that is created can be different from the length of the string buffer passed to this method, depending on how the text has been encoded and stored. This will almost always be the case when the Unicode version of this function is called because the UTF-16 string will be converted and stored as UTF-8 encoded text. This encoding will typically increase the size of the stored object unless the string only contains ASCII characters.

The version of the **PutData** method which accepts a string should only be used to store textual data in a null terminated string, and should never be used to store binary data. If you wish to create or update an object which contains binary data, you should always use use a byte array.

If you want to upload the contents of a file, the **PutFile** method simplifies this process. The example code below demonstrates how the Windows API can be used to read from a local file and store the contents using **PutData**.

If you are storing a large amount of data and want your application to receive progress updates during the data transfer, use the **RegisterEvent** method and provide a pointer to a static callback function that will receive event notifications.

Example

```
HANDLE hFile = INVALID_HANDLE_VALUE;
LPBYTE lpContents = NULL;
DWORD dwLength = 0;
BOOL bFileRead = FALSE;
WEB_STORAGE_OBJECT webObject;

// Open a file on the local system and read the contents
// into a buffer that will be stored on the server
hFile = CreateFile(lpszLocalFile,
                   GENERIC_READ,
                   0,
                   NULL,
                   OPEN_EXISTING,
                   FILE_ATTRIBUTE_NORMAL,
                   NULL);

if (hFile == INVALID_HANDLE_VALUE)
{
    // Unable to open the file
    return;
}

// Get the size of the file and allocate a buffer large
// enough to store the contents of the file
dwLength = GetFileSize(hFile, NULL);
lpContents = (LPBYTE)LocalAlloc(LPTR, dwLength + 1);

if (lpContents == NULL)
{
    // Memory allocation failed
    return;
}

bFileRead = ReadFile(hFile, lpContents, dwLength, &dwLength, NULL);
CloseHandle(hFile);

if (!bFileRead)
{
```

```
    // Unable to read the contents of the file
    return;
}

// Store the contents of the buffer, identifying it as an unstructured
// stream of bytes, and the object is created with read/write access
if (pStorage->PutData(lpszObjectLabel, lpContents, dwLength, &webObject))
{
    // The object was created or replaced, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be created
    CString strError;

    pStorage->GetLastError(strError);
    _tprintf(_T("Unable to create \"%s\" (%s)\n"), lpszObjectLabel,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::PutFile Method

```
BOOL PutFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPWEB_STORAGE_OBJECT lpObject

BOOL PutFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszContentType,
   DWORD dwAttributes,
   LPWEB_STORAGE_OBJECT lpObject
);
```

The **PutFile** method uploads the contents of a local file to a storage container and returns information about the new object.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be uploaded. If a path is not specified, the file will be read from the current working directory. The current user must have read access to the file, and an error will be returned if the method cannot obtain an exclusive lock on the file during the upload process.

lpszObjectLabel

A null-terminated string that specifies the label of the storage object that will be created or replaced. This parameter cannot be NULL or a zero-length string. The method will fail if the label contains any illegal characters.

lpszContentType

A null-terminated string that identifies the contents of the file being uploaded. If this parameter is omitted, a NULL pointer, or specifies a zero-length string, the method will attempt to automatically determine the content type based on the file name extension and the contents of the file.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. If this parameter is omitted, a default value of WEB_OBJECT_NORMAL will be used. This value can be a combination of one or more of the following bit flags using a bitwise OR operation:

Value	Description
WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned

	when enumerated using the **EnumObjects** method. The object can only be accessed directly when specifying its label.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object. This parameter may be omitted or NULL if the information is not required.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **PutFile** method uploads the contents of a local file to the current storage container. The content type, which identifies the type of data stored in the object, and its attributes may be specified by the caller or default values may be used.

If a content type is provided, it must specify a valid MIME media type and subtype. For example, normal text files have a content type of **text/plain** while an XML-formatted text file would have a content type of **text/xml**. Files that contain unstructured binary data are typically identified as **application/octet-stream**. If the content type is not explicitly specified, an attempt will be made to identify it automatically based on contents of the file and the file extension.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this method will fail. To replace a read-only object, the application must first move, rename or delete the existing object.

The **ValidateLabel** method can be used to ensure a label is valid prior to calling this method. Refer to that method for more information about the difference between Windows file names and object labels

If you are uploading a large file and want your application to receive progress updates during the data transfer, use the **RegisterEvent** method and provide a pointer to a static callback function that will receive event notifications.

Example

```
WEB_STORAGE_OBJECT webObject;

// Upload a local file to the storage container, automatically
// determining the content type with normal read/write access
if (pStorage->PutFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // The file was uploaded, display the object metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The file could not be uploaded, display the error
    CString strError;

    pStorage->GetLastError(strError);
    _tprintf(_T("Unable to store \"%s\" (%s)\n"), lpszLocalFile,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebStorage::RegisterAppId Method

```
BOOL RegisterAppId(
   LPCTSTR lpszAppId
);
```

The **RegisterAppId** method registers a unique application identifier with the server.

Parameters

lpszAppId

A null-terminated string which identifies the application requesting access. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the method will fail. See the remarks below on the recommended method for identifying your application.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **RegisterAppId** method registers an application ID with the server which uniquely identifies the application that is requesting access to the storage container. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 64 characters, including the terminating null character.

It is recommended that you use a standard format for the application ID that consists of your company name, application name and optionally a version number. For example:

- MyCompany.MyApplication
- MyCompany.MyApplication.1

It is important to note that with these two example IDs, although they are similar, they reference two different applications. Objects stored using the first ID will not be accessible using the second ID. If you want to store objects that should be shared between all versions of the application, it is recommended that you use the first form, without the version number. If you want to store objects that should only be accessible to a specific version of your application, then it is recommended that you use the second form that includes the version number.

It is safe to call this method with an application ID that was previously registered. If the provided application ID has already been registered, this method will succeed. You can choose to call this method every time your application starts to ensure the application has been registered correctly.

If you no longer wish to use an application ID you have previously registered, you can call the **UnregisterAppId** method. Exercise caution when unregistering an application. This will cause all objects stored using that ID to be deleted by the storage server. Once an application ID has been unregistered, the operation is permanent. Calling **UnregisterAppId** and then **RegisterAppId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

The application ID is intended to be an application defined human-readable string that uniquely identifies your application. If you want to obtain the internal storage ID associated with your

application, use the **GetStorageId** method. The storage ID is a fixed-length string of letters and numbers guaranteed to be unique across all applications that you register.

It is not required for your application to create a unique application ID. Each storage account has a default internal application ID named `SocketTools.Storage.Default`. This default ID is used if a NULL pointer or an empty string is specified to methods like **OpenStorage**. It is intended to identify storage available to all applications that you create.

To enumerate the application IDs registered with your storage account, use the **GetFirstApplication** and **GetNextApplication** methods.

Example

```
 CWebStorage appStorage;
LPCTSTR lpszAppId = _T("MyCompany.WebTest.1");
LPCTSTR lpszLocalFile = _T("TestDocument.pdf");
LPCTSTR lpszObjectLabel = _T("TestDocument.pdf");
WEB_STORAGE_OBJECT webObject = { 0, };

// Register the application ID which identifies the application
if (!appStorage.RegisterAppId(lpszAppId))
{
    tprintf(_T("Unable to register the application ID"));
    _exit(0);
}

// Open the application storage container
if (!appStorage.OpenStorage(lpszAppId, WEB_STORAGE_GLOBAL);
{
    tprintf(_T("Unable to open global storage for this application"));
    _exit(0);
}

// Upload a local file to the storage server and return information
// about the stored object when it completes
if (appStorage.PutFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // Print information about the object that was created
    _tprintf(_T("Object: %s\n"), webObject.szObjectId);
    _tprintf(_T("Label: %s\n"), webObject.szLabel);
    _tprintf(_T("Size: %I64u\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest: %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The upload failed, display error information
    CString strError;

    appStorage.GetLastError(strError);
    _tprintf(_T("Unable to upload \"%s\" (%s)\n"), lpszLocalFile,
(LPCTSTR)strError);
}

// Release the handle allocated for this storage session
appStorage.CloseStorage();
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

CWebStorage::RegisterEvent Method

```
BOOL RegisterEvent(
   UINT nEventId,
   WEBEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. This parameter cannot be zero.

Value	Description
WEB_EVENT_CONNECT	The connection to the storage server has been established and the session has been authenticated. This is the first event that occurs when initiating an operation to create or retrieve a storage object.
WEB_EVENT_DISCONNECT	The connection to the storage server has been closed and the session is terminating. This is the last event that occurs after completing an operation to create or retrieve a storage object.
WEB_EVENT_READ	The contents of an object is being read from the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of retrieving the object contents from the container.
WEB_EVENT_WRITE	The contents of an object is being written to the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of submitting the object contents to the container.
WEB_EVENT_TIMEOUT	The operation has exceeded the specified timeout period. The application may attempt to retry the operation or report an error to the user. This event typically indicates a connectivity problem with the storage server.
WEB_EVENT_CANCEL	The operation has been canceled. This event occurs after the application calls the **Cancel** method while an object is being stored or retrieved.
WEB_EVENT_PROGRESS	A storage operation is in progress. This event periodically occurs as the contents of a storage object is being read or written from the container. To retrieve information about the status of the operation, the

	application should register a handler for this event and call the **GetTransferStatus** method from within that handler.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback method, see the description of the **WebEventProc** callback method. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback method specified by ***lpEventProc***. If the application targets x86 (32-bit) platforms, this parameter must be a 32-bit unsigned integer. If the application targets x64 (64-bit) platforms, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **RegisterEvent** method associates a static callback function with a specific event. The event handler is a **WebEventProc** function that is invoked when the event occurs. Arguments are passed to the method to identify the storage handle, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

Events are only generated as the result of a call to the **GetFile**, **GetData**, **PutFile** and **PutData** methods. Other storage methods will not generate event notifications.

This method is typically used to register an event handler that is invoked while the contents of a storage object is being transferred. The WEB_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one WEB_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The ***dwParam*** parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebStorage::RenameObject Method

```
BOOL RenameObject(
   LPCTSTR lpszOldLabel,
   LPCTSTR lpszNewLabel
);
```

The **RenameObject** method changes the label associated with the storage object.

Parameters

lpszOldLabel

A null-terminated string which specifies the name of the existing storage object to be renamed. This parameter must specify a valid object label and cannot be a NULL pointer or an empty string.

lpszNewLabel

A null-terminated string which specifies a new label for the storage object being moved. This parameter may not be NULL or point to an empty string.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **RenameObject** method is used to change the label for an existing storage object. Although storage object labels are similar to Windows file names, they are case-sensitive. When renaming an object, your application must specify the original label name exactly as it was created. The object label cannot contain wildcard characters.

To duplicate an existing storage object, use the **CopyObject** method. If you need to move the object to a different storage container, use the **MoveObject** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CopyObject, DeleteObject, MoveObject

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::ResetStorage Method

```
BOOL ResetStorage();
```

The **ResetStorage** method resets the application storage container and deletes all stored objects.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The storage container contains information for each of the objects that have been stored using the handle returned by the **OpenStorage** method. Each of these objects are associated with both the application ID and the storage type that was specified by the caller. This method instructs the server to reset the container back to its initial state, deleting all of the objects that were stored in it.

Exercise caution when using this method. The reset operation is immediate and the objects that are stored in the container are permanently deleted. They cannot be recovered by your application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Method failure is typically indicated by a return value such as FALSE, NULL, INVALID_HANDLE or WEBAPI_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. An application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

See Also

GetErrorString, GetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::SetTimeout Method

```
DWORD SetTimeout(
   DWORD dwTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the storage server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

hClient

Handle to the client session.

dwTimeout

The number of seconds to wait for a storage operation to complete.

Return Value

If the method succeeds, the return value is the previous timeout period for the session. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The default timeout period is 10 seconds. The minimum timeout period is 5 seconds, and the maximum timeout period is 60 seconds. Values outside of this range will be normalized internally and will not cause the method to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib

CWebStorage::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** method. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::UnregisterAppId Method

```
BOOL UnregisterAppId(
   LPCTSTR lpszAppId
);
```

The **UnregisterAppId** method unregisters the application identifier and deletes all associated storage objects.

Parameters

lpszAppId

A null-terminated string which specifies the application ID to be deleted. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the method will fail.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **UnregisterAppId** method deletes the internal storage identifier associated with the application ID and revokes all access tokens that were granted for the application. This operation is immediate and permanent.

Exercise caution when using this method. This will permanently delete all objects that were stored for the specified application. Calling **UnregisterAppId** and then **RegisterAppId** again using the same ID will force the system to create new access tokens for your application. You will not be able to regain access to the objects that were previously stored using that ID.

This method cannot be used to unregister the default storage application ID `SocketTools.Storage.Default`. If this ID is specified, the method will fail with an error indicating that the ID is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::UnregisterEvent Method

```
BOOL RegisterEvent(
   UINT nEventId
);
```

The **UnregisterEvent** method removes an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. This parameter cannot be zero. The following values may be used:

Value	Description
WEB_EVENT_CONNECT	The connection to the storage server has been established and the session has been authenticated. This is the first event that occurs when initiating an operation to create or retrieve a storage object.
WEB_EVENT_DISCONNECT	The connection to the storage server has been closed and the session is terminating. This is the last event that occurs after completing an operation to create or retrieve a storage object.
WEB_EVENT_READ	The contents of an object is being read from the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of retrieving the object contents from the container.
WEB_EVENT_WRITE	The contents of an object is being written to the storage container. This event occurs only once after the operation has been initiated by the application. This event can also be generated if there is an error during the process of submitting the object contents to the container.
WEB_EVENT_TIMEOUT	The operation has exceeded the specified timeout period. The application may attempt to retry the operation or report an error to the user. This event typically indicates a connectivity problem with the storage server.
WEB_EVENT_CANCEL	The operation has been canceled. This event occurs after the application calls the **Cancel** method while an object is being stored or retrieved.
WEB_EVENT_PROGRESS	A storage operation is in progress. This event periodically occurs as the contents of a storage object is being read or written from the container. To retrieve information about the status of the operation, the application should register a handler for this event and call the **GetTransferStatus** method from within that handler.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **UnregisterEvent** method removes the association between a specific event and its callback function. This method can be used if the application no longer requires the event notification. All event handlers for the client session are automatically removed when the **CloseStorage** method is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebStorage::UploadFile Method

```
BOOL UploadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPWEB_STORAGE_OBJECT lpObject
);

BOOL UploadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszObjectLabel,
   LPCTSTR lpszAppId,
   DWORD dwStorageType,
   DWORD dwAttributes,
   DWORD dwTimeout,
   LPWEB_STORAGE_OBJECT lpObject,
   WEBEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **UploadFile** method uploads the contents of a local file and creates or overwrites a storage object.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of the local file that will be created or overwritten with the contents of the storage object. If a path is not specified, the file will be created in the current working directory.

lpszObjectLabel

A null-terminated string that specifies the label of the object that should be retrieved from the server.

lpszAppId

A null-terminated string which specifies the application ID for the storage container. The application ID is a string that uniquely identifies the application and can only contain letters, numbers, the period and the underscore character. If this parameter is omitted, NULL or an empty string, the default identifier `SocketTools.Storage.Default` will be used.

dwStorageType

An integer value that identifies the storage container type. If this parameter is omitted, the default value of WEB_STORAGE_GLOBAL will be used. One of the following values may be specified:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as

	defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwAttributes

An unsigned integer that specifies the attributes associated with the storage object. If this parameter is omitted, a default value of WEB_OBJECT_NORMAL will be used. This value can be a combination of one or more of the following bit flags using a bitwise OR operation:

Value	Description
WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
WEB_OBJECT_READONLY	A read-only object that can only be read by the application. Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the **CWebStorage::EnumObjects** method. The object can only be accessed directly when specifying its label.

dwTimeout

An unsigned integer value that specifies a timeout period in seconds. If this value is zero, a default timeout period will be used.

lpObject

A pointer to a WEB_STORAGE_OBJECT structure that will contain additional information about the object that has been downloaded. This parameter may be NULL if the information is not required.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback method, see the description of the **WebEventProc** callback function. If this parameter is NULL, no callback function will be invoked during the data transfer.

dwParam

A user-defined integer value that is passed to the callback function specified by *lpEventProc*. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **UploadFile** method uploads the contents of a local file and either creates a new storage object, or replaces an object if one already exists with the same label. The **UploadFile** method provides a simpler interface that defaults to uploading an object to the global storage container.

If the label identifies an object that already exists in the container, and that object was created with the WEB_OBJECT_READONLY attribute, this method will fail. To replace a read-only object, the application must explicitly move, rename or delete the existing object.

Additional metadata about the object will be returned in the WEB_STORAGE_OBJECT structure provided by the caller, such as the date and time the object was created, the content type and the SHA-256 hash of the object contents.

If you are uploading a large file and want your application to receive progress updates during the data transfer, provide a pointer to a static callback function as the *lpEventProc* parameter. That function will receive event notifications as the data is being uploaded.

Example

```
CWebStorage appStorage;
WEB_STORAGE_OBJECT webObject;

// Upload a local file to the global storage container
if (appStorage.UploadFile(lpszLocalFile, lpszObjectLabel, &webObject))
{
    // The object was uploaded, display the metadata
    _tprintf(_T("Object:  %s\n"), webObject.szObjectId);
    _tprintf(_T("Label:   %s\n"), webObject.szLabel);
    _tprintf(_T("Size:    %lu\n"), webObject.dwObjectSize);
    _tprintf(_T("Digest:  %s\n"), webObject.szDigest);
    _tprintf(_T("Content: %s\n"), webObject.szContent);
}
else
{
    // The object could not be uploaded, display the error
    CString strError;

    appStorage.GetLastError(strError);
    _tprintf(_T("Unable to upload \"%s\" (%s)\n"), lpszLocalFile,
(LPCTSTR)strError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebStorage::ValidateAppId Method

```
BOOL ValidateAppId(
   LPCTSTR lpszAppId
);
```

The **ValidateAppId** method validates the specified application identifier.

Parameters

lpszAppId

A null-terminated string which specifies the application ID to be validated. This parameter cannot be NULL or point to a zero-length string. If the application ID contains illegal characters, the method will fail.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

The **ValidateAppId** method is used to determine if the specified application identifier is valid and has been previously registered using the **RegisterAppId** method. The ID must only consist of ASCII letters, numbers, the period and underscore character. Whitespace characters and non-ASCII Unicode characters are not permitted. The maximum length of an application ID string is 64 characters, including the terminating null character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswebv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

RegisterAppId, UnregisterAppId, ValidateLabel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebStorage::ValidateLabel Method

```
BOOL ValidateLabel(
   LPCTSTR lpszObjectLabel
);
```

The **ValidateLabel** method validates the specified object label.

Parameters

lpszObjectLabel

A null-terminated string which specifies the object label to be validated. This parameter cannot be NULL or point to a zero-length string.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call the **GetLastError** method.

Remarks

Object labels are similar to Windows file names, except they are case-sensitive. The maximum length of a label string is 512 characters, including the terminating null character. Leading and trailing whitespace (spaces, tabs, linebreaks, etc.) are ignored in label names.

Illegal characters include ASCII and Unicode control characters 1 through 31, single quotes (39), double quotes (34), less than symbol (60), greater than symbol (62), pipe (124), asterisk (42) and question mark (63). A null character (0) specifies the end of the label and any subsequent characters are ignored. It is not possible to embed null characters in the label name.

Label names may contain forward slash (47) characters and backslash (92) characters, however it is important to note that objects are not stored in a hierarchical structure. An application can create its own folder-like structure to the labels it creates, but this structure is not imposed or enforced by the library.

If the application is built to use Unicode, labels can contain Unicode characters which are internally encoded as UTF-8. This is important to consider if you have an project built using a multi-byte (ANSI) character set and it needs to access an object that was created using Unicode characters. In that case, the ANSI application must be prepared to handle UTF-8 encoded names and display them appropriately.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: windows.h.

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WEB_STORAGE_APPLICATION

The **WEB_STORAGE_APPLICATION** structure contains information about a registered application.

```
typedef struct _WEB_STORAGE_APPLICATION
{
    TCHAR      szAppId[64];
    TCHAR      szApiKey[64];
    TCHAR      szLuid[64];
    DWORD      dwTokens;
    DWORD      dwReserved;
    SYSTEMTIME stCreated;
    SYSTEMTIME stUpdated;
} WEB_STORAGE_APPLICATION, *LPWEB_STORAGE_APPLICATION;
```

Members

szAppId

A null-terminated string which contains the application ID that was registered using the **RegisterAppId** method.

szApiKey

A null-terminated string which contains the API key value that is used internally by the storage services. The AppID is effectively the human readable alias for this key value used to identify the stored objects for the application. This value is guaranteed to be unique across all applications registered with the storage service.

szLuid

A null-terminated string which specifies a locally unique value associated with the registered application. This value is used internally by the storage service and guaranteed to be unique to the storage account that has registered the application. Note that there are no functions that currently accept the application LUID as parameter, but you may choose to use this value in your own application for other purposes.

dwTokens

An unsigned integer value which specifies the number of access tokens associated with the registered application. Typically there is only one access token associated with a given AppID at any one time, although it is possible that the API may allocate additional access tokens under some circumstances.

dwReserved

An unsigned integer value that is reserved for future use. This value will always be zero.

stCreated

A SYSTEMTIME structure that specifies the date and time the AppID was registered. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone.

stUpdated

A SYSTEMTIME structure that specifies the date and time the AppID object was last updated. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone. When a storage object is first created, this value will be the same as the object creation time.

Remarks

This structure is used in conjunction with the **GetFirstApplication** and **GetNextApplication** methods which enumerate all registered applications for the current storage account.

To adjust the creation and update times to account for the local time zone, use the **SystemTimeToTzSpecificLocalTime** function. If you prefer to use FILETIME values, use the **SystemTimeToFileTime** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

WEB_STORAGE_OBJECT

The **WEB_STORAGE_OBJECT** structure contains information about an individual storage object.

```
typedef struct _WEB_STORAGE_OBJECT
{
    TCHAR      szObjectId[64];
    TCHAR      szLabel[512];
    TCHAR      szDigest[128];
    TCHAR      szContent[128];
    DWORD      dwAttributes;
    DWORD      dwObjectSize;
    SYSTEMTIME stCreated;
    SYSTEMTIME stModified;
} WEB_STORAGE_OBJECT, *WEB_STORAGE_OBJECT;
```

Members

szObjectId

A null-terminated string which contains the unique identifier associated with this object. Object IDs are guaranteed to be unique for each storage object that is created by the application. The maximum length of an object ID is 64 characters, including the terminating null character.

szLabel

A null-terminated string which contains the label assigned to the object by the application. Object labels are case-sensitive and must be unique for each object. An application uses labels to reference an object with a human-recognizable name, rather than referencing them by their object ID. The maximum length of an object label is 512 characters, including the terminating null character.

szDigest

A null-terminated string which specifies the digest of the object contents, computed using an SHA-256 hash. The maximum length of the ***szDigest*** string is 128 characters, including the terminating null character. However, the digest value is always represented as a string of hexadecimal numbers that is exactly 64 characters long. It is important to note that even a zero-length object will have a digest, which is the standard SHA-256 NULL hash value.

szContent

A null-terminated string which specifies the MIME content type for the storage object. The content type is determined by the object label and evaluating the contents of the object. It is also possible for the application to explicitly specify the content type of the object when it is created.

dwAttributes

An unsigned integer value that specifies the attributes for the storage object. The object attributes are comprised of one or more bit flags:

Value	Description
WEB_OBJECT_DEFAULT	Default object attributes. This value is used to indicate the object can be modified, or that the attributes for a previously existing object should not be changed.
WEB_OBJECT_NORMAL	A normal object that that can be read and modified by the application. This is the default attribute for new objects that are created by the application.
WEB_OBJECT_READONLY	A read-only object that can only be read by the application.

	Attempts to modify or replace the contents of the object will fail. Read-only objects can be deleted.
WEB_OBJECT_HIDDEN	A hidden object. Objects with this attribute are not returned when enumerated using the **EnumObjects** method. The object can only be accessed directly when specifying its label.

dwObjectSize

An unsigned integer value that specifies the size of the storage object in bytes. The maximum size of an individual object is determined by the storage quota limits established for the account.

stCreated

A SYSTEMTIME structure that specifies the date and time the storage object was created. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone.

stModified

A SYSTEMTIME structure that specifies the date and time the storage object was last modified. This value is represented using Coordinated Universal Time (UTC) and is not adjusted for the local time zone. When a storage object is first created, this value will be the same as the object creation time.

Remarks

The object content type will always be in the format **type/subtype** where the type specifies a common media type (e.g.: text, audio, video, etc.) and subtype specifies the specific content. The most common content type for text files is **text/plain**. If the content type is unknown, the default content type is **application/octet-stream**.

Text objects may also optionally include the character encoding as part of the content type. For example, if an object contains UTF-8 encoded text, the content type may be returned as **text/plain; charset=utf-8**. If your application is parsing the content types, you must check if a character encoding was also included in the value. Text objects that do not specify an encoding either contain ASCII or text which uses the system code page. Unicode text will always be stored using UTF-8 encoding.

To adjust the object creation and modification times to account for the local time zone, use the **SystemTimeToTzSpecificLocalTime** method. If you prefer to use FILETIME values, use the **SystemTimeToFileTime** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WEB_STORAGE_QUOTA

The **WEB_STORAGE_QUOTA** structure contains information about the current storage account data usage and limits.

```
typedef struct _WEB_STORAGE_QUOTA
{
    DWORD     dwObjects;
    DWORD     dwObjectLimit;
    DWORD     dwObjectSize;
    ULONGLONG ulBytesUsed;
    ULONGLONG ulBytesFree;
    ULONGLONG ulStorageLimit;
} WEB_STORAGE_QUOTA, *LPWEB_STORAGE_QUOTA;
```

Members

dwObjects

An unsigned integer value which specifies the number of storage objects allocated for the account. This value may not exceed the total number of objects specified by the ***dwObjectLimit*** member.

dwObjectLimit

An unsigned integer value which specifies the maximum number of storage objects that may be created. In addition to the limit on the total amount of storage that may be used, there is a limit on the total number of objects that may be created by all applications.

dwObjectSize

An unsigned integer value which specifies the maximum size of an individual storage object. In addition to a limit on the total amount of storage used and the number of objects created, each object stored by the application cannot exceed this size.

ulBytesUsed

An unsigned 64-bit integer value which specifies the total number of bytes of data allocated for all storage objects. This value may not exceed the total number of bytes of storage available, which is specified by the ***ulStorageLimit*** member.

ulBytesFree

An unsigned 64-bit integer value which specifies the number of bytes available for the storage of new objects. This value reflects the total amount of available storage across all applications registered with the development account. If this value is zero, your storage account has reached its storage limit.

ulStorageLimit

An unsigned 64-bit integer value which specifies the maximum number of bytes of data storage available. This limit applies to all applications registered with the development account.

Remarks

Storage quota limits are assigned for each SocketTools development account. The **GetStorageQuota** method will populate this structure with information about the limits on your account. Accounts that are created with an evaluation license have much lower quota limits than a standard account and should be used for testing purposes only. After the evaluation period has ended, all objects stored using the evaluation license will be deleted.

These values do not represent limits on storage usage by a specific application. Quotas limits apply to all applications that are registered with the development account, which is identified with the runtime

license key used to initialize the class instance.

If your storage quota has been exceeded, either because the total number of objects or the total bytes of storage has reached their limit, your applications will be unable to create new objects. Your application can continue to access existing objects, regardless of your current quota limits.

To free storage space, use the **DeleteObject** method to delete individual storage objects that are no longer needed by your application, or use the **ResetStorage** method to delete all objects in a container.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

WEB_STORAGE_TRANSFER

This structure is used by the **CWebStorage::GetTransferStatus** method to return information about a data transfer in progress.

```
typedef struct _WEB_STORAGE_TRANSFER
{
   TCHAR     szObjectLabel[512];
   DWORD     dwStorageType;
   DWORD     dwBytesTotal;
   DWORD     dwBytesCopied;
   DWORD     dwBytesPerSecond;
   DWORD     dwTimeElapsed;
   DWORD     dwTimeEstimated;
} WEB_STORAGE_TRANSFER, *LPWEB_STORAGE_TRANSFER
```

Members

szObjectLabel

A null-terminated string that specifies the label for the object that is being retrieved, created or replaced.

dwStorageType

An integer value that identifies the storage container type. This will be one of the following values:

Value	Description
WEB_STORAGE_GLOBAL	Global storage. Objects stored using this storage type are available to all users. Any changes made to objects using this storage type will affect all users of the application. Unless there is a specific need to limit access to the objects stored by the application to specific domains, local machines or users, it is recommended that you use this storage type when creating new objects.
WEB_STORAGE_DOMAIN	Local domain storage. Objects stored using this storage type are only available to users in the same local domain, as defined by the domain name or workgroup name assigned to the local system. If the domain or workgroup name changes, objects previously stored using this storage type will not be available to the application.
WEB_STORAGE_MACHINE	Local machine storage. Objects stored using this storage type are only available to users on the same local machine. The local machine is identified by unique characteristics of the system, including the boot volume GUID. Objects previously stored using this storage type will not be available on that system if the boot disk is reformatted.
WEB_STORAGE_USER	Current user storage. Objects stored using this storage type are only available to the current user logged in on the local machine. The user identifier is based on the Windows user SID that is assigned when the user account is created. If the user account is deleted, the objects previously stored using this storage type will not be available to the application.

dwBytesTotal

An unsigned integer which specifies the total number of bytes that will be transferred. If the object is being downloaded to the local host, this is the size of the stored object. If the data is being uploaded from the local host to be stored on the server, it is the size of the buffer or local file.

dwBytesCopied

An unsigned integer which specifies the total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the data transfer is completed. This is based on the average number of bytes transferred per second.

CWebView Class

The SocketTools WebView class provides an embedded Chromium-based web browser that can be integrated into desktop applications. The class is implemented using the Microsoft Edge WebView2 runtime and provides a much simpler API which can be used with most languages, without requiring direct use of the COM-based interfaces in the WebView2 SDK.

Library Information

File Name	CSHTMV12.DLL
Version	12.0.3024.1286
LibID	175ACE49-FE5D-46C8-A0EF-5188C97B993D
Import Library	CSHTMV12.LIB
Dependencies	None

Overview

The SocketTools CWebView class makes it possible to embed modern web content into Windows applications using a simple procedural interface. Developers can work entirely with standard data types and function calls, avoiding the complexity of COM programming or .NET interop layers. The API is designed to be language-agnostic and can be called from C or C++, as well as other environments that support invoking functions from a dynamic link library such as Object Pascal and Visual Basic. Applications can use a traditional Windows GUI or be console-based, and functions are thread-safe where appropriate.

Because the class encapsulates the creation of the WebView2 environment and its associated controller, applications require only minimal setup. Developers can host a browser window, execute scripts, or capture output with just a few lines of code. Advanced features such as asynchronous execution, response header enumeration, and event callbacks are supported, but optional, making it easy to start simple and grow into more complex scenarios.

Applications are not limited to navigating to external websites. You can dynamically generate HTML content within your program and load it directly into the browser, making it possible to render reports, status pages, or other application data without creating temporary files. The browser also supports displaying local content using `file://` URLs, including HTML, images, PDF documents, and other formats that WebView2 can natively render. This makes it easy to blend remote and local resources within the same user interface.

When connecting to web servers, the control uses the underlying WebView2 runtime and supports modern versions of HTTP, including HTTP/1.1, HTTP/2, and HTTP/3 where available. Connections are secured with Transport Layer Security (TLS), with support for TLS 1.2 and TLS 1.3 by default, and certificate validation is performed automatically by the runtime. This ensures that applications embedding the browser benefit from the same security standards as Microsoft Edge, including

enforcement of current best practices for encryption and certificate handling.

Unlike most SocketTools libraries which return pseudo-handles to reference client sessions, the WebView class uses window handles (HWND) for nearly all of its functions. The only exceptions are the functions used to create or attach to a WebView instance. This design provides a direct connection between the class and the underlying windowing system, and ensures consistent behavior with standard Windows APIs. Even in console applications, the class creates a host window which provides the handle used with the other functions. Using window handles also makes integration with GUI frameworks such as MFC, WinForms, or WPF more natural, since those frameworks are already designed around standard Windows window management.

Requirements

It is not necessary to download the Microsoft.Web.WebView2 SDK NuGet package and include it in your project to use this class. However, the end-user system must have the current version of the Edge WebView2 Runtime installed. On Windows 11 and Windows 10 version 2004 (build 19041) and later, the runtime is considered part of the operating system and is updated automatically. On earlier platforms such as Windows 7, Windows 8, and Windows 10 builds prior to 19041, you may need to redistribute or install the WebView2 runtime separately. The class includes functions which can tell you if the runtime is installed and what version is available.

For Windows 7 and Windows 8, the last version of the WebView2 runtime available is 109.0.1518.140. This version is supported by SocketTools, however it is important to note that Microsoft is no longer updating the control on those platforms. This means it will no longer receive security updates or other improvements; some features may work differently on older platforms, and newer features will not be available.

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this class, it is recommended that you install the library in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

In addition to the SocketTools library, the WebView2 Runtime must be present on the target system. On current versions of Windows 10 and Windows 11 the runtime is treated as part of the operating system and is updated automatically. On earlier platforms, you may need to redistribute or install the runtime using Microsoft's evergreen installer. We recommend always using the evergreen runtime rather than the fixed version, as it ensures security updates and feature improvements are delivered through Windows Update without requiring changes to your application.

The WebView2 Runtime is available as a separate download from Microsoft. For current links and redistribution guidelines, please refer to the SocketTools knowledge base or Microsoft's official documentation.

CWebView Class Methods

Class	Description
CWebView	Constructor which initializes the current instance of the class.
~CWebView	Destructor which releases resources allocated by the class.
Method	Description
AsyncExecute	Execute JavaScript asynchronously in the current document.
Attach	Attach the browser to an existing host window.
CancelDownload	Cancel the specified file download.
CancelNavigation	Cancel the current navigation and stop loading.
ClearCache	Clear the cache of viewed pages for the current user profile.
ClearCookies	Delete cookies for the current user profile or session.
ClearHeaders	Clear the request and/or response headers for the current session.
ClearHistory	Clear the navigation history for the current session.
Close	Close the window and release all browser resources.
Create	Create an instance of the browser in a new window.
Detach	Detach the browser from its host window without destroying the host window.
DisableEvents	Disable event handling for the specified browser.
EnableEvents	Enable event handling for the specified browser.
EnumDownloads	Enumerate the file identifiers for all downloads during the current session.
Execute	Execute JavaScript and return the result synchronously.
FindBrowser	Locate the associated host or child window handle for an instance.
FreezeEvents	Suspend or re-enable event notifications for the specified browser.
GetAllOptions	Return the current option flags for the browser instance.
GetBackgroundColor	Get the background color used behind the page content.
GetBrowserVersion	Get the installed browser runtime version information.
GetChildWindow	Get the handle of the internal browser child window.
GetContentType	Return the Content-Type from the last response, if available.
GetCurrentUrl	Get the URL of the current document.
GetDocumentLength	Return the length of the current document.
GetDocumentText	Return the content for of the current document.
GetDocumentTitle	Return the document title.
GetDownloadInfo	Return information about the status of the specified download.
GetDownloadPath	Return the full path for the downloaded file.
GetErrorString	Return a description for the specified error code.

GetFilteredText	Return the current document text without HTML formatting.
GetFirstHeader	Begin enumerating response headers and returns the first name/value pair.
GetFocus	Return whether the browser control currently has input focus.
GetHeader	Get the value of a specific response header by name.
GetHeaderCount	Return the number of response headers from the last navigation.
GetHttpStatus	Return the HTTP status code from the last completed navigation.
GetLastError	Return the last error code.
GetNavigationStatus	Return the current navigation state.
GetNavigationTime	Return the elapsed time for the last navigation.
GetNextHeader	Continue header enumeration and return the next name/value pair.
GetOption	Checks whether a specific option flag is enabled.
GetSafeHwnd	Return the handle to the window hosting the browser control.
GetSecurityInfo	Return certificate and host security details for the last navigation.
GetSecurityLevel	Return the evaluated security level for the last navigation.
GetTimeout	Get the number of seconds to wait for a navigation to complete.
GetUserAgent	Return the current User-Agent value for this instance.
GetUserDataFolder	Return the full path to the current user data folder.
GetWebMessage	Retrieve the next pending message sent from the current document.
GetWebResult	Return the result from the most recent completed script execution.
GetZoomLevel	Return the current zoom level as a percentage.
GoBack	Navigate backwards through the browser history.
GoForward	Navigate forwards through the browser history.
Hide	Hide the browser window.
InEvent	Determine if the current thread is executing code within an event handler.
IsAttached	Determine if the class instance is attached to a browser window.
IsInitialized	Determine if the class instance has been initialized.
IsSecure	Determine if the current page was retrieved over a secure connection.
IsVisible	Determine if the browser window is currently visible.
KeyEventHandled	Set an accelerator key event as handled to suppress default processing.
Navigate	Navigate to the specified URL or local file path.
NormalizeUrl	Normalize a URL or path for safe, consistent navigation.
PostWebMessage	Post a string or JSON message to the current page.
PrintDocument	Display the browser print dialog for the current document.
Redraw	Force the host window and browser control to redraw themselves.
Reload	Reload the current document and optionally clear the cache.
Reset	Reset the embedded runtime control.

Resize	Resize the browser inside the host window.
RuntimeAvailable	Determine whether the required runtime is installed and available.
SaveDocument	Save the current document to a local file.
SetBackgroundColor	Set the background color used behind the page content.
SetBounds	Set the position and size of the browser child window.
SetDocumentText	Replace the current document with the specified HTML or plain text.
SetDownloadPath	Change the local file path for the specified download.
SetFocus	Give keyboard focus to the browser control.
SetHeader	Set or override a request header for subsequent navigations.
SetIcon	Set custom large and small icons for the host window.
SetLastError	Set the last error code.
SetOption	Enable or disable a specific option.
SetTimeout	Set the number of seconds to wait for a navigation to complete.
SetUserAgent	Set the default User-Agent string for this instance.
SetZoomLevel	Set the zoom level for the current view.
Show	Show the browser window.
WaitForEvent	Wait until a specific event occurs or the timeout period expires.
WaitUntilClosed	Wait until the host window is closed or destroyed.
WebViewEventProc	An application-defined callback function that processes events generated by the browser.

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::CWebView

```
CWebView();
```

The **CWebView** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **Initialize** method to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

The calling thread must be in a single-threaded apartment (STA). During initialization the library calls **CoInitializeEx** as needed and if your process has already initialized COM as MTA (`COINIT_MULTITHREADED`), initialization will fail. This requirement comes directly from the Edge WebView2 control which cannot be created in an MTA COM application.

Before creating an instance of this class, applications may optionally call **CWebView::RuntimeAvailable** to determine if the Microsoft Edge WebView2 runtime is installed and meets the minimum required version. This can be useful during application startup to provide a clear error message or guidance to the user if the runtime is missing or out of date, rather than attempting to initialize the control and handling the failure afterward.

On modern versions of Windows, the WebView2 runtime is included as part of the operating system and is serviced through Windows Update. However, on older or unsupported versions of Windows the runtime may not be present by default and must be installed separately. In these cases, your application needs to detect the missing runtime and prompt the user to install it.

The latest WebView2 runtime version officially supported on Windows 7 and Windows 8/8.1 is version 109.0.1518.140, released January 2023. After version 109, no further updates, new features, or fixes have been provided for those operating systems. Although this library supports Windows 7 and Windows 8, these platforms are not recommended because they no longer receive security updates for the browser.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

~CWebClient, Attach, Create, Detach, IsInitialized, RuntimeAvailable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::~CWebView

```
~CWebView();
```

The **CWebView** destructor releases resources allocated by the current instance of the **CWebView** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CWebView** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages. The WebView2 instance created by the class will be destroyed. If the class instance was created using a temporary user data folder, all cached data for the session will be deleted and the folder will be removed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::AsyncExecute Method

```
BOOL AsyncExecute(
   LPCTSTR lpszJavaScript,
   DWORD_PTR dwParam
);
```

The **AsyncExecute** method executes a script on the current page, returning the results asynchronously.

Parameters

lpszJavaScript

A null-terminated string which specifies the JavaScript that should be executed in the context of the current page being viewed. This parameter is required and cannot be NULL.

dwParam

An optional parameter which can be used to provide context to the script being executed asynchronously. This user-defined value is passed back to the event handler which is invoked when the result from the script is returned back to the application. If this information is not required, this parameter can be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **AsyncExecute** method evaluates a JavaScript expression within the context of the currently loaded page and returns the result asynchronously. Unlike **Execute**, this method does not block while waiting for the script to complete. Instead, the result is delivered through the `WEBVIEW_EVENT_SCRIPT_COMPLETED` event. The application can use the dwParam value to correlate the completion event with the original request.

The script must be valid JavaScript and should not assume synchronous execution. Results are returned by calling **GetWebResult** which will provide you with the response in JSON-encoded form; for example, string values will be quoted. Because script execution is dispatched to the underlying WebView2 control, this method will fail if navigation is still in progress. Applications should always wait for the `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event before invoking script execution.

Example

```
// A simple event handler implementation
VOID CALLBACK WebViewEventProc(HWND hWnd, UINT uEvent, WPARAM wParam, LPARAM
lParam, DWORD_PTR dwParam)
{
    CWebView *pWebView = reinterpret_cast<CWebView *>(dwParam);

    if (!pWebView)
        return;

    if (uEvent == WEBVIEW_EVENT_SCRIPT_COMPLETED)
    {
        BOOL bSuccess = (BOOL)wParam;

        if (bSuccess)
```

```
        {
            TCHAR szResult[512];
            if (pWebView->GetWebResult(szResult, _countof(szResult)))
            {
                // Get the response from the script
                // szResult will be a null-terminated string which may contain
                // a JSON object or JSON string (quoted and escaped if needed)
            }
        }
        else
        {
            // The script could not be executed
        }
    }
}

void RunExample(CWebView *pWebView)
{
    // Execute a simple script asynchronously
    if (!pWebView->AsyncExecute(_T("document.title"), reinterpret_cast<DWORD_PTR>
(pWebView)))
    {
        DWORD dwError = pWebView->GetLastError();
        // Handle the error condition
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::Attach Method

```
BOOL Attach(
   HWND hWndHost,
   LPCTSTR lpszUrl
);

BOOL Attach(
   HWND hWndHost,
   DWORD dwOptions,
   LPCTSTR lpszUrl,
   LPCTSTR lpszLanguage,
   LPCTSTR lpszDataFolder
);
```

The **Attach** method attaches a new instance of the browser control to a host window.

Parameters

hWndHost

A handle to the window that will serve as a container for the browser control. This may either be a top-level application window or a child window. If the handle does not specify a valid window, the method will fail. This parameter is required and cannot be NULL.

dwOptions

One or more option bitflags. For more information, refer to the Options documentation. Most applications should not use a value of zero for this parameter. If no options are specified, the browser instance will be created with a very restrictive set of permissions that can prevent many websites from functioning correctly.

lpszUrl

A null-terminated string which specifies the initial URL the browser should navigate to after the control has been attached to the window. If this parameter is NULL or an empty string, the browser instance will be created with a blank page. The only schemes permitted are `https://`, `http://` and `file://`. If a domain name is specified without a scheme, it will default to using `https://`.

lpszLanguage

A null-terminated string which specifies an alternate language to use when the browser displays a context menu or dialogs. This value can be a standard language tag in BCP-47 format (such as "en-US") or it can be a string which specifies a hexadecimal Windows locale identifier (such as "0x0409"). It is recommended you use the language tag whenever possible, as Microsoft is deprecating the use of locale identifiers (LCIDs) and their associated APIs. If this parameter is a NULL pointer or an empty string, the browser will use the current default language for the local user.

lpszDataFolder

A folder name where the user profile data will be stored. This is the location where the browser will cache viewed pages, store cookies and form data, and where scripts may store session data. This value may be just a name (such as the name of the application) or an absolute path. If the folder name contains environment variables surrounded in percent (%) symbols, they will be replaced with their value in the current user's environment. If folder name does specify an absolute path, the profile will be stored in the current user's LocalAppData folder. If this parameter is NULL or an empty string, a temporary profile will be created for the session and then automatically deleted when the session ends.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Attach** method binds a new WebView instance to an existing top-level or child window you have already created. The host window must be created on the current UI thread and remain valid for the lifetime of the WebView. Do not call this method from a worker thread or for a window that was created by another thread; if a background thread needs a browser, create a dedicated window on that thread or use **Create** instead. Only one WebView instance can be attached to a given host window at a time. If you need to recreate the browser, call **Detach** before attaching again.

The calling thread must be in a single-threaded apartment (STA). During initialization the library calls **CoInitializeEx** as needed and if your process has already initialized COM as MTA (`COINIT_MULTITHREADED`), the attach will fail. This requirement comes directly from the Edge WebView2 control which cannot be created in an MTA COM application.

The *dwOptions* parameter enables you to specify what features are enabled in the browser. It is recommended that most applications use `WEBVIEW_OPTION_ENABLE_DEFAULT` which enables functionality which is most commonly found in web browsers. If you want your host application to exchange messages with scripts executing in the browser, you should also specify the `WEBVIEW_OPTION_ENABLE_MESSAGES` options. This option must be enabled to use **PostWebMessage** and **GetWebMessage** methods.

When clicking on a link would normally open that page in a new tab or browser window, it will be redirected to the primary browser window by default. This ensures that the browser control retains focus and all events are within the context of that window. If you wish to permit the creation of popup windows and/or support the creation of new browser windows (for example, if a link target is "_blank") then specify the `WEBVIEW_OPTION_ENABLE_NEW_WINDOWS` option. Note that if you permit the creation of new popup windows, it can shift focus away from your main browser window. There is no mechanism in the API to enumerate the child popup windows and they are independent of the window attached to the browser.

By default, the browser will use the language associated with the current user's locale. If you specify an alternate language, this also affects what languages the browser includes with the **Accept-Language** request header. This will provide hints to the website as to what language is preferred when it returns content to the browser. However, it does not guarantee that a website will return content in that language and will not automatically cause a page to be translated from one language to another.

If you pass NULL or an empty string for the *lpszDataFolder* parameter, the library creates a temporary, per-session user-data folder under the current user's `LocalAppData` folder. That folder is flagged as temporary and is automatically deleted when you detach the WebView from the window via **Detach**. If you pass a relative path (such as "MyApp"), the library creates or uses that folder beneath `%LocalAppData%\WebView`, creating a folder path like `%LocalAppData%\WebView\MyApp`.

If you pass a fully qualified path as the *lpszDataFolder* parameter, it will use that path. However, it will not accept paths to unsafe locations and will return an error if your application does not have permission to create a folder in that location. If there are environment variables surrounded by percent (%) symbols, those variables will be expanded when the folder path is resolved. If you enable privacy mode with `WEBVIEW_OPTION_ENABLE_PRIVACY`, the library will ensure the profile is unique to the session by appending a GUID to the base folder and treating it as temporary. The **GetUserDataFolder** method can be used to obtain the full path to the data folder being used.

When multiple WebView instances point at the same user-data folder, they share a single WebView2

profile created with that folder path. In this configuration the browser cache, cookies, history, and site storage are persisted under that folder and are reused across windows and processes, which speeds up subsequent navigations and preserves sign-in/session state. The library passes your folder directly to WebView2 when creating the environment, so any instance using that same path participates in the same profile, and you can clear portions of that profile at runtime via the provided helpers for cache, history, and cookies.

Your **WEBVIEWEVENTPROC** event callback function is invoked on the same thread that owns the WebView window. Because events are raised on the UI thread, long-running work in an event handler can block the user interface and stall navigation. Where possible, defer heavy operations to background threads. You should avoid displaying modal dialogs or message boxes from within event handlers. Also note that some events may fire multiple times during a single navigation. For example, the security state can transition through several levels (unknown, neutral, secure, or warning) before settling on a final value. Applications should be written to handle these changes incrementally.

To present correctly inside a resizable child window, resize the browser view when the host window size changes. The library tracks the host window position but relies on your WM_SIZE handling to drive layout.

Example

```
#include "cstools12.h"

// Windows message handler
static LRESULT CALLBACK WndProc(HWND, UINT, WPARAM, LPARAM);

// WebView event handler for navigation and security events
static VOID CALLBACK WebViewEvents(HWND hWnd, UINT uEvent, WPARAM wParam, LPARAM
lParam, DWORD_PTR dwParam)
{
    switch (uEvent)
    {
    case WEBVIEW_EVENT_NAVIGATION_STARTING:
        OutputDebugString(_T("[WebView] Navigation starting\n"));
        break;

    case WEBVIEW_EVENT_NAVIGATION_COMPLETED:
        if (wParam)
            OutputDebugString(_T("[WebView] Navigation completed\n"));
        else
            OutputDebugString(_T("[WebView] Navigation failed\n"));
        break;

    case WEBVIEW_EVENT_SECURITY_CHANGED:
        OutputDebugString(_T("[WebView] Security changed\n"));
        break;
    }
}

INT WINAPI _tWinMain(HINSTANCE hInstance, HINSTANCE hPrevInstance, LPTSTR
lpCmdLine, INT nCmdShow)
{
    if (!WebViewInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        MessageBox(NULL, _T("Unable to initialize the WebView API"), _T("Error"),
MB_ICONEXCLAMATION);
        return 0;
    }
```

```
    LPCTSTR kClass = _T("MyWebViewWndClass");
    WNDCLASS wc{};
    wc.style = CS_HREDRAW | CS_VREDRAW;
    wc.lpfnWndProc = WndProc;
    wc.hInstance = hInstance;
    wc.hCursor = LoadCursor(nullptr, IDC_ARROW);
    wc.hbrBackground = (HBRUSH)(COLOR_WINDOW + 1);
    wc.lpszClassName = kClass;
    RegisterClass(&wc);

    HWND hWnd = Create(0, kClass, _T("WebView"),
                               WS_OVERLAPPEDWINDOW,
                               CW_USEDEFAULT, CW_USEDEFAULT, 1024, 720,
                               NULL, NULL, hInstance, NULL);

    ShowWindow(hWnd, nCmdShow);
    UpdateWindow(hWnd);

    // A standard Windows message loop
    MSG uMsg;

    while (GetWebMessage(&uMsg, nullptr, 0, 0))
    {
        TranslateMessage(&uMsg);
        DispatchMessage(&uMsg);
    }

    WebViewUninitialize();
    return (int)uMsg.wParam;
}

static LRESULT CALLBACK WndProc(HWND hWnd, UINT uMsg, WPARAM wParam, LPARAM lParam)
{
    switch (uMsg)
    {
    case WM_CREATE:
        // Create a WebView2 browser instance and attach to this window
        {
            DWORD dwOptions = WEBVIEW_OPTION_ENABLE_DEFAULT;
            LPCTSTR pszInitialUrl = _T("https://example.com");
            LPCTSTR pszDataFolder = _T("MyTestApp");

            if (!WebViewAttach(hWnd, dwOptions, pszInitialUrl, NULL, pszDataFolder,
WebViewEvents, 0))
            {
                 MessageBox(NULL, _T("Unable to attach the WebView2 control"),
_T("Error"), MB_ICONEXCLAMATION);
            }
        }
        return 0;

    case WM_SIZE:
        // Make sure the browser window resizes with the window
        {
            RECT rc;
            GetClientRect(hWnd, &rc);
            WebViewSetBounds(hWnd, rc.left, rc.top, rc.right - rc.left, rc.bottom -
rc.top);
```

```
        }
        return 0;

    case WM_DESTROY:
        // Detach the WebView2 browser instance from the window
        WebViewDetachWindow(hWnd);
        PostQuitMessage(0);
        return 0;
    }

    return DefWindowProc(hWnd, uMsg, wParam, lParam);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::CancelDownload Method

```
BOOL CancelDownload(
   DWORD dwFileId
);
```

The **CancelDownload** method cancels the specified download in progress.

Parameters

dwFileId

An integer which specifies a unique file identifier. This value cannot be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **CancelDownload** method causes the specified file download to be canceled. If the transfer has completed or has already been canceled, this method has no effect. This method does not wait for the download to be canceled before it returns; it returns immediately after asynchronously requesting the download be canceled. The **WEBVIEW_EVENT_DOWNLOAD_COMPLETED** event will fire once the download has stopped.

The *dwFileId* value is obtained when the **WEBVIEW_EVENT_DOWNLOAD_STARTING** event is fired and the *lParam* event argument will contain the unique file identifier for the download. You should treat the identifier as an opaque integer and not depend on the value being sequential. It is only guaranteed that the value will be unique for all downloads during the session and is only valid for the browser that initiated the download. Note there can be multiple downloads in progress simultaneously.

The **GetDownloadInfo** method can be used to get the status of the download and determine if it completed successfully, failed or was canceled.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

CWebView::CancelNavigation Method

```
BOOL CancelNavigation();
```

The **CancelNavigation** method cancels any current or pending navigations.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method can be safely called at any time, but only has an effect if the browser is currently in the process of navigating to a new location. A canceled navigation will fire the `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event and the event handler's *wParam* value will be FALSE. The navigation status will also include the `WEBVIEW_STATUS_NAVIGATION_CANCELED` bitflag which can be used to distinguish between a navigation that was canceled and one that failed for another reason.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

GetNavigationStatus, Navigate

CWebView::ClearCache Method

```
BOOL ClearCache();
```

The **ClearCache** method removes visited pages from the cache.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will clear the browser cache for the current session. This can be useful if you wish to force the browser to reload content. If you have created the browser instance using a temporary data folder, or you have specified the `WEBVIEW_OPTION_ENABLE_PRIVACY` option, the browser session will always start with a new user profile and will not contain any cached content.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

ClearCookies, ClearHeaders, ClearHistory, Redraw, Reload

CWebView::ClearCookies Method

```
BOOL ClearCookies(
   BOOL bAllCookies
);
```

The **ClearCookies** method deletes cookies for the current profile or session.

Parameters

bAllCookies

An optional boolean value which specifies if all cookies for the current user profile should be deleted, or only those cookies created during the current session. If this parameter is a non-zero value then all cookies stored in the current user's profile will be deleted.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method deletes cookies that have been created by the current WebView profile. If the *bAllCookies* parameter is set to TRUE, all stored cookies for every site are removed; if set to FALSE, only the cookies associated with the current session are cleared. The effect is comparable to clearing cookies in a regular browser: login sessions, preferences, and other state information stored in cookies will no longer be available. This only affects the WebView's private user data folder and does not modify cookies stored by the user's standalone Edge browser.

If you have used the WebView browser to authenticate with one or more websites, calling this method will typically log you out of those sites and require you to re-authenticate. If you have created the browser instance using a temporary data folder, or you have specified the `WEBVIEW_OPTION_ENABLE_PRIVACY` option, no cookies will be preserved after the session ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::ClearHeaders Method

```
BOOL ClearHeaders(
   DWORD dwHeaderType
);
```

The **ClearHeaders** method clears the current request and/or response headers for the current session.

Parameters

dwHeaderType

An unsigned integer value which may be one of the following values.

Value	Description
WEBVIEW_HEADERS_REQUEST	The custom request headers for the current session should be deleted. These are the HTTP headers which can be set or changed prior to the browser navigating to a new page. The standard request headers included with every request will continue to be sent.
WEBVIEW_HEADERS_RESPONSE	The response headers for the current session should be deleted. These are the headers which are returned by the server after navigation has completed. These headers are automatically deleted with each new navigation, making this option unnecessary in most cases.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method can be used to delete the custom request headers set with **SetHeader** or clear the response headers returned by the previous navigation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

ClearCache, ClearCookies, ClearHistory, GetHeader, SetHeader

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::ClearHistory Method

```
BOOL ClearHistory();
```

The **ClearHistory** method clears the navigation history for the current session.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method clears both the profile's stored browsing history and the navigation history for the current WebView instance. Internally, it uses the WebView2 profile APIs to remove stored history and related download entries, and then resets the back/forward navigation stack. The effect is similar to selecting clearing the browser history in a browser, where visited pages are removed from the user's history, and the in-memory list of sites you can go back or forward to is discarded.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

ClearCache, ClearCookies, ClearHeaders, GoBack, GoForward

CWebView::Close Method

```
BOOL Close();
```

The **Close** method closes the window and releases all browser resources.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **WebViewGetLastError**.

Remarks

This method closes a browser window which was created using the **Create** method. It is recommended that you always use this method to close the window rather than posting a `WM_CLOSE` message because it ensures resources for the window, such as its icons, are released correctly. The process of destroying the window does not occur immediately and when this function returns it is not guaranteed the browser child window and its associated processes have completely stopped. Use the **WaitUntilClosed** method if you wish to wait for the cleanup process to complete.

This method will cause the `WEBVIEW_EVENT_WINDOW_DETACHED` event to fire as part of the normal process of destroying the window. If you implement a handler for this event, you should never delay this process by attempting to show a dialog or request input from the user (for example, by displaying a message box). At the point this event is fired, the browser objects have already been disposed and there is no way to prevent the process from completing.

If this method is not explicitly called, the class destructor will close the hosting window and release the resources allocated for the browser.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

Create, Detach, WaitUntilClosed

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::Create Method

```
BOOL Create(
   LPCTSTR lpszUrl
);

BOOL Create(
   LPCTSTR lpszTitle,
   DWORD dwOptions,
   LPCTSTR lpszDataFolder
);

BOOL Create(
   LPCTSTR lpszTitle,
   DWORD dwStyle,
   LPRECT lpPosition,
   DWORD dwOptions,
   LPCTSTR lpszUrl,
   LPCTSTR lpszLanguage,
   LPCTSTR lpszDataFolder
);
```

The **Create** method creates a new window which hosts an instance of the browser control.

Parameters

lpszTitle

A null-terminated string which specifies the text displayed in the title bar. This parameter may be NULL or an empty string, in which case the title bar is set to the title of the document currently being displayed in the browser and will be automatically updated with subsequent navigations.

dwStyle

An unsigned integer which specifies the window style. This is the same windows style used with the **Create** function. If the value is zero, it will default to using the `WS_OVERLAPPEDWINDOW` style which creates an overlapped window with a caption, system menu and a minimize and maximize button. Some style bitflags will be ignored, such as the `WS_CHILD` style which cannot be applied to this window. This method can only be used to create an application window.

lpPosition

A pointer to a **RECT** structure which defines the position and size of the window. If all structure member values are `>= 0`, their values are passed directly to **Create**. If the top or left values are -1, a default position will be used. For example, if the structure is defined as `{ -1, -1, 800, 600 }` it would create an 800 x 600 window at a default position on the display. If the left or right values are -1, default values are used for the width or height. If all values are negative, the position and size of the window will use default values. If this parameter is NULL, the window will be positioned in the center of the current display with a width and height set to half the display area.

dwOptions

One or more option bitflags. For more information, refer to the Options documentation. Most applications should not use a value of zero for this parameter. If no options are specified, the browser instance will be created with a very restrictive set of permissions that can prevent many websites from functioning correctly.

lpszUrl

A null-terminated string which specifies the initial URL the browser should navigate to after the

window has been created. If this parameter is NULL or an empty string, the browser instance will be created with a blank page. The only schemes permitted are `https://`, `http://` and `file://`. If a domain name is specified without a scheme, it will default to using `https://`.

lpszLanguage

A null-terminated string which specifies an alternate language to use when the browser displays a context menu or dialogs. This value can be a standard language tag in BCP-47 format (such as "en-US") or it can be a string which specifies a hexadecimal Windows locale identifier (such as "0x0409"). It is recommended you use the language tag whenever possible, as Microsoft is deprecating the use of locale identifiers (LCIDs) and their associated APIs. If this parameter is a NULL pointer or an empty string, the browser will use the current default language for the local user.

lpszDataFolder

A folder name where the user profile data will be stored. This is the location where the browser will cache viewed pages, store cookies and form data, and where scripts may store session data. This value may be just a name (such as the name of the application) or an absolute path. If the folder name contains environment variables surrounded in percent (%) symbols, they will be replaced with their value in the current user's environment. If folder name does specify an absolute path, the profile will be stored in the current user's LocalAppData folder. If this parameter is NULL or an empty string, a temporary profile will be created for the session and then automatically deleted when the session ends.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method creates a top-level host window and a WebView runtime on a dedicated UI thread owned by the library. It returns after the window and control have been created and any navigation to the initial URL proceeds asynchronously. The returned window handle can be managed with normal Win32 APIs.

This method requires the single-threaded apartment (STA) COM model. During initialization the library calls **CoInitializeEx** as needed and if your process has already initialized COM as MTA (`COINIT_MULTITHREADED`), a browser instance cannot be created. This requirement comes directly from the Edge WebView2 control which cannot be created in an MTA COM application.

The dwOptions parameter enables you to specify what features are enabled in the browser. It is recommended that most applications use `WEBVIEW_OPTION_ENABLE_DEFAULT` which enables functionality which is most commonly found in web browsers. If you want your host application to exchange messages with scripts executing in the browser, you should also specify the `WEBVIEW_OPTION_ENABLE_MESSAGES` options. This option must be enabled to use **PostWebMessage** and **GetWebMessage** methods.

When clicking on a link would normally open that page in a new tab or browser window, it will be redirected to the primary browser window by default. This ensures that the browser control retains focus and all events are within the context of that window. If you wish to permit the creation of popup windows and/or support the creation of new browser windows (for example, if a link target is "_blank") then specify the `WEBVIEW_OPTION_ENABLE_NEW_WINDOWS` option. Note that if you permit the creation of new popup windows, it can shift focus away from your main browser window. There is no mechanism in the API to enumerate the child popup windows and they are independent of the window you have created.

By default, the browser will use the language associated with the current user's locale. If you specify an alternate language, this also affects what languages the browser includes with the **Accept-Language** request header. This will provide hints to the website as to what language is preferred when it returns content to the browser. However, it does not guarantee that a website will return content in that language and will not automatically cause a page to be translated from one language to another.

If you pass NULL or an empty string for the *lpszDataFolder* parameter, the library creates a temporary, per-session user-data folder under the current user's `LocalAppData` folder. That folder is flagged as temporary and is automatically deleted when you detach the WebView from the window using the **Detach** method. If you pass a relative path (such as "MyApp"), the library creates or uses that folder beneath `%LocalAppData%\WebView`, creating a folder path like `%LocalAppData%\WebView\MyApp`.

If you pass a fully qualified path as the *lpszDataFolder* parameter, it will use that path. However, it will not accept paths to unsafe locations and will return an error if your application does not have permission to create a folder in that location. If there are environment variables surrounded by percent (%) symbols, those variables will be expanded when the folder path is resolved. If you enable privacy mode with `WEBVIEW_OPTION_ENABLE_PRIVACY`, the library will ensure the profile is unique to the session by appending a GUID to the base folder and treating it as temporary. The **GetUserDataFolder** method can be used to obtain the full path to the data folder being used.

When multiple WebView instances point at the same user-data folder, they share a single WebView2 profile created with that folder path. In this configuration the browser cache, cookies, history, and site storage are persisted under that folder and are reused across windows and processes, which speeds up subsequent navigations and preserves sign-in/session state. The library passes your folder directly to WebView2 when creating the environment, so any instance using that same path participates in the same profile, and you can clear portions of that profile at runtime via the provided helpers for cache, history, and cookies.

Event callbacks are invoked on the thread that owns the browser window, not the thread that calls **Create**. This is typically the internal UI thread that runs the message loop for the control. Avoid updating shared globals from both your main thread and the browser thread without synchronization. If you need to communicate back to your main UI, use **PostMessage** or **SendMessage** to send application-defined messages to the window, or use an event, critical section, or message queue rather than directly changing the shared state.

The method can be used from a console application. You do not need to create a message pump on your main thread; the library's hosting thread runs the necessary loop for the browser window. GUI applications can also call this method to create a modeless browser window that you control like any other top-level window.

Example

```
#include "cstools12.h"
#include <stdio.h>

// WebView event handler for navigation and security events
static VOID CALLBACK WebViewEvents(HWND hWnd, UINT uEvent, WPARAM wParam, LPARAM
lParam, DWORD_PTR dwParam)
{
    switch (uEvent)
    {
    case WEBVIEW_EVENT_NAVIGATION_STARTING:
        OutputDebugString(_T("[WebView] Navigation starting\n"));
        break;
```

```
    case WEBVIEW_EVENT_NAVIGATION_COMPLETED:
        if (wParam)
            OutputDebugString(_T("[WebView] Navigation completed\n"));
        else
            OutputDebugString(_T("[WebView] Navigation failed\n"));
        break;

    case WEBVIEW_EVENT_SECURITY_CHANGED:
        OutputDebugString(_T("[WebView] Security changed\n"));
        break;
    }
}

int _tmain(int argc, TCHAR *argv[])
{
    if (!WebViewInitialize(CSTOOLS12_LICENSE_KEY, NULL))
    {
        _tprintf(_T("Unable to initialize the WebView API, error 0x%08lx\n"),
WebViewGetLastError());
        return 1;
    }

    // Create a top-level browser window
    LPCTSTR pszAppTitle = _T("MyWebView");
    LPCTSTR pszInitialUrl = _T("https://example.com");
    LPCTSTR pszDataFolder = _T("MyTestApp");
    DWORD dwOptions = WEBVIEW_OPTION_ENABLE_DEFAULT;
    RECT rcPos = { -1, -1, 1200, 800 };

    CWebView webViewer;
    BOOL bCreated = webViewer.Create(
                            pszAppTitle,          // Window title
                            WS_OVERLAPPEDWINDOW,  // Window style
                            &rcPos,               // Initial position
                            dwOptions,            // Creation options
                            pszInitialUrl,        // Initial URL
                            NULL,                 // Default language
                            pszDataFolder);       // User data folder
    if (!bCreated)
    {
        _tprintf(_T("Unable to create a WebView window\n"));
        return 2;
    }

    // Enable event notifications
    webView.EnableEvents(WebViewEvents, reinterpret_cast<DWORD_PTR>(&webView));

    TCHAR szCmdLine[1024];
    TCHAR *pszCmd;
    TCHAR *pszArg;

    // Read commands from standard input to control the browser
    while (pszCmd = _getts_s(szCmdLine, _countof(szCmdLine)))
    {
        // Trim any leading whitespace
        while (*pszCmd && _istspace(*pszCmd))
            pszCmd++;

        // Look for any arguments to the command
```

```
            pszArg = _tcschr(pszCmd, _T(' '));
            if (pszArg)
                *pszArg++ = TCHAR('\0');

            if (_tcsicmp(pszCmd, _T("url")) == 0)
            {
                // The URL command will navigate to a new URL
                if (pszArg && _tcslen(pszArg) > 0)
                {
                    if (!webViewer.Navigate(WEBVIEW_NAVIGATE_DEFAULT, pszArg))
                    {
                         DWORD dwError = webViewer.GetLastError();
                         _tprintf(_T("Navigate failed with error 0x%08lx\n"), dwError);
                    }
                }
                else
                {
                    _tprintf(_T("This command requires a URL\n"));
                }
            }
            else if (_tcsicmp(pszCmd, "quit") == 0)
            {
                // Exit the loop, closing the browser window
                break;
            }
        }

        // Destroy the browser window and wait for it to close
        webViewer.Close();
        webViewer.WaitUntilClosed(INFINITE);

        return 0;
    }
```

CWebView::Detach Method

```
BOOL Detach();
```

The **Detach** method releases the resources allocated for the browser session.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method is used to detach the browser instance from a window that it was previously attached to using either the **Attach** method. It is automatically called by the class destructor when the browser is no longer needed and the host window is being destroyed. If the browser was created using the **Create** method, calling this method has the same effect as calling the **Close** method.

This method will cause the **WEBVIEW_EVENT_WINDOW_DETACHED** event to fire as part of the normal process of detaching from the window. If you implement a handler for this event, you should never delay this process by attempting to show a dialog or request input from the user (for example, by displaying a message box). At the point this event is fired, the browser objects have already been disposed and there is no way to prevent the process from completing.

If there is a navigation in progress at the time this method is called, it will be canceled. If there are one or more file downloads in progress, the transfers will be aborted.

The current thread will block while it waits for the WebView2 browser process to shutdown gracefully. If the browser becomes non-responsive, this method will wait several seconds before forcibly terminating the child process and continuing with the cleanup process. If a temporary user profile was specified or a private browsing session was created, this method will also clear the browser cache and remove the user data folder that was created for the session.

CWebView::DisableEvents Method

```
BOOL DisableEvents();
```

The **DisableEvents** method disables event handling for the browser.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method removes the currently installed event handler for the browser and clears the user parameter. After it returns, the application will not receive any further browser events until **EnableEvents** is called again with a valid handler. Use this to permanently stop participating in event notifications (for example, during shutdown or when detaching the browser control from the host). Unlike temporarily freezing events, this method completely clears the callback handler for the browser instance.

If you only need to pause notifications temporarily, such as when presenting a modal dialog, performing a batch of UI updates, or executing several programmatic navigations back-to-back, freezing events is the recommended approach. Disabling events should be reserved for longer-term or terminal states, typically when the application is in the process of closing down.

You should not call **DisableEvents** from inside an event handler. Disabling callbacks while you are actively processing an event can lead to subtle reentrancy issues and missed cleanup. If you need to suspend notifications from within an event, call **FreezeEvents** instead, complete your work, and then unfreeze when you are ready to resume event handling.

CWebView::EnableEvents Method

```
BOOL EnableEvents(
   WEBVIEWEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **EnableEvents** method enables event handling for the browser.

Parameters

lpEventProc

A callback function which will be invoked whenever browser events occur. This parameter cannot be NULL. The callback function will be invoked in the context of a separate thread which hosts the browser control, not the thread which calls this method. For more information, refer to the WebViewEventProc and Events documentation.

dwParam

An optional parameter which can be used to provide additional context to the event handler. This user-defined value is passed back to the callback function when an event occurs. If this information is not required, this parameter can be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method assigns or replaces the callback function that receives browser events for the specified host window. It can be used after the browser has been attached to start receiving notifications or to change event handlers at runtime. The change takes effect immediately and subsequent events will be invoked using the new handler.

Event delivery is serialized by the library and this call safely updates the event handler. You cannot specify a NULL pointer as the event handler; if you need to disable events, use the **DisableEvents** method. If events were previously frozen with **FreezeEvents**, calling this method with a new event handler will automatically unfreeze event notifications.

When using this method from within a C++ class, the event callback must be declared as a static function with the **__stdcall** (or **CALLBACK**) calling convention. This is required because the library calls the handler just as it would with any Win32 API callback function, without knowledge of C++ instance objects. Non-static member functions include a hidden **this** pointer parameter, which makes their signature incompatible with the expected **WEBVIEWEVENTPROC** type. A common pattern is to pass the object's ***this*** pointer as the ***dwParam*** value, then cast it back inside the static callback function to access the instance. This preserves object-oriented design while still meeting the calling convention requirements of the API.

CWebView::EnumDownloads Method

```
INT EnumDownloads(
   LPDWORD lpdwFileList,
   INT nMaxFiles
);

INT EnumDownloads(
   DWORD dwStatus,
   LPDWORD lpdwFileList,
   INT nMaxFiles
);
```

The **EnumDownloads** method enumerates the file identifiers for downloads during the current session.

Parameters

dwStatus

A value which specifies the status of the downloads to enumerate. If this value is zero, the method will enumerate all downloads. If this parameter is one of the values listed below, only those downloads which match the specified status will be enumerated. For example, if this parameter is **WEBVIEW_DOWNLOAD_COMPLETED** then only those file downloads which have completed will be enumerated.

Name	Description
WEBVIEW_DOWNLOAD_STARTED	The file download has started and is in-progress.
WEBVIEW_DOWNLOAD_COMPLETED	The file download has completed successfully.
WEBVIEW_DOWNLOAD_CANCELED	The file download has been canceled.
WEBVIEW_DOWNLOAD_FAILED	The file download failed due to a network error or other problem.

lpdwFileList

A pointer to an array of DWORD values which specify the unique file identifier associated with the download. The identifiers can be passed to the **GetDownloadInfo** method to get detailed information about a specific download. This parameter can be NULL, in which case it will be ignored and the method will return the number of downloaded files.

nMaxFiles

The maximum number of file identifiers which can be copied into the *lpdwFileList* array. If the *lpdwFileList* parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of files downloaded during the current session. If there have been no downloads, or if the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **EnumDownloads** method can be used to obtain the identifiers for one or more file downloads that have occurred during the current browser session. Each identifier returned by this method uniquely corresponds to a download and can be used with functions such as **GetDownloadInfo** or

GetDownloadPath to obtain detailed information about the file.

If the *dwStatus* parameter is set to zero, the method enumerates all downloads regardless of their state. Otherwise, only downloads that match the specified status value are included in the enumeration. This allows applications to filter the results to include only downloads that are currently in progress, those that completed successfully, or those that were canceled or failed.

When the *lpdwFileList* parameter is not NULL, the method copies up to *nMaxFiles* identifiers into the specified array. If the number of matching downloads exceeds the array size, only the first *nMaxFiles* identifiers are returned, but the return value will still reflect the total number of matching downloads. This enables the application to first call the method with a NULL pointer to determine how many downloads are available, and then allocate an appropriately sized buffer before retrieving the identifiers.

The enumeration includes both active and completed downloads. If the host window is detached or destroyed, the list of downloads is cleared and further enumeration will return zero results.

Example

```
// Get the total number of downloads
INT nTotal = pWebView->EnumDownloads();

if (nTotal <= 0)
{
    _tprintf(_T("No downloads found.\n"));
    return;
}

// Allocate a buffer for the identifiers
DWORD *pIds = (DWORD*)malloc(nTotal * sizeof(DWORD));
if (!pIds)
    return;

INT nCount = pWebView->EnumDownloads(pIds, nTotal);

// Enumerate each download and print basic info
for (INT nIndex = 0; nIndex < nCount; nIndex++)
{
    WEBVIEW_DOWNLOAD_INFO fileInfo = { sizeof(fileInfo) };

    if (pWebView->GetDownloadInfo(pIds[nIndex], &fileInfo))
    {
        _tprintf(_T("Download %u: %s (%llu/%llu bytes)\n"),
                 fileInfo.dwFileId,
                 fileInfo.szFileName,
                 fileInfo.uiBytesCopied.QuadPart,
                 fileInfo.uiBytesTotal.QuadPart);
    }
}

free(pIds);
```

CWebView::Execute Method

```
INT Execute(
   LPCTSTR lpszJavaScript,
   LPTSTR lpszResult,
   INT nMaxLength
);
```

The **Execute** method executes JavaScript and returns the result synchronously.

Parameters

lpszJavaScript

A null-terminated string which specifies the JavaScript that should be executed in the context of the current page being viewed. This parameter is required and cannot be NULL.

lpszResult

A string buffer which will contain the result returned by the script, either as a JSON object or a JSON string value. If this parameter is NULL, the method will not copy the result but will return the total number of characters in the response, not including the terminating null.

nMaxLength

The maximum number of characters which can be copied into the string buffer, including the terminating null. If the ***lpszResult*** parameter is NULL, this parameter should be zero.

Return Value

If the method succeeds, the return value is the number of characters copied into the result buffer, not including the terminating null. If the function fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Execute** method evaluates a JavaScript expression within the context of the currently loaded page and returns the result synchronously. Unlike **AsyncExecute**, this method blocks the current thread while waiting for the script to complete. If the web page is non-responsive, this method will timeout after approximately two seconds.

If you wish to dynamically allocate a string buffer for the response, you can call this method with the ***lpszResult*** parameter as NULL and the ***nMaxLength*** parameter as zero. The function will return the number of characters in the response, not including the terminating null. You can allocate the buffer and then call **GetWebResult** which will copy the response into the buffer you provide. Because script execution is dispatched to the underlying WebView2 control, this method will fail if navigation is still in progress. Applications should wait for the `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event before invoking script execution.

Example

```
// Execute a simple script that returns a string
INT nLength = pWebView->Execute(_T("document.title"), NULL, 0);

if (nLength > 0)
{
    // Allocate a buffer large enough to hold the result
    LPTSTR lpszResult = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
    if (lpszResult)
    {
```

```
        // Retrieve the result of the script execution
        if (pWebView->GetWebResult(lpszResult, nLength + 1))
        {
            _tprintf(_T("Page title is: %s\n"), lpszResult);
        }
        free(lpszResult);
    }
}
else
{
    _tprintf(_T("Script execution failed\n"));
}
```

Requirements

CWebView::FindBrowser Method

```
HWND FindBrowser(
   HWND hWndParent,
   LPCTSTR lpszSearch,
   DWORD dwFlags,
   LPDWORD lpdwThreadId
);
```

The **FindBrowser** method locates the associated host or child window handle for a browser instance.

Parameters

hWndParent

Handle to the parent window. If this parameter is NULL, it will search all top-level windows. If this parameter is not NULL, it must be a valid window handle and the method will only match against a window which is a child window of the specified handle.

lpszSearch

An optional null-terminated string which specifies a URL. The function will only match those browser windows which have navigated to the specified URL. A simple case-insensitive substring search is performed, but will only match windows created by the current process. If this parameter is NULL or an empty string, the method will not match against any specific URL.

dwFlags

This parameter is reserved for future use and should always be zero. Future versions may expand this to support additional types of matching, such as document titles or more advanced search expressions.

lpdwThreadId

An optional parameter which is a pointer to an unsigned integer value that will contain the thread ID for the browser instance if a matching window is found. If no browser is found, this value will be set to zero. If this information is not required, this parameter can be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **FindBrowser** method can be used to locate the window handle for an existing WebView2 instance that was created by the calling process. This is useful if the application needs to re-establish a reference to a previously created browser window, for example when handling messages or coordinating multiple windows.

If a parent window handle is specified, the method will restrict its search to that window and its children. This is the most efficient approach when the caller already knows the expected parent container. If the parameter is NULL, all top-level windows owned by the process are searched. An optional URL string can also be provided to limit results to windows whose current location contains the specified substring. The search is case-insensitive and only applies to windows created by the current process.

The method only returns a single matching window handle. If multiple instances could match the criteria, the particular instance returned is not guaranteed and the caller should design accordingly. When both the parent handle and search string are NULL, the method simply locates the first available

WebView2 instance owned by the current thread.

If the optional ***lpdwThreadId*** parameter is supplied, it will receive the thread identifier that owns the WebView2 instance. This can be used when thread affinity is important, such as posting messages directly to the UI thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebView::FreezeEvents Method

```
BOOL FreezeEvents(
   BOOL bFreezeEvents
);
```

The **EnableEvents** method suspends or re-enables event notifications for the specified browser.

Parameters

bFreezeEvents

An integer value which specifies if event handling should be frozen. If the value is non-zero, browser events will be suspended until they are re-enabled. If the value is zero, browser events will be re-enabled if an event handler has been defined.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method toggles a per-instance switch for event delivery. When events are frozen, the browser continues to operate normally and still generates events internally, but your application will not be notified of them. The events are not queued while frozen; they are discarded. For developers familiar with COM controls, this mirrors the behavior of `IOleControl::FreezeEvents`. When you unfreeze, only new events that occur after unfreezing will be delivered.

Event freezing can be useful when:

- You are running scripted or programmatic operations that would otherwise flood your event handler, such as multiple page redirects or rapid **AsyncExecute** calls.
- You are making a series of user interface changes and want to avoid reentrant updates. For example, temporarily stopping focus and/or size change events while moving or resizing controls.
- You are showing a modal dialog or performing work where event reentrancy could complicate state management.
- You need to suppress event-driven logic during controlled navigation, such as "silently" reloading a document or navigating to a new location.

Freezing does not alter browser state, navigation, or timers; it only affects your application's callback. To resume normal notifications, call this method with the *bFreezeEvents* parameter as zero. Freezing events will not affect calls to **WaitForEvent**. Because freezing events does not prevent browser events from occurring, they are still processed internally and you can wait for a specific event to complete.

If you discover that subsequent notifications within an event handler would interfere with your application's workflow, it is safe to freeze events from within the handler. After completing the operation, unfreeze events (for example, by posting an application-defined message or using a timer) so events resume normally. You should avoid calling **DisableEvents** from within an event handler, use freezing instead.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebView::GetAllOptions Method

```
BOOL GetAllOptions(
   LPDWORD lpdwOptions
);
```

The **GetAllOptions** method returns the current option flags for the instance.

Parameters

lpdwOptions

A pointer to an unsigned integer which will contain the browser options for the current session. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method returns the options for the current session. For more information about the options available, review the Options documentation. Always check the return value from this method; the option bitflags are only valid if this method returns a non-zero (TRUE) value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::GetBackgroundColor Method

```
BOOL GetBackgroundColor(
   COLORREF *lprbgBackground
);
```

The **GetBackgroundColor** method returns the background color used behind the page content.

Parameters

lprbgBackground

A pointer to an integer which will contain the current background color as an RGB value.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The background color specifies the fill used by the browser window when there is no content to display or the document itself does not define a background. This value only applies to the WebView host surface and does not affect page transparency. The alpha channel is ignored, and the color is treated as fully opaque. By default, the background color for new browser instances will be white.

A **COLORREF** is a 32-bit value used by the Windows API to represent an RGB color. The low-order byte specifies the red component, the next byte the green component, and the third byte the blue component, in the format **0x00BBGGRR**. The high-order byte is unused and should be zero. Note that **COLORREF** is specific to the Windows API and is not the same as the OLE color system (**OLE_COLOR**). OLE uses a slightly different encoding that allows system color values to be specified, which are resolved at runtime. Developers should be careful not to confuse the two.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

CWebView::GetBrowserVersion Method

```
INT GetBrowserVersion(
   LPDWORD lpdwVersionMS,
   LPDWORD lpdwVersionLS,
   LPTSTR lpszVersion,
   INT nMaxLength
);
```

The **GetBrowserVersion** method returns the browser runtime version information.

Parameters

lpdwVersionMS

A pointer to an unsigned integer which contains the major and minor version numbers. This parameter may be NULL.

lpdwVersionLS

A pointer to an unsigned integer which contains the build and release version numbers. This parameter may be NULL.

lpszVersion

A null-terminated string buffer which will contain the version as a printable string. This parameter may be NULL, in which case the version string is not copied but the method will still return the length of the version string if successful. If this parameter is NULL, the *nMaxLength* parameter should have a value of zero.

nMaxLength

An integer which specifies the maximum number of characters which may be copied into the string buffer, including the terminating null. If the *lpszVersion* parameter is NULL, this parameter should be zero.

Return Value

If the method succeeds, the return value is the length of the version string, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetBrowserVersion** method returns the version information for the installed Microsoft Edge WebView2 Runtime. This is the runtime that hosts the embedded browser control, and it is separate from the version of the Edge browser that may be installed on the system. The method can provide the version number as two 32-bit values (major/minor and build/revision), and optionally as a formatted string for display purposes. This method is useful for diagnostics, logging, or when an application requires a specific minimum runtime version to support certain features. If the WebView2 Runtime is not installed or cannot be located, the method will fail and return zero.

The version values returned by *lpdwVersionMS* and *lpdwVersionLS* can be used with the `HIWORD` and `LOWORD` macros to extract the individual components of the version number (for example, major, minor, build, and revision). The printable version string will match the same four-part format commonly shown in Edge and WebView2 documentation (e.g., "`126.0.2592.113`").

The result is independent of whether a WebView window has already been created or attached. It only reflects the version of the installed runtime and does not indicate whether the runtime is currently in use. For cases where you only need to check if a runtime is available, use the **RuntimeAvailable**

method instead.

Example

```
DWORD dwVerMS = 0, dwVerLS = 0;
TCHAR szVersion[64] = {0};

INT nLength = pWebView->GetBrowserVersion(&dwVerMS, &dwVerLS, szVersion,
_countof(szVersion));
if (nLength > 0)
{
    WORD wMajor = HIWORD(dwVerMS);
    WORD wMinor = LOWORD(dwVerMS);
    WORD wBuild = HIWORD(dwVerLS);
    WORD wRevision = LOWORD(dwVerLS);

    _tprintf(_T("WebView2 Runtime Version: %s\n"), szVersion);
    _tprintf(_T("Major=%hu Minor=%hu Build=%hu Revision=%hu\n"), wMajor, wMinor,
wBuild, wRevision);
}
else
{
    _tprintf(_T("Unable to determine WebView2 Runtime version (Error 0x%lx)\n"),
pWebView->GetLastError());
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetChildWindow Method

```
HWND GetChildWindow();
```

The **GetChildWindow** method returns the handle of the internal browser child window.

Parameters

None.

Return Value

If the method succeeds, the return value is a window handle. If the function fails, the return value is NULL. To get extended error information, call **GetLastError**.

Remarks

The value returned by this method is the handle to the internal child window that hosts the WebView control. Applications should treat this handle as an implementation detail and avoid sending messages or altering window styles directly. The control manages this child window and relies on its state for proper operation. Interfering with the child window (for example, by subclassing it, changing its parent, or destroying it) can cause undefined behavior and application instability.

This method is primarily provided to support advanced scenarios where access to the native window handle is unavoidable, such as integrating with APIs that require a child window handle. In most cases, developers should use the higher-level functions in the **CWebView** class instead of interacting with the child window directly.

If you want to get the handle to the window hosting the browser control, use the **GetSafeHwnd** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::GetContentType Method

```
INT GetContentType(
   LPTSTR lpszContentType,
   INT nMaxLength
);
```

The **GetContentType** method returns the content type for the current page.

Parameters

lpszContentType

A string buffer which will contain the MIME content type of the resource returned by the web server. The buffer must be large enough to contain the entire content type string including the terminating null character. If this parameter is NULL, the content type will not be copied but the method will return the length of the `Content-Type` header value.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the buffer, including the terminating null. If the *lpszContentType* parameter is NULL, this value must be zero.

Return Value

If the method succeeds, the return value is the length of the `Content-Type` header value. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetContentType** method returns the MIME type reported by the server in the `Content-Type` response header for the most recent navigation. This value reflects the server's indication of what kind of content is being delivered, such as "`text/html`", "`application/pdf`", or "`image/png`". The returned string is preserved until the next navigation begins, even if the document is cleared or headers are reset.

It is important to note that not all servers will provide a `Content-Type` header. Some intentionally omit this information in combination with a `X-Content-Type-Options: nosniff` header as a security measure to prevent the client from "sniffing" or inferring the type. In such cases, **GetContentType** will return an empty string. Applications should be prepared for this scenario and not assume a value will always be available.

This method is a convenience wrapper around the underlying response header and is useful for distinguishing whether the WebView is rendering standard HTML or other document types. If more detailed information is needed about the response, developers can enumerate the response headers directly using **GetFirstHeader** and **GetNextHeader**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetCurrentUrl Method

```
BOOL GetCurrentUrl(
   LPTSTR lpszUrl,
   INT nMaxLength
);
```

The **GetCurrentUrl** method returns the URL for the current document.

Parameters

lpszUrl

A string buffer which will contain the current URL when the function returns. If this parameter is NULL, the method will not copy anything into the buffer but will return the length of the URL, not including the terminating null character. If a buffer is provided, it must be large enough to contain the entire URL.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null. If the *lpszUrl* parameter is NULL this value should be zero.

Return Value

If the method succeeds, the return value is the length of the current URL, not including the terminating null. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetCurrentUrl** method retrieves the URL associated with the current document loaded in the browser instance. The URL value is available as soon as navigation begins to a new location, so it can be queried during or after the navigation process. This allows applications to obtain the destination address immediately, even before the page has fully loaded or rendered its content.

Note that the current URL may differ from the value originally passed to **Navigate**. The browser engine can normalize the address, such as adjusting letter case, expanding relative paths, or adding default components like a trailing slash. In addition, the current URL can change multiple times during the course of a navigation if the server issues one or more HTTP redirects before the final document is retrieved. For this reason, the URL returned by this method should be treated as the authoritative location of the content currently being displayed.

This method differs from examining the document itself (for example, by executing a script to query `document.URL`) because it reflects the navigation state maintained internally by the control. Applications should use this method to reliably track the current location of the browser instance.

If the **SetDocumentText** method was called to change the current document, the URL returned by this method will typically be `"data:text/html"` which indicates it is a local data source.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetDocumentLength Method

```
INT GetDocumentLength();
```

The **GetDocumentText** method returns the current document length.

Parameters

None.

Return Value

If the method succeeds, the return value is the length of the document text in characters. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetDocumentLength** method returns the number of characters in the current document. This will reflect the state of the document at the time the method is called. If the page has been dynamically modified by scripts after it was initially loaded, those changes will be included. Note that if your project is configured to use Unicode, this value will not be the same as the size of the document in bytes.

This method should only be called after navigation has completed. If called while a page is still loading, the contents of the page may be incomplete or empty. The length of the document includes the HTML markup and inline scripting.

If a blank page is currently being displayed, such as when navigating to `about:blank` or by setting the current document text to an empty string, this method can still return a value. Internally, the browser creates a blank page using the markup `"<html><head></head><body></body></html>"` and this method will return the length of that content.

The **GetFilteredText** method can be used to obtain a filtered version of the text with the HTML markup removed.

Example

```
INT nLength = pWebView->GetDocumentLength();
if (nLength > 0)
{
    LPTSTR pszBuffer = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
    if (!pszBuffer)
    {
        // Virtual memory exhausted
        return;
    }

    nLength = pWebView->GetDocumentText(pszBuffer, nLength + 1);
    if (nLength > 0)
    {
         // Write the document HTML to standard output
        _putts(pszBuffer);
        _puttc(_T('\n'), stdout);
    }

    free(pszBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetDocumentText, GetDocumentTitle, GetFilteredText, Navigate, SetDocumentText

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::GetDocumentText Method

```
INT GetDocumentText(
   LPTSTR lpszText,
   INT nMaxLength
);
```

The **GetDocumentText** method returns the current document text.

Parameters

lpszText

A string buffer which will contain the current document text when the method returns. If this parameter is NULL, the method will not copy anything into the buffer but will return the length of the text, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null. If the *lpszText* parameter is NULL this value should be zero.

Return Value

If the method succeeds, the return value is the length of the document text in characters, not including the terminating null. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetDocumentText** method retrieves the HTML markup for the current document loaded in the browser. This includes the complete contents of the `<html>` element, such as the `<head>` and `<body>` sections, rather than just the visible text.

The text returned will reflect the current state of the document at the time the method is called. If the page has been dynamically modified by scripts after it was initially loaded, those changes will be included. The value may be large, particularly for complex pages, and applications should allocate a buffer of sufficient size by first calling the method with a NULL pointer to determine the required length.

If your project is configured to use a multi-byte character set (ANSI) instead of Unicode, this method will always return the content as UTF-8 encoded text, regardless of the system's current locale or code page. Legacy ANSI code pages cannot reliably represent the full range of characters, and using them in place of Unicode or UTF-8 can lead to data loss or corrupted text.

This method should only be called after navigation has completed. If called while a page is still loading, the results may be incomplete or empty. When the content is provided by a local file or string, the returned HTML will be the original content that was passed to the control. The returned text is raw HTML and may contain scripts, style definitions, and markup that are not directly suitable for display in a plain-text context.

If a blank page is currently being displayed, such as when navigating to `about:blank` or by setting the current document text to an empty string, this method can still return a value. Internally, the browser creates a blank page using the markup `"<html><head></head><body></body></html>"` and that is what this method will return.

The **GetFilteredText** method can be used to obtain a filtered version of the text with the HTML markup removed.

Example

```
INT nLength = pWebView->GetDocumentLength();
if (nLength > 0)
{
    LPTSTR pszBuffer = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
    if (!pszBuffer)
    {
        // Virtual memory exhausted
        return;
    }

    nLength = pWebView->GetDocumentText(pszBuffer, nLength + 1);
    if (nLength > 0)
    {
         // Write the document HTML to standard output
        _putts(pszBuffer);
        _puttc(_T('\n'), stdout);
    }

    free(pszBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetDocumentLength, GetDocumentTitle, GetFilteredText, Navigate, SetDocumentText

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::GetDocumentTitle Method

```
INT GetDocumentTitle(
   LPTSTR lpszTitle,
   INT nMaxLength,
);
```

The **GetDocumentTitle** method returns the document title.

Parameters

lpszTitle

A string buffer which will contain the current document title when the method returns. If this parameter is NULL, the method will not copy anything into the buffer but will return the length of the title, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null. If the *lpszTitle* parameter is NULL this value should be zero.

Return Value

If the method succeeds, the return value is the length of the document title in characters, not including the terminating null. If the document does not have a title or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetDocumentTitle** method returns the current title of the document loaded in the browser. This corresponds to the contents of the `<title>` element in the document's `<head>` section, if one is defined.

The title is not fixed at the time the page is first loaded. A script running in the document can modify the `<title>` element dynamically, and some web applications use this technique to reflect state changes (for example, to indicate new messages or status updates). Because of this, the value returned by this method may change over the lifetime of the page. If the document does not explicitly define a title, the method may return an empty string. Applications that display document titles should be prepared to handle this case.

If the browser window was created using **Create** without a specific title, the application title will be automatically changed to reflect the current document title. This does not happen if the browser window is attached to an existing window or if an application title was specified when the window was created. If you wish to manually update a top-level window title with the current document title, call this method in response to a `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event and then call the **SetWindowText** function to change the text in the window's title bar.

If the current document does not have a title, this method will return zero and the last error code will be set to `NO_ERROR`. If the *lpszTitle* parameter is not NULL, it will be set to an empty string when the method returns. This is not uncommon if the **SetDocumentText** method is called to change the current document and the text does not contain HTML markup or does not include a `<title>` tag.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetDownloadInfo Method

```
BOOL GetDownloadInfo(
   DWORD dwFileId,
   WEBVIEW_DOWNLOAD_INFO *lpInfo
);
```

The **GetDownloadInfo** method returns information about the status of the specified download.

Parameters

dwFileId

An unsigned integer value which uniquely identifies the download. This value cannot be zero.

lpInfo

A pointer to a `WEBVIEW_DOWNLOAD_INFO` structure which will contain information about the specified download when the method returns. The *dwSize* member of this structure must be initialized to the size of the structure prior to being passed to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method returns information about a specific download and is typically called in the context of a download event handler. The *dwFileId* parameter identifies the download to be queried. This identifier can be obtained either through download-related event notifications, where it is provided as the *lParam* value, or by calling the **EnumDownloads** method to enumerate active and completed downloads.

The file identifier should be treated as an opaque value. While it is guaranteed to be unique for the lifetime of the client session, the underlying implementation simply assigns sequential values. Applications must not depend on this behavior, as the specific numbering scheme may change in future versions. Because the identifiers are only unique within a single session, they cannot be used after the browser instance has been detached or destroyed. If you need to track downloads across sessions, you should use the file name or URL rather than the internal identifier.

Information is returned in the `WEBVIEW_DOWNLOAD_INFO` structure, which includes the download status, number of bytes copied, total size, elapsed time, file name, and the source URL. If the specified identifier does not correspond to a valid download, the function will fail.

If you are only interested in the name of the local file used for the specified download, you can use the **GetDownloadPath** function.

Example

```
// Get the total number of downloads
INT nTotal = pWebView->EnumDownloads();

if (nTotal <= 0)
{
    _tprintf(_T("No downloads found.\n"));
    return;
}
```

```
// Allocate a buffer for the identifiers
DWORD *pIds = (DWORD*)malloc(nTotal * sizeof(DWORD));
if (!pIds)
    return;

INT nCount = pWebView->EnumDownloads(pIds, nTotal);

// Enumerate each download and print basic info
for (INT nIndex = 0; nIndex < nCount; nIndex++)
{
    WEBVIEW_DOWNLOAD_INFO fileInfo = { sizeof(fileInfo) };

    if (pWebView->GetDownloadInfo(pIds[nIndex], &fileInfo))
    {
        _tprintf(_T("Download %u: %s (%llu/%llu bytes)\n"),
                 fileInfo.dwFileId,
                 fileInfo.szFileName,
                 fileInfo.uiBytesCopied.QuadPart,
                 fileInfo.uiBytesTotal.QuadPart);
    }
}

free(pIds);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetDownloadPath Method

```
INT GetDownloadPath(
   DWORD dwFileId,
   LPTSTR lpszFilePath,
   INT nMaxLength
);
```

The **GetDownloadPath** method returns the complete path of the local file for the specified download.

Parameters

dwFileId

An unsigned integer value which uniquely identifies the download. This value cannot be zero.

lpszFilePath

A null-terminated string buffer which will contain the full path to the local file. If this parameter is NULL, the file path is not copied but the method will return the length of the file path, not including the terminating null character. It is recommended that this buffer be large enough to store `MAX_PATH` (260) characters.

nMaxLength

An integer value which specifies the maximum number of characters which may be copied into the string buffer, including the terminating null. If the ***lpszFilePath*** parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the length of the local file name, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method returns the complete path to the file that will be created or overwritten during the download. The file path returned by this method is always an absolute path which ensures that the application does not need to resolve relative paths or expand environment variables. The path returned may refer to a file that has not yet been created or fully written if the download is still in progress. Applications should check the download status with **GetDownloadInfo** before assuming the file is complete and ready to use.

The ***dwFileId*** parameter uniquely identifies the download within the current client session. This identifier can be obtained from download-related event notifications or by calling **WebViewEnumDownloads**. As with other functions that use file identifiers, applications should treat this value as opaque and only valid for the lifetime of the session.

If the provided string buffer is too small, the method will return the required length of the file path, not including the terminating null character. The caller can use this information to allocate a sufficiently large buffer and call the method again. There are both ANSI and Unicode versions of this method and the correct version is called based on how the project is configured. If the **GetDownloadPathA** method is called, the file path will always be returned as a UTF-8 encoded string regardless of the current locale.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CWebView::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

GetLastError, SetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::GetFilteredText Method

```
INT GetFilteredText(
   LPTSTR lpszFilteredText,
   INT nMaxLength
);
```

The **GetFilteredText** method filters HTML formatting from the current document and returns plain text in a string buffer.

Parameters

lpszFilteredText

A null-terminated string buffer which will contain the filtered text. If this parameter is NULL and the *nMaxLength* parameter is zero, the method will return the number of characters required to store the filtered text, not including the terminating null character.

nMaxLength

The maximum number of characters which can be copied into the *lpszFilteredText* string buffer. If this value is zero, no characters will be copied to the buffer and the method will return the length of the filtered text, not including the terminating null character. This can be used to determine how much memory should be allocated for the string.

Return Value

If the method succeeds, it will return the number of characters copied into the string buffer, not including the terminating null character. If the *lpszFilteredText* parameter is NULL and *nMaxLength* is zero, the method will return the number of characters in the filtered text without copying any characters. If the method fails, or there is no text in the input buffer, the method will return zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFilteredText** method filters the HTML markup from the document text and returns output suitable for display in text-only environments. HTML tags are removed and entities are converted to their canonical Unicode equivalent. When filtering markup from the text, the method will:

- Remove all leading and trailing whitespace from the text, including newlines.
- Remove script, style, and other non-visible or unsafe elements.
- Convert common tag structures, such as lists and headers, into readable plain text.
- Extract and filter hyperlinks and image alt text, ignoring internal links to other sections.
- Remove any embedded credentials in hyperlinks.
- Decode common HTML entities such as `&trade` and `&copy`, as well as numeric entities like `&#x20.`

The method will remove extraneous whitespace within the text, but will attempt to maintain the structure of ordered and unordered lists. It does not parse the style information or Javascript that may be included in the HTML content. If a paragraph uses a style that would normally prevent it from being rendered in a browser (e.g.: the visibility attribute set to "hidden"), it is ignored and the text will be included in the output. If there are sections which contain preformatted text, such as text inside `<pre>...</pre>` or `<code>...</code>` tags, individual line and paragraph breaks will be preserved.

This method will not remove Unicode characters from the input text. If the HTML markup includes any entities which are represented as Unicode, such as which represents "½", they will be

```
&frac12;
```

returned in the output string buffer as Unicode characters. If the ANSI version of this method is called, Unicode will always be returned as UTF-8 encoded characters.

Example

```
INT nLength = pWebView->GetFilteredText(NULL, 0);
if (nLength > 0)
{
    LPTSTR pszFiltered = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
    if (!pszFiltered )
    {
        // Virtual memory exhausted
        return;
    }

    nLength = pWebView->GetFilteredText(pszFiltered, nLength + 1);
    if (nLength > 0)
    {
         // Write the plain text to standard output
        _putts(pszFiltered);
    }

    free(pszFiltered);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetFirstHeader Method

```
BOOL GetFirstHeader(
   LPTSTR lpszHeaderName,
   INT nMaxNameLen,
   LPTSTR lpszHeaderValue,
   INT nMaxValueLen
);
```

The **GetFirstHeader** method begins enumerating response headers and returns the first name/value pair.

Parameters

lpszHeaderName

A string buffer which will contain the name of the first header returned by the server. If this parameter is NULL it will be ignored.

nMaxNameLen

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderName* string buffer, including the terminating null. If the *lpszHeaderName* parameter is NULL this value should be zero.

lpszHeaderValue

A string buffer which will contain the value of the first header returned by the server. If this parameter is NULL, it will be ignored.

nMaxValueLen

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderValue* string buffer, including the terminating null. If the *lpszHeaderValue* parameter is NULL this value should be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The response headers exposed by this method correspond to the most recent completed navigation for the specified browser instance. Callers typically use this method to start an enumeration and then call **GetNextHeader** repeatedly until it returns FALSE to indicate there are no more headers to enumerate.

Header names are case-insensitive by definition. This method will usually return header names as lower-case values, but applications should never depend on the casing and should compare names case-insensitively. The header names and values are returned exactly as enumerated internally by the WebView2 control.

Some response headers can appear multiple times in a message. For list-valued headers (those defined by the HTTP specifications to be comma-joinable), the implementation may return a single entry with a comma-separated value (e.g., `Accept-Language`, `Cache-Control`, etc.). Other headers must not be combined; for example, each `Set-Cookie` header is returned as a separate name/value pair and will be seen multiple times during enumeration, each with a single cookie value. Code that depends on specific headers should be prepared for either a single combined value or multiple discrete occurrences of the same header name, depending on the header's semantics.

Enumeration reflects a snapshot of the headers for that response. Beginning a new navigation or calling **ClearHeaders** invalidates the current enumeration. Only one header enumeration can be active per browser instance at a time. The enumeration state is not thread-safe, and any access to the response headers should be synchronized across different threads.

If the provided buffers are too small, the header names and values will be truncated to the available space specified by the maximum length parameters. In most cases, a header name is not going to exceed 256 characters and a header value will normally not exceed 5120 characters. Most header values are relatively short, but some headers such as **Set-Cookie** can return much longer values.

This method cannot be called while the browser is in the process of navigating to a new location. It will also fail if the current document is a local file or if the document text was set dynamically using **SetDocumentText**. There are no response headers available in a local context.

Example

```
TCHAR szName[WEBVIEW_MAX_HEADER_NAME];
TCHAR szValue[WEBVIEW_MAX_HEADER_VALUE];

if (pWebView->GetFirstHeader(szName, _countof(szName),
                             szValue, _countof(szValue)))
{
    do
    {
        _tprintf(_T("%s: %s\n"), szName, szValue);
    }
    while (pWebView->GetNextHeader(szName, _countof(szName),
                                   szValue, _countof(szValue)));
}
else
{
    DWORD dwError = pWebView->GetLastError();
    _tprintf(_T("No headers available (error 0x%lx)\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebView::GetFocus Method

```
BOOL GetFocus(
   BOOL *lpbHasFocus
);
```

The **GetFocus** method returns whether the browser has focus.

Parameters

lpbHasFocus

A pointer to a BOOL which will contain TRUE (non-zero) if the browser window has focus and FALSE (zero) if it does not have focus. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetFocus** method queries whether the browser control currently has input focus. This is useful for determining if keyboard input will be directed to the content area of the browser or handled by the host window. The focus state can change dynamically as the user interacts with the application, and applications that track focus should also monitor the `WEBVIEW_EVENT_FOCUS_CHANGED` event.

This method only reports the focus state of the embedded browser, not of the host window itself. For example, a host window may be the active foreground window, but if another control within the host has focus, the browser will not be considered focused. To explicitly give focus to the browser, call **SetFocus**.

Example

```
BOOL bHasFocus = FALSE;

if (pWebView->GetFocus(&bHasFocus))
{
    if (!bHasFocus)
    {
        // Give the browser control focus if it does not have it
        pWebView->SetFocus();
    }
}
else
{
    // Handle error
    DWORD dwError = pWebView->GetLastError();
    _tprintf(_T("GetFocus failed, error=0x%lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::GetHeader Method

```
INT GetHeader(
   LPCTSTR lpszHeaderName,
   LPCTSTR lpszHeaderValue,
   INT nMaxLength
);
```

The **GetHeader** method returns the value of a specific response header by name.

Parameters

lpszHeaderName

A null-terminated string which specifies the response header name. This value is not case-sensitive but must match the complete header name. This parameter cannot be NULL.

lpszHeaderValue

A string buffer which will contain the value of the specified header. If this parameter is NULL then nothing will be copied but the method will return the length of the header value, not including the terminating null.

nMaxLength

The maximum number of characters which may be copied into the string buffer, including the terminating null. If the *lpszHeaderValue* parameter is NULL this value should be zero.

Return Value

If the method succeeds, the return value is the length of the header value, not including the terminating null. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetHeader** method retrieves the value of a specific HTTP response header returned by the server. Header names are matched in a case-insensitive manner, with leading and trailing whitespace automatically trimmed before comparison. If multiple values are present for the specified header name, the behavior depends on the type of header:

- For headers that must not be combined (such as `Set-Cookie` and `Proxy-Authenticate`), only the first value encountered is returned.
- For all other headers, multiple values are joined together and returned as a single comma-separated string, as defined by the HTTP specification.

For headers such as `Set-Cookie`, which may legitimately occur multiple times with distinct values, **GetHeader** will only return the first occurrence. If your application needs to process each value individually, you should use **GetFirstHeader** and **GetNextHeader** to enumerate all response headers rather than relying on this method.

If the *lpszHeaderValue* parameter is NULL, the method returns the number of characters required to store the complete header value, excluding the terminating null. This enables applications to dynamically allocate a buffer of the correct size before retrieving the actual value.

Response headers are only available after navigation has completed. Calling this method while a navigation is still in progress, or when displaying local file or data content, will fail.

The maximum recommended length for a header name is `WEBVIEW_MAX_HEADER_NAME` (256

characters) and for a header value is **WEBVIEW_MAX_HEADER_VALUE** (5120 characters). These limits are intended as practical guidelines, not absolute restrictions.

Example

```
 INT nLength = WebViewGetHeader(hWndWebView, _T("Content-Type"), NULL, 0);
if (nLength <= 0)
{
    _tprintf(TEXT("Unable to get Content-Type header (error 0x%lx)\n"),
WebViewGetLastError());
    return;
}

LPTSTR lpszValue = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
if (!lpszValue)
{
    _tprintf(_T("Out of memory\n"));
    return;
}

if (WebViewGetHeader(hWndWebView, _T("Content-Type"), lpszValue, nLength + 1) > 0)
{
    _tprintf(_T("Content-Type: %s\n"), lpszValue);
}
else
{
    _tprintf(_T("Failed to retrieve Content-Type (error 0x%lx)\n"),
WebViewGetLastError());
}

free(lpszValue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetHeaderCount Method

```
BOOL GetHeaderCount(
   DWORD dwHeaderType,
   LONG *lpnCount
);
```

The **GetHeaderCount** method returns the number of headers defined for the specified header type.

Parameters

dwHeaderType

An unsigned integer which specifies the type of header being checked. It may be one of the following values.

Name	Description
WEBVIEW_HEADERS_REQUEST	The number of custom headers submitted with a request.
WEBVIEW_HEADERS_RESPONSE	The number of headers returned by the server.

lpnCount

A pointer to an integer which will contain the number of headers when the method returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method can be used to determine the number of custom request headers which have been set, or the number of headers returned by the server in response to a navigation. To enumerate the available response headers, use the **GetFirstHeader** and **GetNextHeader** methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::GetHttpStatus Method

```
INT GetHttpStatus();
```

The **GetHttpStatus** method returns the HTTP status code from the last completed navigation.

Parameters

None.

Return Value

If the method succeeds, the return value is a non-zero status code. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method returns the HTTP status code from the server response associated with the last completed navigation. These codes are defined by the HTTP standard and indicate the outcome of the request:

- **100-199**: Informational responses indicating the request is in progress.
- **200-299**: Successful responses, with 200 (OK) being the most common.
- **300-399**: Redirects, such as 301 (Moved Permanently) or 302 (Found).
- **400-499**: Client errors, such as 403 (Forbidden) or 404 (Not Found).
- **500-599**: Server errors, such as 500 (Internal Server Error) or 503 (Service Unavailable).

It is important to note that this value is only meaningful once navigation has completed. During a series of redirects, the status code may change multiple times; the value returned will be from the final response that completed navigation. A return value of `0` indicates the HTTP status code is unavailable. It may also return zero when the browser has navigated to a local file or when HTML content has been supplied directly using the **SetDocumentText** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

CWebView::GetLastError Method

```
DWORD GetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a function's return value indicates that an error has occurred. That is because some functions call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE or NULL. Those functions which call **SetLastError** when they succeed are noted on the method reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::GetNavigationStatus Method

```
BOOL GetNavigationStatus(
   LPDWORD lpdwFlags,
   LPDWORD lpdwError
);
```

The **GetNavigationStatus** method returns the current navigation state.

Parameters

lpdwFlags

A pointer to an unsigned integer which may contain one of more status bitflags. This parameter may be NULL if the status flags are not required.

Name	Description
WEBVIEW_NAVIGATION_REDIRECTED	The navigation was the result of an HTTP redirect.
WEBVIEW_NAVIGATION_USER_INITIATED	Navigation began from a user gesture rather than being initiated by a script.
WEBVIEW_NAVIGATION_LOCAL_DATA	Content was served using local data rather than a full network fetch.

lpdwError

A pointer to a unsigned integer which will contain one of the following error codes. This parameter may be NULL if the error code is not required.

Name	Description
WEBVIEW_ERROR_NONE	No error.
WEBVIEW_ERROR_CERTIFICATE_COMMON_NAME	Certificate common name mismatch.
WEBVIEW_ERROR_CERTIFICATE_EXPIRED	Certificate is expired.
WEBVIEW_ERROR_INVALID_CLIENT_CERTIFICATE	Invalid or untrusted client certificate.
WEBVIEW_ERROR_CERTIFICATE_REVOKED	Certificate has been revoked.
WEBVIEW_ERROR_INVALID_CERTIFICATE	Certificate is invalid for another reason.
WEBVIEW_ERROR_SERVER_UNREACHABLE	Cannot reach the server/host.
WEBVIEW_ERROR_TIMEOUT	Operation timed out.
WEBVIEW_ERROR_INVALID_SERVER_RESPONSE	Server returned an invalid or unexpected response.
WEBVIEW_ERROR_CONNECTION_ABORTED	Connection aborted by the server or network.
WEBVIEW_ERROR_CONNECTION_RESET	Connection was reset.
WEBVIEW_ERROR_DISCONNECTED	Disconnected during the

	operation.
WEBVIEW_ERROR_CANNOT_CONNECT	Failed to establish a connection.
WEBVIEW_ERROR_HOST_NAME_NOT_RESOLVED	DNS resolution failed for the host.
WEBVIEW_ERROR_OPERATION_CANCELED	Operation was canceled by the user or host.
WEBVIEW_ERROR_REDIRECT_FAILED	Redirection failed.
WEBVIEW_ERROR_UNEXPECTED_ERROR	An unexpected error occurred.
WEBVIEW_ERROR_CREDENTIALS_REQUIRED	Authentication credentials are required.
WEBVIEW_ERROR_PROXY_AUTHENTICATION_REQUIRED	Proxy authentication is required.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNavigationStatus** method provides detailed information about the current state of navigation for the specified WebView instance. It can be used to determine if a navigation is still in progress, whether it completed successfully, or if it was canceled or failed due to an error condition. The status flags returned in *lpdwFlags* can be combined to indicate additional context about the navigation, such as whether it was initiated by the user, if the content was served from local data rather than fetched over the network, or if the navigation resulted from an HTTP redirect.

Developers may find this method most useful in the following situations:

- After handling a `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event, to check if the navigation was successful.
- Before retrying or redirecting a failed request, to determine the specific cause of failure.
- When logging diagnostic information about connectivity or certificate errors.
- To distinguish between user-initiated cancellation, network timeouts, or security errors.
- To detect when content was provided from local data rather than fetched remotely.

The error code returned in *lpdwError* provides additional detail when a navigation fails or is blocked. These values cover a wide range of conditions, including invalid or expired certificates, connectivity issues, unreachable hosts, proxy authentication failures, and other network-related problems. If *lpdwError* is `WEBVIEW_ERROR_NONE`, the most recent navigation completed without error.

When navigation involves local files or HTML provided directly to the browser via **SetDocumentText**, the method will typically return `WEBVIEW_ERROR_NONE` and may set `WEBVIEW_NAVIGATION_LOCAL_DATA` in the status flags. This allows the application to detect that the content was not fetched over the network.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CancelNavigation, GetHttpStatus, GetNavigationTime, Navigate

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::GetNavigationTime Method

```
BOOL GetNavigationTime(
   LPDWORD lpdwElapsed,
   LPBOOL lpbNavigating
);
```

The **FunctionName** method returns the elapsed time for the last navigation.

Parameters

lpdwElapsed

A pointer to an unsigned integer which will contain the number of milliseconds elapsed since the current navigation has started.

lpbNavigating

A pointer to an integer which is updated when the method returns. It will contain a non-zero value if the browser is in the process of navigating to a new location. If the browser has completed navigation or the last navigation was canceled, this value will be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetNavigationTime** method measures how long the most recent navigation has taken, reported in milliseconds. If a navigation is currently in progress, the elapsed time represents the duration since the navigation began. If the navigation has already completed, the elapsed time represents the total duration of that navigation. If no navigation has occurred, the elapsed time will be zero.

This method can be used for diagnostics, performance monitoring, or implementing application-level timeouts. For example, an application may track whether a page is taking unusually long to load and decide to cancel the navigation, notify the user, or retry the request. Combined with **GetNavigationStatus**, it provides a way to determine both the state and timing of navigation operations.

Typical usage scenarios for this method include:

- Measuring page load times for performance profiling or telemetry.
- Implementing a custom navigation timeout by checking the elapsed time in a periodic timer.
- Providing user feedback, such as displaying how long a page has been loading.
- Logging navigation duration along with success or failure status for diagnostic purposes.

The *lpbNavigating* parameter indicates whether a navigation is currently in progress when the method is called. This allows developers to distinguish between a completed navigation (where the elapsed time is final) and an in-progress navigation (where the elapsed time is still increasing).

It is important to note that the reported time is based on the browser's internal navigation start and completion timestamps. It reflects the overall duration of the navigation process as observed by the browser, not fine-grained network-level timings such as DNS lookup, TCP connection, or TLS handshake. For most application scenarios this high-level timing is sufficient to evaluate page load performance and detect unusual delays.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebView::GetNextHeader Method

```
BOOL GetNextHeader(
   LPTSTR lpszHeaderName,
   INT nMaxNameLen,
   LPTSTR lpszHeaderValue,
   INT nMaxValueLen
);
```

The **GetNextHeader** method returns the next name/value pair in a response header enumeration.

Parameters

lpszHeaderName

A string buffer which will contain the name of the first header returned by the server. If this parameter is NULL it will be ignored.

nMaxNameLen

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderName* string buffer, including the terminating null. If the *lpszHeaderName* parameter is NULL this value should be zero.

lpszHeaderValue

A string buffer which will contain the value of the first header returned by the server. If this parameter is NULL, it will be ignored.

nMaxValueLen

An integer which specifies the maximum number of characters which can be copied into the *lpszHeaderValue* string buffer, including the terminating null. If the *lpszHeaderValue* parameter is NULL this value should be zero.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method continues the enumeration that was started when the **GetFirstHeader** method was called. Repeatedly call **GetNextHeader** until it returns zero (FALSE) indicating there are no more header values to return. The **GetLastError** function can be used to distinguish between an actual error condition and the end of the enumeration. If the last error code is `ST_ERROR_END_OF_DATA` then all response headers have been enumerated.

If the provided buffers are too small, the header names and values will be truncated to the available space specified by the maximum length parameters. In most cases, a header name is not going to exceed 256 characters and a header value will normally not exceed 5120 characters. Most header values are relatively short, but some headers such as `Set-Cookie` can return much longer values.

This method cannot be called while the browser is in the process of navigating to a new location. It will also fail if the current document is a local file or if the document text was set dynamically using **SetDocumentText**. There are no response headers available in a local context.

Example

```
TCHAR szName[WEBVIEW_MAX_HEADER_NAME];
TCHAR szValue[WEBVIEW_MAX_HEADER_VALUE];
```

```
if (pWebView->GetFirstHeader(szName, _countof(szName),
                             szValue, _countof(szValue)))
{
    do
    {
        _tprintf(_T("%s: %s\n"), szName, szValue);
    }
    while (pWebView->GetNextHeader(szName, _countof(szName),
                                   szValue, _countof(szValue)));
}
else
{
    DWORD dwError = pWebView->GetLastError();
    _tprintf(_T("No headers available (error 0x%lx)\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetOption Method

```
BOOL GetOption(
   DWORD dwOption
   LPBOOL lpbEnabled
);
```

The **GetOption** method checks whether a specific option flag is enabled.

Parameters

dwOption

An unsigned integer which specifies the option to be checked. Refer to the Options documentation for the list of available options. Only a single option may be specified; you cannot combine multiple option bitflags when calling this method.

lpbEnabled

A pointer to an integer which will be updated when the method returns. If the value is non-zero, the option has been enabled. If the value is zero, the option has not been enabled.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetOption** method is used to determine if a specific option has been enabled for the browser instance associated with the specified host window. Each option corresponds to an individual feature or behavior that can be enabled or disabled at creation time or later using **SetOption**.

This method only supports checking a single option value at a time. The *dwOption* parameter must specify exactly one option bitflag, such as `WEBVIEW_OPTION_ENABLE_SCRIPTING` or `WEBVIEW_OPTION_ENABLE_CONTEXT_MENU`. It is not valid to combine multiple bitflags with a bitwise OR. If you need to retrieve the complete set of enabled options, call **GetAllOptions**.

Note that not all options may be applicable after a window has been created. Some options only take effect at creation time and cannot be changed dynamically. For example, options related to profile isolation or privacy modes must be specified before the control is initialized.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

Attach, Create, GetAllOptions, SetOption

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::GetSafeHwnd Method

```
HWND GetSafeHwnd();
```

The **GetSafeHwnd** method returns the handle to the host window.

Parameters

None.

Return Value

If the method succeeds, the return value is a window handle. If the method fails, the return value is NULL. To get extended error information, call **GetLastError**.

Remarks

This method is similar to **CWnd::GetSafeHwnd** in that it returns NULL if the class is not attached to a browser instance. This method would typically be used to retrieve the window handle created using the **Create** method. Note that this is not the handle to the child window used by the WebView2 browser, it is the handle to the window hosting the browser. To get the browser child window, use the **GetChildWindow** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

GetChildWindow, Redraw, SetBounds, SetFocus

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::GetSecurityInfo Method

```
BOOL GetSecurityInfo(
   WEBVIEW_SECURITY_INFO *lpSecurityInfo
);
```

The **GetSecurityInfo** method returns certificate and host security details for the last navigation.

Parameters

lpSecurityInfo

A pointer to a `WEBVIEW_SECURITY_INFO` structure which will contain information about the specified download when the method returns. The ***dwSize*** member of this structure must be initialized to the size of the structure prior to being passed to this method.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetSecurityInfo** method retrieves details about the security state of the current page and populates a `WEBVIEW_SECURITY_INFO` structure. This includes the negotiated TLS protocol, cipher suite, certificate subject and issuer, and the validity period of the certificate. The method also reports an overall security level (***dwLevel***) and condition-specific flags (***dwFlags***) that identify issues such as expired certificates, mixed content, or weak cryptographic algorithms.

The information returned reflects the most recent navigation state. During navigation, these structure values may be provisional. For example, a page may initially appear secure but later be downgraded to a warning state if mixed content is detected. Applications should consider the values as advisory until a `WEBVIEW_EVENT_NAVIGATION_COMPLETED` notification confirms the final state.

The security level (***dwLevel***) is intended for user interface decisions, such as whether to display a lock icon. The flags (***dwFlags***) provide more granular context and may include multiple indicators at once. For instance, a site may be considered secure overall but still include a `WEBVIEW_SECURITY_FLAG_CERT_EXPIRED` flag if the certificate is past its validity period. Because the browser can revise its assessment as resources are loaded, applications that display security indicators should refresh their state after navigation completes. Do not assume that an initially secure status will remain unchanged for the life of the page. Conditions such as mixed content or blocked subresources may alter the security level after the main document is retrieved.

For plain HTTP or local content, the ***szProtocol*** and ***szCipher*** members will be empty, ***dwFlags*** will typically include `WEBVIEW_SECURITY_FLAG_UNENCRYPTED`, and the security level will be `WEBVIEW_SECURITY_LEVEL_INSECURE` or `WEBVIEW_SECURITY_LEVEL_NEUTRAL`. For HTTPS with a valid certificate, the protocol and cipher suite are reported, the subject and issuer strings identify the certificate, and the security level will be `WEBVIEW_SECURITY_LEVEL_SECURE`.

The subject and issuer members are provided for display or logging purposes only; certificate parsing and validation are handled internally by the browser engine. Likewise, the validity dates (***ftValidFrom*** and ***ftValidTo***) are exposed for simple checks but do not require applications to perform their own certificate validation.

Before calling this method, the ***dwSize*** member of the structure must be initialized to the size of the structure. This ensures compatibility with future versions of the library if additional fields are introduced. If the size does not match, the function will fail or only initialize the subset of fields it

recognizes.

Both ANSI (A) and Unicode (W) variants are available. When compiling with UNICODE defined, string members are UTF-16 encoded; otherwise, they are UTF-8 encoded. The **GetSecurityInfo** macro resolves to the appropriate version based on the project's character set.

If you are only interested in determining the current security level of the connection you can use the **GetSecurityLevel** function.

Example

```
// Map security level to text
static LPCTSTR SecLevelToText(DWORD level)
{
    switch (level)
    {
    case WEBVIEW_SECURITY_LEVEL_SECURE: return _T("SECURE");
    case WEBVIEW_SECURITY_LEVEL_WARNING: return _T("WARNING");
    case WEBVIEW_SECURITY_LEVEL_INSECURE: return _T("INSECURE");
    case WEBVIEW_SECURITY_LEVEL_NEUTRAL: return _T("NEUTRAL");
    default: return _T("UNKNOWN");
    }
}

// Print a FILETIME value as YYYY-MM-DD HH:MM:SS
static void PrintFileTime(LPCTSTR label, const FILETIME* pft)
{
    if (!pft || (pft->dwLowDateTime == 0 && pft->dwHighDateTime == 0))
    {
        _tprintf(_T("%s: (not available)\n"), label);
        return;
    }

    FILETIME lft = {0};
    SYSTEMTIME st = {0};

    if (FileTimeToLocalFileTime(pft, &lft) && FileTimeToSystemTime(&lft, &st))
    {
        _tprintf(_T("%s: %04u-%02u-%02u %02u:%02u:%02u\n"),
                 label,
                 (unsigned)st.wYear,
                 (unsigned)st.wMonth,
                 (unsigned)st.wDay,
                 (unsigned)st.wHour,
                 (unsigned)st.wMinute,
                 (unsigned)st.wSecond);
    }
    else
    {
        _tprintf(_T("%s: (conversion failed)\n"), label);
    }
}

// Build and print a readable flag list
static void PrintSecurityFlags(DWORD dwFlags)
{
    if (dwFlags == WEBVIEW_SECURITY_FLAG_NONE)
    {
        _tprintf(_T("Flags: NONE (0x%08lX)\n"), dwFlags);
```

```
        return;
    }

    _tprintf(_T("Flags: 0x%08lX"), dwFlags);

    if (dwFlags & WEBVIEW_SECURITY_FLAG_UNENCRYPTED) _tprintf(_T(" |
UNENCRYPTED"));
    if (dwFlags & WEBVIEW_SECURITY_FLAG_INSECURE) _tprintf(_T(" | INSECURE"));
    if (dwFlags & WEBVIEW_SECURITY_FLAG_CERT_WEAK) _tprintf(_T(" | CERT_WEAK"));
    if (dwFlags & WEBVIEW_SECURITY_FLAG_CERT_ERROR) _tprintf(_T(" | CERT_ERROR"));
    if (dwFlags & WEBVIEW_SECURITY_FLAG_CERT_EXPIRED) _tprintf(_T(" |
CERT_EXPIRED"));
    if (dwFlags & WEBVIEW_SECURITY_FLAG_UNSAFE) _tprintf(_T(" | UNSAFE"));

    _tprintf(_T("\n"));
}

// Query and display the current security info
static void ShowSecurityInfo(CWebView *pWebView)
{
    WEBVIEW_SECURITY_INFO secInfo = { 0 };
    secInfo.dwSize = sizeof(secInfo);

    if (!pWebView->GetSecurityInfo(&secInfo))
    {
        _tprintf(_T("GetSecurityInfo failed (Error 0x%lx)\n"), pWebView-
>GetLastError());
        return;
    }

    _tprintf(_T("Security Level: %s\n"), SecLevelToText(secInfo.dwLevel));
    PrintSecurityFlags(secInfo.dwFlags);

    if (secInfo.szProtocol[0])
        _tprintf(_T("Protocol: %s\n"), secInfo.szProtocol);
    else
        _tprintf(_T("Protocol: (none)\n"));

    if (secInfo.szCipher[0])
        _tprintf(_T("Cipher Suite: %s\n"), secInfo.szCipher);
    else
        _tprintf(_T("Cipher Suite: (none)\n"));

    if (secInfo.szSubject[0])
        _tprintf(_T("Certificate Subject: %s\n"), secInfo.szSubject);
    else
        _tprintf(_T("Certificate Subject: (not available)\n"));

    if (secInfo.szIssuer[0])
        _tprintf(_T("Certificate Issuer: %s\n"), secInfo.szIssuer);
    else
        _tprintf(_T("Certificate Issuer: (not available)\n"));

    PrintFileTime(_T("Valid From"), &secInfo.ftValidFrom);
    PrintFileTime(_T("Valid To "), &secInfo.ftValidTo);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebView::GetSecurityLevel Method

```
BOOL GetSecurityLevel(
   LPDWORD lpdwLevel
);
```

The **GetSecurityLevel** method returns the evaluated security level for the last navigation.

Parameters

lpdwLevel

A pointer to an unsigned integer which will contain the security level when the method returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetSecurityLevel** method provides a simplified way to obtain the current security state of the page displayed in the browser. This value is an overall assessment of the page's security status and is primarily intended for use in user interface logic, such as whether to display a lock icon or warning indicator. The security level does not provide detailed diagnostic information; if your application requires additional context such as certificate details, protocol version, or specific security flags, you should call **WebViewGetSecurityInfo** instead.

The possible values returned in the *lpdwLevel* parameter correspond to the security level constants:

- `WEBVIEW_SECURITY_LEVEL_UNKNOWN`: The security state could not be determined.
- `WEBVIEW_SECURITY_LEVEL_INSECURE`: The page was retrieved over plain HTTP or the certificate is invalid.
- `WEBVIEW_SECURITY_LEVEL_WARNING`: The page uses weak encryption or contains mixed content.
- `WEBVIEW_SECURITY_LEVEL_NEUTRAL`: Local content or the browser is in a transitional state.
- `WEBVIEW_SECURITY_LEVEL_SECURE`: The page was retrieved using HTTPS with a valid certificate.

Because the browser engine may revise the security assessment as additional resources are loaded, the level can change over the course of a navigation. For example, a page may initially appear secure, but once mixed content is detected the level will be downgraded to `WEBVIEW_SECURITY_LEVEL_WARNING.` Applications should refresh their indicators when they receive a `WEBVIEW_EVENT_SECURITY_CHANGED` notification or after navigation has completed.

The level values are ordered, with higher values indicating stronger security. Applications should avoid upgrading an observed level within the same navigation, since subsequent checks may legitimately lower the assessment.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for the navigation to complete.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. A value of zero specifies no timeout period has been specified.

Remarks

The **GetTimeout** method retrieves the current navigation timeout value, expressed in seconds. This value determines how long the library will wait for a navigation request to complete before it is considered to have failed due to a timeout condition.

If the timeout value is set to zero, the control uses the built-in timeouts defined by the underlying WebView2 browser engine. These internal timeouts are adaptive and depend on network conditions, DNS resolution, and connection establishment. In practice, this allows the browser to determine how long to wait before treating a navigation as unresponsive. For most applications, leaving the timeout set to zero provides behavior consistent with the Microsoft Edge browser.

If a non-zero timeout value has been set, navigation will be canceled if the specified number of seconds elapses without the page load completing. This provides a deterministic limit on how long a navigation attempt is allowed to continue before the operation fails. However, specifying a very long timeout value does not guarantee that navigation will continue for that entire duration, since the WebView2 engine may still enforce its own internal limits and terminate the request earlier.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::GetUserAgent Method

```
BOOL GetUserAgent(
   LPTSTR lpszUserAgent,
   INT nMaxLength,
);
```

The **GetUserAgent** method returns the current User-Agent value for this instance.

Parameters

lpszUserAgent

A null-terminated string buffer which will contain the User-Agent string for the current session. If this parameter is NULL, the string will not be copied and the method will return the length of the string, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the *lpszUserAgent* parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of characters in the User-Agent string, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetUserAgent** method retrieves the current User-Agent string used by this browser instance. This value is the exact string sent in the User-Agent header of outgoing HTTP requests and is determined by the underlying Microsoft Edge WebView2 runtime unless explicitly changed with **SetUserAgent**.

The returned value can be used for informational purposes, such as logging the client identity or displaying diagnostic information to the user. It is also useful if your application needs to capture and preserve the default User-Agent string before setting a custom one.

If the *lpszUserAgent* parameter is `NULL`, the method returns the length of the string in characters. This allows the caller to allocate a buffer of the appropriate size before retrieving the value. When a valid buffer is provided, the string copied to it will always be null-terminated.

The User-Agent value applies to the entire lifetime of the browser instance. Once it has been changed, all subsequent navigations will use the new string until explicitly reset or the instance is destroyed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetUserDataFolder Method

```
INT GetUserDataFolder(
   LPTSTR lpszDataFolder,
   INT nMaxLength,
);
```

The **GetUserDataFolder** method returns the full path to the user data folder for the current session.

Parameters

lpszDataFolder

A null-terminated string buffer which will contain the path to user data folder for the session. If this parameter is NULL, the string will not be copied and the method will return the length of the path, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the ***lpszDataFolder*** parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of characters in the User-Agent string, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **User Data Folder** (UDF) is the WebView2 profile directory that Chromium uses to persist browsing state for this instance. It contains the browser cache, cookies, localStorage/IndexedDB data, service worker state, visited link history, site permissions, and other profile data. Each ***distinct*** folder path corresponds to a distinct browser profile. Multiple WebView2 instances that point to the same folder will share the same profile (and therefore share cookies, storage, and authentication state). Using different folder paths isolates profiles.

The user data folder is chosen when the WebView instance is created or attached via **Attach** or **Create** and cannot be changed afterwards. If your application needs to switch profiles (for example, to use a different folder), you must destroy the current instance and create a new one with the desired folder.

If your application does not specify a folder or uses an empty string as the folder path, the library creates a unique per-session folder under the current user's local profile. This is an ***ephemeral profile*** that is not intended to be reused across browser instances. By default, this temporary folder is removed when the instance is detached; if the process terminates unexpectedly, the folder may remain and can be safely deleted later.

In contrast, specifying an explicit, persistent folder (for example, a subdirectory under `%LocalAppData%\WebView\YourApp`) gives you a shared profile that persists across sessions and can be reused by multiple WebView2 instances to enable single sign-on, shared cookies, and faster subsequent navigations due to caching. Use this approach when you want consistent, long-lived browser state.

The reported folder path is always an absolute, normalized local path. Environment variables in the path you supply at creation time are expanded; forward slashes are normalized to backslashes and relative names are resolved beneath the current user's local application data folder. The library rejects invalid or unsafe locations (e.g.: device names, system directories, UNC or extended path prefixes, or

root drive targets) and will create intermediate directories as needed for valid paths. For multithreaded applications, you should use explicit absolute paths rather than relying on the process current directory.

Important: The user data folder is managed internally by the the WebView2 runtime, and your application should never attempt to modify, move, or delete any of the files it contains while a browser instance is active. The contents are in use by the rendering engine and interfering with them can result in data corruption or unexpected behavior. If you need to remove or relocate a profile, ensure that all browser instances using that folder have been completely closed. If you want to delete certain data, such as cookies or the browser history, use the methods provided specifically for that purpose.

You can call **GetUserDataFolder** at any time after the instance has been created to discover which profile directory is in use. Passing *lpszDataFolder* as `NULL` returns the required buffer length so you can allocate a buffer of the appropriate size; the returned length does not include the terminating null character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetWebMessage Method

```
BOOL GetWebMessage(
   LPTSTR lpszMessage,
   INT nMaxLength
);
```

The **GetWebMessage** method retrieves the next pending message sent from the current document.

Parameters

lpszMessage

A null-terminated string buffer which will contain the message sent from the current document. If this parameter is NULL, the message will not be copied and the method will return the length of the message, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the *lpszMessage* parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of characters in the message, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetWebMessage** method retrieves the most recent message sent from script code running in the browser. This is typically used to enable interaction between the web content displayed in the browser and the host application. For example, a page might notify the application when a user completes a form, clicks a button, or when some script logic produces a result that the native application needs to act upon. This provides a simple and secure channel for exchanging data between the web page and the host, without requiring the page to reload or navigate to a new URL.

Messages are sent from JavaScript using the following method:

```
window.chrome.webview.postMessage(value);
```

When a script in the browser sends a message, the `WEBVIEW_EVENT_MESSAGE_RECEIVED` event will fire and your event handler should call this method to retrieve the value posted by the script. The `value` parameter can be any JSON-serializable object or a simple string. The format of the message depends on the type of value that was posted:

- If the message was a structured JavaScript object or array, it will be returned as a JSON object string using a format like `{"key":"value"}`.
- If the message was a string, it will be returned as a JSON-formatted string with surrounding quotes and any special characters will be escaped, such as `"Hello\nWorld"`.

Applications that need to process these messages should parse the result as JSON to properly distinguish between plain strings and structured data.

Important: Message passing is disabled by default. To enable this functionality, the browser must be created or attached with the `WEBVIEW_OPTION_ENABLE_MESSAGES` flag. If this option is not specified, no messages will be received and this method will not return any content.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

Attach, Create, GetDocumentText, GetWebResult, PostWebMessage

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::GetWebResult Method

```
BOOL GetWebResult(
   LPTSTR lpszResult,
   INT nMaxLength
);
```

The **GetWebResult** method returns the result from the most recent completed script execution.

Parameters

lpszResult

A null-terminated string buffer which will contain the result from the script that was previously executed. If this parameter is NULL, the result will not be copied and the method will return the length of the string, not including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer. If the *lpszResult* parameter is NULL, this value should be zero.

Return Value

If the method succeeds, the return value is the number of characters in the result string, not including the terminating null character. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetWebResult** method retrieves the result of the most recent JavaScript expression executed in the browser using either the **AsyncExecute** or **Execute** methods. The result is provided as a JSON-formatted string, which may be either a quoted string with escaped characters or a JSON object, depending on the value returned by the script. Applications that expect structured data should parse the returned string using a JSON parser.

Only the result from the most recently executed script is retained. Executing another script will overwrite the previous result, even if the value has not yet been retrieved. If your application needs to preserve earlier results, it should copy the returned string into its own buffer for later use.

When using **AsyncExecute**, the result is available once the `WEBVIEW_EVENT_SCRIPT_COMPLETED` event has been raised. Attempting to call **GetWebResult** before the event is delivered will return an empty string. When using **Execute**, the script is executed synchronously and the result is immediately available.

The maximum length of the result string is limited by the size of the buffer provided. If the *lpszResult* parameter is NULL, the function will return the required length of the result string in characters, not including the terminating null, which can be used to allocate a buffer of the appropriate size.

Example

```
// Execute a simple script that returns a string
INT nLength = pWebView->Execute(_T("document.title"));

if (nLength > 0)
{
    // Allocate a buffer large enough to hold the result
    LPTSTR lpszResult = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));
    if (lpszResult)
```

```
    {
        // Retrieve the result of the script execution
        if (pWebView->GetWebResult(lpszResult, nLength + 1))
        {
            _tprintf(_T("Page title is: %s\n"), lpszResult);
        }
        free(lpszResult);
    }
}
else
{
    _tprintf(_T("Script execution failed\n"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::GetZoomLevel Method

```
BOOL GetZoomLevel(
   INT *lpnPercent
);
```

The **GetZoomLevel** method returns the current zoom level as a percentage.

Parameters

lpnPercent

A pointer to an integer which will contain the current zoom level as a percentage value when the method returns. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GetZoomLevel** method returns the current zoom level of the browser window as an integer percentage value. A zoom level of **100** indicates that the page is being displayed at its normal size without any scaling applied. Values greater than **100** mean that the content is being magnified, and values less than **100** mean that the content is being reduced.

The zoom level is constrained by the limits defined for the control. By default, the minimum zoom level is **25** (25%) and the maximum zoom level is **400** (400%). Attempts to set values outside of this range using **SetZoomLevel** will be clamped to the supported range.

This method can be used to determine the current scaling when an application wants to preserve a user's preferred zoom level across sessions, or to query whether the content is being displayed at the default size. If the method fails, the contents of the ***lpnPercent*** parameter are undefined and should not be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

SetZoomLevel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::GoBack Method

```
BOOL GoBack();
```

The **GoBack** method navigates backwards through the browser history.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GoBack** method navigates the browser to the previous page in its session history, if one is available. This is equivalent to selecting the Back button in a standard web browser. If there is no previous entry in the history list, the method will succeed but no navigation will occur. The availability of backward navigation can be determined by handling the `WEBVIEW_EVENT_HISTORY_CHANGED` event and checking for the `WEBVIEW_MOVE_BACKWARD_ENABLED` flag.

Calling **ClearHistory** will remove the session history for the browser instance. After the history has been cleared, calling **GoBack** will have no effect until new pages have been visited.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

ClearHistory, GoForward, Navigate

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::GoForward Method

```
BOOL GoForward();
```

The **GoForward** method navigates forwards through the browser history.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **GoForward** method navigates the browser to the next page in its session history, if one is available. This is equivalent to selecting the Forward button in a standard web browser.

If there is no forward entry in the history list, the method will succeed but no navigation will occur. The availability of forward navigation can be determined by handling the `WEBVIEW_EVENT_HISTORY_CHANGED` event and checking for the `WEBVIEW_MOVE_FORWARD_ENABLED` flag.

Calling **ClearHistory** will remove the session history for the browser instance. After the history has been cleared, calling **GoForward** will have no effect until new pages have been visited.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

ClearHistory, GoBack, Navigate

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::Hide Method

```
BOOL Hide();
```

The **Hide** method hides the browser window.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Hide** method changes the visibility state of the browser control. When the browser was created as a top-level window using **Create**, this method internally calls the standard **ShowWindow** API to hide the entire browser window. The window will be restored with the **Show** method.

When the browser is embedded in an existing host window using **Attach**, the method does not change the visibility of the parent window. Instead, it sends an internal message to the control to hide the child window which contains the WebView2 browser. This enables the host application to change the visibility of the browser control independently of other controls in the same window.

This method does not destroy the browser instance or unload its current content. Hiding the browser simply makes it invisible; it can be shown again without requiring a reload of the current document. The current visibility state can be queried using the **IsVisible** method.

Hiding the browser window can also provide performance benefits in scenarios where the application does not need to display the page contents for a period of time. While background tasks such as script execution and network activity continue as normal, the browser will not spend resources on rendering or updating the visual output when the control is not visible. This can reduce CPU and GPU usage, particularly when the page is dynamic or graphically intensive.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

CWebView::InEvent Method

```
BOOL InEvent();
```

The **InEvent** method determines if the current thread is executing code within an event handler.

Parameters

None.

Return Value

If the current thread is executing code within the context of an event handler, the return value is non-zero; otherwise the return value is zero.

Remarks

The **InEvent** method checks a thread-local flag that is set whenever your code is executing inside an event handler. This allows an application to determine if the current call stack is the result of an event callback (for example, a navigation completed event or a message received event) rather than code executing on its own.

Knowing whether you are inside a event handler can be useful for several reasons:

- **Reentrancy detection**. Certain API functions should not be called while an event is still being processed, since this can cause re-entrant behavior or unexpected state changes in the underlying WebView2 control. For example, it is not permitted to attempt another navigation or reset the browser state while inside a navigation event handler.
- **Thread marshalling**. Event handlers are typically invoked on the UI thread associated with the WebView instance. By checking this method, the application can decide whether it needs to marshal an operation to the browser's thread or whether it is already executing in the correct context.
- **Application logic**. In some cases you may want to avoid triggering further navigation, script execution, or message posting in direct response to a particular event. This method lets you distinguish between code running in an event handler versus code running elsewhere in your application.

The return value from this method is only valid for the calling thread. Each thread maintains its own state, so a worker thread will always return FALSE unless it is actively executing a event callback on that thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::IsAttached Method

```
BOOL IsAttached();
```

The **IsAttached** method determines if the class instance is attached to a window.

Parameters

None.

Return Value

If the class instance is attached to a host window, the return value is non-zero. If class is not attached to a window, the return value is zero.

Remarks

The **IsAttached** method checks whether the class instance has been attached to a window with the **Attach** method, or the class has been used to create a new top-level browser window with the **Create** method. To get the window handle to the host window, use the **GetSafeHwnd** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

Attach, Create, GetSafeHwnd

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

When the class is initialized, it will also attempt to load the WebView2 runtime. The calling thread must be in a single-threaded apartment (STA). During initialization the class calls **CoInitializeEx** as needed and if your process has already initialized COM as MTA (`COINIT_MULTITHREADED`), initialization will fail. This requirement comes directly from the Edge WebView2 control which cannot be created in an MTA COM application.

The **RuntimeAvailable** method can be used to determine if the Microsoft Edge WebView2 runtime is installed and meets the minimum required version. This can be useful during application startup to provide a clear error message or guidance to the user if the runtime is missing or out of date, rather than attempting to initialize the control and handling the failure afterward. This is a static method which can be called without creating an instance of the **CWebView** class.

On modern versions of Windows, the WebView2 runtime is included as part of the operating system and is serviced through Windows Update. However, on older or unsupported versions of Windows the runtime may not be present by default and must be installed separately. In these cases, your application needs to detect the missing runtime and prompt the user to install it.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtpv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::IsSecure Method

```
BOOL IsSecure();
```

The **IsSecure** method determines if the current page was retrieved using a secure connection.

Parameters

None.

Return Value

If the connection was secure, the return value is non-zero. If the connection was not secure or there were problems (such as an expired certificate), the return value is zero.

Remarks

The **IsSecure** method checks whether the current page was retrieved using a secure connection. Because the security state of the session changes several times as a page is loaded, this value should only be considered authoritative after navigation has completed. It is possible for the method to initially return **TRUE** as the page is loading, but return **FALSE** when navigation completes if the page contains mixed content.

This method only returns **TRUE** if the document and all its assets were retrieved using a secure connection. The security certificate must be valid and the connection cannot use weak encryption or deprecated cipher suites. If a secure connection was used but there were problems detected with the certificate or security protocol, this method will return **FALSE**. For more information about the connection, use the **GetSecurityInfo** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

GetSecurityInfo, GetSecurityLevel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::IsVisible Method

```
BOOL IsVisible();
```

The **IsVisible** method determines if the browser window is currently visible.

Parameters

None.

Return Value

If the browser window is visible, the return value is non-zero. If the window is not visible or has been closed, the return value is zero.

Remarks

The **IsVisible** method checks whether the browser window is currently visible. A return value of **TRUE** means that the browser window is being displayed. A return value of **FALSE** indicates that the window has been hidden using the **Hide** method or the window was closed.

This method only reports on the visibility state that was explicitly set through the API. It does not reflect other factors that might affect whether the browser content is actually visible to the user, such as the host window being minimized, overlapped by another window, or located off screen.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

GetFocus, Hide, Redraw, SetBounds, SetFocus, Show

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::KeyEventHandled Method

```
BOOL KeyEventHandled(
   BOOL bHandled
);
```

The **KeyEventHandled** method sets an accelerator key event as handled.

Parameters

bHandled

An integer which specifies if the accelerator key event was handled by the application. A non-zero value indicates the application has handled the accelerator key event and the WebView2 control should not process the event. A value of zero specifies that the browser should handle the accelerator key using it's normal, default behavior.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **KeyEventHandled** method is used in conjunction with the **WebViewEventProc** callback when the application receives a `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS` event. By calling this method and specifying that the key event has been handled, the application can prevent the browser from processing the key itself.

This mechanism is useful when you want to disable or override the default behavior of certain keys within the embedded browser. For example, you may wish to prevent the user from pressing **F12** to open the developer tools, block function keys that have meaning in your application, or intercept combinations such as **Ctrl+P** or **Ctrl+S** to substitute your own print or save functionality.

If *bHandled* is non-zero, the event is considered handled by the host application and WebView2 will not process the key. If *bHandled* is zero, the key is passed through and processed normally according to the browser's default behavior. This method should typically be called during the event handler for `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS`.

Note that this method only affects accelerator key events when the `WEBVIEW_OPTION_ENABLE_ACCELERATORS` option has been specified when creating or attaching the WebView. It does not apply to ordinary text input within form fields or content editable regions in the page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebView::Navigate Method

```
BOOL Navigate(
   DWORD dwFlags,
   LPCTSTR lpszUrl
);
```

The **Navigate** method navigates to the specified URL or local file path.

Parameters

dwFlags

An unsigned integer which specifies additional options for how the navigation will be performed.

Value	Description
WEBVIEW_NAVIGATE_DEFAULT	Use the default navigation behavior. The specified URL or local file path is normalized and used without additional restrictions.
WEBVIEW_NAVIGATE_SAFE_URL	Perform additional safety checks on the input before navigation. This will reject unsafe or malformed URLs, filter out potentially harmful schemes, and block traversal sequences (such as `../../`) in local paths. This option is recommended when the URL or path is provided by external or untrusted input.

lpszUrl

A null-terminated string which specifies the URL or local file to navigate to. Any leading and trailing whitespace will be removed and the URL will be normalized to ensure that it specifies a valid location. If the URL only specifies a domain name (such as `"example.com"`) the browser will default to using a secure connection. This parameter cannot be NULL.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Navigate** method accepts both standard web URLs such as `https://www.example.com/` and local file paths which are automatically normalized and converted into `file://` URLs. This allows an application to load either remote web content or content from the local filesystem.

When a local file path is specified, the method validates the path to ensure that it refers to a valid, absolute file system location and is not under restricted system folders (such as the Windows or Program Files directories). Relative paths are resolved against the current working directory, but it is recommended that applications provide absolute paths to avoid ambiguity in multithreaded or service-hosted environments.

File names and paths are normalized before navigation. Illegal or reserved device names (such as `CON`, `AUX`, or `NUL`) and paths containing invalid characters will be rejected. UNC paths and extended-length paths using the `\\?\` prefix are not supported. If the path points to a valid file, it will be loaded into the WebView using the appropriate `file://` URL form.

If the *dwFlags* parameter specifies `WEBVIEW_NAVIGATE_SAFE_URL`, the URL or path will undergo

additional checks to ensure that it does not contain unsafe schemes, fragments, or traversal sequences. This is useful when the application accepts untrusted input that may be used for navigation.

Note that navigation to local files is supported, but applications should exercise caution when mixing remote and local content, as this may have cross-origin security implications. If your application needs to load dynamic HTML content, consider using **SetDocumentText** instead.

This method only supports navigation to standard web and local resources. Valid URL schemes are limited to `http://`, `https://`, `file://`, and `about:blank`. Other protocols or custom application schemes are not supported and will cause the method to fail. This includes the `edge://settings/profile` page or any other internal configuration settings for the Edge browser. If your application needs to handle such protocols, you should implement a custom handler to intercept those links and handle them externally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::NormalizeUrl Method

```
INT NormalizeUrl(
   LPCTSTR lpszUrl,
   DWORD dwFlags,
   LPTSTR lpszNormalized,
   INT nMaxLength
);

INT NormalizeUrl(
   LPCTSTR lpszUrl,
   DWORD dwFlags,
   CString& strNormalized
);
```

The **NormalizeUrl** method parses and normalizes a URL into a safe, navigable form.

Parameters

lpszUrl

A null-terminated string which specifies the URL to be normalized. This parameter cannot be NULL or an empty string.

dwFlags

Specifies one or more bit flags that control how the URL is normalized. A value of zero specifies that only standard normalization will be performed, such as removing any leading and trailing whitespace and ensuring the URL does not contain any illegal characters. Multiple flags may be combined using a bitwise or operator.

Value	Description
URL_FLAG_DEFAULT_HTTPS	When no URL scheme is provided and no scheme is otherwise required, select **`https://`** by default. If an explicit port is present, port 443 selects **`https`** and any other port selects **`http`**. Explicit input schemes are preserved.
URL_FLAG_REQUIRE_HTTP	When no scheme is provided, force **`http://`**. If the input already specifies a scheme, it is preserved.
URL_FLAG_REQUIRE_HTTPS	When no scheme is provided, force **`https://`**. If the input already specifies a scheme, it is preserved.
URL_FLAG_REJECT_LOCALHOST	Reject URLs that specify **`localhost`** as the host name.
URL_FLAG_REJECT_IPV4	Reject URLs that specify a numeric IPv4 address (for example, **`192.0.2.1`**) as the host.
URL_FLAG_REJECT_IPV6	Reject URLs that specify a bracketed IPv6 address (for example, **`[2001:db8::1]`**) as the host.
URL_FLAG_ASCII_HOSTNAME	Host names are checked to ensure that they only contain legal ASCII characters. Unicode host names are converted to ASCII (punycode) before validation, and the host name is normalized to lowercase.
URL_FLAG_ESCAPE_PATH	Percent-encode the path component as needed. Non-ASCII characters are encoded as UTF-8 and then percent-encoded

	per byte. Valid **%HH** sequences are preserved and upper-cased. The path is also normalized by removing duplicate slashes and collapsing **.** and **..** segments of the path.
URL_FLAG_ESCAPE_QUERY	Percent-encode the query and fragment tail as needed. The first **?** is treated as the start of the tail and characters commonly used in queries (such as **&**, **=**, **+**, **;**, **#**) are permitted unescaped. Non-ASCII characters are encoded as UTF-8 and then percent-encoded.
URL_FLAG_VALIDATE_UTF8	Applicable to projects using a multi-byte character set. Require the URL to use UTF-8 encoding and fail if the method encounters an invalid Unicode character. When this flag is not specified, and the URL does not use UTF-8 encoding, the method attempts to normalize the URL using the active code page.
URL_FLAG_REJECT_LOCAL_FILES	Reject absolute local and UNC paths and existing **file://** URLs. When specified, UNC paths are also rejected and unsafe file extensions are not allowed.
URL_FLAG_REJECT_UNC_PATHS	When local file normalization is permitted, reject UNC paths (for example, **\\server\share**). Files paths which use a mapped drive to a network share will be allowed.
URL_FLAG_ALLOW_UNSAFE_FILES	When converting local/UNC paths to **file://** URLs or normalizing existing **file://** URLs, permit any file extension. If this option is not specified, only a common set of safe, renderable file types are allowed. This includes HTML files, text files and common image formats.

lpszNormalized

A null-terminated string buffer which will contain the normalized URL when the method returns. This parameter may be NULL, in which case the method returns the number of characters required to store the normalized URL. If a buffer is provided, it must be large enough to contain the entire URL. An alternate version of this method accepts a **CString** which will contain the normalized URL when the method returns.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null character. If this parameter is zero, the method will return the number of characters required to store the normalized URL and no characters will be copied into the buffer.

Return Value

An integer which specifies the length of the normalized URL, not including the terminating null character. A return value of zero indicates the URL could not be normalized, either due to an invalid URL or the output buffer not being large enough to store the complete URL. Call the **GetLastError** method for more information about the cause of the failure.

Remarks

The **NormalizeUrl** method parses and normalizes a candidate URL without navigating. In most cases you do not need to call this method directly because the **Navigate** method already performs basic

normalization internally before it passes the URL to the browser. Use **NormalizeUrl** when you want to enforce additional policy restrictions with the option flags, or notify users of clear validation failures before attempting navigation.

Normalization includes, depending on the flags you choose:

- Scheme defaults and enforcement. If the input omits a scheme, you can default to HTTPS (`URL_FLAG_DEFAULT_HTTPS`) or require http:// or https:// explicitly using `URL_FLAG_REQUIRE_HTTP` or `URL_FLAG_REQUIRE_HTTPS`. If the normalizer cannot accept the scheme under your selected policy, the call fails. The same default behavior is applied with the **Navigate** method.
- Hostname policy. You may reject localhost, numeric IPv4, or bracketed IPv6 literals, or enforce ASCII hostnames (Unicode hostnames are converted to Punycode and lower-cased). The host parsing also ensures the input isn't a Windows path accidentally pasted in place of a URL.
- Path and query normalization. Paths may be percent-encoded as needed, duplicate slashes removed, and path traversal segments are collapsed; queries and fragments may be percent-encoded while preserving common query delimiters.
- Local file handling. Absolute local and UNC paths or existing file:// URLs can be converted to a normalized file:// form unless you explicitly reject them with `URL_FLAG_REJECT_LOCAL_FILES` (and optionally the `URL_FLAG_REJECT_UNC_PATHS` option). If you intend to only permit web content, enable these reject flags. At navigation time the library also tracks whether the target is a local file.
- If your project uses the multi-byte character set instead of Unicode, and `URL_FLAG_VALIDATE_UTF8` is specified, the method will fail if the URL contains any invalid UTF-8 encoding. Without this flag, if the method detects invalid UTF-8 characters, it will attempt to validate the URL using the active code page. It is recommended that applications use UTF-8 or UTF-16 Unicode whenever possible.

This method validates and normalizes URLs but does not expand redirects, verify server reachability, or fetch headers. Use it to block undesired inputs before navigation (such as disallowing bare IPs or local files), or to present a user-friendly, fully qualified URL.

Example

```
// Match the safe normalization options and forbid local files
DWORD dwNormFlags =
    URL_FLAG_DEFAULT_HTTPS |
    URL_FLAG_ASCII_HOSTNAME |
    URL_FLAG_ESCAPE_PATH |
    URL_FLAG_ESCAPE_QUERY |
    URL_FLAG_REJECT_LOCAL_FILES |
    URL_FLAG_REJECT_UNC_PATHS;

// If normalization or navigation fails, save the last error code
DWORD dwError = NO_ERROR;

// Check how long the normalized URL will be
INT nLength = pWebView->NormalizeUrl(pszUserInput, dwNormFlags, NULL, 0);
if (nLength <= 0)
    dwError = pWebView->GetLastError();

if (dwError == NO_ERROR)
```

```
{
    // Allocate buffer and normalize again
    LPTSTR pszNormalizedUrl = (LPTSTR)malloc((nLength + 1) * sizeof(TCHAR));

    if (!pszNormalizedUrl)
         return; // Failed; virtual memory exhausted

    nLength = pWebView->NormalizeUrl(pszUserInput, dwNormFlags, pszNormalizedUrl,
nLength + 1);
    if (nLength <= 0)
    {
        dwError = pWebView->GetLastError();
    }
    else
    {
        // Navigate using the normalized URL
        if (!pWebView->Navigate(pszNormalizedUrl))
            dwError = pWebView->GetLastError();
    }

    free(pszNormalizedUrl);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebView::PostWebMessage Method

```
BOOL PostWebMessage (
   LPCTSTR lpszMessage
);
```

The **PostWebMessage** function posts a string or JSON message to the current page.

Parameters

lpszMessage

A null-terminated string which contains the message to be sent to the current page. This parameter cannot be NULL or an empty string.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **PostWebMessage** method sends a message from the host application to the currently loaded page using the WebView2 messaging channel. The call is asynchronous: if it is invoked from a thread other than the thread that created the browser instance, the method marshals the request to the UI thread and returns immediately, with delivery performed later on that thread. Internally, this posts a private window message to the host window; when handled, it forwards the text using the `ICoreWebView2::PostWebMessageAsString` method.

For a page to receive messages from the host, web messaging must be enabled. When the `WEBVIEW_OPTION_ENABLE_MESSAGES` option is set, the wrapper enables web messages in the control settings (exposing `window.chrome.webview` to the script) and wires the corresponding message events. If this option is not enabled, the page will not see the messaging object and cannot receive messages.

On the JavaScript side, the page subscribes to messages using the standard listener pattern. Messages posted with this method are delivered as strings to the page's handler:

```
window.chrome.webview.addEventListener('message', (event) => {
 // event.data is the string posted by WebViewPostWebMessage
 const text = event.data;
 // If you know the string is JSON, you can parse it explicitly
 // const obj = JSON.parse(text);
});
```

Because delivery is asynchronous, there is no built-in acknowledgement and ordering is not guaranteed across navigations. If the page navigates or reloads after you call **PostWebMessage**, a listener registered on the previous document will not receive later messages.

Messages are Unicode strings and you should avoid sending very large payloads. For large data transfers, consider using application-level protocols rather than embedding large content in a single message. This method is primarily intended to enable your host application to notify the web page the user has taken some action which should be reflected in the browser. The web page can send messages back to your application using `window.chrome.webview.postMessage(value)` and you can receive those messages using the **GetWebMessage** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::PrintDocument Method

```
BOOL PrintDocument(
   DWORD dwOptions
);
```

The **PrintDocument** method displays the browser print dialog for the current document.

Parameters

dwOptions

An unsigned integer which specifies how the print dialog should be displayed.

Value	Description
WEBVIEW_PRINT_DIALOG_DEFAULT	Use Edge's print preview dialog, equivalent to the **Ctrl+P** experience. This dialog provides preview capabilities and additional print options.
WEBVIEW_PRINT_DIALOG_SYSTEM	Use the native system print dialog. This dialog allows the user to select a printer and set standard options, but does not provide a preview of the document.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **PrintDocument** method displays the print dialog for the currently loaded document. The dialog is shown asynchronously and the method will return once the print user interface has been invoked. This method does not perform the printing operation itself; it only initiates the print workflow and allows the user to select a printer, adjust preferences, and confirm printing.

This method can only be called after navigation has completed and the current document is fully loaded. If navigation is still in progress when the method is called, it will fail with an error indicating that the operation is in progress. This method only supports interactive printing through a user interface. If you need to programmatically export the document without user interaction, use the **SaveDocument** method instead.

It is recommended that most applications use the default dialog. The `WEBVIEW_PRINT_DIALOG_SYSTEM` option shows a simplified print dialog provided by browser. This is not the same dialog exposed by the Windows Common Controls API through the **PrintDlg** or **PrintDlgEx** functions, and it may differ in appearance and available options depending on the platform and version of the WebView2 runtime.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::Redraw Method

```
BOOL Redraw();
```

The **Redraw** method forces the host window and browser control to redraw.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Redraw** method reloads the current document and forces both the host window and the embedded WebView2 child window to repaint themselves. This differs from **Reload**, which simply reloads the page (similar to pressing **F5**) but does not explicitly invalidate and redraw the hosting window.

Internally, this method clears the browser cache and then forces a redraw by updating the control bounds and notifying the browser that the parent window has changed. If the host window itself is visible, it is also invalidated and updated to ensure that the client area is repainted.

Because this method performs multiple operations that can be relatively expensive, applications should generally prefer **Reload** unless a complete repaint of both the control and the host window is required. For example, it can be used if rendering artifacts are visible after a resize or when switching between different DPI contexts.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

ClearCache, Reload, Reset

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::Reload Method

```
BOOL Reload(
   BOOL bClearCache
);
```

The **Reload** method reloads the current document and optionally clears the cache.

Parameters

bClearCache

An integer which indicates if the document cache for the session should be cleared. A non-zero value specifies the cache should be cleared; zero specifies the cache should not be cleared.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Reload** method refreshes the currently loaded page, similar to pressing **F5** in a web browser. If the *bClearCache* parameter is non-zero, the document cache is also cleared before reloading, ensuring that all resources are fetched again from the server instead of being served from the local cache.

This method is generally preferred over **Redraw** when an application only needs to reload the content without forcing the host window and browser control to repaint. It provides a lightweight way to refresh the page and optionally reset cached resources, without the overhead of a full redraw of the hosting window.

An application would typically use this method in response to a user action or when it needs to ensure the latest version of a document is displayed after cached data may have become stale.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

ClearCache, Redraw

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::Reset Method

```
BOOL Reset();
```

The **Reset** method resets the embedded runtime control.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Reset** method clears the state of the current browser session and restores it to its default configuration. This includes discarding cached content, navigation history, and any data associated with the last document. The control is then navigated to an empty `about:blank` page and the zoom level is reset to its default value.

Internally, this method releases cached strings such as the most recent message, script result, and document text, clears the current HTTP status and security information, removes cached data, and clears the session history. A navigation to **about:blank** is performed, and the host window is invalidated to ensure that the client area is repainted. The call blocks until the navigation has completed or the operation times out.

Because this method performs a complete reset of the WebView2 control, it should be used in situations where the browser needs to be returned to a known, clean state (for example, when reinitializing a session or preparing the control for a new task). Applications that only need to refresh the current document should use **Reload** or **Redraw** instead, as they are lighter-weight operations.

This method cannot be called while a navigation is already in progress. Attempting to do so will fail with an error code indicating that the operation is in progress. As with other navigation-related functions, it must be called on the thread that owns the browser window, or the request will be marshaled back to the UI thread.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

ClearCache, Redraw, Reload

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::Resize Method

```
BOOL Resize();
```

The **Resize** method resizes the browser child window to the size of its host window.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Resize** method updates the position and size of the embedded browser window to the size of client area of the host window. It calls the ***put_Bounds*** method on the underlying WebView2 controller to resize the child window that renders the web content. The coordinates and dimensions are determined by calling the Win32 function **GetClientRect** with the host window.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

Redraw, SetBounds

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::RuntimeAvailable Method

```
static BOOL RuntimeAvailable();
```

The **RuntimeAvailable** method determines whether the required runtime is installed and available.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **RuntimeAvailable** method checks whether the Microsoft Edge WebView2 runtime is installed and meets the minimum required version for this library. If the runtime is available, the method returns `TRUE`; otherwise, it returns `FALSE` and sets the last error code to indicate whether the runtime is missing or is an unsupported version. If the runtime is not installed, the last error code will be set to `ST_ERROR_WEBVIEW2_NOT_INSTALLED`. If the installed runtime is older than the minimum supported version (currently `102.0.1245.22`), the last error code will be set to `ST_ERROR_INVALID_WEBVIEW2_VERSION`.

This is a static method which can be called before creating an instance of the **CWebView** class. It allows an application to check for the availability of the WebView2 runtime at startup, and optionally provide a more helpful error message to the user before attempting to create or attach a browser control. Developers may wish to call this method during application startup or installation checks. For example, if the runtime is not present or is too old, the application can inform the user that they must install or update the Microsoft Edge WebView2 runtime in order to use features which require embedded web content.

If the method succeeds, it only guarantees that the required runtime is installed and is a sufficient version. It does not initialize or configure the runtime; that process occurs inside the **CWebView** class constructor.

Example

```
CWebView *pWebView = NULL;

INT APIENTRY wWinMain(HINSTANCE hInstance, HINSTANCE hPrevInstance, LPWSTR
lpCmdLine, INT nCmdShow)
{
    if (!CWebView::RuntimeAvailable())
    {
        MessageBox(NULL,
                   _T("The Microsoft Edge WebView2 runtime is not available."),
                   _T("MyApp"), MB_ICONERROR | MB_OK);

        return 0; // Exit application
    }

    // Create a new instance of the CWebView class
    pWebView = new CWebView();

    if (!pWebView->IsInitialized())
    {
```

```
        MessageBoxW(NULL,
                    L"Unable to initialize the SocketTools WebView library",
                    L"MyApp", MB_ICONERROR | MB_OK);
        return 0;
    }

    // Create your main window, attach the browser, etc.

    return 0;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::SaveDocument Method

```
BOOL SaveDocument(
   UINT uFileType
   LPCTSTR lpszFileName
);
```

The **SaveDocument** method saves the current document to a local file.

Parameters

uFileType

An unsigned integer which specifies the format the document should be saved as.

Value	Description
WEBVIEW_FILE_TYPE_DEFAULT	Save using a format inferred from the file extension. If the file extension is not recognized, the contents will be saved as plain text. For example, if you specify a file name with the `.html` extension, it will be saved in HTML format. If the file name has a `.pdf` extension, it will be saved as a PDF.
WEBVIEW_FILE_TYPE_TEXT	Saves the current document as plain text. The HTML tags are removed and entities are converted to their UTF-8 equivalent. Extraneous whitespace within the text will be removed, but the overall structure of ordered and unordered lists will be preserved. Choose this format if you wish to save only the text content of a document.
WEBVIEW_FILE_TYPE_HTML	Saves the current document as a UTF-8 encoded HTML file. This includes the complete source for the page, but does not include any of the additional assets such as images. Choose this format if you wish to save the document as an editable HTML file.
WEBVIEW_FILE_TYPE_JSON	Saves the current document as a JSON formatted string. The string will be quoted and reserved characters will be escaped. Choose this format if you wish to preserve the HTML document as a JSON string for logging or embedding in a JSON object.
WEBVIEW_FILE_TYPE_MHTML	Saves the current document as a single-file web archive (MHTML) that inlines the HTML content and all of the resources it references. This format calls the DevTools `Page.captureSnapshot` method in the browser and writes the returned data to disk. MHTML is useful for offline archiving since it combines images, styles and scripts together in a single file.
WEBVIEW_FILE_TYPE_PDF	Saves the current document as a PDF file which produces a paginated document suitable for printing and distribution. This is functionally similar to using the browser to print to a PDF, but does not display a dialog to the user.

WEBVIEW_FILE_TYPE_JPEG	Save the current document view as a JPEG image. JPEG is a widely used image format optimized for photographs and complex images with smooth gradients. It uses lossy compression to significantly reduce file size while maintaining acceptable visual quality.
WEBVIEW_FILE_TYPE_PNG	Save the current document view as a PNG image. PNG is a lossless image format designed for crisp detail and high fidelity, especially in graphics with sharp edges, text, or flat colors. Although PNG files are typically larger than JPEGs, they preserve exact image data without quality loss.
WEBVIEW_FILE_TYPE_WEBP	Save the current document view as a WebP image. WebP is a modern image format developed by Google that supports both lossy and lossless compression, as well as transparency and animation. It delivers smaller file sizes compared to JPEG and PNG while maintaining comparable or better visual quality.

lpszFileName

A null-terminated string which specifies the name of the local file. If the path includes environment variables enclosed in percent (%) symbols, the variables will be expanded. This parameter cannot be NULL and must specify a valid file path. The file name cannot specify a device, folder name or system file. If the file is marked as read-only, the method will fail.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SaveDocument** method saves the current page to a local file in the format specified by the *uFileType* parameter. The operation is synchronous, processing messages while the browser completes the action, and only returns once the document has been created or the operation has failed. A temporary file is created during the save process and then moved into place, replacing any existing file. This ensures that an existing file will not be changed unless the browser indicates the save operation was successful. Saving is not permitted while a navigation is in progress, and attempts to do so will fail with an error.

The file name specified must be valid, and environment variables in the path are expanded before use. When **WEBVIEW_FILE_TYPE_DEFAULT** is specified, the format is inferred from the file extension. For example, **.html** or **.htm** will save the document as HTML, **.pdf** will create a PDF file and **.png** will save the page as a PNG image. If no recognized extension is present, the page will be saved as plain text by default.

When saving the current document as plain text, the HTML markup will be removed and it will be saved as a UTF-8 encoded text file. When saving as HTML, the method saves the complete HTML source for the page. The JSON format also saves the HTML markup, but encodes it as a quoted JSON string with reserved characters escaped. Note that all text-related formats are saved using UTF-8 multi-byte encoding without a byte order mark (BOM). The text will not be automatically converted to the current user's locale. Most modern text editors automatically recognize UTF-8 encoding, but some legacy applications may assume the text is localized to the current code page.

The MHTML option creates a single-file archive which contains the page content and all of its resources such as images, style sheets, and scripts. This format is often used for offline archiving or sharing since everything is contained in one file. Saving as PDF renders the page into a paginated print-style format suitable for distribution. These formats all operate on the complete document, including content that extends beyond the visible area.

By contrast, saving as an image (JPEG, PNG, or WebP) captures only the visible viewport of the page at the time the method is called. Content that requires scrolling will not be included in the saved image. PNG is lossless and preserves transparency, while JPEG and WebP use compression to produce smaller files. WEBP generally offers better quality at a reduced size compared to JPEG, but support for the format may vary between applications. If you want a pixel-perfect representation of the current page as it appears on the screen, particularly if it contains a lot of text, it is recommended that you use the PNG format.

Because this method blocks the current thread until the save completes, it may take a noticeable amount of time to return if the current document is very large. If the method is called from a worker thread, the request is marshaled to the UI thread that manages the browser control. For applications with a graphical interface, it is recommended that you display the standard hourglass (or other busy indicator) while the save is in progress to provide a visual cue to the user.

If you want a copy of the HTML or plain text contents of the current page without saving it to a file, use the **GetDocumentText** or **GetFilteredText** methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::SetBackgroundColor Method

```
BOOL SetBackgroundColor(
   COLORREF rgbBackground
);
```

The **SetBackgroundColor** method changes the background color used behind the page content.

Parameters

rgbBackground

An integer value which specifies the background color.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The background color specifies the fill used by the browser window when there is no content to display or the document itself does not define a background. This value only applies to the WebView host surface and does not affect page transparency. The alpha channel is ignored, and the color is treated as fully opaque.

It is important to note that this setting does not override the background defined by the currently loaded page. If the page specifies its own background color or image, that content will take precedence and may obscure the configured color. For example, setting the background to white will not force web pages to appear white unless the page itself has transparent regions.

Applications can use this method to provide a consistent appearance for empty or loading views, but should not rely on the background color as a substitute for page styling. When a browser instance is first created, the default background color is white.

A **COLORREF** is a 32-bit value used by the Windows API to represent an RGB color. The low-order byte specifies the red component, the next byte the green component, and the third byte the blue component, in the format **0x00BBGGRR**. The high-order byte is unused and should be zero. Note that **COLORREF** is specific to the Windows API and is not the same as the OLE color system (**OLE_COLOR**). OLE uses a slightly different encoding that allows system color values to be specified, which are resolved at runtime. Developers should be careful not to confuse the two.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::SetBounds Method

```
BOOL SetBounds(
   LPRECT lpRect
);

BOOL SetBounds(
   INT xPos,
   INT yPos,
   INT nWidth,
   INT nHeight
);
```

The **SetBounds** method sets the position and size of the browser child window.

Parameters

lpRect

A pointer to a `RECT` structure which specifies the position and dimensions of the browser window. If this version of the method is called, this parameter cannot be NULL.

xPos

The x-position of the child window. This is a client area coordinate of the host window, not a screen position.

yPos

The y-position of the child window. This is a client area coordinate of the host window, not a screen position.

nWidth

The width of the child window. This is expressed in device units for the host window's client area.

nHeight

The height of the child window. This is expressed in device units for the host window's client area.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetBounds** method updates the position and size of the embedded browser window relative to the client area of the host window. It calls the ***put_Bounds*** method on the underlying WebView2 controller to resize the child window that renders the web content. The specified coordinates and dimensions must fall within the client area of the host window associated with the browser instance. Attempting to specify bounds outside of the host window will result in clipping or the control being partially hidden.

The *nWidth* and *nHeight* parameters are device units, the same pixel units that the Win32 API uses with functions like **MoveWindow** and **SetWindowPos**. If the host window was created as a per-monitor DPI-aware window, the values your application gets with a `WM_SIZE` message are already scaled for the current DPI and you should just pass those values directly to this method. If your application is not DPI-aware, Windows will attempt to scale the values for you through DPI virtualization. It is important to note that these values are not logical units like Twips and they are not independent of DPI scaling.

Typically this method is called from within a **WM_SIZE** or **WM_MOVE** message handler so that the browser control resizes and repositions itself along with the parent window. You can also call this function directly to dock the browser into a specific portion of the host window's client area, such as aligning it within a child frame or panel.

In most applications it is sufficient to call this method in response to a **WM_SIZE** message so the browser control resizes along with the client area of the host window. However, in a per-monitor DPI-aware application it may also be useful to call this method when handling **WM_MOVE**. This is because moving a top-level window between monitors can trigger a DPI change even if the window size itself does not change. Reapplying the bounds in response to **WM_MOVE** ensures the control is correctly adjusted to the new scaling factor. For applications that are not DPI-aware, handling **WM_MOVE** is generally unnecessary since the client area origin remains at (0,0) and Windows applies DPI virtualization automatically.

Calling **SetBounds** does not affect the visibility of the browser window. To hide or show the control, use the **Hide** or **Show** methods, and to query its visibility, use **IsVisible**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::SetDocumentText Method

```
BOOL SetDocumentText(
   LPCTSTR lpszText
);
```

The **SetDocumentText** method replaces the current document with the specified HTML or plain text.

Parameters

lpszText

A null-terminated string which specifies the HTML or plain text that should replace the current document. If this parameter is NULL the current document will be cleared.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetDocumentText** method replaces the currently displayed content with the specified HTML or plain text. If the text does not contain any markup, it will be wrapped in HTML as preformatted text and displayed using the default monospaced font. If the *lpszText* parameter is `NULL` or an empty string, the browser will display a blank page.

The string passed to this method is normally rendered directly by the browser. If the string is very large (over 256 KiB), the library will first write the text to a local temporary file and then instruct the browser to navigate to that file. This is done to work around limitations in the Edge WebView2 control when handling long inline strings. The temporary file will be automatically deleted when it is no longer needed.

If your project is configured to use a multi-byte character set (ANSI) instead of Unicode, this method will always interpret the *lpszText* string as UTF-8 encoded text, regardless of the system's current locale or code page. Legacy ANSI code pages cannot reliably represent the full range of characters, and using them in place of Unicode or UTF-8 can lead to data loss or corrupted text.

Important: It is possible to embed markup that references images, scripts, or other resources located on the Internet. While this is supported, you should be aware of potential risks when combining local content with external resources. This can create mixed-content scenarios and introduce cross-origin or security issues. Applications that render untrusted content should avoid linking to remote resources and ensure that the HTML provided is properly validated.

Example

In this example, the method replaces the current page with a basic HTML document. The `<img>` tag references an external image from a website. This is supported, but as noted above, applications should carefully consider the security implications of mixing local content with external resources.

```
// Replace the current document with a simple HTML page
LPCTSTR pszHtml =
    _T("<html><head><title>Hello</title></head>")
    _T("<body><h1>Hello, world!</h1>")
    _T("<p>This content was created dynamically.</p>")
    _T("<img src=\"https://example.com/logo.png\" alt=\"Logo\"/>")
    _T("</body></html>");

if (!pWebView->SetDocumentText(pszHtml))
```

```
{
    DWORD dwError = pWebView->GetLastError();
    // Handle the error
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::SetDownloadPath Method

```
BOOL SetDownloadPath(
   DWORD dwFileId,
   LPCTSTR lpszFilePath
);
```

The **SetDownloadPath** method changes the location of the local file for the specified download.

Parameters

dwFileId

An unsigned integer value which uniquely identifies the download. This value cannot be zero.

lpszFilePath

A null-terminated string which specifies the new path for the downloaded file. This value may be a `file://` URL or it may specify a local file path. If the path contains environment variables surrounded with percent (%) symbols, the variables will be expanded. This parameter cannot be NULL or an empty string.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The specified path may be provided as either a file:// URL or a local file system path. If a file:// URL is given, it will be converted to a local path before use. Environment variables enclosed in percent signs (such as `%TEMP%`) are expanded automatically. If the path refers to an existing directory rather than a file name, the original file's base name is preserved and the file will be created in that directory. This allows applications to easily redirect a download into a specific folder without changing the file name.

The method always normalizes the provided path. If a relative path is specified, it is resolved against the current working directory of the process. Because this can lead to unpredictable results in multithreaded applications, it is strongly recommended that applications always provide absolute paths. By default, downloaded files are typically stored in the current user's Downloads folder.

Several restrictions are enforced on the path to help ensure safety and compatibility. Device names such as `CON`, `PRN`, or `NUL` are not permitted. Downloads cannot be redirected into system folders such as the Windows folder or Program File folder. The path cannot contain reserved characters, and files that are marked as read-only will not be overwritten. If any of these conditions are detected, the method will fail with an error.

This method can only be called within a handler for the `WEBVIEW_EVENT_DOWNLOAD_STARTING` event. Once the download has begun, the local file path cannot be changed. If you wish to move the file after it has been downloaded, you can use the **GetDownloadPath** method to obtain its current location and then use a Win32 function like **MoveFileEx** to move the file to a new folder.

Note that you should avoid showing modal dialogs such as the common "Save File" dialog within event handlers. Because the browser events are raised within the context of the WebView2 UI thread, displaying a dialog asking the user for a new download location can prevent the control from processing its internal message loop, potentially leading to stalled downloads.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::SetFocus Method

```
BOOL SetFocus();
```

The **SetFocus** method changes focus to the browser control.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetFocus** method gives input focus to the embedded browser control. Once focus has been set, keyboard input such as typing or navigation keys will be directed to the content displayed by the control rather than to other controls in the host window. This is equivalent to the user clicking inside the browser area.

Setting focus does not make the host window itself the active foreground window. If the host window is not active, input will still not be directed to the browser until the window is activated by the user or programmatically. Applications that need to determine whether the browser currently has focus can call **GetFocus**.

Example

```
BOOL bHasFocus = FALSE;

if (pWebView->GetFocus(&bHasFocus))
{
    if (!bHasFocus)
    {
        // Give the browser control focus if it does not have it
        pWebView->SetFocus();
    }
}
else
{
    // Handle error
    DWORD dwError = pWebView->GetLastError();
    _tprintf(_T("GetFocus failed, error=0x%lx\n"), dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::SetHeader Method

```
BOOL SetHeader (
   LPCTSTR lpszHeaderName,
   LPCTSTR lpszHeaderValue
);
```

The **SetHeader** function sets a request header value to be included with subsequent navigations.

Parameters

lpszHeaderName

A null-terminated string which specifies the name of the request header value to set or change.

lpszHeaderValue

A null-terminated string which specifies the value of the header. If this value is NULL or an empty string, the request header will be removed.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetHeader** method adds or updates a custom request header that will be included with subsequent navigations. Request header names are not case-sensitive, and any leading or trailing whitespace is ignored. If the specified header value is NULL or an empty string, the header will be removed from the current list of custom headers. These changes only affect future requests; they do not modify headers already sent for the current navigation.

Certain standard headers are controlled by the underlying WebView2 control and may be ignored if set programmatically. Examples include `Host`, `Referer`, `Origin`, `User-Agent`, and most authentication headers. Attempting to override these may have no effect. For headers that can be set, the specified values will be merged with the default request headers used by WebView2 when making requests. If you wish to change the `User-Agent` header value, use the **SetUserAgent** method.

When defining custom request headers, it is recommended to use names prefixed with X- (for example, `X-Application-ID` or `X-Request-Token`). This convention helps distinguish application-specific headers from those defined by the HTTP standard, and reduces the likelihood of conflicts with headers that are managed internally by WebView2 or intermediaries such as proxies and gateways. While most modern systems will accept arbitrary header names, following this convention improves compatibility and avoids unexpected behavior.

If you need to clear all custom request headers that have been set, call **ClearHeaders** with the `WEBVIEW_HEADERS_REQUEST` option.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::SetIcon Method

```
BOOL SetIcon(
   HINSTANCE hResInst,
   LPCTSTR lpszIconName,
   UINT uResId,
   DWORD dwFlags
);

BOOL SetIcon(
   LPCTSTR lpszIconName,
   DWORD dwFlags
);
```

The **SetIcon** method sets custom large and small icons for the host window.

Parameters

hResInst

Handle to the module instance that contains the icon resource. If this parameter is NULL, the *lpszIconName* parameter should specify the path to an icon file.

lpszIconName

A null-terminated string that specifies the name of the icon resource or a path to an icon file. If this parameter is not NULL, it takes precedence over *uResId*.

uResId

An unsigned integer which specifies the numeric identifier of the icon resource within the module. This is used when *lpszIconName* is NULL.

dwFlags

An unsigned integer which specifies which icons to update. This must be one or more of the values shown in the following table.

Value	Description
WEBVIEW_ICON_BIG	Update the large window icon.
WEBVIEW_ICON_SMALL	Update the small window icon.
WEBVIEW_ICON_BOTH	Update both large and small icons.
WEBVIEW_ICON_DPI_AWARE	Choose the system-recommended small icon size for the current DPI when possible.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetIcon** method updates the large and/or small icons associated with the host window created using the **Create** or **Create** method. This is equivalent to sending the `WM_SETICON` message to the host window, but automatically handles both the large and small icons and supports DPI-aware sizing when requested.

If the *hRetInst* parameter is not NULL, either a string resource name (*lpszIconName*) or a numeric

resource identifier (*uResId*) can be specified to identify the icon. If both are provided, the string resource name takes precedence. The resource must exist in the module instance specified by *hResInst*. If neither *lpszIconName* nor *uResId* resolves to a valid icon, the method fails.

if the *hResInst* parameter is NULL, the *lpszIconName* parameter must specify the name of a file which contains the icon and the *uResId* parameter is ignored. It is recommended that you provide an absolute path to the icon file. If the path includes environment variables surrounded with percent (%) symbols, those variables will be automatically expanded. The file must use the standard Windows icon format.

The *dwFlags* parameter determines which icons are updated. You can set the large icon (used in the Alt-Tab interface and title bar), the small icon (shown in the window caption and taskbar), or both. If `WEBVIEW_ICON_DPI_AWARE` is specified, the system will choose an appropriate small icon size based on the current display scaling.

Windows icons are stored in the standard `.ico` file format, which can contain one or more images at different resolutions and color depths. When you compile icons into your application's resources and reference them by name or identifier, Windows will automatically select the most appropriate image for the current display settings. This allows a single icon resource to provide 16x16, 32x32, 48x48, or higher-resolution images within the same file.

The operating system chooses which image to use based on context and DPI scaling. For example, a 16x16 version may be displayed in a window caption or taskbar, while a 32x32 or 48x48 version may be shown in the Alt-Tab interface or Windows Explorer. If `WEBVIEW_ICON_DPI_AWARE` is specified, the system can pick a small-icon size that best matches the current DPI rather than always defaulting to 16x16.

Calling this method does not destroy the icon resource itself; ownership remains with the module that loaded it. If you dynamically create icons at runtime using **CreateIcon** or **LoadImage**, you are responsible for releasing them with **DestroyIcon** if they are no longer needed.

This method can only be used with windows created by this library, it cannot be used with windows you attach the browser to using the **Attach** method.

Example

```
// Define the path to the application's icon file
LPCTSTR pszIconFile = _T("%LocalAppData%\\MyApp\\MyApp.ico");

if (pWebView->Create(_T("about:blank"))
{
    // Set both large and small icons for the WebView host window
    pWebView->SetIcon(pszIconFile, WEBVIEW_ICON_BOTH | WEBVIEW_ICON_DPI_AWARE);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE or NULL. Those functions which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

GetErrorString, GetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::SetOption Method

```
BOOL SetOption(
   DWORD dwOption,
   BOOL bEnable
);
```

The **SetOption** method enables or disables a specific option.

Parameters

dwOption

An unsigned integer which specifies the option to be changed. Refer to the Options documentation for the list of available options. Only a single option may be specified; you cannot combine multiple option bitflags when calling this method.

bEnable

An integer value which specifies if the option should be enabled. If this value is non-zero, the option is enabled. If the value is zero, the option is disabled.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetOption** method enables or disables a single option for the browser instance attached to the specified host window. Each option corresponds to a specific feature or behavior such as scripting, zoom controls, developer tools, or privacy settings. Only one option bitflag may be specified in the *dwOption* parameter when calling this method. It is not valid to combine multiple option flags with a bitwise OR. If you need to change the state of multiple options, call this method once for each option you want to modify.

Some options can be changed dynamically at runtime, while others only take effect during creation of the browser control. For example, options related to scripting, dialogs, or developer tools can typically be toggled while the control is active. In contrast, options that affect the user data folder, profile isolation, or privacy mode must be set at creation time using **Attach** or **Create**. Attempting to change those options will fail once the browser control has been created.

If the method succeeds, the option state will be updated immediately. The application can verify the new state by calling **GetOption** or by retrieving all current options with **GetAllOptions**. If the method fails, no changes are made and extended error information can be obtained with **GetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

CWebView::SetTimeout Method

```
INT SetTimeout(
   INT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the browser will wait for a response from the server.

Parameters

nTimeout

The number of seconds to wait for the navigation to complete.

Return Value

If the method succeeds, the return value is zero. If the function fails, the return value is WEBVIEW_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **SetTimeout** method specifies the maximum number of seconds that the library should wait for a navigation request to complete. This timeout begins when navigation starts and ends when the navigation completes or fails.

If the timeout period is set to zero, the library does not enforce its own timer and instead relies on the default timeouts implemented by the WebView2 engine. These built-in timeouts automatically handle conditions such as slow DNS resolution, stalled connections, or unreachable servers, and generally behave in the same way as the Microsoft Edge browser.

If a non-zero timeout period is specified, the control will cancel the navigation if the internal timer exceeds that value and the page has not finished loading. When this occurs, the navigation is stopped and a timeout error is reported through the standard navigation event notifications. This allows applications to fail fast in cases where a site is not responding, rather than waiting for the browser's adaptive timeouts to expire.

Note that specifying a very large timeout value will not force the browser to wait indefinitely. The WebView2 engine may still apply its own internal maximums and terminate the navigation earlier if it decides the request cannot succeed. Applications should select timeout values that balance responsiveness and reliability.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

See Also

Attach, Create, GetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::SetUserAgent Method

```
BOOL SetUserAgent(
   LPCTSTR lpszUserAgent
);
```

The **SetUserAgent** method changes the default User-Agent string for this instance.

Parameters

lpszUserAgent

A null-terminated string which specifies the new User-Agent header value for subsequent requests. If this parameter is NULL or an empty string, the User-Agent header will revert back to the default value used by the Edge WebView2 control.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetUserAgent** method sets the string that will be sent in the User-Agent header for all subsequent HTTP requests made by this browser instance. This method should always be used to modify the User-Agent header value; you should not set the header directly using the **SetHeader** function.

Applications may want to override the default User-Agent in several scenarios:

- Requesting a mobile or tablet version of a site by providing a User-Agent string that identifies as a mobile browser.
- Emulating a different browser for testing purposes.
- Including custom product tokens identifying the host application to the server.

The general format of a User-Agent string follows the conventions described in RFC 9110:

```
User-Agent: product / version (comment) [ product / version ... ]
```

For example, a typical User-Agent string might look like:

```
Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like
Gecko) Chrome/140.0.0.0 Safari/537.36 Edg/140.0.0.0
```

This value is global to the instance. Once changed, it will remain in effect until explicitly reset or until the browser window is destroyed. When setting a custom User-Agent value, developers should ensure it is a syntactically valid string. Some websites may reject requests or provide degraded functionality if the value is malformed or omits key tokens.

If you want to change the User-Agent string to identify your application, it is recommended that you append your application name and version to the default value.

Example

```
// First, get the length of the current User-Agent string
INT nLength = pWebView->GetUserAgent(NULL, 0);
if (nLength <= 0)
{
    _tprintf(_T("Unable to get User-Agent string (error 0x%lx)\n"), pWebView-
```

```
>GetLastError());
    return;
}

// Allocate a buffer large enough to append the application name and version;
// note the leading space in the name to separate it from other tokens
const TCHAR szAppId[] = _T(" MyApp/1.0");

INT nTotalLength = nLength + (INT)_tcslen(szAppId) + 1;
LPTSTR lpszUserAgent = (LPTSTR)malloc(nTotalLength * sizeof(TCHAR));

if (!lpszUserAgent)
    return;

// Retrieve the current User-Agent value from the browser
if (pWebView->GetUserAgent(lpszUserAgent, nTotalLength) <= 0)
{
    _tprintf(_T("Failed to copy User-Agent string (error 0x%lx)\n"), pWebView-
>GetLastError());
    free(lpszUserAgent);
    return;
}

// Append our application identifier to the User-Agent string
_tcscat_s(lpszUserAgent, nTotalLength, szAppId);

// Update the User-Agent header with the new value
if (!pWebView->SetUserAgent(lpszUserAgent))
{
    _tprintf(_T("Failed to update the User-Agent string (error 0x%lx)\n"),
pWebView->GetLastError());
}
else
{
    _tprintf(_T("User-Agent successfully updated to:\n%s\n"), lpszUserAgent);
}

free(lpszUserAgent);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib
Unicode: Implemented as Unicode and ANSI versions

CWebView::SetZoomLevel Method

```
BOOL SetZoomLevel(
   INT nPercent
);
```

The **SetZoomLevel** method changes the current browser zoom level.

Parameters

nPercent

An integer which specifies the zoom level as a percentage. The minimum zoom level is 25 and the maximum is 400.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **SetZoomLevel** method changes the zoom level of the current browser window to the specified percentage. A zoom level of **100** represents the default size with no scaling applied. Larger values magnify the content, while smaller values reduce it.

The zoom percentage is constrained by the limits defined for the control. The minimum supported zoom level is **25** (25%) and the maximum is **400** (400%). If a value outside of this range is specified, it will be clamped to the nearest valid zoom level.

Changing the zoom level affects how the page content is displayed but does not alter the underlying document. This is equivalent to adjusting the zoom in a standard web browser. The new zoom level applies to the current browser instance and will remain in effect until it is changed again, or the instance is destroyed.

If the method fails, the zoom level remains unchanged. To query the current zoom level, call **GetZoomLevel**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::Show Method

```
BOOL Show();
```

The **Show** method shows the browser window.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **Show** method changes the visibility state of the browser control. When the browser was created as a top-level window using **Create**, this method internally calls the standard **ShowWindow** API to show the entire browser window.

When the browser is embedded in an existing host window using **Attach**, the method does not change the visibility of the parent window. Instead, it sends an internal message to the control to show the child window which contains the WebView2 browser. This enables the host application to enable visibility of the browser control independently of other controls in the same window.

The current visibility state can be queried using the **IsVisible** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

CWebView::WaitForEvent Method

```
BOOL WaitForEvent(
   UINT uEventId,
   DWORD dwMilliseconds
);
```

The **WaitForEvent** method waits until a specific event occurs or the timeout period expires.

Parameters

uEventId

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the Events documentation.

dwMilliseconds

The number of milliseconds to wait for the event to occur. If this amount of time elapses, the method returns. If this value is zero, the method will return successfully if the last event handled matches the ***uEventId*** parameter. This can be used to effectively poll the browser to determine if the specified event has occurred. This value may be `INFINITE` in which case the function will not return until the event occurs.

Return Value

If the method succeeds, the return value is non-zero. If the method fails or the timeout period is exceeded, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WaitForEvent** method suspends the calling thread until the specified event is raised or the timeout interval expires. While waiting, this method continues to process the thread's Windows message queue. This ensures that the user interface remains responsive and that event callbacks are able to execute on the correct thread.

Because messages are dispatched while this method blocks, application code must be written with the possibility of reentrancy in mind. That is, another message handler or event callback may run before **WaitForEvent** returns. If your application maintains shared state, you should use appropriate synchronization (critical sections, mutexes, etc.) to ensure it remains consistent.

This method should generally be called from the same thread that created the browser instance. Calling it from a worker thread that does not own a message loop may prevent events from being delivered. If you require a fully non-blocking design, you should use the event callback function specified when creating or attaching the browser window, rather than waiting synchronously.

You should not call **WaitForEvent** from within an event handler. Doing so can result in unexpected behavior, as the method will attempt to wait for additional events and dispatch messages while another event is already being processed. This may lead to subtle reentrancy issues or even deadlocks depending on the event ordering. Event handlers should return promptly, and synchronous waits should be performed only outside of callback contexts.

Note that if ***dwMilliseconds*** is set to `INFINITE`, the method will not return until the event occurs. To avoid unresponsive behavior, it is recommended you use a finite timeout value unless you are certain the event will always be signaled within a reasonable period.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Attach, Create, WaitUntilClosed, WebViewEventProc

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWebView::WaitUntilClosed Method

```
BOOL WaitUntilClosed(
   DWORD dwMilliseconds
);
```

The **WaitUntilClosed** method waits until the host window is closed or destroyed.

Parameters

dwMilliseconds

The number of milliseconds to wait for the browser window to close. If this amount of time elapses, the method returns. If this value is zero, the method will not enter a wait state and returns immediately. This value may be `INFINITE` in which case the function will not return until the window is closed.

Return Value

If the browser window has been closed, the return value is non-zero. If the timeout period has been exceeded or the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

The **WaitUntilClosed** method blocks the calling thread until the browser window created by **Create** has been closed or destroyed, or until the specified timeout interval has elapsed. Internally, this method waits on the thread handle associated with the WebView2 instance using the `WaitForSingleObject` function.

This method can only be used with browser windows that were created by this class using the **Create** method. It is not valid to call this method with an instance that was attached to a window using **Attach**. Attempting to do so will cause the method to fail.

Unlike **WaitForEvent**, this method does not process any Windows messages while it is waiting. As a result, it should not be used by applications that have a message loop, such as GUI programs that create windows with menus, controls, or dialog boxes. Because messages are not dispatched, the application's user interface may become unresponsive if this method is called from the primary UI thread.

This method is intended primarily for use in console applications or background worker threads, where it may be necessary to determine when the browser window has been closed by the user. GUI applications should use the `WEBVIEW_EVENT_WINDOW_DETACHED` event notification instead of calling this method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cshtmv12.lib

Create, WebViewEventProc

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WebViewEventProc Function

```
VOID CALLBACK WebViewEventProc(
    HWND hWndHost,
    UINT uEventId,
    WPARAM wParam,
    LPARAM lParam,
    DWORD_PTR dwParam
);
```

The **WebViewEventProc** function is an application-defined callback function that processes events generated by the browser.

Parameters

hWndHost

Handle to the client session.

uEventId

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the Events documentation.

wParam

An integer value that depends on the event context. This value is commonly used by an event to indicate success (1) or failure (0). It may also be used to indicate a transition in state. Refer to the events documentation for information about how this parameter may be used by a specific event.

lParam

An integer value that depends on the event context. This value is commonly used by an event to provide a status code or error code, depending whether the operation which raised the event succeeded or failed. Refer to the events documentation for information about how this parameter may be used by a specific event.

dwParam

A user-defined integer value which was provided when the event callback was specified. This is typically used to provide additional context to the event or associate the event with a specific object. If this user-defined parameter was not specified when the browser window was attached or created, this value will be zero.

Return Value

None.

Remarks

The class invokes the callback function whenever an event occurs. Applications are not required to implement event handlers for each event, and may choose to not provide any event handlers by passing NULL as the callback function parameter. A minimal implementation would typically create handlers for the `WEBVIEW_EVENT_NAVIGATION_STARTING` event which notifies the application when the browser is beginning to navigate to a new location, and the `WEBVIEW_EVENT_NAVIGATION_COMPLETED` event which indicates the navigation has completed.

When you attach a browser instance to an existing window, the callback function is always invoked on the same UI thread that owns that window, ensuring events are processed in the context of the caller's thread. However, if you create a new browser window using the **Create** method, a different thread manages the top-level window and message loop, and in that case the callback function is invoked on

the thread that owns the browser window rather than the thread that created it. This distinction is important when your application accesses shared data or resources from within the event handler. To avoid race conditions or undefined behavior, ensure that access to shared state is synchronized using mutexes, critical sections, or other appropriate synchronization primitives.

It is important to keep event handlers responsive. Because events are raised on the UI thread, long-running work in an event handler can block the user interface and stall navigation. Where possible, defer heavy operations to background threads. Avoid displaying modal dialogs or message boxes from within event handlers. Also note that some events may fire multiple times during a single navigation. For example, the security state can transition through several levels (unknown, neutral, secure, or warning) before settling on a final value. Applications should be written to handle these changes incrementally.

After the browser has been attached to a window, it is possible to change the event handler using the **EnableEvents** function. This changes the event handler for the browser instance, and from that point forward all event notifications will be routed to the new handler.

When defining an event handler within a C++ class, the event callback must be declared as a static function with the **__stdcall** calling convention. This is required because the library calls the handler just as it would with any Win32 API callback function, without knowledge of C++ instance objects. Non-static member functions include a hidden **this** pointer parameter, which makes their signature incompatible with the expected **WEBVIEWEVENTPROC** type. A common pattern is to pass the object's ***this*** pointer as the ***dwParam*** value, then cast it back inside the static callback function to access the instance. This preserves object-oriented design while still meeting the calling convention requirements of the API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

CWebView Data Structures

- WEBVIEW_DOWNLOAD_INFO
- WEBVIEW_SECURITY_INFO

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

WEBVIEW_DOWNLOAD_INFO

The **WEBVIEW_DOWNLOAD_INFO** structure contains information about the current state of a file download.

```
typedef struct _WEBVIEW_DOWNLOAD_INFO
{
    DWORD dwSize;
    DWORD dwFileId;
    DWORD dwStatus;
    ULARGE_INTEGER uiBytesTotal;
    ULARGE_INTEGER uiBytesCopied;
    DWORD dwTimeElapsed;
    TCHAR szFileName[260];
    TCHAR szFileUrl[2048];
} WEBVIEW_DOWNLOAD_INFO, *LPWEBVIEW_DOWNLOAD_INFO;
```

Members

dwSize

Specifies the size of the structure in bytes. This member must be initialized by the caller.

dwFileId

A unique identifier assigned to the download. This value can be used with functions such as **GetDownloadInfo** and **CancelDownload** to query or manage the download.

dwStatus

Indicates the current state of the download. This will be one of the following values:

Name	Description
WEBVIEW_DOWNLOAD_STARTED	The file download has started and is in-progress.
WEBVIEW_DOWNLOAD_COMPLETED	The file download has completed successfully.
WEBVIEW_DOWNLOAD_CANCELED	The file download has been canceled.
WEBVIEW_DOWNLOAD_FAILED	The file download failed due to a network error or other problem.

uiBytesTotal

The total size of the file, in bytes, as reported by the server. If the server did not provide the file size, this value may be zero.

uiBytesCopied

The number of bytes that have been downloaded so far. If the download has completed, this value will be equal to ***uiBytesTotal***. If the total size is unknown, this value still reflects the number of bytes received.

dwTimeElapsed

The elapsed time for the download, in milliseconds. For completed downloads this is the total time from start to finish. For active downloads this is the time since the download began. If the download has not started, this value is zero.

szFileName

A null-terminated string which specifies the local file name associated with the download. If the application has not changed the file path using **SetDownloadPath**, this will be the default file name

assigned by the browser. Typically the file will be stored in the current user's Downloads folder.

szFileUrl

A null-terminated string which specifies the URL of the file being downloaded. This is the fully qualified resource location provided to the browser.

Remarks

This structure provides detailed information about the progress and final state of a download managed by the browser. Before calling a function that populates this structure, such as **GetDownloadInfo**, the caller must set the ***dwSize*** member to the size of the structure. This ensures that applications remain compatible if new fields are added in future updates.

The ***uiBytesTotal*** and ***uiBytesCopied*** members allow applications to report download progress or log completed downloads. If the total file size is not known, ***uiBytesTotal*** will be zero and applications should base their progress reporting on the number of bytes copied alone.

The ***dwFileId*** member can be obtained from **WebViewEnumDownloads**, and is required to retrieve download information or to cancel a pending download.

Both ANSI (A) and Unicode (W) versions of this structure are provided. Applications that call **GetDownloadInfoW** will populate the wide-character members of the structure (such as ***szFileName*** and ***szFileUrl***) with UTF-16 encoded text. Applications that call **GetDownloadInfoA** will receive the ANSI version of the structure, where those same members are returned as UTF-8 encoded strings. The default **WEBVIEW_DOWNLOAD_INFO** macro maps to one or the other depending on whether the UNICODE preprocessor symbol is defined at compile time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h.
Unicode: Implemented as Unicode and ANSI versions

WEBVIEW_SECURITY_INFO

The **WEBVIEW_SECURITY_INFO** structure contains information about the current state of a secure connection.

```
typedef struct _WEBVIEW_SECURITY_INFO
{
    DWORD dwSize;
    DWORD dwFlags;
    DWORD dwLevel;
    TCHAR szProtocol[32];
    TCHAR szCipher[64];
    TCHAR szSubject[128];
    TCHAR szIssuer[128];
    FILETIME ftValidFrom;
    FILETIME ftValidTo;
} WEBVIEW_SECURITY_INFO, *LPWEBVIEW_SECURITY_INFO;
```

Members

dwSize

Specifies the size of the structure in bytes. This member must be initialized by the caller.

dwFlags

A bitmask that provides additional detail about the connection and certificate state. One or more values may be set to indicate conditions such as unencrypted content, use of weak algorithms, or general certificate errors. It may be one or more of the security flags listed below.

Name	Description
WEBVIEW_SECURITY_FLAG_NONE	No additional security indicators.
WEBVIEW_SECURITY_FLAG_UNENCRYPTED	Content is not encrypted.
WEBVIEW_SECURITY_FLAG_INSECURE	Site is insecure using outdated protocols or weak ciphers.
WEBVIEW_SECURITY_FLAG_CERT_WEAK	The certificate uses weak signatures.
WEBVIEW_SECURITY_FLAG_CERT_ERROR	The certificate is invalid. This is a general error condition.
WEBVIEW_SECURITY_FLAG_CERT_EXPIRED	The certificate expired but is otherwise valid.
WEBVIEW_SECURITY_FLAG_UNSAFE	The site is considered potentially unsafe (it failed reputation checks).

dwLevel

Overall security level for the current page. This is a summarized assessment intended for UI decisions, such as showing a lock icon or warning. It maps to one of the security level values listed below.

Name	Description
WEBVIEW_SECURITY_LEVEL_UNKNOWN	The security state could not be determined.
WEBVIEW_SECURITY_LEVEL_INSECURE	The page was retrieved using plain HTTP or the site has an invalid certificate.

WEBVIEW_SECURITY_LEVEL_WARNING	The page contains mixed content or only weak encryption is available.
WEBVIEW_SECURITY_LEVEL_NEUTRAL	Local content or the browser is in a transitional/loading state.
WEBVIEW_SECURITY_LEVEL_SECURE	The page was retrieved using HTTPS and the site has a valid certificate.

szProtocol

A null-terminated string that names the negotiated security protocol, such as `"TLS 1.3"` or `"TLS 1.2"`. For plain HTTP and local content, this string is empty.

szCipher

A null-terminated string that identifies the selected cipher suite, such as `"TLS_AES_128_GCM_SHA256"`. This string is empty if the site is not secure or local content is being displayed.

szSubject

A null-terminated string which contains the certificate subject. Typically this includes the common name (CN) and/or subject alternative name which matches the hostname.

szIssuer

A null-terminated string which specifies the certificate issuer. This is normally the name of the Certificate Authority (CA) which provided the certificate.

ftValidFrom

The date and time when the certificate was issued. This is represented as a standard FILETIME structure.

ftValidTo

The date and time when the certificate expires. This is represented as a standard FILETIME structure.

Remarks

The security information reflects the state of the last navigation. During navigation, values can be provisional; the final, authoritative values are available after the navigation completes. The ***dwLevel*** value is an assessment that may be adjusted by the engine for conditions such as mixed content, weak ciphers, or certificate problems. The ***dwFlags*** field provides the underlying reasons and may have multiple bitflags set. Applications should check for combinations (for example, a page might be secure overall but also report a warning flag if subresources were blocked).

For plain HTTP (unencrypted) pages, ***dwLevel*** is typically `WEBVIEW_SECURITY_LEVEL_INSECURE`. The ***szProtocol*** and ***szCipher*** members are empty strings and ***dwFlags*** will include `WEBVIEW_SECURITY_FLAG_UNENCRYPTED`. For HTTPS with a valid certificate, ***dwLevel*** is typically `WEBVIEW_SECURITY_LEVEL_SECURE`, and other members identify the negotiated TLS version and cipher suite. If the certificate is expired or otherwise invalid, the security level is downgraded and the corresponding certificate flags are set.

The ***szSubject*** and ***szIssuer*** strings are for display and logging purposes; certificate parsing and validation is handled by the browser. The validity timestamps (***ftValidFrom*** and ***ftValidTo***) are provided to enable simple checks, but applications do not need to implement certificate validation logic themselves.

Set the ***dwSize*** member to the actual size of the structure before calling **GetSecurityInfo**. If the caller passes a different size than expected, the method will fail or only populate the fields known to that size.

Both ANSI (`A`) and Unicode (`W`) variants are provided. When compiling with `UNICODE` defined, the `TCHAR` strings are UTF-16. In ANSI builds, they are UTF-8. The **GetSecurityInfo** macro resolves to the appropriate version based on the project's character set.

Because the browser can update security state as additional resources are loaded, applications that display a security indicator should refresh it on navigation completion events. Treat the security level as ordered and do not "upgrade" a previously observed state during the same navigation unless a later callback provides a higher confidence result. Note that it's also possible for the security level to be `WEBVIEW_SECURITY_LEVEL_SECURE` during navigation, but may be downgraded to `WEBVIEW_SECURITY_LEVEL_WARNING` when navigation completes due to mixed content in the page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h.
Unicode: Implemented as Unicode and ANSI versions

CWebView Constants

Name	Value	Description
Options		
WEBVIEW_OPTION_ENABLE_NOTHING	0	No options enabled. This is very restrictive and will not permit the use of JavaScript.
WEBVIEW_OPTION_ENABLE_ACCELERATORS	0x00001	Enables common keyboard accelerators (e.g., Ctrl+L, F5). Accelerator key events are surfaced via `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS`.
WEBVIEW_OPTION_ENABLE_CONTEXT_MENU	0x00002	Shows the built-in right-click context menu. Clear this to fully suppress the menu.
WEBVIEW_OPTION_ENABLE_STATUSBAR	0x00004	Displays status text (e.g., link targets, loading state) in the bottom-left status area.
WEBVIEW_OPTION_ENABLE_ZOOM_CONTROL	0x00008	Allows user zoom (Ctrl+Plus/Minus, Ctrl+mouse-wheel). If disabled, zoom remains fixed unless set by API.
WEBVIEW_OPTION_ENABLE_AUDIO	0x00010	Permits audio playback in the WebView. Disable to mute at the engine level.
WEBVIEW_OPTION_ENABLE_AUTOFILL	0x00020	Enables form autofill suggestions where available.
WEBVIEW_OPTION_ENABLE_PASSWORD_AUTOSAVE	0x00040	Allows the engine to offer saving website passwords/credentials.
WEBVIEW_OPTION_ENABLE_PRIVACY	0x00080	Enable private browsing
WEBVIEW_OPTION_ENABLE_SCRIPTING	0x00100	Enables JavaScript execution. Disabling blocks script evaluation and script-initiated behaviors.
WEBVIEW_OPTION_ENABLE_DIALOGS	0x00200	Allows script dialogs (alert/confirm/prompt) and related UI. Disable to suppress script-driven dialogs.
WEBVIEW_OPTION_ENABLE_DEVTOOLS	0x00400	Permits opening Developer Tools (e.g., F12). Disable to block DevTools access.
WEBVIEW_OPTION_ENABLE_NEW_WINDOWS	0x00800	Allows the creation of new popup windows
WEBVIEW_OPTION_ENABLE_MESSAGES	0x01000	Enables `window.chrome.webview.postMessage` communication from the page to the host.
WEBVIEW_OPTION_ENABLE_EXTERNAL_DROP	0x02000	Allows external drag-and-drop (e.g., files from Explorer) into the WebView surface.
WEBVIEW_OPTION_RESTRICT_NAVIGATION	0x10000	Blocks navigations after the initial page

		load unless explicitly permitted by the host.
WEBVIEW_OPTION_RESTRICT_DOWNLOADS	0x20000	Blocks attempts to download files through the browser.
WEBVIEW_OPTION_EXCLUSIVE_PROFILE	0x40000	Require exclusive use of the user data folder
WEBVIEW_OPTION_TRANSPARENT_BACKGROUND	0x80000	Renders with a transparent background where content allows; the host window should support composition.
WEBVIEW_OPTION_ENABLE_DEFAULT	0x0031F	Convenience preset enabling the most common interactive features for typical app scenarios.
Navigation Flags		
WEBVIEW_NAVIGATION_REDIRECTED	0x0001	The navigation was the result of an HTTP redirect.
WEBVIEW_NAVIGATION_USER_INITIATED	0x0002	Navigation began from a user gesture rather than being initiated by a script.
WEBVIEW_NAVIGATION_LOCAL_DATA	0x1000	Content was served using local data rather than a full network fetch.
Accelerator Key Flags		
WEBVIEW_ACCELERATOR_KEY_DOWN	0x0001	Indicates an accelerator key-down event.
WEBVIEW_ACCELERATOR_KEY_UP	0x0002	Indicates an accelerator key-up event.
WEBVIEW_ACCELERATOR_KEY_SYSTEM	0x0004	Indicates a system key event using the Alt key, similar to `WM_SYSKEY`.
History Movement Flags		
WEBVIEW_MOVE_BACKWARD_ENABLED	0x0001	Backward navigation is currently available.
WEBVIEW_MOVE_FORWARD_ENABLED	0x0002	Forward navigation is currently available.
Navigation Error Codes		
WEBVIEW_ERROR_NONE	0	No error.
WEBVIEW_ERROR_CERTIFICATE_COMMON_NAME	1	Certificate common name mismatch.
WEBVIEW_ERROR_CERTIFICATE_EXPIRED	2	Certificate is expired.
WEBVIEW_ERROR_INVALID_CLIENT_CERTIFICATE	3	Invalid or untrusted client certificate.
WEBVIEW_ERROR_CERTIFICATE_REVOKED	4	Certificate has been revoked.
WEBVIEW_ERROR_INVALID_CERTIFICATE	5	Certificate is invalid for another reason.
WEBVIEW_ERROR_SERVER_UNREACHABLE	6	Cannot reach the server/host.
WEBVIEW_ERROR_TIMEOUT	7	Operation timed out.
WEBVIEW_ERROR_INVALID_SERVER_RESPONSE	8	Server returned an invalid or unexpected response.

WEBVIEW_ERROR_CONNECTION_ABORTED	9	Connection aborted by the server or network.
WEBVIEW_ERROR_CONNECTION_RESET	10	Connection was reset.
WEBVIEW_ERROR_DISCONNECTED	11	Disconnected during the operation.
WEBVIEW_ERROR_CANNOT_CONNECT	12	Failed to establish a connection.
WEBVIEW_ERROR_HOST_NAME_NOT_RESOLVED	13	DNS resolution failed for the host.
WEBVIEW_ERROR_OPERATION_CANCELED	14	Operation was canceled by the user or host.
WEBVIEW_ERROR_REDIRECT_FAILED	15	Redirection failed.
WEBVIEW_ERROR_UNEXPECTED_ERROR	16	An unexpected error occurred.
WEBVIEW_ERROR_CREDENTIALS_REQUIRED	17	Authentication credentials are required.
WEBVIEW_ERROR_PROXY_AUTHENTICATION_REQUIRED	18	Proxy authentication is required.
Events		
WEBVIEW_EVENT_WINDOW_ATTACHED	1	attached to the host window. This is the first event that fires after the browser is created.
WEBVIEW_EVENT_WINDOW_DETACHED	2	detached from the host window. This is the last event that fires before the browser is destroyed.
WEBVIEW_EVENT_FOCUS_CHANGED	3	focus changed. The ***wParam*** value indicates if focus was gained (1) or lost (0).
WEBVIEW_EVENT_ACCELERATOR_KEYPRESS	4	Accelerator key event. The ***wParam*** value is the virtual-key code and ***lParam*** is the accelerator flags.
WEBVIEW_EVENT_NAVIGATION_STARTING	5	Navigation starting. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the navigation flags.
WEBVIEW_EVENT_NAVIGATION_COMPLETED	6	Navigation completed. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the error code.
WEBVIEW_EVENT_SECURITY_CHANGED	7	Security level changed. The ***wParam*** is the security level and ***lParam*** is the security flags.
WEBVIEW_EVENT_HISTORY_CHANGED	8	Back/forward availability changed. The ***wParam*** value is the history movement flags.
WEBVIEW_EVENT_DOWNLOAD_STARTING	9	A download has been initiated. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the file ID.
WEBVIEW_EVENT_DOWNLOAD_COMPLETED	10	A download has completed. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the file ID.

WEBVIEW_EVENT_MESSAGE_RECEIVED	11	Message received from a script on the page.
WEBVIEW_EVENT_SCRIPT_COMPLETED	12	Script execution completed. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the user-defined parameter.
Status Flags		
WEBVIEW_STATUS_SESSION_IDLE	0	No navigation in progress, the browser is in an idle state.
WEBVIEW_STATUS_NAVIGATING	0x0001	Currently navigating to a new location.
WEBVIEW_STATUS_NAVIGATION_ERROR	0x0002	The navigation failed due to an error.
WEBVIEW_STATUS_NAVIGATION_CANCELED	0x0004	The navigation was canceled by the user or host.
WEBVIEW_STATUS_NAVIGATION_TIMEOUT	0x0008	The navigation exceeded the configured timeout period.
WEBVIEW_STATUS_NAVIGATION_BLOCKED	0x0010	The navigation was blocked by policy.
WEBVIEW_STATUS_CONNECTION_FAILED	0x0100	The connection attempt failed or hostname was invalid.
WEBVIEW_STATUS_CONNECTION_ABORTED	0x0200	The connection was aborted or reset.
WEBVIEW_STATUS_SECURITY_WARNING	0x1000	The page includes insecure/mixed content or weak encryption was detected.
Icon Flags		
WEBVIEW_ICON_BIG	0x0001	Update the large window icon.
WEBVIEW_ICON_SMALL	0x0002	Update the small window icon.
WEBVIEW_ICON_BOTH	0x0003	Update both large and small icons.
WEBVIEW_ICON_DPI_AWARE	0x0100	Choose the system-recommended small icon size for the current DPI when possible.
Navigate Flags		
WEBVIEW_NAVIGATE_DEFAULT	0	Default navigation behavior.
WEBVIEW_NAVIGATE_SAFE_URL	0x0001	Applies additional URL safety checks and normalization before navigating.
Header Type Flags		
WEBVIEW_HEADERS_REQUEST	0x0001	Specifies custom request headers supplied by the client.
WEBVIEW_HEADERS_RESPONSE	0x0002	Specifies headers returned by the server in the last response.
Print Dialog Flags		

WEBVIEW_PRINT_DIALOG_DEFAULT	0	Use Edge's print preview dialog, equivalent to the Ctrl+P experience.
WEBVIEW_PRINT_DIALOG_SYSTEM	0x0001	Use the native system print dialog. Does not include print preview.
File Types (Save Document)		
WEBVIEW_FILE_TYPE_DEFAULT	0	Save using a format inferred from the file extension.
WEBVIEW_FILE_TYPE_TEXT	1	Save the document as a plain text file.
WEBVIEW_FILE_TYPE_HTML	2	Save the document as an HTML file.
WEBVIEW_FILE_TYPE_JSON	3	Save the document as JSON formatted string with reserved characters encoded.
WEBVIEW_FILE_TYPE_MHTML	4	Save the document as an MHTML single-file archive which includes all page assets.
WEBVIEW_FILE_TYPE_PDF	5	Save the document as a PDF file.
WEBVIEW_FILE_TYPE_JPEG	101	Save the current view as a JPEG image.
WEBVIEW_FILE_TYPE_PNG	102	Save the current view as a PNG image.
WEBVIEW_FILE_TYPE_WEBP	103	Save the current view as a WEBP image.
Download Status		
WEBVIEW_DOWNLOAD_STARTED	1	The file download has started and is in-progress.
WEBVIEW_DOWNLOAD_COMPLETED	2	The file download has completed successfully.
WEBVIEW_DOWNLOAD_CANCELED	3	The file download has been canceled.
WEBVIEW_DOWNLOAD_FAILED	4	The file download failed due to a network error or other problem.
Zoom		
WEBVIEW_ZOOM_MIN_PERCENT	25	Minimum zoom level as a percentage.
WEBVIEW_ZOOM_MAX_PERCENT	400	Maximum zoom level as a percentage.
WEBVIEW_ZOOM_DEFAULT	100	Default zoom level as a percentage.
Security Levels		
WEBVIEW_SECURITY_LEVEL_UNKNOWN	0	The security state could not be determined.
WEBVIEW_SECURITY_LEVEL_INSECURE	1	The page was retrieved using plain HTTP or the site has an invalid certificate.
WEBVIEW_SECURITY_LEVEL_WARNING	2	The page contains mixed content or only weak encryption is available.
WEBVIEW_SECURITY_LEVEL_NEUTRAL	3	Local content or the browser is in a transitional/loading state.

WEBVIEW_SECURITY_LEVEL_SECURE	4	The page was retrieved using HTTPS and the site has a valid certificate.
WEBVIEW_SECURITY_LEVEL_LOW	1	Alias of `WEBVIEW_SECURITY_LEVEL_WARNING`.
WEBVIEW_SECURITY_LEVEL_HIGH	4	Alias of `WEBVIEW_SECURITY_LEVEL_SECURE`.
Security Flags		
WEBVIEW_SECURITY_FLAG_NONE	0	No additional security indicators.
WEBVIEW_SECURITY_FLAG_UNENCRYPTED	0x0001	Content is not encrypted.
WEBVIEW_SECURITY_FLAG_INSECURE	0x0002	Site is insecure using outdated protocols or weak ciphers.
WEBVIEW_SECURITY_FLAG_CERT_WEAK	0x0004	The certificate uses weak signatures.
WEBVIEW_SECURITY_FLAG_CERT_ERROR	0x0008	The certificate is invalid. This is a general error condition.
WEBVIEW_SECURITY_FLAG_CERT_EXPIRED	0x0010	The certificate expired but is otherwise valid.
WEBVIEW_SECURITY_FLAG_UNSAFE	0x0020	The site is considered potentially unsafe (it failed reputation checks).

CWebView Class Events

The class library reports state changes and notifications through a user-defined callback function which is specified when a browser instance is created or attached to a window. For more information, refer to the **WebViewEventProc** function. It is not required for an application to implement handlers for each event. When there is no event handler for a specific event, the browser takes its default action for that event. For example, if your application does not implement a handler for the `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS` event then all accelerator key events are processed normally by the browser control.

Event Constants

Name	Description
WEBVIEW_EVENT_WINDOW_ATTACHED	This event is raised after the WebView2 control has been successfully attached to the specified host window. At this point the browser environment has been created, the controller has been initialized, and the browser instance is ready to accept navigation requests and configuration changes. Applications often use this event to perform initialization tasks such as setting a custom user agent, applying option flags, or starting the first navigation to a default URL. The event confirms that the control is operational and that subsequent API calls will succeed. The *wParam* value indicates success (1) or failure (0). If the browser could not be attached to the window, the *lParam* value will contain the HRESULT code returned by the browser's COM interface.
WEBVIEW_EVENT_WINDOW_DETACHED	This event occurs when the WebView2 control has been detached from its host window, either because the host window is being destroyed or because the application explicitly requested detachment. After this event has fired, the instance is no longer valid and should not be used for navigation or script execution. Applications typically use this event to clean up resources associated with the WebView, save state, or update their user interface to reflect that the browser view is no longer available. Any references to the WebView instance should be considered invalid after detachment.
WEBVIEW_EVENT_FOCUS_CHANGED	This event is raised whenever the browser window gains or loses keyboard focus relative to its host window. The *wParam* value indicates if focus was gained (1) or lost (0). This allows the application to track when user input is directed to the embedded browser versus other controls in the window. For example, you might use this event to update menu state, adjust shortcut key handling, or provide visual cues when the browser window is active.
WEBVIEW_EVENT_ACCELERATOR_KEYPRESS	This event is raised when the user presses an accelerator key combination such as the arrow keys, Page Up and Page Down, Insert, Delete, or other keys that the embedded

	browser normally handles. The ***wParam*** value is the virtual-key code and ***lParam*** is the accelerator flags. The event gives your application a chance to intercept these keystrokes before they are processed by the browser. This is especially useful when you want to provide custom navigation, prevent certain keys from being used, or integrate the control with application-level keyboard shortcuts. To prevent the default behavior being taken by the browser, call the **KeyEventHandled** method from within this event.
WEBVIEW_EVENT_NAVIGATION_STARTING	This event is fired when a new navigation request begins. The ***wParam*** value indicates success (1) or failure (0) and ***lParam*** is the navigation flags. The event is raised before any network request is made, ensuring that no data is sent until the handler has had a chance to approve or deny the navigation. The **GetNavigationUrl** method can be called to determine the new URL the browser is navigating to and the **CancelNavigation** method can be used to prevent the navigation.
WEBVIEW_EVENT_NAVIGATION_COMPLETED	This event is raised when a navigation request has finished loading. It is triggered regardless of whether the navigation succeeded or failed, with the ***wParam*** value indicating success (1) or failure (0). If the navigation has failed, the ***lParam*** value is the error code. Applications typically handle this event to update their UI once the content has loaded, or to implement custom error handling when navigation fails. Because the event always fires, even on errors, it is a reliable notification point for the end of a navigation sequence.
WEBVIEW_EVENT_SECURITY_CHANGED	This event occurs when the security level of the current connection changes. The ***wParam*** value is the security level and ***lParam*** is the security flags. For example, the level may change from neutral to secure once a certificate has been validated, or from secure to warning if mixed content is detected. Additional information about the state of the connection can be obtained by calling the **GetSecurityInfo** method. Applications often use this event to update visual indicators such as a padlock icon or to apply additional security-related policies. It is important to note that this event may be raised multiple times during a single navigation, and earlier values should be discarded in favor of the most recent state.
WEBVIEW_EVENT_HISTORY_CHANGED	This event occurs whenever the browsing history changes. The ***wParam*** value is the history movement flags. Navigating to a new page, using the **GoBack** or **GoForward** methods, or programmatically calling navigation methods can trigger this event. Your application can respond by enabling or disabling UI elements such as toolbar buttons depending on whether it is possible to go

	back or forward.
WEBVIEW_EVENT_DOWNLOAD_STARTING	This event occurs when a file download is initiated either by a user clicking on a link or navigating to a URL which specifies content that cannot be rendered in the browser. The *wParam* value indicates success (1) or failure (0) and *lParam* is the unique file identifier which can be used to identify the specific download. This identifier can be used with the **GetDownloadInfo** method to obtain information about the download in progress.
WEBVIEW_EVENT_DOWNLOAD_COMPLETED	This event occurs when a file download has completed. The *wParam* value indicates success (1) or failure (0) and *lParam* is the unique file identifier. If the file download is canceled, it is considered to be a failed download. The **GetDownloadInfo** method can be used to obtain information about the download, such as the total number of bytes copied, how much time elapsed and the full path of the local file that was created.
WEBVIEW_EVENT_MESSAGE_RECEIVED	This event occurs when a message is posted from JavaScript code in the web page using `window.chrome.webview.postMessage`. The message is delivered as a string, which can be retrieved using the **GetWebMessage** method. The message may include structured data such as JSON or it may be a simple JSON formatted string. This event provides a two-way communication channel between the page content and the host application, allowing developers to implement hybrid scenarios where the web page can notify the native host of user actions, requests, or state changes. If messages are not enabled, this event will not be raised.
WEBVIEW_EVENT_SCRIPT_COMPLETED	This event is raised when a script execution initiated by the application completes. The *wParam* value indicates success (1) or failure (0) and *lParam* is the user-defined parameter provided when the **AsyncExecute** method was called. The **GetWebResult** method can be called to obtain the result of the script execution. If the script contained errors or could not be executed, the status will reflect a failure condition. Applications typically use this event to retrieve values from the page, execute custom logic in response to script results, or detect when asynchronous script operations have finished. Because script execution is asynchronous, this event is the definitive way to know when a script call has finished.

Remarks

Some events, such as `WEBVIEW_EVENT_NAVIGATION_STARTING` and `WEBVIEW_EVENT_ACCELERATOR_KEYPRESS`, allow your application to influence behavior by canceling an action or handling a keypress. Others, like `WEBVIEW_EVENT_HISTORY_CHANGED` or `WEBVIEW_EVENT_SECURITY_CHANGED`, are informational and allow you to update user interface

elements or record state.

If your application does not enable specific options (such as allowing scripts, dialogs, or message passing), the corresponding events will not be raised. For example, if messages are disabled, the `WEBVIEW_EVENT_MESSAGE_RECEIVED` event will never occur. This makes it important to configure options appropriately for the scenarios you wish to support.

CWebView Class Options

When creating or attaching a WebView instance, a set of options can be specified that control its behavior. These options are defined as a collection of bitmask flags that can be combined together. The *dwOptions* parameter passed to methods such as **Create** or **Attach** may include one or more of these values.

Option Constants

Name	Description
WEBVIEW_OPTION_ENABLE_ACCELERATORS	Enables support for browser accelerator keys such as function keys (F1 for help, F5 for refresh, etc.) and standard navigation shortcuts. With this option enabled, the WebView responds to built-in key combinations in the same way a full browser does. Disabling it prevents end users from triggering those behaviors, which may be desirable in kiosk or custom application scenarios where you want to restrict keyboard input to only what your application explicitly supports.
WEBVIEW_OPTION_ENABLE_CONTEXT_MENU	Enables the default right-click context menu provided by the browser. This menu exposes commands such as Back, Forward, Reload, and View Source. In an embedded control, this may not always be appropriate since it can expose functionality you do not want available to users. Disabling this option suppresses the default context menu entirely, leaving you free to implement your own context handling if needed.
WEBVIEW_OPTION_ENABLE_STATUSBAR	Shows the built-in status bar, which normally appears at the bottom left of the control when hovering over a link. It provides basic feedback about navigation targets but has no interactive features. In a minimal UI, you may prefer to disable this so the embedded control presents only the rendered page without browser chrome. Developers can still query navigation state programmatically regardless of this setting.
WEBVIEW_OPTION_ENABLE_ZOOM_CONTROL	Enables zoom support through keyboard and mouse input (Ctrl+Plus, Ctrl+Minus, Ctrl+Mouse Wheel). With this enabled, end users can adjust the document's scaling factor directly. When disabled, zooming is locked at 100%, ensuring that the page is always displayed at its natural size. This can be useful in applications where layout fidelity is important and user scaling could cause unexpected clipping or misalignment.
WEBVIEW_OPTION_ENABLE_AUDIO	Enables audio playback within the WebView. When this option is disabled, the control is effectively

	muted and no sound is produced, regardless of the page content. Applications that need to enforce silent operation, such as monitoring dashboards, may want to leave this option disabled. This flag maps to the runtime's muting APIs and can be toggled dynamically after creation.
WEBVIEW_OPTION_ENABLE_AUTOFILL	Enables the use of autofill for HTML forms. When enabled, the control can suggest previously entered values for form fields such as names, addresses, or other personal data. Disabling this option prevents the runtime from remembering or suggesting values, which is often preferable in scenarios where privacy is a concern or where data entry should always be manual.
WEBVIEW_OPTION_ENABLE_PASSWORD_AUTOSAVE	Enables automatic saving of credentials in the runtime's password store. When this option is set, the control prompts to save usernames and passwords entered in forms, making them available for later autofill. While convenient for end users, applications embedding the control may choose to disable this to avoid storing sensitive information on the client system, particularly in enterprise or shared environments.
WEBVIEW_OPTION_ENABLE_PRIVACY	Enables the equivalent of InPrivate browsing in Microsoft Edge or Incognito mode in Google Chrome. If this option is specified, the user profile is not persisted beyond the current session. Browsing and search history will not be preserved, all cookies are temporary, data entered in form fields will not be saved and passwords will not be stored. Any general location information used by the browser is cleared when the instance is closed. This option can only be specified when the browser instance is created or attached to a window. You cannot enable privacy mode after a browser session has started.
WEBVIEW_OPTION_ENABLE_SCRIPTING	Enables JavaScript execution within the WebView. Nearly all modern websites depend on JavaScript, so disabling this option will significantly limit what pages can display or function correctly. However, for controlled content where scripting is unnecessary or potentially unsafe, disabling this can enforce a higher level of security and prevent active content from running. Some other options, such as enabling dialogs shown in the browser or receiving messages from the web application requires scripting to be enabled. If your application is only displaying local, static HTML content then you may not need to enable this option.

WEBVIEW_OPTION_ENABLE_DIALOGS	Enables support for default script dialogs such as alert, confirm, and prompt. If disabled, those dialogs are suppressed and scripts attempting to display them will fail silently. This prevents unexpected modal UI from appearing in your application, but may also break sites that rely on these dialogs for basic interaction. If you enable scripting, it is recommended that you enable this option as well.
WEBVIEW_OPTION_ENABLE_DEVTOOLS	Enables the integrated Developer Tools (DevTools) interface. When enabled, users can press standard shortcuts (such as F12) or use the context menu to open the DevTools window and inspect the page. For production applications, you may want to disable this to prevent end users from inspecting or modifying content. During development or debugging, enabling it provides the same diagnostic features found in Microsoft Edge.
WEBVIEW_OPTION_ENABLE_NEW_WINDOWS	Enables the creation of new popup windows by scripts and/or support the creation of new browser windows (for example, if a link target is "_blank"). By default, navigations that would open a new window are redirected internally so the new page is displayed within the same browser window. Note that if you permit the creation of new popup windows, it can shift focus away from your main browser window. There is no mechanism in the API to enumerate the child popup windows and they are independent of the window attached to the browser.
WEBVIEW_OPTION_ENABLE_MESSAGES	Enables communication between the web page and the host application through the **`window.chrome.webview.postMessage`** API. This allows JavaScript running in the page to send messages back to your application, enabling advanced integration scenarios. If disabled, such messages are blocked and the corresponding events will never occur in your host code. This is commonly enabled when embedding custom HTML user interfaces that need to exchange data with the native application.
WEBVIEW_OPTION_ENABLE_EXTERNAL_DROP	Enables the WebView to accept external file drops, such as dragging and dropping a file from Windows Explorer into the control. If disabled, drop operations are ignored and the page cannot receive file input in this way. Applications that want to support drag-and-drop uploads or similar features can enable this option, but in contexts where security is important it may be best to disable it to prevent accidental or malicious file submission.

	Accepting dropped files requires scripting to be enabled.
WEBVIEW_OPTION_RESTRICT_NAVIGATION	Restricts navigation after the initial page has loaded. Attempts to navigate beyond this initial page will automatically be canceled when this option is specified. This is useful for scenarios like embedded help viewers, dashboards, or authentication windows where you want to confine the user to a specific site or document. The restriction applies to both user-initiated actions such as clicking links and programmatically navigating to a new URL.
WEBVIEW_OPTION_RESTRICT_DOWNLOADS	Prevents the browser from downloading files. Attempts to download a file will be immediately canceled and no download UI will be displayed to the user. Normally, downloads are permitted and files will be stored in the current user's Downloads folder. If you wish to selectively prevent certain types of downloads, you can monitor the download events and decide individually whether the file should be downloaded based on the name, extension or location.
WEBVIEW_OPTION_EXCLUSIVE_PROFILE	Requires exclusive use of the default user profile stored in the data folder selected when the browser instances is created. If this option is enabled, the browser will attempt to obtain an exclusive lock on the profile which stores the current user's cached pages, browser history, cookies and passwords. Normally this session data can be shared with other processes, but this option ensures that only the current process may access it while the browser session is active. If another browser session is sharing the same data, the creation process will fail. This option can only be specified when the browser instance is created or attached to a window.
WEBVIEW_OPTION_TRANSPARENT_BACKGROUND	Configures the WebView to render with a transparent background rather than an opaque surface. This allows the host application to blend the browser content with custom UI elements or backgrounds. It is particularly useful for overlay scenarios, custom skins, or when compositing content with layered windows. Developers should be aware that transparent rendering may affect performance on some systems and should test carefully in their application's UI context.

Remarks

Most of these options can be toggled dynamically at runtime using the **SetOption** method, although some are only effective when set at creation time. Options are applied by mapping directly to the

underlying WebView2 runtime's settings and may depend on a minimum runtime version. If an option is not supported by the installed version of the WebView2 runtime, calls to enable it will fail silently.

The **WEBVIEW_OPTION_ENABLE_DEFAULT** macro combines the most commonly used options, including accelerator keys, context menu, status bar, zoom control, audio, scripting, and dialogs. This provides a browser-like experience suitable for most applications. Developers with stricter requirements for security or a highly customized UI should select individual flags instead of relying on the defaults. For applications in managed environments, kiosk systems, or where privacy is a concern, it is recommended to only enable those specific features which are required for normal operation.

The **WEBVIEW_OPTION_ENABLE_PRIVACY** option causes the WebView2 instance to create a unique, temporary user data folder with a new user profile. It will not have access to the browsing history, saved form data or passwords for any other instance. When the browser is closed or detached from its host window, that temporary profile will be automatically deleted. There can be a minor performance cost related to creating and deleting these temporary profiles, particularly if a large amount of data has been cached during the session.

As with private browsing using a web browser like Microsoft Edge or Google Chrome, enabling privacy does not prevent an employer or Internet provider from being able to monitor your activity. Websites can still track your behavior, particularly if scripting is enabled because most sites use scripts as part of their analytics tracking. Private browsing will block third-party cookies by default, but otherwise permits the use of cookies during the session. Any data stored using the HTML5 web storage APIs will also be deleted when a private session ends.

Whois Protocol Class Library

Request registration information for an Internet domain name.

Reference

- Class Methods
- Error Codes

Library Information

Class Name	CWhoisClient
File Name	CSWHOV12.DLL
Version	12.0.3024.1286
LibID	A3CFB881-EB11-4A10-95A2-C357BF955F74
Import Library	CSWHOV12.LIB
Dependencies	None
Standards	RFC 954

Overview

The Whois protocol library provides an interface for requesting registration information for an Internet domain name. When a domain name is registered, the organization that registers the domain must provide certain contact information along with technical information such as the primary name servers for that domain. The library provides an API for requesting that information and returning it to the program so that it can be displayed or processed. This library would be most commonly used to query the server at **whois.internic.net** to obtain information about a specific Internet domain name or an administrative contact at that domain.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing

applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Whois Protocol Class Methods

Class	Description
CWhoisClient	Constructor which initializes the current instance of the class
~CWhoisClient	Destructor which releases resources allocated by the class
Method	Description
AttachHandle	Attach the specified client handle to this instance of the class
AttachThread	Attach the specified client handle to another thread
Cancel	Cancel the current blocking operation
Connect	Connect to the specified server
DetachHandle	Detach the handle for the current instance of this class
DisableEvents	Disable asynchronous event notification
DisableTrace	Disable logging of network function calls
Disconnect	Disconnect from the current server
EnableEvents	Enable asynchronous event notification
EnableTrace	Enable logging of network function calls to a file
FreezeEvents	Suspend or resume event handling by the calling process
GetErrorString	Return a description for the specified error code
GetHandle	Return the client handle used by this instance of the class
GetLastError	Return the last error code
GetStatus	Return the current client status.
GetTimeout	Return the number of seconds until an operation times out
IsBlocking	Determine if the client is blocked, waiting for information
IsConnected	Determine if the client is connected to the server
IsInitialized	Determine if the class has been successfully initialized
IsReadable	Determine if there is data available to be read from the server
Read	Read data returned by the server
RegisterEvent	Register an event callback function
Search	Search for the specified record
SetLastError	Set the last error code
SetTimeout	Set the number of seconds until an operation times out
ShowError	Display a message box with a description of the specified error
WhoisEventProc	Callback method that processes events generated by the client

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::CWhoisClient Method

```
CWhoisClient();
```

The **CWhoisClient** constructor initializes the class library and validates the license key at runtime.

Remarks

If the constructor fails to validate the runtime license, subsequent methods in this class will fail. If the product is installed with an evaluation license, then the application will only function on the development system and cannot be redistributed.

The constructor calls the **WhoisInitialize** function to initialize the library, which dynamically loads other system libraries and allocates thread local storage. If you are using this class within another DLL, it is important that you do not create or destroy an instance of the class from within the **DllMain** function because it can result in deadlocks or access violation errors. You should not declare static or global instances of this class within another DLL if it is linked with the C runtime library (CRT) because it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

~CWhoisClient, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::~CWhoisClient

```
~CWhoisClient();
```

The **CWhoisClient** destructor releases resources allocated by the current instance of the **CWhoisClient** object. It also uninitializes the library if there are no other concurrent uses of the class.

Remarks

When a **CWhoisClient** object goes out of scope, the destructor is automatically called to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all handles that were created for the client session are destroyed.

The destructor is not called explicitly by the application.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CWhoisClient

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::AttachHandle Method

```
VOID AttachHandle(
   HCLIENT hClient
);
```

The **AttachHandle** method attaches the specified client handle to the current instance of the class.

Parameters

hClient

The handle to the client session that will be attached to the current instance of the class object.

Return Value

None.

Remarks

This method is used to attach a client handle created outside of the class using the SocketTools API. Once the client handle is attached to the class, the other class member functions may be used with that client session.

If a client handle has already been created for the class, that handle will be released when the new handle is attached to the class object. If you want to prevent the previous client session from being terminated, you must call the **DetachHandle** method. Failure to release the detached handle may result in a resource leak in your application.

Note that the ***hClient*** parameter is presumed to be a valid client handle and no checks are performed to ensure that the handle is valid. Specifying an invalid client handle will cause subsequent method calls to fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

AttachThread, DetachHandle, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::AttachThread Method

```
DWORD AttachThread(
   DWORD dwThreadId
);
```

The **AttachThread** method attaches the specified client handle to another thread.

Parameters

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the method succeeds, the return value is the thread ID of the previous owner. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **AttachThread** method can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the method, the original owner of the handle can be restored before the worker thread terminates.

This method should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **AttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **Cancel** method and then release the handle after the blocking method exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the client handle used by the class until the destructor is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

AttachHandle, Cancel, Connect, DetachHandle, Disconnect, GetHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::Cancel Method

```
INT Cancel();
```

The **Cancel** method cancels any outstanding blocking operation in the client, causing the blocking method to fail. The application may then retry the operation or terminate the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

When the **Cancel** method is called, the blocking method will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

IsBlocking

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::Connect Method

```
BOOL Connect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout
);
```

The **Connect** method establishes a connection with the specified server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 43.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, the return value is zero. To get extended error information, call **GetLastError**.

Remarks

This method will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling the **Connect** method in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Disconnect, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::DetachHandle Method

```
HCLIENT DetachHandle();
```

The **DetachHandle** method detaches the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to detach a client handle created by the class for use with the SocketTools API. Once the client handle is detached from the class, no other class member functions may be called. Note that the handle must be explicitly released at some later point by the process or a resource leak will occur.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

CWhoisClient::DisableEvents Method

```
INT DisableEvents();
```

The **DisableEvents** method disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

None.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **DisableEvents** method is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this method has been called.

This method is automatically called if the client has event notification enabled, and the **Disconnect** method is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

EnableEvents, RegisterEvent

CWhoisClient::DisableTrace Method

```
BOOL DisableTrace();
```

The **DisableTrace** method disables the logging of network function calls.

Parameters

None.

Return Value

If the method succeeds, the return value is non-zero. If the method fails, a value of zero is returned.

Remarks

This method will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this method is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

CWhoisClient::EnableEvents Method

```
INT EnableEvents(
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **EnableEvents** method enables event notifications using Windows messages.

This method has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **RegisterEvent** method to register an event handler which is invoked when an event occurs.

Parameters

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **EnableEvents** method is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation.

	This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

To disable event notification, call the **DisableEvents** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

CWhoisClient::EnableTrace Method

```
BOOL EnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **EnableTrace** method enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the method succeeds, the return value is non-zero. A return value of zero indicates an error. Failure typically indicates that the log file cannot be created.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this method, and is not associated with a specific class instance. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

CWhoisClient::FreezeEvents Method

```
INT FreezeEvents(
   BOOL bFreeze
);
```

The **FreezeEvents** method is used to suspend and resume event handling by the client.

Parameters

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

CWhoisClient::GetErrorString Method

```
INT GetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);

INT GetErrorString(
   DWORD dwErrorCode,
   CString& strDescription
);
```

The **GetErrorString** method is used to return a description of a specific error code. Typically this is used in conjunction with the **GetLastError** method for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length. An alternate form of the method accepts a **CString** variable which will contain the error description.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the method succeeds, the return value is the length of the description string. If the method fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the method is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CWhoisClient::GetHandle Method

```
HCLIENT GetHandle();
```

The **GetHandle** method returns the client handle associated with the current instance of the class.

Parameters

None.

Return Value

This method returns the client handle associated with the current instance of the class object. If there is no active client session, the value INVALID_CLIENT will be returned.

Remarks

This method is used to obtain the client handle created by the class for use with the SocketTools API.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

CWhoisClient::GetLastError Method

```
DWORD GetLastError();

DWORD GetLastError(
   CString& strDescription
);
```

Parameters

strDescription

A string which will contain a description of the last error code value when the method returns. If no error has been set, or the last error code has been cleared, this string will be empty.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **SetLastError** method. The Return Value section of each reference page notes the conditions under which the method sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **GetLastError** method immediately when a method's return value indicates that an error has occurred. That is because some methods call **SetLastError**(0) when they succeed, clearing the error code set by the most recently failed method.

Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WHOIS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

The description of the error code is the same string that is returned by the **GetErrorString** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

GetErrorString, SetLastError, ShowError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::GetStatus Method

```
INT GetStatus();
```

The **GetStatus** method the current status of the client session.

Parameters

None.

Return Value

If the method succeeds, the return value is the client status code. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The **GetStatus** method returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
WHOIS_STATUS_UNUSED	No connection has been established.
WHOIS_STATUS_IDLE	The client is current idle and not sending or receiving data.
WHOIS_STATUS_CONNECT	The client is establishing a connection with the server.
WHOIS_STATUS_READ	The client is reading data from the server.
WHOIS_STATUS_WRITE	The client is writing data to the server.
WHOIS_STATUS_DISCONNECT	The client is disconnecting from the server.

In a multithreaded application, any thread in the current process may call this method to obtain status information for the specified client session. To obtain status information about a file transfer, use the **GetTransferStatus** method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

IsBlocking, IsInitialized, IsReadable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::GetTimeout Method

```
INT GetTimeout();
```

The **GetTimeout** method returns the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

None.

Return Value

If the method succeeds, the return value is the timeout period in seconds. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections. A value of zero indicates that the default timeout period of 20 seconds should be used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

Connect, IsReadable, Read, SetTimeout

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::IsBlocking Method

```
BOOL IsBlocking();
```

The **IsBlocking** method is used to determine if the client is currently performing a blocking operation.

Parameters

None.

Return Value

If the client is performing a blocking operation, the method returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the method returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking method may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **IsBlocking** method can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Cancel, GetStatus, IsConnected, IsInitialized, IsReadable, Read

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::IsConnected Method

```
BOOL IsConnected();
```

The **IsConnected** method is used to determine if the client is currently connected to a server.

Parameters

None.

Return Value

If the client is connected to a server, the method returns a non-zero value. If the client is not connected, or the client handle is invalid, the method returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

GetStatus, IsBlocking, IsInitialized, IsReadable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::IsInitialized Method

```
BOOL IsInitialized();
```

The **IsInitialized** method returns whether or not the class object has been successfully initialized.

Parameters

None.

Return Value

This method returns a non-zero value if the class object has been successfully initialized. A return value of zero indicates that the runtime license key could not be validated or the networking library could not be loaded by the current process.

Remarks

When an instance of the class is created, the class constructor will attempt to initialize the component with the runtime license key that was created when SocketTools was installed. If the constructor is unable to validate the license key or load the networking libraries, this initialization will fail.

If SocketTools was installed with an evaluation license, the application cannot be redistributed to another system. The class object will fail to initialize if the application is executed on another system, or if the evaluation period has expired. To redistribute your application, you must purchase a development license which will include the runtime key that is needed to redistribute your software to other systems. Refer to the Developer's Guide for more information.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

CWhoisClient, IsBlocking, IsConnected

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::IsReadable Method

```
BOOL IsReadable(
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **IsReadable** method is used to determine if data is available to be read from the server.

Parameters

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the method returns a non-zero value. If the client cannot read any data, the method returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

GetStatus, IsBlocking, IsConnected, IsInitialized

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::Read Method

```
INT Read(
   LPBYTE lpBuffer,
   INT cbBuffer
);

INT Read(
   CString& strBuffer,
   INT cbBuffer
);
```

The **Read** method reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

lpBuffer

Pointer to the buffer in which the data will be copied. An alternate form of this method allows a **CString** variable to be passed and data read from the socket will be returned in that string.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the method succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

When **Read** is called and the client is in non-blocking mode, it is possible that the method will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

EnableEvents, IsBlocking, IsReadable, RegisterEvent

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CWhoisClient::RegisterEvent Method

```
INT RegisterEvent(
   UINT nEventId,
   WHOISEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **RegisterEvent** method registers an event handler for the specified event.

Parameters

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
WHOIS_EVENT_CONNECT	The connection to the server has completed.
WHOIS_EVENT_DISCONNECT	The server has closed the connection to the client. The client should read any remaining data and disconnect.
WHOIS_EVENT_READ	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_WRITE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
WHOIS_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
WHOIS_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **WhoisEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR.

To get extended error information, call **GetLastError**.

Remarks

The **RegisterEvent** method associates a callback function with a specific event. The event handler is an **WhoisEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

The callback function specified by the *lpEventProc* parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

The *dwParam* parameter is commonly used to identify the class instance which is associated with the event that has occurred. Applications will cast the **this** pointer to a DWORD_PTR value when calling this function, and then the event handler will cast it back to a pointer to the class instance. This gives the handler access to the class member variables and methods.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

CWhoisClient::Search Method

```
INT Search(
   LPCTSTR lpszKeyword,
   UINT nSearchType
);
```

The **Search** method submits the specified keyword to the server.

Parameters

lpszKeyword

Points to a string which specifies the query keyword. It may be a handle, name or mailbox.

nSearchType

The type of search being performed. One of the following values may be used:

Value	Description
WHOIS_SEARCH_ANY	Search for any record that matches the specified keyword.
WHOIS_SEARCH_HANDLE	Search only for handles that match the specified keyword.
WHOIS_SEARCH_MAILBOX	Search only for mailboxes that match the specified keyword.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Example

```
CWhoisClient whoisClient;

// Connect to the WHOIS server at whois.internic.net
if (whoisClient.Connect(_T("whois.internic.net")) == FALSE)
{
    whoisClient.ShowError();
    return;
}

// Request information about the sockettools.com domain name
if (whoisClient.Search(_T("sockettools.com")) == WHOIS_ERROR)
{
    whoisClient.ShowError();
    whoisClient.Disconnect();
    return;
}

// Read the response from the server, which contains information
// about the domain and the registry that maintains the record
CString strResult;
CString strBuffer;
INT nResult;

do
{
    if ((nResult = whoisClient.Read(strBuffer)) > 0)
        strResult += strBuffer;
```

```
}
while (nResult > 0);

// If there was an error reading the data, alert the user
if (nResult == WHOIS_ERROR)
    whoisClient.ShowError();

whoisClient.Disconnect();
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

CWhoisClient::SetLastError Method

```
VOID SetLastError(
   DWORD dwErrorCode
);
```

The **SetLastError** method sets the last error code for the current thread. This method is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most methods will set the last error code value when they fail; a few methods set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or WHOIS_ERROR. Those methods which call **SetLastError** when they succeed are noted on the method reference page.

Applications can retrieve the value saved by this method by using the **GetLastError** method. The use of **GetLastError** is optional; an application can call the method to determine the specific reason for a method failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

See Also

CWhoisClient::SetTimeout Method

```
INT SetTimeout(
   UINT nTimeout
);
```

The **SetTimeout** method sets the number of seconds the client will wait for a response from the server. Once the specified number of seconds has elapsed, the method will fail and return to the caller.

Parameters

nTimeout

The number of seconds to wait for a blocking operation to complete.

Return Value

If the method succeeds, the return value is zero. If the method fails, the return value is WHOIS_ERROR. To get extended error information, call **GetLastError**.

Remarks

The timeout value is only used with blocking client connections.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib

CWhoisClient::ShowError Method

```
INT ShowError(
   LPCTSTR lpszAppTitle,
   UINT uType,
   DWORD dwErrorCode
);
```

The **ShowError** method displays a message box which describes the specified error.

Parameters

lpszAppTitle

A null-terminated string which specifies the title of the message box that is displayed. If this argument is NULL or omitted, then the default title of "Error" will be displayed.

uType

An unsigned integer which specifies the type of message box that will be displayed. This is the same value that is used by the **MessageBox** method in the Windows API. If a value of zero is specified, then a message box with a single OK button will be displayed. Refer to that method for a complete list of options.

dwErrorCode

Specifies the error code that will be used when displaying the message box. If this argument is zero, then the last error that occurred in the current thread will be displayed.

Return Value

If the method is successful, the return value will be the return value from the **MessageBox** function. If the method fails, it will return a value of zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswhov12.lib
Unicode: Implemented as Unicode and ANSI versions

Domain Name Service Library

Resolve domain names into Internet addresses and return information about a remote host, such as the servers that are responsible for accepting mail for the domain.

Reference

- Functions
- Constants
- Data Structures
- Error Codes

Library Information

File Name	CSDNSV12.DLL
Version	12.0.3024.1286
LibID	C887CFA2-F7A7-4A9F-8AF2-48ED79642023
Import Library	CSDNSV12.LIB
Dependencies	None
Standards	RFC 1034

Overview

The Domain Name Services (DNS) protocol is what applications use to resolve domain names into Internet addresses as well as provide other information about a domain. All of the SocketTools libraries provide basic domain name resolution functionality, but the Domain Name Services library gives an application direct control over what servers are queried, the amount of time spent waiting for a response and the type of information that is returned.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing

applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Domain Name Service Functions

Function	Description
DnsAttachThread	Attach the specified client handle to another thread.
DnsCancel	Cancel an outstanding nameserver query.
DnsCloseHandle	Close the current client session.
DnsCreateHandle	Create a new handle for the current client session.
DnsDisableTrace	Disable logging of network function calls.
DnsEnableTrace	Enable logging of network function calls to a file.
DnsEnumHostAliases	Enumerate the aliases for the specified host name or address.
DnsEnumMailExchanges	Return a list of mail exchanges for the specified host name or IP address.
DnsFormatAddress	Convert a numeric IPv4 address to a string.
DnsGetAddress	Convert an IPv4 address string in dotted notation to a numeric IP address.
DnsGetAddressFamily	Return the address family for the specified IP address.
DnsGetDefaultHostFile	Return the full path to the default host file on the local system.
DnsGetDefaultServicesFile	Return the full path the default services file on the local system.
DnsGetErrorString	Return a description for the specified error code.
DnsGetHostAddress	Return the IP address for the specified hostname.
DnsGetHostByAddress	Return a pointer to data for the specified host IP address.
DnsGetHostByName	Return a pointer to data for the specified host name.
DnsGetHostFile	Return the name of the current host file.
DnsGetHostInfo	Return additional information for the specified host.
DnsGetHostName	Return the host name for the specified IP address.
DnsGetHostServices	Return a list of services supported by the specified host.
DnsGetLastError	Return the last error code.
DnsGetLocalAddress	Return the IP address for the local host.
DnsGetLocalDomain	Return the local domain name for the current session.
DnsGetLocalName	Return the local host name.
DnsGetMailExchange	Return the host that processes mail for the specified domain.
DnsGetRecord	Return record data for the current host.
DnsGetResolverAddress	Return address of last nameserver that resolved query.
DnsGetResolverOptions	Return the current resolver options for the specified client session.
DnsGetRetryCount	Get the number of times the query is sent to each server.
DnsGetServerAddress	Return the address of the specified nameserver.
DnsGetServerPort	Return the port of the specified nameserver.
DnsGetServiceName	Return the name of a service assigned to the specified port number.

DnsGetServicePort	Return the port number assigned to the specified service name.
DnsGetTimeout	Get the number of seconds until a query times out.
DnsHostNameToUnicode	Converts the canonical form of a host name to its Unicode version.
DnsInitialize	Initialize the library and validates the specified license key at runtime.
DnsMatchHostName	Match a host name against of list of addresses including wildcards.
DnsNormalizeHostName	Return the canonical form of a host name.
DnsRegisterServer	Add a nameserver address to the current session.
DnsReset	Reset the current client state.
DnsSetHostFile	Specify the name of an alternate file to use when resolving hostnames and IP addresses.
DnsSetLastError	Set the last error code.
DnsSetLocalDomain	Set the local domain name for the current session.
DnsSetResolverOptions	Set the resolver options for the specified client session.
DnsSetRetryCount	Set the number of times the query is sent to each server.
DnsSetTimeout	Set the number of seconds until a query times out.
DnsUninitialize	Terminates the use of the library.
DnsUnregisterServer	Remove a nameserver address from the current session.

DnsAttachThread Function

```
DWORD WINAPI DnsAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **DnsAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **DnsAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **DnsAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **DnsCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the ***dwThreadId*** parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **DnsUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

See Also

DnsCancel Function

```
INT WINAPI DnsCancel(
   HCLIENT hClient
);
```

The **DnsCancel** function cancels any outstanding queries initiated by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

DnsCloseHandle Function

```
INT WINAPI DnsCloseHandle(
   HCLIENT hClient
);
```

The **DnsCloseHandle** function closes the handle and releases any memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

See Also

DnsCreateHandle Function

```
HCLIENT WINAPI DnsCreateHandle(
    INT nTimeout,
    INT nRetries,
    DWORD dwOptions
);
```

The **DnsCreateHandle** function creates a new handle which can be used to query the default nameservers configured for the local host.

Parameters

nTimeout

The number of seconds that the client will wait for a response before failing the query. The constant DNS_TIMEOUT can be used to specify the default timeout period of 15 seconds.

nRetries

The number of attempts the client will make to resolve a query after a timeout. The constant DNS_RETRIES can be used to specify the default retry count of 4.

dwOptions

An unsigned integer that specifies one or more resolver options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
DNS_OPTION_NONE	No additional resolver options specified. This is the default value, and it is recommended that most applications do not specify additional options unless the implications of doing so are understood.
DNS_OPTION_PROMOTE	Promotes the server that successfully completed the last query to the first server that will be used to resolve subsequent queries. This option can improve performance in some cases where one or more of the registered servers are non-responsive. This option takes precedence over the DNS_OPTION_ROTATE option.
DNS_OPTION_ROTATE	Enables a round-robin selection of nameservers when performing queries. Normally each nameserver is queried in the same order. This option rotates the available nameservers so a different server is used with each query.
DNS_OPTION_AUTHONLY	Require the answer from the nameserver to be authoritative, not from the server's cache. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_PRIMARY	Queries are only accepted from the primary nameserver. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_NORECURSE	Disable the sending of recursive queries to the nameserver. Specifying this option will disable the bit in

	the DNS request header that specifies recursion is desired.
DNS_OPTION_NOSEARCH	Disable additional queries of higher domains in the search list if the host name cannot be resolved. If this option is specified, and the host name cannot be resolved using the local domain name an error is returned immediately. This option is ignored if no local domain has been specified or if the DNS_OPTION_NOSUFFIX option has been specified.
DNS_OPTION_NOSUFFIX	Disable additional queries using the local domain name if the host name is not a fully qualified domain name and cannot be resolved. This option is ignored if no local domain has been specified.
DNS_OPTION_NONAMECHECK	Disable checking the host name for invalid characters, such as the underscore and control characters. By default, host names are checked to ensure they're valid before submitting a query to the nameserver.
DNS_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsCreateHandle** function returns a handle to the application which can be used to perform nameserver queries. By default, the library will use the nameservers which are configured for the local host. To determine the IP addresses of those nameservers, use the **DnsGetServerAddress** function.

To specify alternate nameservers, either as replacements for or additions to the default nameservers, use the **DnsRegisterServer** function.

It is recommended that most applications do not specify any resolver options and use the default behavior. Specifying these options without understanding how they can affect standard queries can result in unexpected failures. In particular, caution should be used when specifying the DNS_OPTION_NORECURSE and DNS_OPTION_NOSEARCH options as they change the normal process of resolving a host name.

Specifying the DNS_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csdnsv12.lib

DnsDisableTrace Function

```
BOOL WINAPI DnsDisableTrace();
```

The **DnsDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an internal failure to release the resources allocated for the logging session.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

See Also

DnsEnableTrace

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

DnsEnableTrace Function

```
BOOL WINAPI DnsEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **DnsEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsEnumHostAliases Function

```
INT WINAPI DnsEnumHostAliases(
   HCLIENT hClient,
   LPCTSTR lpszHostName,
   LPTSTR *lpszHostAlias,
   INT nMaxAliases
);
```

The **DnsEnumHostAliases** function returns a list of aliases for the specified host name or IP address.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string that contains the hostname to be resolved. If a fully qualified domain name is not provided, the default local domain will be used. This value may also be an IP address.

lpszHostAlias

Pointer to an array of string pointers which specify one or more host aliases. If the application needs to store these values, a local copy should be made because they are invalidated when another host name is resolved.

nMaxAliases

The maximum number of aliases in the array. This parameter must have a value of at least one, or an error will be returned.

Return Value

If the function succeeds, the return value is the number of host aliases. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify the host aliases or free any of the values. This function uses an internal data structure to store the host information and only one copy of this structure is allocated per thread. The application must copy any information it needs before issuing any other function calls.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetHostAddress, DnsGetHostName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

DnsEnumMailExchanges Function

```
INT WINAPI DnsEnumMailExchanges(
   HCLIENT hClient,
   LPCTSTR lpszHostName,
   LPTSTR *lpszMailExchanges,
   INT nMaxMailExchanges
);
```

The **DnsEnumMailExchanges** function returns a list of mail exchanges for the specified host name or IP address.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string that contains the hostname or domain name to be queried.

lpszMailExchanges

Pointer to an array of string pointers which specify one or more mail exchanges. If the application needs to store these values, a local copy should be made because they are invalidated when another host name is resolved. The list of mail exchange records is sorted in priority order, from highest (i.e., those whose preference value is smallest) to lowest.

nMaxMailExchanges

The maximum number of mail exchanges in the array. If this parameter is 0, then the function will return the number of mail exchanges, but the list of mail exchanges will not be output in *lpszMailExchanges*.

Return Value

If the function succeeds, the return value is the number of mail exchanges. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify the mail exchange host names or free any of the values. This function uses an internal data structure to store the host information and only one copy of this structure is allocated per thread. The application must copy any information it needs before issuing any other function calls.

Example

```
// Count the number of mail exchanges
if ((nMX = DnsEnumMailExchanges(hClient,szHostName, NULL, 0)) == DNS_ERROR)
{
    dwError = DnsGetLastError();
    DnsGetErrorString(dwError, szError, BUFSIZE);
    printf("DnsEnumMailExchanges failed for %s: %s\n", szHostName, szError);
}
else
{
    int nIndex;
    printf("%d MX for %s\n",nMX, szHostName);
```

```
    // Allocate memory for the list of mail exchanges
    lpszMailExchanges = (LPTSTR *)malloc(nMX * sizeof(LPTSTR));

    // Retrieve the list of mail exchanges
    nMX = DnsEnumMailExchanges(hClient, szHostName, lpszMailExchanges, nMX);

    for (nIndex = 0; nIndex < nMX; nIndex++)
         printf("#%d: %s\n", nIndex+1, *lpszMailExchanges++);

    free(lpszMailExchanges);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

DnsFormatAddress Function

```
INT WINAPI DnsFormatAddress(
   LPINTERNET_ADDRESS lpAddress,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **DnsFormatAddress** function converts a numeric IPv4 or IPv6 address to a string.

Parameters

lpAddress

A pointer to an INTERNET_ADDRESS structure which specifies the numeric IPv4 or IPv6 address to be converted into a string.

lpszAddress

A null-terminated string which will contain the converted IPv4 address in dot-notation. This string should be at least 16 characters in length.

nMaxLength

The maximum number of characters which may be copied in to the string buffer.

Return Value

If the function succeeds, the return value is the length of the string buffer. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetAddress Function

```
INT WINAPI DnsGetAddress(
   LPCTSTR lpszAddress,
   INT nAddressFamily,
   LPINTERNET_ADDRESS lpAddress
);
```

The **DnsGetAddress** function converts an address string to a numeric IPv4 or IPv6 address.

Parameters

lpszAddress

A null-terminated string which specifies an IPv4 address in dotted notation.

nAddressFamily

An integer value which specifies the type of IP address. If this parameter is zero, the address family will be determined automatically based on the format of the address string. If this parameter is DNS_ADDRESS_IPV4, the address must be in IPv4 format, and if it is DNS_ADDRESS_IPV6, the address must be in IPv6 format.

lpAddress

A pointer to an INTERNET_ADDRESS structure that will contain the numeric form of the IPv4 or IPv6 address in network byte order when the function returns.

Return Value

If the function succeeds, the return value is the address family for the IP address. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

This function will only accept a string that is in the proper format for an IP address, and cannot be used to resolve a host name. To perform host name resolution, use the **DnsGetHostAddress** function. To convert a numeric address to an address string, use the **DnsFormatAddress** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetAddressFamily Function

```
INT WINAPI DnsGetAddressFamily(
   LPCTSTR lpszAddress
);
```

The **DnsGetAddressFamily** function returns the address family for the specified IP address.

Parameters

lpszAddress

A null-terminated string which specifies an IPv4 or IPv6 address.

Return Value

If the function succeeds, the return value is DNS_ADDRESS_IPV4 if the address is in IPv4 format, or DNS_ADDRESS_IPV6 if the address is in IPv6 format. If the address string is not in a recognized format, it returns DNS_ADDRESS_ANY.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetDefaultHostFile Function

```
INT WINAPI DnsGetDefaultHostFile(
    LPTSTR lpszFileName,
    INT nMaxLength
);
```

The **DnsGetDefaultHostFile** function returns the fully qualified path name of the host file on the local system. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **DnsGetHostAddress** and **DnsGetHostName** functions. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

lpszFileName

Pointer to a string buffer that will contain the fully qualified path to the default host file. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. A return value of zero indicates that the default host file could not be determined for the current platform. To get extended error information, call **DnsGetLastError**.

Remarks

This function returns the location of the host file and does not determine if the file actually exists. The default location for this file is in a protected area of the Windows operating system and can only be modified by a process with administrative privileges.

The default host file is processed before performing a nameserver lookup when resolving a hostname into an IP address, or an IP address into a hostname. To specify an alternate local host file, use the **DnsSetHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetDefaultServicesFile Function

```
INT WINAPI DnsGetDefaultServicesFile(
    LPTSTR lpszFileName,
    INT nMaxLength
);
```

The **DnsGetDefaultServicesFile** function returns the fully qualified path name of the services file on the local system. The services file is used as a database that maps a port number to a service name, and is used by the **DnsGetServiceName** and **DnsGetServicePort** functions. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
name port/protocol [alias ...]
```

For example, one typical entry maps the service name "http" to port 80, the standard port for the Hypertext Transfer Protocol. This would be entered as:

```
http 80/tcp www www-http
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

lpszFileName

Pointer to a string buffer that will contain the fully qualified path to the default services file. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null byte.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. A return value of zero indicates that the default services file could not be determined for the current platform. To get extended error information, call **DnsGetLastError**.

Remarks

This function returns the location of the services file and does not determine if the file actually exists. The default location for this file is in a protected area of the Windows operating system and can only be modified by a process with administrative privileges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetErrorString Function

```
INT WINAPI DnsGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **DnsGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **DnsGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The last-error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is 0, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetHostAddress Function

```
INT WINAPI DnsGetHostAddress(
   HCLIENT hClient,
   INT nAddressFamily,
   LPCTSTR lpszHostName,
   LPTSTR lpszHostAddress,
   INT nMaxLength
);
```

The **DnsGetHostAddress** function resolves the specified host name, storing the IP address in the provided buffer.

Parameters

hClient

Handle to the client session.

nAddressFamily

An integer value which specifies the type of address that should be returned. A value of DNS_ADDRESS_IPV4 specifies that the IPv4 address for the host should be returned. A value of DNS_ADDRESS_IPV6 specifies that the IPv6 address for the host should be returned. A value of DNS_ADDRESS_ANY specifies that if the host only has an IPv6 address, that value should be returned, otherwise return the IPv4 address for the host.

lpszHostName

Pointer to the string that contains the hostname to be resolved. If a fully qualified domain name is not provided, the default local domain will be used.

lpszHostAddress

Pointer to the buffer that will contain the IP address, stored as a string in dot notation. This buffer should be at least 48 characters in length to accommodate both IPv4 and IPv6 addresses. The format of the address is determined by the address family specified.

nMaxLength

The maximum length of the string buffer. The maximum length of the buffer must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the host address buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetHostAddress** function may return an address in either IPv4 or IPv6 format, depending on the address family that is specified and what records exist for the host. If your application does not support the IPv6 address format, you must specify the ***nAddressFamily*** parameter as DNS_ADDRESS_IPV4 to prevent the possibility of an IPv6 address being returned.

If the ***nAddressFamily*** parameter is specified as DNS_ADDRESS_ANY, this function will first check for an IPv4 address record for the host. If it exists, it will return that address. If the host does not have an IPv4 address, it will then check for an IPv6 address record and return that address. This gives preference to IPv4 addresses, but your application should never depend on this behavior. In the future, this function may change to give preference to IPv6 addresses.

To determine what format an address is in, use the **DnsGetAddressFamily** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsEnumHostAliases, DnsGetAddressFamily, DnsGetHostName, DnsGetMailExchange, DnsGetRecord

DnsGetHostByAddress Function

```
LPHOSTENT WINAPI DnsGetHostByAddress(
    HCLIENT hClient,
    LPVOID lpvAddress,
    INT cbAddress,
    INT nAddressFamily
);
```

The **DnsGetHostByAddress** function returns a pointer to a HOSTENT structure which contains the results of a successful search for the host specified by address parameter.

Parameters

hClient

Handle to the client session.

lpvAddress

Pointer to an integer IPv4 address in network byte order.

cbAddress

The length of the address in bytes; this value should always be 4.

nAddressFamily

The type of address being resolved; this value should always be DNS_ADDRESS_IPV4 as defined in the Windows Sockets header file.

Return Value

If the function succeeds, the return value is a pointer to a HOSTENT structure. If the function fails, the return value is NULL. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify this structure or to free any of its components. Only one copy of this structure is allocated per thread, so the application should copy any information it needs before issuing any other function calls. To convert an IPv4 address string in dotted notation to a 32-bit IP address, use the **DnsGetAddress** function.

This function is included for compatibility with existing applications which already use the HOSTENT structure. Because this function returns a pointer to a complex structure, it may not be suitable for some programming languages. There is no Unicode version of the HOSTENT structure and members will return pointers to ANSI strings even if the application is compiled to use Unicode.

This function is not compatible with IPv6 addresses. For applications that must support both IPv4 and IPv6 address formats, use the **DnsGetHostAddress** and **DnsGetHostName** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetHostByName Function

```
LPHOSTENT WINAPI DnsGetHostByName(
    HCLIENT hClient,
    LPCTSTR lpszHostName
);
```

The **DnsGetHostByName** function returns a pointer to a HOSTENT structure which contains the results of a successful search for the host specified in the name parameter.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string that contains the hostname to be resolved. If a fully qualified domain name is not provided, the default local domain will be used.

Return Value

If the function succeeds, the return value is a pointer to a HOSTENT structure. If the function fails, the return value is NULL. To get extended error information, call **DnsGetLastError**.

Remarks

The application must never attempt to modify this structure or to free any of its components. Only one copy of this structure is allocated per thread, so the application should copy any information it needs before issuing any other function calls. This function will automatically resolve an IP address passed as a string, converting it to numeric form and calling the **DnsGetHostByAddress** function.

This function is included for compatibility with existing applications which already use the HOSTENT structure. Because this function returns a pointer to a complex structure, it may not be suitable for some programming languages. There is no Unicode version of the HOSTENT structure and members will return pointers to ANSI strings even if the application is compiled to use Unicode.

This function is not compatible with IPv6 addresses. For applications that must support both IPv4 and IPv6 address formats, use the **DnsGetHostAddress** and **DnsGetHostName** functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetHostAddress, DnsGetHostByAddress, DnsGetHostInfo, DnsGetHostName, DnsGetHostServices, DnsGetMailExchange, DnsGetRecord, DnsGetResolverAddress, DnsRegisterServer

DnsGetHostFile Function

```
INT WINAPI DnsGetHostFile(
   HCLIENT hClient,
   LPTSTR lpszFileName,
   INT nMaxLength
);
```

The **DnsGetHostFile** function returns the name of the host file previously set using the **DnsSetHostFile** function. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **DnsGetHostAddress** and **DnsGetHostName** function.

Parameters

hClient

Handle to the client session.

lpszFileName

Pointer to a string buffer that will contain the host file name. It is recommended that this buffer be at least MAX_PATH characters in size. This parameter may be NULL, in which case the function will return the length of the string, not including the terminating null character.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. A return value of zero indicates no host file has been specified or the function was unable to determine the file name. To get extended error information, call **DnsGetLastError**.

Remarks

This function returns the name of the host file that is cached in memory for the current thread. If an alternate host file has not been specified, this function will return the path to the default host file. The contents of the file on the disk may have changed after the file was loaded into memory. To reload the host file or clear the cache, call the **DnsSetHostFile** function.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

The host file returned by this function may be different than the default host file for the local system. To determine the file name for the default host file, use the **DnsGetDefaultHostFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetHostInfo Function

```
INT WINAPI DnsGetHostInfo(
   HCLIENT hClient,
   LPCTSTR lpszHostName,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **DnsGetHostInfo** function returns the HINFO record for the specified hostname. This information, if it is provided, typically specifies the operating system type and hardware platform.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the host information buffer is returned. A return value of zero indicates that no information is available for the specified host. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

Many systems to do not maintain HINFO records for a site since that information can potentially be used to compromise system security. The information is typically used for administrative purposes with internal networks.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

DnsGetHostName Function

```
INT WINAPI DnsGetHostName(
   HCLIENT hClient,
   LPCTSTR lpszHostAddress,
   LPTSTR lpszHostName,
   INT nMaxLength
);
```

The **DnsGetHostName** function resolves the specified IP address, storing the fully qualified host name in the provided buffer.

Parameters

hClient

Handle to the client session.

lpszHostAddress

Pointer to a string that specifies an IPv4 or IPv6 formatted address.

lpszHostName

Pointer to the buffer that will contain the fully qualified domain name for the specified host. This buffer should be at least 64 characters in length.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the host name buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetHostName** function first looks to see if there is an entry in the local host file for the specified IP address, and if one exists, it will return the host name for that address. If you do not want to use the local host file at all, and only return an host name if a DNS query resolves the address, use the **DnsGetRecord** function and specify a record type of DNS_RECORD_PTR.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetHostServices Function

```
INT WINAPI DnsGetHostServices(
   HCLIENT hClient,
   LPCTSTR lpszHostName,
   INT nProtocol,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **DnsGetHostServices** function returns the WKS (Well Known Services) record for the specified hostname and protocol. This information, if it is provided, typically specifies the names of those services supported on the host.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

nProtocol

The protocol for those services that information should be returned about. The following protocols are recognized:

Value	Description
INET_PROTOCOL_TCP	Services that use the Transmission Control Protocol (TCP)
INET_PROTOCOL_UDP	Services that use the User Datagram Protocol (UDP)

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the host services buffer is returned. A return value of zero indicates that no information is available for the specified host. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

Many systems to do not maintain complete services records for a site since that information can potentially be used to compromise system security. An application should not depend on this information being available for any given record.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

Unicode: Implemented as Unicode and ANSI versions

DnsGetLastError Function

```
DWORD WINAPI DnsGetLastError();
```

Parameters

None.

Return Value

The return value is the calling thread's last-error code value. Functions set this value by calling the **DnsSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last-error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **DnsGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **DnsSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or DNS_ERROR. Those functions which call **DnsSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

DnsGetLocalAddress Function

```
INT WINAPI DnsGetLocalAddress(
   HCLIENT hClient,
   INT nAddressFamily,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **DnsGetLocalAddress** function returns the IP address for the local host.

hClient

Handle to the client session.

nAddressFamily

An integer value which specifies the type of address that should be returned. A value of DNS_ADDRESS_IPV4 specifies that the IPv4 address for the host should be returned. A value of DNS_ADDRESS_IPV6 specifies that the IPv6 address for the host should be returned. A value of DNS_ADDRESS_ANY specifies that if the host only has an IPv6 address, that value should be returned, otherwise return the IPv4 address for the host.

lpszAddress

Pointer to the buffer that will contain the IP address, stored as a string in dot notation. This buffer should be at least 40 characters in length to accommodate both IPv4 and IPv6 addresses.

nMaxLength

The maximum length of the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the host address buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetLocalAddress** function may return an address in either IPv4 or IPv6 format, depending on the address family that is specified and what records exist for the host. If your application does not support the IPv6 address format, you must specify the ***nAddressFamily*** parameter as DNS_ADDRESS_IPV4 to prevent the possibility of an IPv6 address being returned.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetLocalDomain Function

```
INT WINAPI DnsGetLocalDomain(
   HCLIENT hClient,
   LPTSTR lpszDomain,
   INT nMaxLength
);
```

The **DnsGetLocalDomain** function copies the local domain name into the specified buffer. The value returned is the same value that was set with the **DnsSetLocalDomain** function. If no local domain name has been set, an empty string is returned.

Parameters

hClient

Handle to the client session.

lpszDomain

Pointer to the buffer that is used to store the local domain name. If no local domain name has been set, this buffer will be set to a zero-length string.

nMaxLength

The maximum number of bytes to copy into the buffer, including the null character terminator.

Return Value

If the function succeeds, the return value is the length of the domain name string. A return value of zero indicates that no local domain name has been set. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetLocalName Function

```
INT WINAPI DnsGetLocalName(
   HCLIENT hClient,
   LPTSTR lpszLocalName,
   INT nMaxLength
);
```

The **DnsGetLocalName** function returns the local host name.

Parameters

hClient

Handle to the client session.

lpszLocalName

Pointer to a string buffer that will contain the local host name. It is recommended that this buffer be at least 64 characters in size.

nMaxLength

The maximum number of characters that may be copied to the string buffer.

Return Value

If the function succeeds, the return value is the length of the local host name. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

);
```

The **DnsGetMailExchange** function returns the mail exchange (MX) record information for the specified domain. This information, if it is provided, identifies a server responsible for processing mail for the given domain.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

lpnPreference

Pointer to the integer which will contain the preference for the specified mail exchange host.

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the buffer is returned. A return value of zero indicates that no information is available for the specified host. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The mail exchange record is typically used by mail delivery agents to determine what system is responsible for accepting mail addressed to a given domain. This function will return the first MX record provided by the server. Note that some domains may have multiple mail servers. To enumerate all of the mail exchange records for a domain, use the **DnsEnumMailExchanges** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetRecord Function

```
INT WINAPI DnsGetRecord(
   HCLIENT hClient,
   LPCTSTR lpszHostName,
   INT nRecordType,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **DnsGetRecord** function returns the specified record information for the given hostname.

Parameters

hClient

Handle to the client session.

lpszHostName

Pointer to the string which specifies the host name that information will be returned for.

nRecordType

The record type for the information that should be returned. The following record types are recognized:

Value	Description
DNS_RECORD_NONE	No record type
DNS_RECORD_ADDRESS	IPv4 host address
DNS_RECORD_NS	Authoritative nameserver
DNS_RECORD_CNAME	Canonical host name (alias)
DNS_RECORD_SOA	Start of Authority
DNS_RECORD_WKS	Well known services
DNS_RECORD_PTR	Domain name
DNS_RECORD_HINFO	Host information
DNS_RECORD_MINFO	Mailbox information
DNS_RECORD_MX	Mail exchange host
DNS_RECORD_TXT	Text strings
DNS_RECORD_AAAA	IPv6 host address
DNS_RECORD_LOC	Location information
DNS_RECORD_UINFO	User information
DNS_RECORD_UID	User ID
DNS_RECORD_GID	Group ID

lpszBuffer

Pointer to the buffer which will contain the host information returned by the nameserver.

nMaxLength

Maximum number of characters that may be copied into the specified buffer, including the null character terminator.

Return Value

If the function succeeds, the length of the information buffer is returned. A return value of zero indicates that no information for that record is available for the specified host. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsGetRecord** function can be used to resolve a host name into an IPv4 address using the record type DNS_RECORD_ADDRESS, or an IPv6 address using the record type DNS_RECORD_AAAA. It can also be used to perform a reverse lookup and resolve an IP address into a host name by using the record type DNS_RECORD_PTR.

To determine the host that serves as the primary or master DNS for a zone, the record name should be specified as the domain name (e.g.: microsoft.com) and the record type should be DNS_RECORD_SOA. The value returned will the fully qualified domain name for host.

Note that this function does not reference a local host file when resolving host names or addresses. If the record lookup fails, this function will return an error even if there's an entry for the host in the file that has been specified by a call to **DnsSetHostFile**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetResolverAddress Function

```
INT WINAPI DnsGetResolverAddress(
    HCLIENT hClient,
    LPTSTR lpszAddress,
    INT nMaxLength
);
```

The **DnsGetResolverAddress** returns the address of the nameserver that resolved the last query.

Parameters

hClient

Handle to the client session.

lpszAddress

A null-terminated string buffer that will contain the address of the nameserver when the function returns. This buffer should be large enough to store both IPv4 and IPv6 addresses, with a minimum length of 40 characters. If this parameter is NULL, it will be ignored.

nMaxLength

The maximum number of characters that can be copied into the string buffer. If this value is zero, the *lpszAddress* parameter will be ignored and the function will return the length of the address.

Return Value

If the function succeeds, the return value is the length of the address, not including the terminating null character. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetResolverOptions Function

```
DWORD WINAPI DnsGetResolverOptions(
    HCLIENT hClient
);
```

The **DnsGetResolverOptions** function returns the options that have been set for the client session.

Parameters

hClient

Handle to the client session

Return Value

If the function succeeds, the return value is the resolver options set for the client session. If the client handle is invalid or no resolver options have been specified, the function will return zero.

Remarks

The **DnsGetResolverOptions** function can be used to determine which resolver options have been specified for the client session. For a list of the available options, refer to the documentation for the **DnsSetResolverOptions** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

DnsGetRetryCount Function

```
INT WINAPI DnsGetRetryCount(
    HCLIENT hClient
);
```

The **DnsGetRetryCount** returns the retry count for the current client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the retry count. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The retry count determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

DnsGetServerAddress Function

```
INT WINAPI DnsGetServerAddress(
   HCLIENT hClient,
   INT nServer,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **DnsGetServerAddress** function returns the address of the registered nameserver.

Parameters

hClient

Handle the client session.

nServer

The index into the client's nameserver table. This index is the same value that is passed to the **DnsRegisterServer** function when the nameserver is registered.

lpszAddress

A null-terminated string buffer that will contain the address of the nameserver when the function returns. This buffer should be large enough to store both IPv4 and IPv6 addresses, with a minimum length of 40 characters. If this parameter is NULL, it will be ignored.

nMaxLength

The maximum number of characters that can be copied into the string buffer. If this value is zero, the *lpszAddress* parameter will be ignored and the function will return the length of the address.

Return Value

If the function succeeds, the return value is the length of the address, not including the terminating null character. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetServerPort Function

```
INT WINAPI DnsGetServerPort(
   HCLIENT hClient,
   INT nServer
);
```

The **DnsGetServerPort** function returns the port number registered to the specified nameserver.

Parameters

hClient

Handle the client session.

nServer

The index into the client's nameserver table. This index is the same value that is passed to the **DnsRegisterServer** function when the nameserver is registered.

Return Value

If the function succeeds, the return value is the specified port number. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

DnsGetServiceName Function

```
INT WINAPI DnsGetServiceName(
   HCLIENT hClient,
   INT nServicePort,
   INT nServiceType,
   LPTSTR lpszServiceName,
   INT nMaxLength
);
```

The **DnsGetServiceName** function returns the service name assigned to the specified port number.

Parameters

hClient

Handle to the client session.

nServicePort

An integer which specifies the port number. This value must be a valid port number in the range of 1 through 65535.

nServiceType

An integer which specifies the protocol associated with the service. This may be one of the following values:

Value	Description
DNS_SERVICE_ANY	Match the first service entry for the specified port number regardless of the protocol used.
DNS_SERVICE_TCP	Match a service entry for the specified port number which uses the TCP protocol.
DNS_SERVICE_UDP	Match a service entry for the specified port number which uses the UDP protocol.

lpszServiceName

A null-terminated string buffer which will contain the name of the service assigned to the port number when the function returns. This parameter cannot be NULL and the buffer must be large enough to store the complete service name, including the terminating null character.

nMaxLength

An integer which specifies the maximum number of characters which can be copied into the string buffer.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer, not including the terminating null character. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Remarks

Port numbers can be assigned human readable service names to make them easier to reference. This function will return the name assigned to the specified port number. If the port number does not have an assigned name, this function will return zero and the last error code will be set to ST_ERROR_INVALID_SERVICE_NAME.

Most applications should use DNS_SERVICE_ANY to return the service name assigned to a port number. Services typically use the same name and port number regardless of the protocol used to establish a connection with them. However, specifying a protocol can enable your application to determine if the service supports the protocol. For example, calling this function with port number 21 and DNS_SERVICE_UDP would result in an error because FTP only supports TCP connections.

Service names are assigned by the Internet Assigned Numbers Authority (IANA) and the database of recognized service names can be returned by calling the **DnsGetDefaultServicesFile** function. The default location for this file is in a protected area of the Windows operating system and can only be modified by a process with administrative privileges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetServicePort Function

```
INT WINAPI DnsGetServicePort(
   HCLIENT hClient,
   LPCTSTR lpszServiceName,
   INT nServiceType
);
```

The **DnsGetServicePort** function returns the port number assigned to the specified service.

Parameters

hClient

Handle to the client session.

lpszServiceName

A null-terminated string which specifies the service name. Service names are not case sensitive.

nServiceType

An integer which specifies the protocol associated with the service. This may be one of the following values:

Value	Description
DNS_SERVICE_ANY	Match the first service entry for the specified port number regardless of the protocol used.
DNS_SERVICE_TCP	Match a service entry for the specified port number which uses the TCP protocol.
DNS_SERVICE_UDP	Match a service entry for the specified port number which uses the UDP protocol.

Return Value

If the function succeeds, the return value is the port number assigned to the service name. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

Port numbers can be assigned human readable service names to make them easier to reference. This function will return the port number assigned to the specified service name. If the service name does not exist, this function will return DNS_ERROR and the last error code will be set to ST_ERROR_INVALID_SERVICE_NAME.

Most applications should use DNS_SERVICE_ANY to return the port number assigned to a service. Services typically use the same name and port number regardless of the protocol used to establish a connection with them. However, specifying a protocol can enable your application to determine if the service supports the protocol. For example, calling this function with the service name `"ftp"` and DNS_SERVICE_UDP would result in an error because FTP only supports TCP connections.

Service names are assigned by the Internet Assigned Numbers Authority (IANA) and the database of recognized service names can be returned by calling the **DnsGetDefaultServicesFile** function. The default location for this file is in a protected area of the Windows operating system and can only be modified by a process with administrative privileges.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsGetTimeout Function

```
INT WINAPI DnsGetTimeout(
   HCLIENT hClient
);
```

The **DnsGetTimeout** function returns the timeout value for the current client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The timeout value determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

DnsHostNameToUnicode Function

```
INT WINAPI DnsHostNameToUnicode(
   LPCTSTR lpszHostName,
   LPTSTR lpszUnicodeName,
   INT nMaxLength
);
```

The **DnsHostNameToUnicode** function converts the canonical form of a host name to its Unicode version.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero-length string.

lpszUnicodeName

Pointer to the string buffer that will contain the original Unicode version of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that can be copied to the ***lpszUnicodeName*** string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsHostNameToUnicode** function will convert the encoded ASCII version of a host name to its Unicode version. Although any valid host name is accepted by this function, it is intended to convert a Punycode encoded host name to its original Unicode character encoding.

If the Unicode version of this function is used, the value returned in ***lpszUnicodeName*** will be a Unicode string using UTF-16 encoding. If the ANSI version of this function, the value returned will be a Unicode string using UTF-8 encoding. To display a UTF-8 encoded host name, your application will need to convert it to UTF-16 using the **MultiByteToWideChar** function.

Although this function performs checks to ensure that the ***lpszHostName*** parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the DnsGetHostAddress function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetHostAddress, DnsNormalizeHostName

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

DnsInitialize Function

```
BOOL WINAPI DnsInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **DnsInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **DnsInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **DnsUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **DnsInitialize** or **DnsUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsCloseHandle, DnsCreateHandle, DnsUninitialize

DnsMatchHostName Function

```
BOOL WINAPI DnsMatchHostName(
   HCLIENT hClient,
   LPCTSTR lpszHostName,
   LPCTSTR lpszHostMask
   BOOL bResolve
);
```

The **DnsMatchHostName** function matches a host name against one more strings that may contain wildcards.

Parameters

hClient

Handle to the client session.

lpszHostName

A null-terminated string which specifies the host name or IP address to match.

lpszHostMask

A null-terminated string which specifies one or more values to match against the host name. The asterisk character can be used to match any number of characters in the host name, and the question mark can be used to match any single character. Multiple values may be specified by separating them with a semicolon.

bResolve

A boolean value which specifies if the host name or IP address should be resolved when matching the host against the mask string. If this parameter is non-zero, two checks against the host mask string will be performed; once for the host name specified and once for its IP address. If this parameter is zero, then the match is made only against the host name string provided.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsMatchHostName** function provides a convenient way for an application to determine if a given host name matches one or more mask strings which may contain wildcard characters. For example, the host name could be "www.microsoft.com" and the host mask string could be "*.microsoft.com". In this example, the function would return a non-zero value indicating the host name matched the mask. However, if the mask string was "*.net" then the function would return zero, indicating that there was no match. Multiple mask values can be combined by separating them with a semicolon; for example, the mask "*.com;*.org" would match any host name in either the .com or .org top-level domains.

If an internationalized domain name (IDN) is specified, it will be converted internally to an ASCII string using Punycode encoding. The host mask will be matched against this encoded version of the host name, not its Unicode version.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

DnsGetAddress, DnsGetHostAddress, DnsGetHostName, DnsGetLocalAddress

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

DnsNormalizeHostName Function

```
INT WINAPI DnsNormalizeHostName(
   LPCTSTR lpszHostName,
   LPTSTR lpszNormalized,
   INT nMaxLength
);
```

The **DnsNormalizeHostName** function returns the canonical form of a host name in the specified buffer.

Parameters

lpszHostName

Pointer to the host name as a null-terminated string. This parameter cannot be a NULL pointer or a zero-length string.

lpszNormalized

Pointer to the string buffer that will contain the canonical form of the host name, including the terminating null character. It is recommended that this buffer be at least 256 characters in size. This parameter cannot be a NULL pointer.

nMaxLength

The maximum number of characters that can be copied to the ***lpszNormalized*** string buffer. This parameter cannot be zero, and must include the terminating null character.

Return Value

If the function succeeds, the return value is the number of characters copied into the string buffer. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsNormalizeHostName** function will remove all leading and trailing whitespace characters from the host name and fold all upper-case characters to lower-case. If an internationalized domain name (IDN) containing Unicode characters is passed to this function, it will be converted to an ASCII compatible format for domain names.

If the Unicode version of this function is used, the host name will be converted from UTF-16 to UTF-8 and then processed. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended that you use the Unicode version.

Although this function performs checks to ensure that the ***lpszHostName*** parameter is in the correct format and does not contain any illegal characters or malformed encoding, it does not validate the existence of the domain name. To check if the host name exists and has a valid IP address, use the DnsGetHostAddress function.

It is recommended that you use this function if your application needs to store the host name, and if accepts a host name as user input. It is not necessary to call this function prior to calling the other DNS API functions that accept a host name as a parameter. Those functions already normalize the host name and perform checks to ensure it is in the correct format.

If the ***lpszHostName*** parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address. To determine if

the IP address has a corresponding host name, use the DnsGetHostName method.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsRegisterServer Function

```
INT WINAPI DnsRegisterServer(
   HCLIENT hClient,
   INT nServer,
   LPCTSTR lpszHostAddress,
   INT nPort
);
```

The **DnsRegisterServer** function registers a nameserver with the current client session. The nameserver is used to resolve queries issued by the client, such as returning the IP address for a given host name. At least one nameserver must be registered by the client before queries are issued.

Parameters

hClient

Handle to the client session.

nServer

The index into the client nameserver table. This index, starting at 0, is used to specify which slot in the client's nameserver table will be used to store the nameserver information.

lpszHostAddress

A null-terminated string that specifies the IP address of the nameserver to be registered. Note that hostnames cannot be specified.

nPort

The port number that the specified nameserver is accepting queries on. This value may be set to zero, in which case it will use the default port value.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

DnsReset Function

```
INT WINAPI DnsReset(
   HCLIENT hClient
);
```

The **DnsReset** function resets the current state of the client session. The timeout and retry counts are set to their default values, the local domain name is cleared and all registered servers are removed from the client nameserver table.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

DnsSetHostFile Function

```
INT WINAPI DnsSetHostFile(
   HCLIENT hClient,
   LPCTSTR lpszFileName
);
```

The **DnsSetHostFile** function specifies the name of an alternate file to use when resolving hostnames and IP addresses. The host file is used as a database that maps an IP address to one or more hostnames, and is used by the **DnsGetHostAddress** and **DnsGetHostName** functions. The file is a plain text file, with each line in the file specifying a record, and each field separated by spaces or tabs. The format of the file must be as follows:

```
ipaddress hostname [hostalias ...]
```

For example, one typical entry maps the name "localhost" to the local loopback IP address. This would be entered as:

```
127.0.0.1 localhost
```

The hash character (#) may be used to specify a comment in the file, and all characters after it are ignored up to the end of the line. Blank lines are ignored, as are any lines which do not follow the required format.

Parameters

hClient

Handle to the client session.

lpszFileName

Pointer to a string that specifies the name of the file. If the parameter is NULL, then the current host file is cleared from the cache and only the default host file will be used to resolve hostnames and addresses.

Return Value

If the function succeeds, the return value is the number of entries in the host file. A return value of DNS_ERROR indicates failure. To get extended error information, call **DnsGetLastError**.

Remarks

This function loads the file into memory allocated for the current thread. If the contents of the file have changed after the function has been called, those changes will not be reflected when resolving hostnames or addresses. To reload the host file from disk, call this function again with the same file name. To remove the alternate host file from memory, specify a NULL pointer as the parameter.

If a host file has been specified, it is processed before the default host file when resolving a hostname into an IP address, or an IP address into a hostname. If the host name or address is not found, or no host file has been specified, a nameserver lookup is performed.

To determine if an alternate host file has been specified, use the **DnsGetHostFile** function. A return value of zero indicates that no alternate host file has been cached for the current thread.

A system may have a default host file, which is used to resolve hostnames before performing a nameserver lookup. To determine the name of this file, use the **DnsGetDefaultHostFile** function. It is not necessary to specify this default host file, since it is always used to resolve host names and addresses.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

DnsSetLastError Function

```
VOID WINAPI DnsSetLastError(
   DWORD dwErrorCode
);
```

The **DnsSetLastError** function sets the error code for the current thread. This function is typically used to clear the last error by passing a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the error code for the current thread. A value of zero clears the last error code.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or DNS_ERROR. Those functions which call **DnsSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **DnsGetLastError** function. The use of **DnsGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

DnsSetLocalDomain Function

```
INT WINAPI DnsSetLocalDomain(
   HCLIENT hClient,
   LPCTSTR lpszDomain
);
```

Parameters

hClient

Handle to the client session.

lpszDomain

Pointer to the string which contains the local domain name. This is used as a default value when a query does not explicitly specify a domain name.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib
Unicode: Implemented as Unicode and ANSI versions

DnsSetResolverOptions Function

```
DWORD WINAPI DnsSetResolverOptions(
    HCLIENT hClient,
    DWORD dwOptions
);
```

The **DnsSetResolverOptions** function changes the resolver options for the specified client session.

Parameters

hClient

Handle to the client session.

dwOptions

An unsigned integer that specifies one or more resolver options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
DNS_OPTION_NONE	No additional resolver options specified. This is the default value, and it is recommended that most applications do not specify additional options unless the implications of doing so are understood.
DNS_OPTION_PROMOTE	Promotes the server that successfully completed the last query to the first server that will be used to resolve subsequent queries. This option can improve performance in some cases where one or more of the registered servers are non-responsive. This option takes precedence over the DNS_OPTION_ROTATE option.
DNS_OPTION_ROTATE	Enables a round-robin selection of nameservers when performing queries. Normally each nameserver is queried in the same order. This option rotates the available nameservers so a different server is used with each query.
DNS_OPTION_AUTHONLY	Require the answer from the nameserver to be authoritative, not from the server's cache. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_PRIMARY	Queries are only accepted from the primary nameserver. This option is included for future expansion as most servers do not support this feature and will ignore it.
DNS_OPTION_NORECURSE	Disable the sending of recursive queries to the nameserver. Specifying this option will disable the bit in the DNS request header that specifies recursion is desired.
DNS_OPTION_NOSEARCH	Disable additional queries of higher domains in the search list if the host name cannot be resolved. If this option is specified, and the host name cannot be resolved using the local domain name an error is

	returned immediately. This option is ignored if no local domain has been specified or if the DNS_OPTION_NOSUFFIX option has been specified.
DNS_OPTION_NOSUFFIX	Disable additional queries using the local domain name if the host name is not a fully qualified domain name and cannot be resolved. This option is ignored if no local domain has been specified.
DNS_OPTION_NONAMECHECK	Disable checking the host name for invalid characters, such as the underscore and control characters. By default, host names are checked to ensure they're valid before submitting a query to the nameserver.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **DnsGetLastError**.

Remarks

The **DnsSetResolverOptions** function changes the resolver options for the specified client session, modifying how nameserver queries are processed. It is recommended that most applications do not specify any resolver options and use the default behavior. Specifying these options without understanding how they can affect standard queries can result in unexpected failures. In particular, caution should be used when specifying the DNS_OPTION_NORECURSE and DNS_OPTION_NOSEARCH options as they change the normal process of resolving a host name.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

DnsSetRetryCount Function

```
INT WINAPI DnsSetRetryCount(
   HCLIENT hClient,
   INT nRetries
);
```

The **DnsSetRetryCount** function sets the number of attempts that the client will make attempting to resolve a query. When used in conjunction with the **DnsSetTimeout** function, it determines the total amount of time the client will spend attempting to resolve a query.

Parameters

hClient

Handle to the client session.

nRetries

The number of attempts the client will make, per nameserver, to resolve a query.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The retry count determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

See Also

DnsSetTimeout Function

```
INT WINAPI DnsSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **DnsSetTimeout** function sets the number of seconds that the client will wait for a response from a nameserver. The timeout value is used each time a server in the client's nameserver table is queried. When used in conjunction with the **DnsSetRetryCount** function, it determines the total amount of time the client will spend attempting to resolve a query.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds until the client times out waiting for a response from a nameserver.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Remarks

The timeout value determines the amount of time the client will wait for a response from each query, the effective amount of time the client will wait increases with each nameserver and the total number of retries specified. For example, with two nameservers registered with the client, with a default of 4 retries per nameserver and a timeout value of 10 seconds, would cause the client to wait a total of 80 seconds until it returns an error indicating that it was unable to resolve the query.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

See Also

DnsGetRetryCount, DnsGetTimeout, DnsSetRetryCount

DnsUninitialize Function

```
VOID WINAPI DnsUninitialize();
```

The **DnsUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **DnsInitialize** call before it can call any of the other the library functions. When it has finished using the library, the application must call **DnsUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **DnsUninitialize** for every successful call to **DnsInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

See Also

DnsInitialize, DnsCloseHandle, DnsCreateHandle

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

DnsUnregisterServer Function

```
INT WINAPI DnsUnregisterServer(
    HCLIENT hClient,
    INT nServer
);
```

The **DnsUnregisterServer** function removes the specified nameserver information from the client. Unregistering a server prevents the client from using that server to satisfy subsequent DNS queries.

Parameters

hClient

Handle to the client session.

nServer

The index into the client's nameserver table. This index is the same value that is passed to the **DnsRegisterServer** function when the nameserver is registered.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is DNS_ERROR. To get extended error information, call **DnsGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csdnsv12.lib

Domain Name Service Data Structures

- HOSTENT
- INTERNET_ADDRESS

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

HOSTENT

The **HOSTENT** structure contains information about a domain name, including its IP address and any aliases which may be defined.

```
typedef struct _HOSTENT
{
   char *  h_name;
   char ** h_aliases;
   short   h_addrtype;
   short   h_length;
   char ** h_addr_list;
} HOSTENT, *LPHOSTENT;
```

Members

h_name

The fully qualified domain name (FQDN) that caused the nameserver server to return a reply.

h_aliases

A NULL-terminated array of alternate names.

h_addrtype

The type of address being returned.

h_length

The length, in bytes, of each address.

h_addr_list

A NULL-terminated list of addresses for the host. Addresses are returned in network byte order. The macro **h_addr** is defined to be **h_addr_list**[0] for compatibility with older software.

Remarks

This structure is intended to be used for backwards compatibility with legacy applications and should not be used with new applications. You cannot use this structure to obtain information for a host which is assigned an IPv6 address. Applications should use the **DnsGetHostAddress** and **DnsGetHostName** functions which support both IPv4 and IPv6 addresses.

The application must never attempt to modify this structure or free any of its members. There is no Unicode version of this structure, string pointers will always specify ANSI strings, even if the application is compiled to use Unicode. Only one copy of this structure is allocated per thread, so the application should copy any information it needs before calling any other functions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: winsock2.h.

See Also

DnsGetHostAddress, DnsGetHostByAddress, DnsGetHostByName, DnsGetHostName

INTERNET_ADDRESS

This structure represents a numeric IPv4 or IPv6 address in network byte order.

```
typedef struct _INTERNET_ADDRESS
{
     INT    ipFamily;
     BYTE   ipNumber[16];
}  INTERNET_ADDRESS, *LPINTERNET_ADDRESS;
```

Members

ipFamily

An integer which identifies the type of IP address. It will be one of the following values:

Value	Description
INET_ADDRESS_UNKNOWN	The address has not been specified or the bytes in the ***ipNumber*** array does not represent a valid address. Functions which populate this structure will use this value to indicate that the address cannot be determined.
INET_ADDRESS_IPV4	Specifies that the address is in IPv4 format. The first four bytes of the ***ipNumber*** array are significant and contains the IP address. The remaining bytes are not significant and an application should not depend on them having any particular value, including zero.
INET_ADDRESS_IPV6	Specifies that the address is in IPv6 format. All bytes in the ***ipNumber*** array are significant. Note that it is possible for an IPv6 address to actually represent an IPv4 address. This is indicated by the first 10 bytes of the address being zero.

ipNumber

A byte array which contains the numeric form of the IP address. This array is large enough to store both IPv4 (32 bit) and IPv6 (128 bit) addresses. The values are stored in network byte order.

Remarks

The **INTERNET_ADDRESS** structure is used by some functions to represent an Internet address in a binary format that is compatible with both IPv4 and IPv6 addresses. Applications that use this structure should consider it to be opaque, and should not modify the contents of the structure directly.

For compatibility with legacy applications that expect an IP address to be 32 bits and stored in an unsigned integer, you can copy the first four bytes of the ***ipNumber*** array using the **CopyMemory** function or equivalent. Note that if this is done, your application should always check the ***ipFamily*** member first to make sure that it is actually an IPv4 address.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Domain Name Service Constants

Value	Description
DNS_RECORD_NONE	No record type
DNS_RECORD_ADDRESS	Host address
DNS_RECORD_NS	Authoritative nameserver
DNS_RECORD_CNAME	Canonical name (alias)
DNS_RECORD_SOA	Start of Authority
DNS_RECORD_WKS	Well known services
DNS_RECORD_PTR	Domain name
DNS_RECORD_HINFO	Host information
DNS_RECORD_MINFO	Mailbox information
DNS_RECORD_MX	Mail exchange host
DNS_RECORD_TXT	Text strings
DNS_RECORD_LOC	Location information
DNS_RECORD_UINFO	User information
DNS_RECORD_UID	User ID
DNS_RECORD_GID	Group ID

File Encoding Library

A utility library for encoding, compressing, and encrypting files.

Reference

- Functions

Library Information

File Name	CSNCDV12.DLL
Version	12.0.3024.1286
LibID	B1B7354C-B0D2-4BD1-858B-9B0423768198
Import Library	CSNCDV12.LIB
Dependencies	None
Standards	RFC 1738, RFC 1951, RFC 2045, RFC 8089

Overview

The File Encoding library is a versatile collection of functions for transforming and processing file and memory data. Originally focused on encoding binary files into text formats such as Base64 and Uuencode for use in email and newsgroups, the library has since expanded into a broader utility toolkit. It now includes support for a variety of encoding formats including Base32, Base58, and Base85, along with functions for decoding, compression, and expansion of files and buffers.

In addition to encoding and decoding, the library provides robust support for AES-256 encryption and decryption of strings, files, and memory blocks. It also includes utilities for comparing file contents, computing message digests, converting text files between different Unicode and legacy code pages, and determining the encoding of existing files. For applications that require unique identifiers, the library offers functions to create, parse, and manipulate UUIDs (GUIDs), including sequential, namespace-based, and custom values. There are also helpers for working with file URLs, verifying Unicode content, and generating secure tokens.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on

ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

File Encoding Functions

Function	Description
AesDecryptBuffer	Decrypt a buffer previously encrypted using the AesEncryptBuffer function
AesDecryptFile	Decrypt a file previously encrypted using the AesEncryptFile function
AesDecryptString	Decrypt a string previously encrypted using the AesEncryptString function
AesEncryptBuffer	Encrypt a memory buffer using 256-bit AES encryption
AesEncryptFile	Encrypt the contents of a file using 256-bit AES encryption
AesEncryptString	Encrypt a null-terminated string using 256-bit AES encryption
CompareFile	Compare the contents of two files to determine if they are identical
CompareFileEx	Compare the contents of two files or the contents of a file against message digest
CompressBuffer	Compress the contents of the specified buffer
CompressFile	Compress the contents of the specified file
CompressFileEx	Compress the contents of the specified file with additional options
ConvertTextFile	Convert the contents of a text file from one code page to another
CreateCustomGuid	Create a unique GUID which includes a 32-bit user-defined value
CreateGuidFromString	Parse a string which contains a GUID and return its value
CreateHexStringFromGuid	Create a string of hexadecimal digits from the specified GUID
CreateNamespaceGuid	Create a deterministic namespace identifier from the specified GUID
CreateSequentialGuid	Create a unique sequential GUID which can be sorted lexicographically
CreateStringFromGuid	Create a string representation of the specified GUID
CreateUniqueToken	Create a unique cryptographically secure token string
DecodeBuffer	Decode an encoded string, storing the result in the specified buffer
DecodeFile	Decode the contents of a file using the specified decoding method
EncodeBuffer	Encode the contents of a buffer using the specified encoding method
EncodeFile	Encode the contents of a file using the specified encoding method
ExpandBuffer	Expand the contents of a previously compressed buffer
ExpandFile	Expand the contents of a previously compressed file
ExpandFileEx	Expand the contents of a previously compressed file with additional options
FilterHtmlFile	Filters the contents of an HTML file and returns the text in a string buffer
FilterHtmlText	Removes HTML formatting from a string and returns simplified plain text
FilterMarkdownText	Removes Markdown formatting from a string and returns simplified plain text
FilterUnicodeText	Filters and replaces confusable characters and symbols in a Unicode string
GetCustomGuidValue	Return the custom 32-bit value used to create a Version 8 GUID.
GetFileCodePage	Determine what code page was used to create the specified text file

GetFileNameUrl	Return a file URL which conforms to the standard file URI scheme
GetFileTimeFromGuid	Return the timestamp from a sequential GUID in a FILETIME structure
GetLocalMachineGuid	Return a unique identifier for the local machine
GetMessageDigest	Compute a message digest for a buffer, string or data file
GetSystemTimeFromGuid	Return the timestamp from a sequential GUID in a SYSTEMTIME structure
GetTimeFromGuid	Returns the 64-bit timestamp value from a sequential GUID
GetUrlFileName	Parse a file URL and return the corresponding local file name or UNC path
IsEqualGuidString	Compare two strings containing GUIDs and determine if they are the same value
IsHtmlText	Determine whether a string appears to contain HTML formatting
IsMarkdownText	Determine whether a string appears to contain Markdown formatting
IsUnicodeConfusable	Determine if a Unicode string contains confusable characters
IsUnicodeText	Determine if a text buffer contains valid Unicode characters
IsValidFileUrl	Determine if a file URL is valid and optionally check if the file exists
NormalizeUrl	Validate and normalize a string which specifies a web address or local file URL
UnicodeDecodeText	Decode UTF-8 encoded text and return a localized string
UnicodeEncodeText	Encode a text buffer and return a UTF-8 encoded string

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

AesDecryptBuffer Function

```
BOOL WINAPI AesDecryptBuffer(
   LPCTSTR lpszPassword,
   LPCVOID lpvInputBuffer,
   DWORD dwInputSize
   LPVOID lpvOutputBuffer,
   LPDWORD lpdwOutputSize
);
```

The **AesDecryptBuffer** function decrypts the contents of a memory buffer.

Parameters

lpszPassword

A null-terminated string of characters that will be used to generate the decryption key. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

lpvInputBuffer

The buffer which contains the data to be decrypted.

dwInputSize

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

The buffer which will contain the decrypted data when the function returns. This memory must be allocated by the application and be large enough to contain all of the decrypted data. If the output buffer is not large enough, the function will fail. This parameter cannot be NULL.

lpdwOutputSize

The number of bytes that may be copied into the output buffer. This parameter must be initialized to a non-zero value. When the function returns, the actual number of bytes of decrypted data is returned in this parameter. This parameter cannot be NULL.

Return Value

A non-zero value is returned if the data was successfully decrypted. A zero value indicates that the data could not be decrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesDecryptBuffer** function will decrypt a block of memory using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The value of the ***lpszPassword*** parameter must be identical to the value used to encrypt the data using the **AesEncryptBuffer** function.

This function cannot be used to decrypt data that was encrypted using another third-party library or utility. It can only be used to decrypt data that was previously encrypted using the **AesEncryptBuffer** function.

If you wish to decrypt the contents of a file, use the **AesDecryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other

countries. If the required cryptographic provider is not available, the function will fail.

Example

```
#define MAX_BUFFER_SIZE 1024

BYTE lpInputBuffer[MAX_BUFFER_SIZE] = "The quick brown fox jumps over the lazy
dog.";
BYTE lpEncryptedBuffer[MAX_BUFFER_SIZE + 256];
BYTE lpDecryptedBuffer[MAX_BUFFER_SIZE];

DWORD dwInputSize = (DWORD)strlen((LPCSTR)lpInputBuffer);
DWORD dwEncryptedSize = sizeof(lpEncryptedBuffer);
DWORD dwDecryptedSize = sizeof(lpDecryptedBuffer);

LPCTSTR lpszPassword = _T("MySecretPassword");

BOOL bResult = FALSE;

// Encrypt the data
bResult = AesEncryptBuffer(lpszPassword,
                           lpInputBuffer,
                           dwInputSize,
                           lpEncryptedBuffer,
                           &dwEncryptedSize);

if (!bResult)
{
    _tprintf(_T("Encryption failed, error 0x%08lX\n"), GetLastError());
    return;
}

// Decrypt the data
bResult = AesDecryptBuffer(lpszPassword,
                           lpEncryptedBuffer,
                           dwEncryptedSize,
                           lpDecryptedBuffer,
                           &dwDecryptedSize);

if (!bResult)
{
    _tprintf(_T("Decryption failed, error 0x%08lX\n"), GetLastError());
    return;
}

// Verify the decrypted data matches the original input
// Note that encrypted data is binary and may contain embedded nulls
if (dwDecryptedSize == dwInputSize &&
    memcmp(lpInputBuffer, lpDecryptedBuffer, dwInputSize) == 0)
{
    _tprintf(_T("Success: Decrypted data matches original input.\n"));
}
else
{
    _tprintf(_T("Error: Decrypted data does not match original input.\n"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

AesDecryptFile Function

```
BOOL WINAPI AesDecryptFile(
   LPCTSTR lpszPassword,
   LPCTSTR lpszInputFile,
   LPCTSTR lpszOutputFile
);
```

The **AesDecryptFile** function decrypts the contents of a file.

Parameters

lpszPassword

A null-terminated string of characters that will be used to generate the decryption key. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

lpszInputFile

A null-terminated string which specifies the name of the file to be decrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

A null-terminated string which specifies the name of the file that will contain the decrypted data. If the file exists, it will be overwritten. It must be a regular file that can be opened for writing by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesDecryptFile** function will decrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and stores the decrypted data in the specified output file. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The ***lpszPassword*** value must be identical to the value used to encrypt the file using the **AesEncryptFile** function.

This function cannot be used to decrypt a file that was encrypted using another third-party library or utility. It can only be used to decrypt a file that was previously encrypted using the **AesEncryptFile** function.

A temporary file is created during the decryption process and the output file is created or overwritten only if the input file could be successfully decrypted. If the decryption fails, no output file will be created.

If you wish to decrypt the contents of a memory buffer or string, use the **AesDecryptBuffer** or **AesDecryptString** functions.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

AesDecryptString Function

```
LONG WINAPI AesDecryptString(
   LPCTSTR lpszPassword,
   LPCTSTR lpszInputString,
   LPTSTR lpszOutputString,
   LONG nMaxLength
);
```

The **AesDecryptString** function decrypts the contents of a string.

Parameters

lpszPassword

A null-terminated string of characters that will be used to generate the decryption key. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used to decrypt the data. Password strings that exceed 215 characters will be truncated.

lpszInputString

A null-terminated string which contains the data to be decrypted. The encrypted input data must be base64 encoded and identical to the encrypted string returned by the **AesEncryptString** function. If this parameter is NULL or points to an empty string the function will fail.

lpszOutputString

The buffer which will contain the decrypted string data. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that can be copied to the output string buffer. The output buffer must be large enough to store the complete decrypted string and is terminated with a null character. This value must be greater than zero. If the output string buffer is not large enough, the function will fail.

Return Value

The number of characters of decrypted text copied to the string buffer, not including the terminating null character. A zero value indicates that the string could not be decrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesDecryptString** function will decrypt a string using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the decrypted string o the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the decryption process. The ***lpszPassword*** value must be identical to the value used to encrypt the data using the **AesEncryptString** function.

Due to how the SHA-256 hash is generated, this function cannot be used to decrypt strings that were encrypted using another third-party library. It can only be used to decrypt strings that were previously encrypted using **AesEncryptString**.

If you wish to decrypt the contents of a file, use the **AesDecryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
LPCTSTR lpszPassword = _T("NFr-E{Ki3_1w0iV+LI@z");
TCHAR szDecryptedText[MAX_STRING_LENGTH];

INT nLength = AesDecryptString(lpszPassword,
                               szEncryptedText,
                               szDecryptedText,
                               MAX_STRING_LENGTH);

if (nLength > 0)
{
    _tprintf(_T("The decrypted string is \"%s\"\n"), szDecryptedText);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

AesEncryptBuffer Function

```
BOOL WINAPI AesEncryptBuffer(
   LPCTSTR lpszPassword,
   LPCVOID lpvInputBuffer,
   DWORD dwInputSize
   LPVOID lpvOutputBuffer,
   LPDWORD lpdwOutputSize
);
```

The **AesEncryptBuffer** function encrypts the contents of a memory buffer.

Parameters

lpszPassword

A null-terminated string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this function. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

lpvInputBuffer

The buffer which contains the data to be encrypted.

dwInputSize

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

The buffer which will contain the encrypted data when the function returns. This memory must be allocated by the application and be large enough to contain all of the encrypted data. The amount encrypted data returned will always be larger than the amount of data specified by ***dwInputSize***. If the output buffer is not large enough, the function will fail. This parameter cannot be NULL.

lpdwOutputSize

The number of bytes that may be copied into the output buffer. This parameter must be initialized to a non-zero value. When the function returns, the actual number of bytes of encrypted data is returned in this parameter. This parameter cannot be NULL.

Return Value

A non-zero value is returned if the data was successfully encrypted. A zero value indicates that the data could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesEncryptBuffer** function will encrypt a block of memory using a 256-bit AES (Advanced Encryption Standard) algorithm and returns the encrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process. A library-defined internal value is incorporated when deriving the encryption key to inhibit casual decryption using external tools. This function is intended as a convenience for encrypting application data using a password-derived key. It is not designed as a general-purpose encrypted data format for interoperability with other libraries or utilities. Applications should use the corresponding **AesDecryptBuffer** function to decrypt the data.

It is recommended that most applications specify a password value. If the ***lpszPassword*** parameter is NULL or specifies a zero-length string, any application using this function with a NULL or empty password will be able to decrypt the data using the **AesDecryptBuffer** function without specifying a

password. This behavior is intended for convenience and should not be considered secure for protecting sensitive data. If the Unicode version of this function is called, the *lpszPassword* value will be encoded using UTF-8 prior to the hash value being generated.

The amount of encrypted data returned by this function will always be somewhat larger than the original unencrypted data. If your application dynamically allocates a buffer to store the encrypted data, it is recommended that you allocate a buffer that is at least 256 bytes larger than the input data. Allocating a significantly larger buffer is typically unnecessary. If the output buffer provided is not large enough, the function will fail and the **GetLastError** function will return ERROR_INSUFFICIENT_BUFFER.

The encrypted data returned by this function can contain embedded nulls and should be typically handled as byte values. If you wish to encrypt strings and store the encrypted values (for example, encrypting an API key and storing it in a configuration file used by your application), use the **AesEncryptString** function. It will perform the same 256-bit AES encryption, but return the encrypted data as a base64 encoded string rather than binary data.

If your application is also using the **CompressBuffer** function to compress the data, it is recommended that you call **CompressBuffer** before calling **AesEncryptBuffer**. You will typically achieve a better compression rate on unencrypted data than attempting to compress data which has been encrypted with this function.

If you wish to encrypt the contents of a file, use the **AesEncryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
#define MAX_BUFFER_SIZE 1024

BYTE lpInputBuffer[MAX_BUFFER_SIZE] = "The quick brown fox jumps over the lazy
dog.";
BYTE lpEncryptedBuffer[MAX_BUFFER_SIZE + 256];
BYTE lpDecryptedBuffer[MAX_BUFFER_SIZE];

DWORD dwInputSize = (DWORD)strlen((LPCSTR)lpInputBuffer);
DWORD dwEncryptedSize = sizeof(lpEncryptedBuffer);
DWORD dwDecryptedSize = sizeof(lpDecryptedBuffer);

LPCTSTR lpszPassword = _T("MySecretPassword");

BOOL bResult = FALSE;

// Encrypt the data
bResult = AesEncryptBuffer(lpszPassword,
                           lpInputBuffer,
                           dwInputSize,
                           lpEncryptedBuffer,
                           &dwEncryptedSize);

if (!bResult)
{
    _tprintf(_T("Encryption failed, error 0x%08lX\n"), GetLastError());
    return;
}
```

```
// Decrypt the data
bResult = AesDecryptBuffer(lpszPassword,
                           lpEncryptedBuffer,
                           dwEncryptedSize,
                           lpDecryptedBuffer,
                           &dwDecryptedSize);

if (!bResult)
{
    _tprintf(_T("Decryption failed, error 0x%08lX\n"), GetLastError());
    return;
}

// Verify the decrypted data matches the original input
// Note that encrypted data is binary and may contain embedded nulls
if (dwDecryptedSize == dwInputSize &&
    memcmp(lpInputBuffer, lpDecryptedBuffer, dwInputSize) == 0)
{
    _tprintf(_T("Success: Decrypted data matches original input.\n"));
}
else
{
    _tprintf(_T("Error: Decrypted data does not match original input.\n"));
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

AesEncryptFile Function

```
BOOL WINAPI AesEncryptFile(
   LPCTSTR lpszPassword,
   LPCTSTR lpszInputFile,
   LPCTSTR lpszOutputFile
);
```

The **AesEncryptFile** function encrypts the contents of a file.

Parameters

lpszPassword

A null-terminated string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this function. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

lpszInputFile

A null-terminated string which specifies the name of the file to be encrypted. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

A null-terminated string which specifies the name of the file that will contain the encrypted data. If the file exists, it will be overwritten. It must be a regular file that can be opened for writing by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

Return Value

A non-zero value is returned if the string was successfully encrypted. A zero value indicates that the string could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesEncryptFile** function will encrypt the contents of a file using a 256-bit AES (Advanced Encryption Standard) algorithm and returns the encrypted data to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process. A library-defined internal value is incorporated when deriving the encryption key to inhibit casual decryption using external tools. This function is intended as a convenience for encrypting files using a password-derived key. It is not designed as a general-purpose function for interoperability with other libraries or platforms. Applications should use the corresponding **AesDecryptFile** function to decrypt the file.

It is recommended that most applications specify a password value. If the *lpszPassword* parameter is NULL or specifies a zero-length string, any application using this function with a NULL or empty password will be able to decrypt the data using the **AesDecryptFile** function without specifying a password. This behavior is intended for convenience and should not be considered secure for protecting sensitive data. If the Unicode version of this function is called, the *lpszPassword* value will be encoded using UTF-8 prior to the hash value being generated.

A temporary file is created during the encryption process and the output file is created or overwritten only if the input file could be successfully encrypted. If the encryption fails, no output file will be created.

The input file contents will always be processed as a binary data stream. If you use this function to encrypt a text file, the output file will contain binary characters, not printable text. If you wish to transfer or store the encrypted data as text, it should be encoded using the **EncodeFile** function after calling **AesEncryptFile**.

If your application is also using the **CompressFile** function to compress the data, it is recommended that you call **CompressFile** before calling **AesEncryptFile**. You will typically achieve a better compression rate on unencrypted data than than attempting to compress data which has been encrypted with this function.

If you wish to encrypt the contents of a memory buffer or string, use the **AesEncryptBuffer** or **AesEncryptString** functions.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

AesEncryptString Function

```
LONG WINAPI AesEncryptString(
   LPCTSTR lpszPassword,
   LPCTSTR lpszInputString,
   LONG nInputLength
   LPTSTR lpszOutputString,
   LONG nMaxLength
);
```

The **AesEncryptString** function encrypts the contents of a string.

Parameters

lpszPassword

A null-terminated string of characters that will be used to generate the encryption key. Passwords are case sensitive and must match exactly when decrypting data that was previously encrypted using this function. This parameter may be NULL or a zero-length string, in which case a default internal hash value is used. Password strings that exceed 215 characters will be truncated.

lpszInputString

A null-terminated string which contains the text to be encrypted. If the Unicode version of this function is called, the string is automatically UTF-8 encoded prior to being encrypted.

nInputLength

The number of characters in the input string which will be encrypted. If this value is -1, the length of the input string is determined automatically by counting the number of of characters up to the terminating null byte. Note that with Unicode strings, this value must represent the number of characters in the string, not the number of bytes allocated for the string.

lpszOutputString

The buffer which will contain a base64 encoded encrypted string when the function returns. This memory must be allocated by the application and be large enough to contain all the encrypted data. The amount encrypted data returned will always be larger than the amount of data specified by ***nInputLength***. If the output string buffer is not large enough, the function will fail. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that can be copied to the output string buffer. The output buffer must be large enough to store the complete encrypted string which is encoded using base64 and terminated with a null character. This value must be greater than zero. If the output string buffer is not large enough, the function will fail.

Return Value

The number of characters of encrypted text copied to the string buffer, not including the terminating null character. A zero value indicates that the string could not be encrypted. To get extended error information, call **GetLastError**.

Remarks

The **AesEncryptString** function will encrypt a string using a 256-bit AES (Advanced Encryption Standard) algorithm and returns a copy of the encrypted data as a base64 encoded string to the caller. The password (or passphrase) provided by the caller is used to generate a SHA-256 hash value which is used as part of the encryption process. The identical password is required to decrypt the data

using the **AesDecryptString** function.

It is recommended that most applications specify a password value. If the *lpszPassword* parameter is NULL or specifies a zero-length string, a default internal hash value is used. This means that any other application which uses a NULL password value will be able to decrypt the data. If the Unicode version of this function is called, the *lpszPassword* value will be encoded using UTF-8 prior to the hash value being generated.

Due to how the SHA-256 hash is generated, the encrypted data cannot be decrypted using another third-party library with the same password value. It can only be decrypted using the **AesDecryptString** function.

The amount of encrypted data returned by this function will always be larger than original unencrypted data. If your application dynamically allocates a block of memory to store the encrypted string, provide a maximum output string size that is at least several hundred bytes larger than the unencrypted data. If the output string is not large enough, the function will fail and the **GetLastError** function will return ERROR_INSUFFICIENT_BUFFER.

The string provided to this function cannot contain embedded nulls and and should not be used to encrypt binary data. If you wish to encrypt binary data, use the **AesEncryptBuffer** function. It will perform the same 256-bit AES encryption and return the encrypted data into an buffer provided by the caller.

If you wish to encrypt the contents of a file, use the **AesEncryptFile** function.

This function uses the Microsoft CryptoAPI and the RSA AES cryptographic provider. This provider may not be available in some languages, countries or regions. The availability of this provider may also be constrained by cryptography export restrictions imposed by the United States or other countries. If the required cryptographic provider is not available, the function will fail.

Example

```
LPCTSTR lpszPassword = _T("NFr-E{Ki3_1w0iV+LI@z");
LPCTSTR lpszPlainText = _T("The quick brown fox jumped over the lazy dog.");
TCHAR szEncryptedText[MAX_STRING_LENGTH];

INT nLength = AesEncryptString(lpszPassword,
                               lpszPlainText,
                               -1,
                               szEncryptedText,
                               MAX_STRING_LENGTH);

if (nLength > 0)
{
    _tprintf(_T("The encrypted string is \"%s\"\n"), szEncryptedText);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

CompareFile Function

```
BOOL WINAPI CompareFile(
   LPCTSTR lpszFile1,
   LPCTSTR lpszFile2
);
```

The **CompareFile** function compares the contents of two files to determine if they are identical.

Parameters

lpszFile1

A null-terminated string which specifies the name of the first file to compare. This parameter must specify the name of a file which exists and can be opened for read access by the current process. If the file name specifies a directory or device name, the function will fail. This parameter cannot be NULL or a zero-length string. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters after the variable expansion, they will be removed.

lpszFile2

A null-terminated string which specifies the name of the second file to compare. This parameter must specify the name of a file which exists and can be opened for read access by the current process. If the file name specifies a directory or device name, the function will fail. This parameter cannot be NULL or a zero-length string. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters after the variable expansion, they will be removed.

Return Value

A non-zero value is returned if the two files are identical. A value of zero indicates the files are different or an error has occurred. Check the value returned by the **GetLastError** function to determine the reason the file comparison was not successful. If the files are identical, this function will clear the last error code for the current thread.

Remarks

The **CompareFile** function can be used compare the contents of two files to determine if they are the same. If you need to perform a more complex file comparison, such as comparing the file creation or modification timestamps or verifying the file contents match a computed hash value, use the **CompareFileEx** function.

If the *lpszFile1* and *lpszFile2* file names resolve to the same file on the disk, this function will succeed without checking the contents of the file. This check is performed immediately after the file names have been expanded and converted to absolute paths. The function will still return an error if the file not does actually exist or is not a regular file.

To avoid potential problems with relative pathing in multithreaded applications, it is recommended you use absolute paths whenever possible. If you do not specify an absolute path, the file locations will be considered relative to the current working directory for the process. Because this is shared between all threads, it is possible for one thread to change the current working directory at any time and this can create inconsistent results. If you must use relative paths in a multithreaded application, use a mutex or critical section to ensure other threads cannot change the current working directory for the process while performing the file comparison.

This function will normalize the file names provided by the caller and perform checks to make sure the

names do not contain illegal characters. If the name includes quotes, wildcard characters or other invalid symbols the function will fail and return zero with the last error code set to ST_ERROR_INVALID_FILE_NAME. It is permitted to use forward slashes in path names and these will be converted to the standard backslash character used with Windows paths. This function cannot be used to compare the contents of NTFS alternate data streams.

This function is defined using an alias which automatically selects an ANSI or Unicode version based on the value of the UNICODE preprocessor macro. If you use the ANSI version of this function, the expanded file names will always be considered UTF-8 encoded strings, regardless of the current locale of the application. If your application uses file names which contain non-ASCII characters, you should always use the Unicode version of the function, even if your project is configured to use a multi-byte character set.

Example

```
// Compare the contents of two files
LPCTSTR lpszFile1 = _T("%USERPROFILE%\\AppName\\ProjectData.db");
LPCTSTR lpszFile2 = _T("%TEMP%\\BackupData.db");

BOOL bIdentical = CompareFile(lpszFile1, lpszFile2);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

CompareFileEx Function

```
BOOL WINAPI CompareFileEx(
   LPCTSTR lpszFile1,
   LPCTSTR lpszFile2,
   DWORD dwOptions,
   LPCTSTR lpszDigest
);
```

The **CompareFileEx** function compares the contents of two files with an optional message digest.

Parameters

lpszFile1

A null-terminated string which specifies the name of the first file to compare. This parameter must specify the name of a file which exists and can be opened for read access by the current process. If the file name specifies a directory or device name, the function will fail. This parameter cannot be NULL or a zero-length string. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters after the variable expansion, they will be removed.

lpszFile2

A null-terminated string which specifies the name of the second file to compare. If this parameter is NULL or a zero-length string, the ***lpszDigest*** parameter must specify a valid message digest and the contents of the first file will be compared against that digest. If this parameter specifies a file name, the file must exist and the current process must be able to open it for read access. If the file name specifies a directory or device name, the function will fail. It is permitted to use environment variables in the file name by surrounding the variable name with the percent symbol. If the file name contains any leading or trailing space characters after the variable expansion, they will be removed.

dwOptions

An unsigned integer value which specifies one or more option flags which will control how the files are compared. It may be one or more of the following values:

Value	Description
COMPARE_FILE_DEFAULT	Use the default comparison option, which is to perform a byte comparison of both files. If the ***lpszDigest*** parameter is not NULL or a zero-length string, the function will compare the message digest against the contents of the file. If the ***lpszDigest*** parameter has a value and no specific hash algorithm has been specified as one of the options, the hash type will be automatically determined based on its value
COMPARE_FILE_CONTENTS	Perform a byte comparison of the two files. This option requires both files be specified. The current process must be able to open both files for exclusive read access. If either file is opened for write access, the function will fail. The ***lpszFile2*** parameter must specify a valid file name if this option is used.
COMPARE_FILE_TIME_CREATED	Compare the file creation times for both files and only

	consider them to be identical if the creation times are identical. If this option is specified and the creation times are different, the function will return zero even if the contents of the two files are identical. The ***lpszFile2*** parameter must specify a valid file name if this option is used.
COMPARE_FILE_TIME_MODIFIED	Compare the file modification times for both files and only consider them to be identical if the modification times are identical. If this option is specified and the modification times are different, the function will return zero even if the contents of the two files are identical. The ***lpszFile2*** parameter must specify a valid file name if this option is used.
COMPARE_FILE_DIGEST_MD5	Use the MD5 algorithm to compute 128-bit hash value for the contents of the first file and compare this against the specified digest string. This algorithm is the most efficient method to compute a hash to verify data integrity, however it is not considered cryptographically secure and hash collision is possible. When this option is used the ***lpszDigest*** parameter must specify a valid MD5 hash as a 32 digit hexadecimal string.
COMPARE_FILE_DIGEST_SHA1	Use the SHA-1 algorithm to compute 160-bit hash value for the contents of the first file and compare this against the specified digest string. This algorithm is comparable to the MD5 algorithm and has a lower chance of hash collision; however, it is not considered cryptographically secure and hash collision is possible. When this option is used the ***lpszDigest*** parameter must specify a valid SHA-1 hash as a 40 digit hexadecimal string.
COMPARE_FILE_DIGEST_SHA256	Use the SHA-256 algorithm to compute a 256-bit hash value for the contents of the first file and compare this against the specified digest string. This is a cryptographically secure algorithm which is more compute intensive than either MD5 or SHA-1, but the chance of a hash collision is extremely low and typically not a concern for most applications. When this option is used the ***lpszDigest*** parameter must specify a valid SHA-256 hash as a 64 digit hexadecimal string.

lpszDigest

A null-terminated string which specifies a sequence of hexadecimal numbers which are used to compare against the computed hash value for the file. If this parameter is not NULL and no option is specified to indicate the hash type, it will be inferred from the length of the string. If this parameter is NULL or a zero-length string, it will be ignored. The case of the hexadecimal digits in the string are ignored and it is permitted, but not required, to prefix the string with either "0x" or "&H" to indicate it is a hexadecimal value. If the string does not specify a valid hexadecimal number or is not a value computed using one of the supported hash algorithms, the function will fail.

Return Value

A non-zero value is returned if the files are identical using the specified criteria. A value of zero indicates the files are different or an error has occurred. Check the value returned by the **GetLastError** function to determine the reason the file comparison was not successful. If the files are identical, this function will clear the last error code for the current thread.

Remarks

The **CompareFileEx** function can be used to either compare the contents of two files or compare the contents of a file against a pre-computed hash value to determine if they match. In addition to comparing file contents, the function can also check the file creation and/or modification times to ensure they are the same. You can use the **GetMessageDigest** function to compute a hash value for a file.

In most cases, an application will specify either two files to compare or a message digest value. If you call the function using two file names and a message digest, the contents of both files must be identical and the computed hash value must match the specified message digest. If any of the requirements are are not satisfied, the function will return zero (false). For example, if the actual contents of the two files are identical, but the value specified by ***lpszDigest*** does not match the computed hash value of files, the function will still return zero.

This function performs the comparison in a way to minimize potential disk I/O whenever possible. First, the size of the two files are compared and if they are different, no further checks are performed. Next, if either the COMPARE_FILE_TIME_CREATED or COMPARE_FILE_TIME_MODIFIED options have been specified, the file timestamps are compared and no further checks are performed if they do not match. A byte comparison of both files will only be performed after the other comparison criteria has been satisfied.

Comparing the contents of a file against a message digest value is the most expensive operation in terms of memory and processor utilization. The larger the files are, and the more complex the hash algorithm, the more compute-intensive the operation will be. In most cases, the SHA-1 algorithm provides a good balance between resource utilization and minimizing the possibility of hash collisions where different files could potentially generate the same hash value.

If it is critically important to minimize the possibility of a hash collision, use the SHA-256 algorithm; however, be aware of the impact it can have on performance when used with very large files. The current thread will block while the hash is being computed and if a large amount of data is being processed, this may cause the application to become non-responsive. In that case, it is recommended you create a background worker thread and call this function from within that worker thread, rather than inside the main UI thread.

To avoid potential problems with relative pathing in multithreaded applications, it is recommended you use absolute paths whenever possible. If you do not specify an absolute path, the file locations will be considered relative to the current working directory for the process. Because this is shared between all threads, it is possible for one thread to change the current working directory at any time and this can create inconsistent results. If you must use relative paths in a multithreaded application, use a mutex or critical section to ensure other threads cannot change the current working directory for the process while performing the file comparison.

This function will normalize the file names provided by the caller and perform checks to make sure the names do not contain illegal characters. If the name includes quotes, wildcard characters or other invalid symbols the function will fail and return zero with the last error code set to ST_ERROR_INVALID_FILE_NAME. It is permitted to use forward slashes in path names and these will be converted to the standard backslash character used with Windows paths. This function cannot be used

to compare the contents of NTFS alternate data streams.

This function is defined using an alias which automatically selects an ANSI or Unicode version based on the value of the UNICODE preprocessor macro. If you use the ANSI version of this function, the expanded file names will always be considered UTF-8 encoded strings, regardless of the current locale of the application. If your application uses file names which contain non-ASCII characters, you should always use the Unicode version of the function, even if your project is configured to use a multi-byte character set.

Example

```
// Compare the contents of a file against an SHA-1 hash value
LPCTSTR lpszFile = _T("%USERPOFILE%\\Documents\\Projects\\MyDocument.docx");
LPCTSTR lpszSHA1 = _T("541E43FDC612E41C02B770A2FD87EBB4A12EA800");
BOOL bIdentical;

bIdentical = CompareFileEx(
                lpszFile,
                NULL,
                COMPARE_FILE_DIGEST_SHA1,
                lpszSHA1);

// Compare the contents of two files
LPCTSTR lpszFile1 = _T("%USERPROFILE%\\AppName\\ProjectData.db");
LPCTSTR lpszFile2 = _T("%TEMP%\\BackupData.db");

bIdentical = CompareFileEx(
                lpszFile1,
                lpszFile2,
                COMPARE_FILE_CONTENTS,
                NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

CompressBuffer Function

```
BOOL WINAPI CompressBuffer(
   LPVOID lpvInputBuffer,
   DWORD cbInputBuffer
   LPVOID lpvOutputBuffer,
   LPDWORD lpcbOutputBuffer
);
```

The **CompressBuffer** function compresses the contents of the specified buffer.

Parameters

lpvInputBuffer

The buffer which contains the data to be compressed.

cbInputBuffer

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

The buffer which will contain the compressed data. This parameter may be NULL, which can be used to determine the size of the of the resulting compressed data prior to allocating memory for it.

lpcbOutputBuffer

The number of bytes that may be copied into the output buffer. If the ***lpvOutputBuffer*** parameter is not NULL, this must be initialized to a non-zero value. When the function returns, the actual number of bytes of compressed data is returned in this parameter.

Return Value

A non-zero value is returned if the data was successfully compressed. A zero value indicates that the data could not be compressed.

Remarks

This function will use the default Deflate algorithm to compress the contents of the buffer. This is a compression algorithm which combines the LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. It generally provides a good balance between the data compression ratio and system resources used. The compression ratio achieved by the **CompressBuffer** function will depend on the type of data being compressed.

The compressed data can be expanded to its original contents by calling the **ExpandBuffer** function.

Example

```
cbOutputBuffer = 0;
bResult = CompressBuffer(lpInputBuffer,
                         cbInputBuffer,
                         NULL,
                         &cbOutputBuffer);

if (bResult)
{
    lpOutputBuffer = (LPBYTE)LocalAlloc(LPTR, cbOutputBuffer);
    bResult = CompressBuffer(lpInputBuffer,
                             cbInputBuffer,
                             lpOutputBuffer,
```

```
                                &cbOutputBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib

CompressFile Function

```
BOOL WINAPI CompressFile(
   LPCTSTR lpszInputFile,
   LPCTSTR lpszOutputFile
);
```

The **CompressFile** function compresses the contents of the specified file.

Parameters

lpszInputFile

A null-terminated string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name. An error will be returned if this parameter is NULL or a zero-length string.

lpszOutputFile

The name of the file that is to contain the compressed file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name. If this parameter is NULL or a zero-length string, the compression is performed in-place.

Return Value

A non-zero value is returned if the file was successfully compressed. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The compression ratio achieved by the **CompressFile** function depends on the type of file that is being compressed. The compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

This function will use the default Deflate algorithm to compress the file. This is a compression algorithm which combines the LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. It generally provides a good balance between the data compression ratio and system resources used. You can use the **CompressFileEx** function to specify an alternate compression algorithm if you wish to perform more resource-intensive file compression.

If the output file already exists, it will be replaced with the compressed contents of the input file. If the compression fails for any reason, the output file will be deleted and the last error code will be updated indicating the cause of the failure. If you want to ensure an existing output file will be preserved if an error occurs, you should create a temporary file and use it as the output file. If this function succeeds, then you can rename or move the temporary file using a function like **MoveFileEx**.

It is possible to compress the input file in-place by specifying the ***lpszOutputFile*** parameter as a NULL pointer or zero-length string. In this case, the contents of the input file will be compressed to a temporary file and if the compression succeeds, the original input file will be replaced by the temporary file. If an error occurs, the input file will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

CompressFileEx Function

```
BOOL WINAPI CompressFileEx(
   LPCTSTR lpszInputFile,
   LPCTSTR lpszOutputFile,
   DWORD dwCompressionType,
   DWORD dwCompressionLevel,
   LPVOID lpvReserved,
   DWORD dwReserved
);
```

The **CompressFileEx** function compresses the contents of the specified file.

Parameters

lpszInputFile

A null-terminated string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name. An error will be returned if this parameter is NULL or a zero-length string.

lpszOutputFile

The name of the file that is to contain the compressed file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name. If this parameter is NULL or a zero-length string, the compression is performed in-place.

dwCompressionType

A numeric value which determines the algorithm that will be used to compress the data. One of the following values may be specified. By default, the Deflate algorithm is used.

Value	Description
COMPRESSION_TYPE_DEFLATE	A compression algorithm that combines the LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. Deflate is widely used by compression software and provides a good balance between the data compression ratio and system resources used. This is the default compression method.
COMPRESSION_TYPE_BZIP2	A compression algorithm that rearranges blocks of data in sorted order and then uses Huffman coding to process different frequencies of data within the block. Burrows-Wheeler compression provides a better compression ratio than the Deflate algorithm, however it requires more resources to perform the compression.
COMPRESSION_TYPE_LZMA	A compression algorithm that combines the LZ77 algorithm for dictionary-based compression with range encoding to efficiently represent repetitive patterns in the data. LZMA can achieve higher compression ratios than Deflate or the Burrows-Wheeler algorithms; however, it

	requires more memory and CPU resources due to the larger dictionary sizes and more complex encoding algorithm.

dwCompressionLevel

A numeric value which specifies the compression level to use. A value of zero specifies that the default compression level appropriate for the selected algorithm should be used, balancing resource usage and the compression ratio of the data. A value of 1 specifies that the compression should be performed using minimal memory resources, at the expense of the compression ratio. The maximum value of 9 specifies that the algorithm should use more memory to achieve the maximum compression ratio. It is recommended that most applications use the default value of zero.

lpvReserved

A reserved parameter which should always be NULL.

dwReserved

A reserved unsigned integer value which should always be zero.

Return Value

A non-zero value is returned if the file was successfully compressed. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The compression ratio achieved by the **CompressFileEx** function depends on the type of file that is being compressed. The compressed file is not stored in an archive format that is recognized by third-party applications such as PKZip or WinZip.

If the output file already exists, it will be replaced with the compressed contents of the input file. If the compression fails for any reason, the output file will be deleted and the last error code will be updated indicating the cause of the failure. If you want to ensure an existing output file will be preserved if an error occurs, you should create a temporary file and use it as the output file. If this function succeeds, then you can rename or move the temporary file using a function like **MoveFileEx**.

It is possible to compress the input file in-place by specifying the ***lpszOutputFile*** parameter as a NULL pointer or zero-length string. In this case, the contents of the input file will be compressed to a temporary file and if the compression succeeds, the original input file will be replaced by the temporary file. If an error occurs, the input file will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

ConvertTextFile Function

```
BOOL WINAPI ConvertTextFile(
   LPCTSTR lpszInputFile,
   UINT uInputCodePage,
   LPCTSTR lpszOutputFile,
   UINT uOutputCodePage,
   DWORD dwOptions,
);
```

The **ConvertTextFile** function converts a text file from one code page to another.

Parameters

lpszInputFile

A null-terminated string which specifies the name of the text file to be converted. The file path can include environment variables surrounded by percent symbols and those variables will be automatically expanded. If you do not specify a full path, the file name will be relative to the current working directory. This parameter cannot be NULL.

uInputCodePage

An integer value which specifies the code page of the input file to be converted. A value of zero specifies the current active code page for the process. An invalid code page will cause the function to fail.

lpszOutputFile

A null-terminated string which specifies the name of the text file to be created. The file path can include environment variables surrounded by percent symbols and those variables will be automatically expanded. If you do not specify a full path, the file name will be relative to the current working directory. If the file does not exist, it will be created. If the file does exist, it will be overwritten. It is permitted for the input file and output file names to be the same, in which case the input file will be replaced. This parameter cannot be NULL unless the FILE_CONVERT_VALIDATE option has been specified.

uOutputCodePage

An integer value which specifies the new encoding. A value of zero specifies the current active code page. An invalid code page will cause the function to fail. If the input file is a Unicode text file and the output code page is not Unicode, data may be lost or corrupted in the file.

dwOptions

An unsigned integer value which specifies one or more option flags which will control how the file is converted. It may be one or more of the following values:

Value	Description
FILE_CONVERT_DEFAULT	The default conversion option, only converting between code pages. The end-of-line character sequences in the text file will not be normalized and the file permissions and timestamps will not be preserved.
FILE_CONVERT_UNICODE	The input file will be checked to determine if it contains valid UTf-8 or UTF-16 encoding. If the file does not contain Unicode text, the conversion will default to using the specified code page. If this option is used with FILE_CONVERT_STRICT and the input file is not Unicode

	text, the function will fail. This option is typically used when you know the input file contains Unicode text, but you are unsure which specific encoding it uses. You can specify the input code page as CP_ACP (0) which will cause the conversion to use the current active code page if the input file is not Unicode text.
FILE_CONVERT_NORMALIZE	If the input text file contains UNIX style end-of-line characters (linefeeds), these will be normalized to the Windows end-of-line character sequence (carriage-return and linefeed). This option will have no effect if the file already uses the Windows end-of-line conventions. This option is typically used when it's possible the input file was copied or downloaded from a non-Windows system and you want to ensure it is consistent with other Windows text files.
FILE_CONVERT_PRESERVE	The output file will have the same attributes, file creation and file modification times as the original input file. If this option is not specified, the output file will have default attributes and current time values. If the output file already exists, this option does not preserve the attributes and timestamps of the file being replaced.
FILE_CONVERT_UTF8_BOM	Ensure that a UTF-8 byte order mark (BOM) is written to the beginning of the output file. This option is only used when the input file is converted to UTF-8, otherwise the option is ignored. The use of byte order marks in UTF-8 encoded text files is uncommon and not all text editors may recognize them.
FILE_CONVERT_NO_BOM	Prevent a byte order mark (BOM) from being written to the beginning of the output file whenever it converted to any Unicode encoding. This is the default for UTF-8, so this option does not need to specified if you converting the input file to UTF-8. Using this option when converting files to UTF-16LE or UTF-16BE is supported, but it is not recommended. Without a BOM, text editors may not recognize the contents as being UTF-16 encoded and may consider the file to binary instead of text.
FILE_CONVERT_STRICT	Perform strict checks during the conversion process. This option will cause the conversion to fail if the file contents cannot be converted without error using the specified code page. By default, characters which cannot be converted using the given code page will be substituted with a placeholder symbol. If this option is not used, it can result in potential data loss if you attempt to convert a Unicode text file to an ANSI code page, such as converting UTF-8 to Windows 1252.
FILE_CONVERT_VALIDATE	The conversion will be performed but an output file is not created or replaced. This option can be used to determine if

	a conversion would be successful without affecting the output file. If this option is used, any output file name passed to this function is ignored.

Return Value

A non-zero value is returned if the file could be converted to the specific code page. A value of zero indicates the conversion process failed. Check the value returned by the **GetLastError** function to determine the reason the file conversion was not successful.

Remarks

The **ConvertTextFile** function converts a text file from one character encoding to another using Windows code pages. It supports UTF-8, UTF-16 (little-endian and big-endian), and common Windows ANSI code pages. It can also normalize line endings and preserve file metadata such as creation/modification times and attributes.

The following Unicode encodings are supported:

- UTF-8 (CP_UTF8, 65001)
  A variable-length encoding where ASCII characters (U+0000-U+007F) are stored as single bytes. Non-ASCII characters use 2-4 bytes. UTF-8 is backward-compatible with ASCII and is commonly used with various Internet protocols. Byte order is not an issue, though a byte order mark (BOM) `EF BB BF` is optional.
- UTF-16LE (1200)
  Encodes characters as 2 or 4 bytes using little-endian byte order. Often includes a BOM `FF FE` to indicate endianness. It is the native encoding for Windows Unicode text.
- UTF-16BE (1201)
  Similar to UTF-16LE, but uses big-endian byte order. Typically includes a BOM `FE FF`. This encoding is occasionally used on UNIX-based systems but is rarely used on Windows.

The code pages for UTF-16LE and UTF-16BE are defined by Microsoft, but they cannot be used with the **WideCharToMultiByte** or **MultiByteToWideChar** functions. Normally, they are only supported for use with managed applications. However, this function will recognize them as valid code pages and perform the appropriate conversion. Unlike UTF-8 which has a defined macro `CP_UTF8`, there are no corresponding macros for UTF-16 in the Windows SDK.

A byte order mark (BOM) may help identify the encoding to some text editors but may also cause compatibility issues with tools that are not designed to be aware of Unicode.

- UTF-16LE and UTF-16BE output includes a BOM unless `FILE_CONVERT_NO_BOM` is specified.
- UTF-8 output does not include a BOM unless `FILE_CONVERT_UTF8_BOM` is specified.

The function can normalize line endings in the input file to match Windows conventions (CRLF) using the `FILE_CONVERT_NORMALIZE` option. This is useful when converting files originally created on UNIX (LF) or macOS Classic (CR). If the file already uses the Windows CRLF convention for the end-of-line, this option will be ignored and has no effect on the output.

When `FILE_CONVERT_UNICODE` is used, the function first checks for a BOM to identify UTF-8 or UTF-16 encodings. If no BOM is found, it analyzes the byte patterns near the beginning of the file to detect if the content is valid UTF-8 or contains UTF-16 characteristics. If detection fails, the code page specified by the *uInputCodePage* parameter will be used. The detection of UTF-8 encoded text without a BOM performs checks to ensure it uses correct codepoints and does not have characters

outside the valid range, therefore it should be considered reliable in determining if it is valid UTF-8 text.

For text files using UTF-16 without a BOM, there is no stringent check that can be made to determine which is being used. Instead, the function uses heuristics to guess which is most likely depending on the order of null bytes and character sequences in the text. While it is generally accurate with text files, it is possible the function could mistakenly identify a binary file as being either UTF-16LE or UTF-16BE encoded text.

If the output code page does not normally support all of the characters used with the input text, they will be replaced with placeholder symbols (typically a "?" character) and the conversion will proceed. This is most often the case if the input and output code pages are not compatible (for example, attempting to convert a text file which was created using Greek code page (1253) to Western European (1252). It can also occur if you attempt to convert a Unicode text file to an ANSI code page. In most cases, the only completely safe conversion is when you convert to a Unicode encoding or between two different Unicode encodings.

To prevent potential data loss or corruption of the output file, use the `FILE_CONVERT_STRICT` option. When this option is used, the function fails when:

- An invalid or ambiguous encoding is detected.
- Any characters cannot be represented in the output encoding.
- The file ends with incomplete multi-byte sequences.

For a complete list of Windows code pages, you can refer to the table of code page identifiers in the Windows SDK documentation. The more common code pages are:

Code Page	Description	Encoding Type
65001	UTF-8	Unicode (variable)
1200	UTF-16 Little Endian (UTF-16LE)	Unicode (fixed)
1201	UTF-16 Big Endian (UTF-16BE)	Unicode (fixed)
1252	Western European (Windows Latin 1)	ANSI
1251	Cyrillic (Windows)	ANSI
1250	Central European (Windows)	ANSI
1253	Greek (Windows)	ANSI
1254	Turkish (Windows)	ANSI
1255	Hebrew (Windows)	ANSI
1256	Arabic (Windows)	ANSI
1257	Baltic (Windows)	ANSI
1258	Vietnamese (Windows)	ANSI
874	Thai (Windows)	ANSI
932	Japanese (Shift-JIS)	DBCS
936	Simplified Chinese (GB2312)	DBCS

949	Korean (Unified Hangul Code)	DBCS
950	Traditional Chinese (Big5)	DBCS

In addition to the code pages listed above, you can also use 0 as a code page. This is defined in the Windows SDK as **CP_ACP** which refers to the system's current ANSI code page. It should only be used when explicitly relying on the default behavior for the local system. The code pages marked as DBCS (Double Byte Character Set) are commonly used for East Asian languages and support a mixture of single- and multi-byte sequences.

Example

```
// Convert a UTF-16 text file to UTF-8
LPCTSTR lpszInputFile = _T("%USERPROFILE%\\Documents\\WideTextFile.txt");
LPCTSTR lpszOutputFile = _T("%USERPROFILE%\\Documents\\TextFile.txt");

BOOL bConverted = ConvertTextFile(
                      lpszInputFile, 1200,
                      lpszOutputFile, CP_UTF8,
                      FILE_CONVERT_DEFAULT);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

CreateCustomGuid Function

```
BOOL WINAPI CreateCustomGuid(
    LPGUID lpGuid,
    DWORD dwValue
);
```

The **CreateCustomGuid** function creates a custom GUID that embeds a 32-bit application-defined value.

Parameters

lpGuid

A pointer to a GUID structure which will contain the generated GUID when the function returns. This parameter cannot be NULL.

dwValue

A 32-bit unsigned integer value to embed in the generated GUID. This value is stored in the `Data1` field of the GUID and can represent a counter, identifier, or application-defined metadata. If this value is zero, a random 32-bit value will be used instead.

Return Value

A non-zero value is returned if the function was successful. A return value of zero indicates an error. Call the **GetLastError** function for more information about the cause of the failure.

Remarks

The **CreateCustomGuid** function generates a unique 128-bit value that conforms to the Version 8 UUID format as described in RFC 9562. Version 8 UUIDs are designed to support application-specific customization while preserving the structural format of standard UUIDs, including proper version and variant bits.

Unlike Version 1 and Version 7 UUIDs, which encode timestamps, Version 8 UUIDs allow the application to define the semantics of part or all of the UUID content. This implementation stores the 32-bit ***dwValue*** in the `Data1` field of the GUID, followed by 96 bits of cryptographically secure random data. This provides a balance between custom application meaning and guaranteed uniqueness.

If ***dwValue*** is set to zero, the function will use a randomly generated 32-bit value to avoid producing UUIDs that begin with all-zero bits, which may be interpreted as placeholders or uninitialized values in some systems. To obtain the random value from a GUID which was previously generated by this function, use the **GetCustomGuidValue** function.

This function is particularly useful for:

- Generating UUIDs that embed object or session identifiers.
- Encoding a partition key, process ID, or user-defined code for categorization or routing.
- Maintaining backward compatibility with systems that require uniqueness but also need embedded metadata.

When a custom value is specified, only the first 32 bits of the UUID are application-defined. The remaining 96 bits are cryptographically random, making collisions extremely unlikely. The probability of a collision after generating ***n*** GUIDs with the same value is approximately:

$$p \approx n^2 / 2^{97}$$

After generating one million GUIDs with the same custom value, the probability of a collision would still be less than 1 in 10^{20}. In practice, even if the same 32-bit custom value is embedded millions or billions of times, the risk of a collision is negligible.

If you need to create a unique value that uses more than 96 bits of entropy, or you prefer to create a unique token value which is not formatted as a GUID, use the **CreateUniqueToken** function. This function allows you to specify the number of bits of entropy used to create a cryptographically secure token and the algorithm used to encode the randomized data.

As with other UUID formats, the terms GUID (Globally Unique Identifier) and UUID (Universally Unique Identifier) refer to the same 128-bit data structure. While Microsoft traditionally uses the term GUID in Windows development, the terms are interchangeable in both specification and practice.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CreateGuidFromString Function

```
BOOL WINAPI CreateGuidFromString(
    LPCTSTR lpszGuid,
    LPGUID lpGuid
);
```

The **CreateGuidFromString** function parses a string and returns of a GUID value.

Parameters

lpszGuid

A null-terminated string which represents the GUID. This parameter cannot be NULL or a zero-length string. See the remarks below for more information about how the string is parsed.

lpGuid

A pointer to a GUID structure which will contain the parsed GUID in binary form when the function returns. This parameter cannot be NULL. The structure members will be initialized to zero when the function is called and if the string can be parsed, will be updated with the GUID values when it returns. If the function fails, this will contain a GUID_NULL value.

Return Value

A non-zero value is returned if the string contains a valid GUID. A return value of zero indicates the string could not be parsed. For more information, call the **GetLastError** function.

Remarks

The **CreateGuidFromString** function parses a string to determine if it contains a valid GUID value. If it does, it will populate a GUID structure with the appropriate values. This function differs from the **UuidFromString** function which is part of the Windows RPC API and will not accept a NULL pointer to represent a GUID_NULL value. In the context of an RPC call, a missing UUID might be considered to be a default or unspecified value; however, this function is intended to parse and validate the string and performs stricter checks on the input.

The typical format for a GUID string would be:

```
xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx
```

When parsing the string representation of the GUID, it will ignore leading and trailing whitespace. If the GUID is enclosed in braces or brackets, the value will be extracted from within them and other characters in the string will be ignored. The hexadecimal values in the string may be separated by a dash or spaces; however, it is not required for the GUID to include separators. For example, all of these string values can be parsed:

```
"550e8400-e29b-41d4-a716-446655440000"
"550E8400 e29b 41d4 a716 446655440000"
"550E8400E29B41D4A716446655440000"
"This string {550e8400-e29b-41d4-a716-446655440000} contains a GUID"
```

If the GUID is enclosed in brace characters `{}` or bracket characters `[]` it must include both the opening and closing braces or brackets. If the GUID is not enclosed in braces or brackets, the string must only contain the GUID value and no extraneous characters other than whitespace.

This function will validate the GUID to ensure it is complete and does not use an invalid version number. You should always check the return value because the function may fail if it's passed a string which generally looks like a valid GUID but does not specify all of the hexadecimal digits (for example,

one too many or few digits) or uses a version number which is outside of the accepted range based on RFC 4122.

Note: The terms GUID (Globally Unique Identifier) and UUID (Universally Unique Identifier) refer to the same 128-bit identifier structure. Microsoft adopted the term GUID early on with the introduction of COM (Component Object Model), and it became the standard terminology in Windows development. Meanwhile, UUID originated from the Open Software Foundation (OSF) and was later standardized by the IETF in RFC 4122. While the names differ, the structure and format are identical, and the terms are used interchangeably in practice.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

CreateHexStringFromGuid Function

```
INT WINAPI CreateHexStringFromGuid(
    LPCGUID lpGuid,
    LPTSTR lpszHexString,
    INT nMaxLength
);
```

The **CreateHexStringFromGuid** function creates a hexadecimal representation of the specified GUID.

Parameters

lpGuid

A pointer to a GUID structure. If this parameter is NULL or GUID_NULL the function will return a string with all zeroes.

lpszHexString

A null-terminated string buffer which will contain the hexadecimal representation of the GUID. The buffer must be large enough to include the terminating null character. This parameter cannot be NULL. If the function fails, an empty string will be returned to the caller.

nMaxLength

The maximum number of characters which may be copied into the string buffer. The minimum length for the buffer must be 33 characters. This parameter cannot be zero.

Return Value

If the function succeeds, it returns the number of characters copied into the buffer provided. If the function fails, it will return zero.

Remarks

The **CreateHexStringFromGuid** function returns a string representation of a GUID as a series of hexadecimal digits. Unlike the **CreateStringFromGuid** function, the string returned by this function does not contain any separator characters. If successful, the return value will always be 32 because a GUID represents a 128 byte value.

This function does not validate the GUID structure provided by the caller. For example, it will create a string representation of a GUID which uses a version number which is not valid per RFC 4122. This means it is possible for you to create a string which cannot be parsed by the **CreateGuidFromString** function which does perform checks to ensure the GUID version is valid.

For more information about GUIDs and creating a string which uses the standard notation for GUIDs refer to the **CreateStringFromGuid** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CreateNamespaceGuid Function

```
BOOL WINAPI CreateNamespaceGuid(
    LPCGUID lpNamespace,
    LPCVOID lpvBuffer,
    DWORD dwBufferSize,
    LPGUID lpGuid
);
```

The **CreateNamespaceGuid** function creates a deterministic namespace identifier using the specified GUID.

Parameters

lpNamespace

A pointer to a GUID structure which specifies a valid GUID. This parameter may be NULL or GUID_NULL.

lpvBuffer

A pointer to an arbitrary block of data used to construct the namespace GUID. The contents of the buffer will be hashed using SHA-1 and that value will be combined with the ***lpNamespace*** parameter to create the GUID. This parameter cannot be NULL.

dwBufferSize

An unsigned integer which specifies the number of bytes to be read from the ***lpvBuffer*** parameter. If this value is -1 the function will consider the contents of ***lpvBuffer*** to be a null-terminated UTF-8 encoded string and automatically calculate the length. You should not pass a UTF-16 string as the buffer parameter because the high byte of the character will be interpreted as a terminating null. This value cannot be zero.

lpGuid

A pointer to a GUID structure which will contain the namespace GUID constructed by this function. This parameter cannot be NULL and it will always be initialized to GUID_NULL when the function is called. If the function returns successfully, it will contain a valid Version 5 UUID per RFC 4122.

Return Value

A non-zero value is returned if the function was successful. A return value of zero indicates an error. Call the **GetLastError** function for more information about the cause of the failure.

Remarks

Version 5 UUIDs are deterministic identifiers that are generated by computing a SHA-1 hash of a namespace GUID combined with an arbitrary block of data. The result is a UUID that will always be the same for a given namespace and input value. This makes Version 5 UUIDs ideal for scenarios where consistent identifiers are required for the same logical input, such as mapping a domain name, file path, or object name to a unique ID across different systems or sessions.

The **CreateNamespaceGuid** function adheres to RFC 4122, Section 4.3 and generates UUIDs using the Version 5 algorithm. Unlike Version 4 UUIDs, which are entirely random, Version 5 UUIDs provide stable, reproducible identifiers that are collision-resistant within the specified namespace. By varying the namespace (e.g., for different application subsystems or identity types), you can ensure that the same data produces unique UUIDs within each logical context. This technique is commonly used for consistent resource identifiers, object fingerprints, and mapping of human-readable names to binary IDs.

Although SHA-1 is no longer recommended for cryptographic security purposes, it is still used in Version 5 UUIDs because the UUID standard (RFC 4122) explicitly defines the use of SHA-1 for generating name-based identifiers. In this context, SHA-1 is not used to ensure confidentiality or authentication, but rather to provide a compact and deterministic hash of input data with a very low probability of collision. The 160-bit output of SHA-1 is truncated to 128 bits for use as a UUID, and the version and variant bits are set accordingly. While newer standards may adopt different algorithms (such as SHA-256 in custom UUID formats), SHA-1 remains sufficient and interoperable for RFC 4122 Version 5 UUIDs.

Note: The terms GUID (Globally Unique Identifier) and UUID (Universally Unique Identifier) refer to the same 128-bit identifier structure. Microsoft adopted the term GUID early on with the introduction of COM (Component Object Model), and it became the standard terminology in Windows development. Meanwhile, UUID originated from the Open Software Foundation (OSF) and was later standardized by the IETF in RFC 4122. While the names differ, the structure and format are identical, and the terms are used interchangeably in practice.

CreateGuidFromString, CreateHexStringFromGuid, CreateSequentialGuid, CreateStringFromGuid, GetLocalMachineGuid, IsEqualGuidString

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

CreateSequentialGuid Function

```
BOOL WINAPI CreateSequentialGuid(
   LPGUID lpGuid,
   ULARGE_INTEGER* lpTimestamp
);
```

The **CreateSequentialGuid** function creates a unique sequential GUID which can be sorted lexicographically.

Parameters

lpGuid

A pointer to a GUID structure which will contain the generated GUID when the function returns. This parameter cannot be NULL.

lpTimestamp

A pointer to a variable that receives the timestamp encoded in the GUID, expressed as the number of milliseconds since the Unix epoch (January 1, 1970 UTC). This parameter is optional and may be NULL if the timestamp is not required.

Return Value

A non-zero value is returned if the function was successful. A return value of zero indicates an error. Call the **GetLastError** function for more information about the cause of the failure.

Remarks

The **CreateSequentialGuid** function generates a unique 128-bit value which uses the Version 7 UUID format as described in RFC 9562. It is a new generation method designed to address limitations of older UUID versions. Unlike Version 1 UUIDs, which also embed a timestamp but expose MAC addresses and have coarse time granularity, Version 7 UUIDs are privacy-preserving, forward-compatible, and use millisecond resolution for broader applicability and improved precision.

Version 7 UUIDs are time-based identifiers that encode the number of milliseconds since the Unix epoch (January 1, 1970 UTC) directly into the high-order bits of the UUID. This provides a naturally sortable identifier that preserves creation order and facilitates efficient indexing, logging, and storage in systems that rely on time-based sequencing.

The timestamp portion of a Version 7 UUID represents the number of milliseconds since the epoch, encoded as an unsigned 48-bit integer. This allows for chronological sorting of UUIDs without parsing or inspecting the full binary payload. The remaining bits are randomly generated using a secure system-level random number generator to prevent collisions and ensure entropy across processes, machines, and time intervals.

Version 7 UUIDs are particularly useful for:

- Generating IDs in web APIs, message brokers, and event logs that must reflect creation time.
- Replacing monotonically increasing integers with sortable UUIDs to avoid predictability.
- Designing database indexes that benefit from insertion-order locality without needing sequential integer keys.

The *lpTimestamp* parameter can be used to obtain the the value which corresponds to the encoded time value in the generated GUID. This value can be used for sorting, temporal analysis, or debugging purposes. If you do not require access to the time, this parameter may be set to NULL. To obtain the

timestamp value as a FILETIME structure used by the Win32 API, use the **GetFileTimeFromGuid** function.

Note: Although Version 7 UUIDs are still in the draft standard phase (RFC 9562), they are widely supported by modern tools. The GUIDs produced by **CreateSequentialGuid** conform to the expected structure and semantics defined in the RFC, ensuring forward compatibility with future standards and implementations. This function generates the timestamp using the internal system clock using the highest precision possible. If the system clock is not synchronized with a time server, this may cause time drift in the generated GUID.

As with other UUID formats, the terms GUID (Globally Unique Identifier) and UUID (Universally Unique Identifier) refer to the same 128-bit data structure. While Microsoft traditionally uses the term GUID in Windows development, the terms are interchangeable in both specification and practice.

Example

```
GUID guid = {0};
ULARGE_INTEGER uiTimestamp = {0};

// Create a GUID based on the current date and time
if (CreateSequentialGuid(&guid, &uiTimestamp))
{
    TCHAR szGuid[64] = _T("");
    TCHAR szTime[64] = _T("");
    SYSTEMTIME guidTime = {0};

    CreateStringFromGuid(&guid, szGuid, 64);

    // Get the GUID timestamp as a SYSTEMTIME structure and create
    // a human-readable string; we could also use the GetDateFormat
    // and GetTimeFormat functions in the Win32 API
    //
    // Note the date and time will be in UTC and not localized
    // for the current time zone. The SystemTimeToTzSpecificLocalTime
    // function can convert it to local time

    if (GetSystemTimeFromGuid(&guid, &guidTime))
    {
        wsprintf(szTime, _T("%04d-%02d-%02d %02d:%02d:%02d.%d"),
                 guidTime.wYear,
                 guidTime.wMonth,
                 guidTime.wDay,
                 guidTime.wHour,
                 guidTime.wMinute,
                 guidTime.wSecond,
                 guidTime.wMilliseconds);
    }
    else
    {
        _tprintf(_T("GetSystemTimeFromGuid failed with error 0x%08lX\n"),
GetLastError());
        return;
    }

    // Show the GUID created along with the timestamp value and creation time
    _tprintf(_T("%s (%I64d) created %s\n"), szGuid, uiTimestamp.QuadPart, szTime);
}
```

CreateStringFromGuid Function

```
INT WINAPI CreateStringFromGuid(
    LPCGUID lpGuid,
    LPTSTR lpszGuid,
    INT nMaxLength
);
```

The **CreateStringFromGuid** function creates a string representation of the specified GUID.

Parameters

lpGuid

A pointer to a GUID structure. If this parameter is NULL or GUID_NULL the function will return a string with all zeroes.

lpszGuid

A null-terminated string buffer which will contain the representation of the GUID. The buffer must be large enough to include the terminating null character. This parameter cannot be NULL. If the function fails, an empty string will be returned to the caller.

nMaxLength

The maximum number of characters which may be copied into the string buffer. The minimum length for the buffer must be 37 characters. This parameter cannot be zero.

Return Value

If the function succeeds, it returns the number of characters copied into the buffer provided. If the function fails, it will return zero.

Remarks

The **CreateStringFromGuid** function returns a string representation of a GUID as a series of hexadecimal digits separated into groups using dashes. A GUID (Globally Unique Identifier), also known as a UUID (Universally Unique Identifier), is a 128-bit value used to uniquely identify objects. The structure is defined in RFC 4122 and is widely used in software development for identifiers that must be unique without requiring central coordination. In memory, a GUID is typically represented as a structure composed of four fields: a 32-bit integer (`Data1`), two 16-bit integers (`Data2` and `Data3`), and an array of eight bytes (`Data4`). This layout is consistent with Microsoft's definition in the Windows SDK, and the binary format preserves the required field order and endianness conventions.

GUIDs are commonly serialized into a human-readable string representation, consisting of 32 hexadecimal digits separated by hyphens in the format 8-4-4-4-12, for example:

```
550e8400-e29b-41d4-a716-446655440000
```

The string may optionally be enclosed in braces and the hex digits are case-insensitive. GUID strings are used with Windows in a wide variety of contexts including database keys, COM object identifiers, licensing systems, configuration files, and as identifiers for volumes, devices, or user sessions. The string returned by this function will not be enclosed in braces.

The 128-bit GUID format includes a 4-bit version field that identifies how the value was generated. Commonly used versions include Version 1 (timestamp and MAC address), Version 3 (name-based with MD5 hash), Version 4 (random or pseudo-random), and Version 5 (name-based with SHA-1). Newer drafts introduce Version 6 (time-ordered for improved database indexing), Version 7 (based on Unix timestamps and random bits), and Version 8 (reserved for custom or experimental use). The

version is encoded in the high nibble of the third field (Data3) and provides insight into the origin and structure of the UUID, which can be useful for debugging or ensuring compliance with application-specific requirements.

This function does not validate the GUID structure provided by the caller. For example, it will create a string representation of a GUID which uses a version number which is not valid per RFC 4122. This means it is possible for you to create a string which cannot be parsed by the **CreateGuidFromString** function which does perform checks to ensure the GUID version is valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

CreateUniqueToken Function

```
INT WINAPI CreateUniqueToken(
    LPTSTR lpszToken,
    INT nMaxLength,
    INT nBitLength,
    DWORD dwEncoding
);
```

The **CreateUniqueToken** function generates a unique, cryptographically secure token.

Parameters

lpszToken

A null-terminated string buffer that receives the null-terminated token. The buffer must be large enough to hold the encoded token and its null terminator. If the function fails, an empty string is returned. This parameter is required and cannot be NULL.

nMaxLength

The maximum number of characters that may be copied to the output buffer, including the null terminator. If the buffer is too small to contain the token string, the function will fail.

nBitLength

The number of bits of entropy to use when generating the token. This value must be between 64 and 4096. If the value is not a power of two, it will be automatically rounded up to the nearest power of two. If the value is out of bounds, it will be clamped to the closest valid value. If this parameter is zero, a 128 bit random value will be used to generate the token.

dwEncoding

The encoding algorithm used to convert the randomized data into a printable string. This value must be one of the following encoding constants:

Value	Description
TOKEN_ENCODE_BASE64	Use the Base64 algorithm, a widely supported encoding for binary data. Produces compact output, but includes characters like **+**, **/**, and **=** which may require escaping in URLs or filenames. Useful when interoperability is a priority.
TOKEN_ENCODE_BASE58	Use the Base58 algorithm, designed to generate compact, human-friendly tokens. It excludes ambiguous characters (**`0`**, **`O`**, **`l`**, **`I`**), making it ideal for printed or typed identifiers and safe for use in URLs.
TOKEN_ENCODE_BASE32	Use the Base32 algorithm, which encodes data using 32 unambiguous alphanumeric characters. A good choice for case-insensitive systems or manually entered codes, such as backup codes or license keys.
TOKEN_ENCODE_BASE85	Use the Base85 algorithm for high-density output using the full printable ASCII range. Generates shorter tokens than Base64, but includes punctuation characters, which may not be suitable for all systems without additional escaping.

Return Value

If the function succeeds, it will return the length of the token string not including the terminating null character. If the function fails, it will return a value of zero. Call the **GetLastError** function for more information about the cause of the failure.

Remarks

The **CreateUniqueToken** function generates a unique, cryptographically secure token string using the specified encoding format. The token is based on high-entropy random data generated using a secure operating system API and encoded into a compact, printable string. This function is suitable for generating session identifiers, authentication tokens, API keys, or any other unique identifier that must be unguessable and globally unique.

If the ***dwEncoding*** parameter is zero, the function defaults to Base58 encoding, which provides a short, URL-safe, and visually unambiguous format. This is ideal for user-facing or embedded tokens. Each supported encoding format has distinct characteristics:

- **Base64** is compact and compatible with email and web services, but may require escaping for use in URLs or filenames. These tokens can use digits, upper and lower case letters, the **+** and **/** symbols.
- **Base58** avoids ambiguous characters and is well-suited for tokens shown to or entered by users. These tokens use digits and upper and lower case letters without any symbols.
- **Base32** is case-insensitive and easy to read, with predictable output length, making it ideal for printed codes. These tokens only use digits and lower case letters without any symbols.
- **Base85** minimizes token length while remaining printable, but the inclusion of symbols may limit usability in some contexts. These tokens use digits, upper and lower case letters and punctuation characters.

Trailing padding characters (**=**) are automatically removed from Base64 and Base32 encoding to create more compact tokens since decoding is not required.

The ***nBitLength*** value determines the amount of entropy used to generate the token. Values are normalized to the nearest power of two and limited to a maximum of 4096 bits (512 bytes) to ensure performance and memory efficiency. In most cases, a token with 128 bits of entropy is more than sufficient. With 128 bits, over **5.1 quintillion** tokens can be safely generated before the chance of a collision becomes statistically significant.

If you wish to create a token which embeds a specific custom value and uses 96 bits of entropy, you can use the **CreateCustomGuid** function. This function generates a custom 128-bit GUID which embeds an application-defined value and returns a standard version 8 UUID in the standard dash notation.

Example

```
TCHAR szToken[MAX_TOKEN_STRING] = _T("");

// Create a Base32 token using 128 bits of entropy
if (CreateUniqueToken(szToken, MAX_TOKEN_STRING, 128, TOKEN_ENCODE_BASE32))
{
    _tprintf(_T("%s\n"), szToken);
}
else
{
    _tprintf(_T("CreateUniqueToken failed with error 0x%08lX\n"), GetLastError());
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

DecodeBuffer Function

```
INT WINAPI DecodeBuffer(
   LPCTSTR lpszInput,
   LPBYTE lpOutput,
   INT cbOutput,
   DWORD dwOptions
);
```

The **DecodeBuffer** function decodes an encoded string, and stores the result in the specified buffer.

Parameters

lpszInput

A null-terminated string which contains the base64 encoded text.

lpOutput

A pointer to a byte array buffer which is used to store the decoded data. It is recommended that the buffer be as large as the length of the encoded string.

cbOutput

A long integer which specifies the maximum number of bytes which may be stored in the buffer.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
DATA_DECODE_BASE64	Use the Base64 algorithm, a widely supported method for encoding binary data as text. It is the standard used by most modern email clients and web applications. This is the default encoding algorithm and should be used by most applications.
DATA_DECODE_QUOTED	Use the quoted-printable algorithm for encoding the data. Most printable characters are left as-is, with control characters and 8-bit characters encoded as their hexadecimal value. Note that this option cannot be combined with the other encoding methods.
DATA_DECODE_URL	Use the URL encoding algorithm for encoding the data. Letters and numbers are left as-is, with control characters, most punctuation and 8-bit characters encoded as their hexadecimal value. Note that this option cannot be combined with the other encoding methods.
DATA_DECODE_BASE58	Use the Base58 algorithm, which produces a compact, human-readable encoded string. Commonly used for short binary identifiers such as cryptocurrency addresses. This algorithm should not be used with large files. Refer to the remarks below for more information about Base58.
DATA_DECODE_BASE32	Use the Base32 algorithm, which encodes binary data into a limited set of 32 alphanumeric characters. Commonly used in systems where case-insensitive encoding is

	required or where data may be transcribed manually. See remarks below for more details about Base32.
DATA_DECODE_BASE85	Use the Base85 algorithm, which encodes binary data into a more compact form than Base64. Useful when file size reduction is critical and full ASCII compatibility is required. See remarks below for more details about Base85.
DATA_DECODE_Z85	Use the Z85 algorithm which is a high-density binary-to-text encoding algorithm designed for use in structured data protocols. It converts 4 bytes (32 bits) of binary data into 5 printable ASCII characters using a compact, fixed character set.
DATA_DECODE_COMPRESSED	The data was compressed prior to being encoded, and should be expanded after the decoding has completed successfully. This option is ignored if the encoding type is not base64. This should only be used if it was specified when the data was encoded.

Return Value

If the function succeeds, it will return the number of bytes decoded and stored in the buffer. If the function fails, it will return -1. Failure typically indicates that the encoded string was corrupted or the buffer is not large enough to store the decoded data.

Remarks

The **DecodeBuffer** function is used to decode a block of data that was previously encoded with the **EncodeBuffer** function. To decode the contents of a file, it is recommended that you use the **DecodeFile** function instead.

To convert UTF-8 encoded text to UTF-16 or localized MBCS (multibyte character set) text, use the **UnicodeDecodeText** function. If you wish to convert the contents of a text file to a different Unicode encoding, use the **ConvertTextFile** function.

Unlike Base64 or Base85, the Z85 encoding algorithm enforces strict alignment. The input string must always be a multiple of 5 characters. It does not use padding and does not support decoding of partial blocks. Any attempt to decode a string whose size is not evenly divisible by 5 will result in an error. This constraint ensures predictable output sizes and simplifies integration with fixed-width protocols.

For more information about the other encoding algorithms, refer to the **EncodeFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

DecodeFile Function

```
BOOL WINAPI DecodeFile(
   LPCTSTR lpszInputFile,
   LPCTSTR lpszOutputFile,
   DWORD dwOptions,
   DWORD dwReserved
);
```

The **DecodeFile** function opens and decodes an encoded file, storing the contents in the specified file.

Parameters

lpszInputFile

A null-terminated string which specifies the name of the file to be decoded. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

The name of the file that is to contain the decoded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

dwOptions

An unsigned integer which specifies the decoding method and optional behaviors. The low-word of this parameter specifies the decoding method and the high-word specifies additional options. You may only select one decoding algorithm or the function will fail.

Value	Description
FILE_DECODE_BASE64	Use the Base64 algorithm, a widely supported method for encoding binary data as text. It is the standard used by most modern email clients and web applications. This is the default encoding algorithm and should be used by most applications.
FILE_DECODE_UUCODE	Use the uuencode algorithm, a legacy encoding format traditionally used on UNIX systems and in early email software. This option is primarily included for compatibility with older applications. This algorithm should not be used with new applications.
FILE_DECODE_QUOTED	Use the quoted-printable encoding scheme, which encodes only non-printable characters. Often used in email messages to preserve text readability while ensuring compatibility. This algorithm should only be used when the content is primarily text which may include some 8-bit characters. Do not use this algorithm to encode large amounts of binary data.
FILE_DECODE_YENCODE	Use the yEnc algorithm, a compact encoding method commonly used for binary file attachments in Usenet newsgroups. It offers higher efficiency than traditional

	uuencode or Base64. This algorithm is primarily used with USENET newsgroups.
FILE_DECODE_BASE58	Use the Base58 algorithm, which produces a compact, human-readable encoded string. Commonly used for short binary identifiers such as cryptocurrency addresses. This algorithm should not be used with large files. Refer to the remarks below for more information about Base58.
FILE_ENCODE_BASE32	Use the Base32 algorithm, which encodes binary data into a limited set of 32 alphanumeric characters. Commonly used in systems where case-insensitive encoding is required or where data may be transcribed manually. See remarks below for more details about Base32.
FILE_ENCODE_BASE85	Use the Base85 algorithm, which encodes binary data into a more compact form than Base64. Useful when file size reduction is critical and full ASCII compatibility is required. See remarks below for more details about Base85.
FILE_DECODE_COMPRESSED	Compress the file prior to encoding. This option may be combined with an encoding method to reduce file size. The resulting file must be decompressed after decoding.

dwReserved

This parameter is reserved and should always be set to zero.

Return Value

A non-zero value is returned if the file was successfully decoded. A zero value indicates that the file does not exist, the encoded file was damaged or the output file could not be created.

Remarks

The **DecodeFile** function decodes files that were previously encoded through a call to the **EncodeFile** function or by a third-party application such as an email client. The option to expand a previously compressed file requires that the function be able to create a temporary file on the local system in the directory specified by the TEMP environment variable. This function can only expand a file that was previously compressed with the **EncodeFile** or **CompressFile** functions.

For more information about the encoding algorithms, refer to the **EncodeFile** function.

EncodeBuffer Function

```
INT WINAPI EncodeBuffer(
   LPBYTE lpInput,
   INT cbInput,
   LPTSTR lpszOutput,
   INT cchOutput,
   DWORD dwOptions
);
```

The **EncodeBuffer** function encodes the contents of the specified byte array, converting the data into printable text.

Parameters

lpInput

A buffer that contains the data to be encoded.

cbInput

A long integer which specifies the number of characters in the buffer which should be encoded.

lpszOutput

A null-terminated string that will be used to store the encoded text. The length of the string must be at least 33% larger than the number of bytes being encoded, and will be terminated with a null byte.

cchOutput

The maximum number of characters that may be stored in the string buffer. If this value is too small to store the encoded text, the function will fail.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
DATA_ENCODE_BASE64	Use the Base64 algorithm, a widely supported method for encoding binary data as text. It is the standard used by most modern email clients and web applications. This is the default encoding algorithm and should be used by most applications.
DATA_ENCODE_QUOTED	Use the quoted-printable algorithm for encoding the data. Most printable characters are left as-is, with control characters and 8-bit characters encoded as their hexadecimal value. Note that this option cannot be combined with the other encoding methods.
DATA_ENCODE_URL	Use the URL encoding algorithm for encoding the data. Letters and numbers are left as-is, with control characters, most punctuation and 8-bit characters encoded as their hexadecimal value. Note that this option cannot be combined with the other encoding methods.
DATA_ENCODE_BASE58	Use the Base58 algorithm, which produces a compact, human-readable encoded string. Commonly used for

	short binary identifiers such as cryptocurrency addresses. This algorithm should not be used with large files. Refer to the remarks below for more information about Base58.
DATA_ENCODE_BASE32	Use the Base32 algorithm, which encodes binary data into a limited set of 32 alphanumeric characters. Commonly used in systems where case-insensitive encoding is required or where data may be transcribed manually. See remarks below for more details about Base32.
DATA_ENCODE_BASE85	Use the Base85 algorithm, which encodes binary data into a more compact form than Base64. Useful when file size reduction is critical and full ASCII compatibility is required. See remarks below for more details about Base85.
DATA_ENCODE_Z85	Use the Z85 algorithm which is a high-density binary-to-text encoding algorithm designed for use in structured data protocols. It converts 4 bytes (32 bits) of binary data into 5 printable ASCII characters using a compact, fixed character set.
DATA_ENCODE_COMPRESSED	The data should be compressed before it is encoded. To restore the original data, it must be expanded after it has been decoded. This option is ignored if the encoding type is not base64.
DATA_ENCODE_LINEBREAK	The encoded data should broken into multiple lines of text if the resulting string is longer than 72 characters. This option is ignored if the encoding type is not Base64, Base32 or quoted-printable. This option should be specified if the encoded data is going to be included in an email message.

Return Value

If the function succeeds, it will return the number of bytes encoded and stored in the string. If the function fails, it will return -1. Failure typically indicates that the buffer is not large enough to store the encoded data.

Remarks

The **EncodeBuffer** function is used to encode a block of data and store it in the specified string buffer as printable text. To encode the contents of a file it is recommended that you use the **EncodeFile** function instead.

To convert a string to UTF-8 encoded text, use the **UnicodeEncodeText** function. To convert UTF-8 encoded text to UTF-16 or localized MBCS (multibyte character set) text, use the **UnicodeDecodeText** function. If you wish to convert the contents of a text file to a different Unicode encoding, use the **ConvertTextFile** function.

Unlike Base64 or Base85, the Z85 encoding algorithm enforces strict alignment. The input must be a multiple of 4 bytes and the encoded output is always a multiple of 5 characters. It does not use padding and does not support encoding of partial blocks. Any attempt to encode a buffer whose size is not evenly divisible by 4 will result in an error. This constraint ensures predictable output sizes and simplifies integration with fixed-width protocols.

Z85 is best suited for encoding small binary buffers in memory, such as cryptographic keys, binary hashes, or compact data blocks transmitted in messaging systems. However, Z85 is not appropriate for encoding files unless their size is guaranteed to be a multiple of 4 bytes. Supporting arbitrary-length files would require either padding or a custom wrapper format to store the original length, which would violate the Z85 specification and reduce interoperability. For general-purpose encoding or file storage, Base64 or Base85 is recommended instead.

For more information about the other encoding algorithms, refer to the **EncodeFile** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

EncodeFile Function

```
BOOL WINAPI EncodeFile(
   LPCTSTR lpszInputFile,
   LPCTSTR lpszOutputFile,
   DWORD dwOptions,
   DWORD dwReserved
);
```

The **EncodeFile** function opens and encodes a file, storing the contents as printable text in the specified file.

Parameters

lpszInputFile

A null-terminated string which specifies the name of the file to be encoded. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name.

lpszOutputFile

The name of the file that is to contain the encoded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name.

dwOptions

An unsigned integer which specifies the encoding method and optional behaviors. The low-word of this parameter specifies the encoding method and the high-word specifies additional options. You may only select one encoding algorithm or the function will fail.

Value	Description
FILE_ENCODE_BASE64	Use the Base64 algorithm, a widely supported method for encoding binary data as text. It is the standard used by most modern email clients and web applications. This is the default encoding algorithm and should be used by most applications.
FILE_ENCODE_UUCODE	Use the uuencode algorithm, a legacy encoding format traditionally used on UNIX systems and in early email software. This option is primarily included for compatibility with older applications. This algorithm should not be used with new applications.
FILE_ENCODE_QUOTED	Use the quoted-printable encoding scheme, which encodes only non-printable characters. Often used in email messages to preserve text readability while ensuring compatibility. This algorithm should only be used when the content is primarily text which may include some 8-bit characters. Do not use this algorithm to encode large amounts of binary data.
FILE_ENCODE_YENCODE	Use the yEnc algorithm, a compact encoding method commonly used for binary file attachments in Usenet newsgroups. It offers higher efficiency than traditional

	uuencode or Base64. This algorithm is primarily used with USENET newsgroups.
FILE_ENCODE_BASE58	Use the Base58 algorithm, which produces a compact, human-readable encoded string. Commonly used for short binary identifiers such as cryptocurrency addresses. This algorithm should not be used with large files. Refer to the remarks below for more information about Base58.
FILE_ENCODE_BASE32	Use the Base32 algorithm, which encodes binary data into a limited set of 32 alphanumeric characters. Commonly used in systems where case-insensitive encoding is required or where data may be transcribed manually. See remarks below for more details about Base32.
FILE_ENCODE_BASE85	Use the Base85 algorithm, which encodes binary data into a more compact form than Base64. Useful when file size reduction is critical and full ASCII compatibility is required. See remarks below for more details about Base85.
FILE_ENCODE_COMPRESSED	Compress the file prior to encoding. This option may be combined with an encoding method to reduce file size. The resulting file must be decompressed after decoding.

dwReserved

This parameter is reserved and should always be set to zero.

Return Value

A non-zero value is returned if the file was successfully encoded. A zero value indicates that the input file does not exist or the output file could not be created.

Remarks

The **EncodeFile** function is used to convert binary files into text-based representations using one of several supported encoding formats. This is useful when transmitting binary data over protocols that are not 8-bit clean, such as email or text-based APIs. If compression is enabled with FILE_ENCODE_COMPRESSED, the input file will be compressed to a temporary file created in the directory specified by the system's TEMP environment variable. The encoded file is not in a standard archive format and must be decompressed using the **DecodeFile** or **ExpandFile** functions.

If you wish to convert the contents of a text file to a different Unicode encoding, use the **ConvertTextFile** function.

Base64

Base64 is the most commonly used encoding scheme for converting binary data into a text format. It encodes data in blocks of 3 bytes into 4 printable ASCII characters using a well-defined 64-character alphabet. This method is efficient and highly compatible with a wide range of systems, including email clients, web browsers, APIs, and storage systems that expect text input. The Base64 algorithm includes padding to ensure the output is always a multiple of four characters, which helps with alignment and parsing. It is ideal for encoding attachments, configuration files, cryptographic hashes, and any other binary data where compactness and compatibility are important. Base64 is also significantly faster than more complex schemes like Base58, and should be used whenever performance and size efficiency are important, particularly when encoding large files or data streams.

Base58

Base58 is a binary-to-text encoding scheme designed to represent binary data in a compact, human-readable format. It is most commonly known for its use in cryptocurrency applications, particularly Bitcoin addresses. Unlike Base64, which uses a fixed-length representation and padding, Base58 avoids visually similar characters and does not include padding. The Base58 alphabet omits the characters `0` (zero), `O` (capital o), `I` (capital i), and `l` (lowercase L) to reduce the risk of confusion when viewing or entering an encoded string.

Base58 encodes data by interpreting it as a large integer and as a result, the byte order matters. In typical Base58 usage (e.g., Bitcoin), the input is treated as a big-endian number where the most significant byte comes first. This affects how the data is divided and converted to Base58 digits during encoding. However, not all implementations follow this convention. Some online tools or libraries may treat input as little-endian (least significant byte first), leading to different encoded outputs for the same binary data. Both decode to the same binary value and are valid, but they are not interchangeable.

Important: Never use Base58 to encode large files. While Base58 is excellent for encoding small identifiers or hashes, it is not designed for high-performance or large-scale encoding. Base58 encoding is significantly slower than Base64 because it does not operate on fixed-size blocks and requires arbitrary-precision arithmetic with repeated division and modulo operations. If the file is more than a few kilobytes, you should use the Base64 algorithm for encoding.

Base32

Base32 is a text encoding scheme that represents binary data using a set of 32 alphanumeric characters (A–Z and 2–7). It is designed to be case-insensitive, making it suitable for environments where case preservation is unreliable, such as DNS records, QR codes, and certain user-facing identifiers.

Unlike Base64, Base32 uses only uppercase letters and digits, avoiding symbols and padding characters that might be problematic in legacy systems. This makes it easier to transcribe or read aloud, and less prone to corruption when copied manually. However, the tradeoff is reduced efficiency because Base32 requires more characters to encode the same amount of data. Specifically, it encodes every 5 bytes of input as 8 characters of output, resulting in roughly a 60% size increase.

Base32 is useful when binary data must be represented in a constrained character set and the encoded string may be used in contexts that ignore case or disallow punctuation. Examples include secret keys for two-factor authentication (TOTP), unique file identifiers, or human-readable hash values. For general-purpose file encoding, Base64 remains the preferred format due to its higher efficiency and broader adoption.

Base85

Base85 is a high-efficiency binary-to-text encoding method that encodes every 4 bytes of binary data into 5 ASCII characters. Compared to Base64, it provides a more compact representation of binary data, increasing output size by only ~25% rather than 33%. This makes Base85 particularly useful in bandwidth-sensitive applications or when embedding binary data into text files.

The Base85 alphabet includes a wide range of printable ASCII characters, avoiding control characters and whitespace. Unlike Base64, Base85 does not use padding and encodes data in fixed-length 4-byte blocks. Any remaining bytes at the end of the input are encoded using special logic to maintain compactness.

Base85 is an excellent choice when both compactness and full ASCII compatibility are important. It is faster and more efficient than Base58 for larger files, and often preferred over Base64 in advanced document formats and embedded applications. However, due to the expanded character set, it may be less readable and harder to work with manually than Base32 or Base64. For general use, Base64 remains the best compromise between readability, efficiency, and compatibility.

Uuencode / Uudecode

Uuencode (Unix-to-Unix encode) is a legacy encoding format originally developed for transmitting binary files over systems that only supported 7-bit ASCII text, such as early UNIX-based email and file transfer systems. It encodes binary data into lines of printable characters, including a header line that specifies file permissions and a filename. The corresponding uudecode tool can extract and reconstruct the original file from this format.

Although largely obsolete today, uuencode remains useful for compatibility with older systems, embedded environments, and some command-line tools. However, it is less space-efficient than modern alternatives like Base64 and lacks support for Unicode or MIME encoding standards.

Quoted-Printable Encoding

Quoted-printable is a MIME-compliant encoding scheme designed for encoding data that is mostly ASCII text but may contain a few non-printable or special characters. It represents such characters as =XX, where XX is the two-digit hexadecimal value of the byte. Line breaks and spaces at the end of lines are also handled carefully to preserve formatting across different systems. Quoted-printable is ideal for encoding email content in ISO-8859-1 or UTF-8 where text needs to remain mostly readable while ensuring it passes through 7-bit transport layers. It is not efficient for arbitrary binary files, as it may significantly increase the size of the encoded output when many bytes require escaping.

yEnc Encoding

yEnc is a compact binary-to-text encoding format developed as an improvement over uuencode for posting files to Usenet newsgroups. It provides much better space efficiency (only ~1-2% overhead compared to 33% for Base64 or uuencode) and supports 8-bit clean encoding using simple transformations. yEnc files typically include headers and checksums to support multipart files, resume downloads, and error detection. Although it is not a formal Internet standard, yEnc is widely supported by Usenet clients and utilities that deal with large binary file transfers over NNTP. It is best suited for large attachments or downloads over older protocols that favor plain text.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

ExpandBuffer Function

```
BOOL WINAPI ExpandBuffer(
   LPVOID lpvInputBuffer,
   DWORD cbInputBuffer
   LPVOID lpvOutputBuffer,
   LPDWORD lpcbOutputBuffer
);
```

The **ExpandBuffer** function expands the contents of the previously compressed buffer.

Parameters

lpvInputBuffer

The buffer which contains the compressed data.

cbInputBuffer

The number of bytes in the input buffer. This value must be greater than zero.

lpvOutputBuffer

The buffer which will contain the expanded data. This parameter may be NULL, which can be used to determine the size of the of the resulting expanded data prior to allocating memory for it.

lpcbOutputBuffer

The number of bytes that may be copied into the output buffer. If the ***lpvOutputBuffer*** parameter is not NULL, this must be initialized to a non-zero value. When the function returns, the actual number of bytes of expanded data is returned in this parameter.

Return Value

A non-zero value is returned if the data was successfully expanded. A zero value indicates that the data could not be expanded. Failure typically indicates that the compressed data was not in a recognized format.

Remarks

The compressed data buffer passed to the **ExpandBuffer** function must have been compressed by either the **CompressBuffer** or **CompressFile** functions. Data read from files that were compressed using third-party utilities such as WinZip will not be recognized by this function.

Example

```
cbOutputBuffer = 0;
bResult = ExpandBuffer(lpInputBuffer,
                       cbInputBuffer,
                       NULL,
                       &cbOutputBuffer);

if (bResult)
{
    lpOutputBuffer = (LPBYTE)LocalAlloc(LPTR, cbOutputBuffer);
    bResult = ExpandBuffer(lpInputBuffer,
                           cbInputBuffer,
                           lpOutputBuffer,
                           &cbOutputBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib

ExpandFile Function

```
BOOL WINAPI ExpandFile(
   LPCTSTR lpszInputFile,
   LPCTSTR lpszOutputFile
);
```

The **ExpandFile** function expands the contents of a previously compressed file.

Parameters

lpszInputFile

A null-terminated string which specifies the name of the file to be compressed. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name. An error will be returned if this parameter is NULL or a zero-length string.

lpszOutputFile

The name of the file that is to contain the expanded file data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name. If this parameter is NULL or a zero-length string, the compression is performed in-place.

Return Value

A non-zero value is returned if the file was successfully expanded. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The **ExpandFile** function can only expand files that were previously compressed using the **CompressFile** function. It cannot expand the contents of a file stored in an archive format used by third-party applications such as PKZip or WinZip.

This function will use the default Deflate algorithm to expand the contents of the file. If the file was compressed using **CompressFileEx** using anything other than COMPRESSION_TYPE_DEFLATE, the file must be expanded using the **ExpandFileEx** function. This function will fail if a different compression algorithm was used to compress the file.

If the output file already exists, it will be replaced with the expanded contents of the compressed input file. If the input file cannot be expanded for any reason, the output file will be deleted and the last error code will be updated indicating the cause of the failure. If you want to ensure an existing output file will be preserved if an error occurs, you should create a temporary file and use it as the output file. If this function succeeds, then you can rename or move the temporary file using a function like **MoveFileEx**.

It is possible to expand the input file in-place by specifying the ***lpszOutputFile*** parameter as a NULL pointer or zero-length string. In this case, the contents of the input file will be expanded to a temporary file and if the operation is successful, the original compressed input file will be replaced by the temporary file. If an error occurs, the input file will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

CompressFile, CompressFileEx, DecodeFile, EncodeFile, ExpandFileEx

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

ExpandFileEx Function

```
BOOL WINAPI ExpandFileEx(
   LPCTSTR lpszInputFile,
   LPCTSTR lpszOutputFile,
   DWORD dwCompressionType,
   LPVOID lpvReserved,
   DWORD dwReserved
);
```

The **ExpandFileEx** function expands the contents of the previously compressed file.

Parameters

lpszInputFile

A null-terminated string which specifies the name of the file which contains the compressed data. The file must exist, and it must be a regular file that can be opened for reading by the current process. An error will be returned if a character device, such as CON: is specified as the file name. An error will be returned if this parameter is NULL or a zero-length string.

lpszOutputFile

The name of the file that is to contain the expanded data. If the file exists, it must be a regular file that can be opened for writing by the current process and will be overwritten. If the file does not exist, it will be created. An error will be returned if a character device, such as CON: is specified as the file name. If this parameter is NULL or a zero-length string, the compression is performed in-place.

dwCompressionType

A numeric value which determines the algorithm that was used to compress the data. One of the following values may be specified. By default, the Deflate algorithm is used.

Value	Description
COMPRESSION_TYPE_UNKNOWN	The function should attempt to determine what compression algorithm was used when the data was compressed. This is done by examining the header block of the file and checking for certain signatures which can identify the algorithm. If the algorithm cannot be determined, the function will fail. It is recommended that most applications explicitly specify the compression algorithm.
COMPRESSION_TYPE_DEFLATE	A compression algorithm that combines the LZ77 algorithm for creating common substrings and Huffman coding to process the different frequencies of byte sequences in the data stream. Deflate is widely used by compression software and provides a good balance between the data compression ratio and system resources used. This is the default compression method.
COMPRESSION_TYPE_BZIP2	A compression algorithm that rearranges blocks of data in sorted order and then uses Huffman coding to process different frequencies of data within the block.

	Burrows-Wheeler compression provides a better compression ratio than the Deflate algorithm, however it requires more resources to perform the compression.
COMPRESSION_TYPE_LZMA	A compression algorithm that combines the LZ77 algorithm for dictionary-based compression with range encoding to efficiently represent repetitive patterns in the data. LZMA can achieve higher compression ratios than Deflate or the Burrows-Wheeler algorithms; however, it requires more memory and CPU resources due to the larger dictionary sizes and more complex encoding algorithm.

lpvReserved

A reserved parameter which should always be NULL.

dwReserved

A reserved unsigned integer value which should always be zero.

Return Value

A non-zero value is returned if the file was successfully expanded. A zero value indicates that the input file could not be read or that the output file could not be created.

Remarks

The **ExpandFileEx** function can only expand files that were previously compressed using the **CompressFile** or **CompressFileEx** functions. It cannot expand the contents of a file stored in an archive format used by third-party applications such as PKZip or WinZip.

The value of the *dwCompressionType* parameter must match the value which was used with the **CompressFileEx** function. This function will fail if you specify a different compression algorithm than what was used to compress the file. Although your application can use COMPRESSION_TYPE_UNKNOWN and attempt to automatically determine how the file was compressed, this is not always reliable.

If the output file already exists, it will be replaced with the expanded contents of the compressed input file. If the input file cannot be expanded for any reason, the output file will be deleted and the last error code will be updated indicating the cause of the failure. If you want to ensure an existing output file will be preserved if an error occurs, you should create a temporary file and use it as the output file. If this function succeeds, then you can rename or move the temporary file using a function like **MoveFileEx**.

It is possible to expand the input file in-place by specifying the *lpszOutputFile* parameter as a NULL pointer or zero-length string. In this case, the contents of the input file will be expanded to a temporary file and if the operation is successful, the original compressed input file will be replaced by the temporary file. If an error occurs, the input file will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib

Unicode: Implemented as Unicode and ANSI versions

FilterHtmlFile Function

```
INT WINAPI FilterHtmlFile(
   LPCTSTR lpszFileName,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **FilterHtmlFile** function filters HTML formatting from the specified file and returns plain text in an output buffer.

Parameters

lpszFileName

A null-terminated string which specifies the name of the file that contains the HTML text to be filtered and normalized. The file must exist and the current process must have read access. The file path may include environment variables surrounded with percent (%) symbols, in which case the variables will be expanded. This parameter cannot be NULL.

lpszBuffer

A null-terminated string buffer which will contain the filtered text. The buffer must be large enough to contain the entire string and a terminating null character or the function will fail. If this parameter is NULL and the ***nMaxLength*** parameter is zero, the function will return the number of characters required to store the filtered text, not including the terminating null character.

nMaxLength

The maximum number of characters which can be copied into the ***lpszOutput*** string buffer. If this value is zero, no characters will be copied to the output buffer and the function will return the length of the filtered output, not including the terminating null character. This can be used to determine how much memory should be allocated to store the filtered text.

Return Value

If the function succeeds, it will return the number of characters copied into the output buffer, not including the terminating null character. If the ***lpszBuffer*** parameter is NULL and ***nMaxLength*** is zero, the function will return the number of characters in the filtered text without copying any characters. If the function fails, or there is no text in the input buffer, the function will return zero.

Remarks

The **FilterHtmlFile** function processes a file containing HTML formatted text and returns output suitable for display in text-only environments. HTML tags are removed and entities are converted to their canonical Unicode equivalent. When filtering markup from the text, the function will:

- Remove script, style, and other non-visible or unsafe elements.
- Convert common tag structures, such as lists and headers, into readable plain text.
- Extract and filter hyperlinks and image alt text, ignoring internal links to other sections.
- Remove any embedded credentials in hyperlinks.
- Decode common HTML entities such as `&trade` and `&copy`, as well as numeric entites like `&#x20.`
- Remove all leading and trailing whitespace from the output, including newlines.

Byte Order Marks

A byte order mark (BOM) is a special sequence of bytes at the beginning of a text file that identifies

the encoding used to store the file's contents. In Unicode formats like UTF-8 or UTF-16, this helps software distinguish between different encodings and can also indicate the byte order (big-endian or little-endian). The presence of a BOM will affect how the content is filtered and the following BOMs are recognized:

- UTF-8 BOM (**`EF BB BF`**) the text is processed as UTF-8 and then filtered.
- UTF-16LE BOM (**`FF FE`**) the text is converted to UTF-8 and then filtered.
- UTF-16BE BOM (**`FE FF`**) the text is converted to UTF-16LE, then to UTF-8 and then filtered.

If you call the ANSI version of this function (**FilterHtmlFileA**), the contents will always be returned as UTF-8 encoded text. If you call the Unicode version of the function (**FilterHtmlFileW**), the contents will always be returned as UTF-16LE encoded text. If the file includes a BOM, this will determine how the contents are converted between the different encoding types. If the file does not contain a BOM, it is presumed to contain UTF-8 encoded text.

The function will remove extraneous whitespace within the text, but will attempt to maintain the structure of ordered and unordered lists. It does not parse the style information or Javascript that may be included in the HTML content. If a paragraph uses a style that would normally prevent it from being rendered in a browser (e.g.: the visibility attribute set to "hidden"), it is ignored and the text will be included in the output.

If you are concerned that the HTML may contain obfuscated text or confusable Unicode homoglyphs, you can pass the output from this function to the **FilterUnicodeText** function. However, you should not do this if the original HTML content includes non-Latin characters or symbols because it can cause the text to become unreadable. For example, if the HTML content contains Greek text, those characters may be corrupted during the text normalization process that decomposes the Unicode characters and replaces homoglyphs with standard representations of those characters.

Note: This function returns the number of characters in the filtered text, not including the terminating null. When dynamically allocating memory for the output buffer, make sure you include additional space for the null character. When using the ANSI version of this function, size the *nMaxLength* parameter for the number of UTF-8 bytes required, not the original file size, since UTF-16 to UTF-8 conversion may increase the byte count. If you are unsure as to how much memory is needed, you can pass in *lpszBuffer* as `NULL` and *nMaxLength* as **`0`** to have the function calculate the required size. Be aware that this approach will cause the HTML file to be opened, read and filtered twice.

Most applications export HTML to a file as UTF-8 encoded text. However, some legacy applications may export HTML to text files using a locale-specific character set. In this case, you can use the **ConvertTextFile** function to convert the contents of the file from a specific code page to a Unicode compatible format.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

Example

```
LPCTSTR pszFileName = _T("%USERPROFILE%\\Documents\\TestPage.html");

// Calculate the number of characters required to store the filtered HTML.
// For situations where you know that you're going to be working with
```

```
// relatively small files, it can be more efficient to preallocate a fixed
// size buffer rather than filtering the file twice.

INT cchFiltered = FilterHtmlFile(pszFileName, NULL, 0);
if (cchFiltered > 0)
{
    LPTSTR pszFiltered = (LPTSTR)malloc((cchFiltered + 1) * sizeof(TCHAR));

    if (pszFiltered == NULL)
    {
        // Virtual memory exhausted
        return;
    }

    cchFiltered = FilterHtmlFile(pszFileName, pszFiltered, cchFiltered + 1);
    if (cchFiltered > 0)
    {
        // Write the filtered text to standard output
        _fputts(pszFiltered, stdout);
        fflush(stdout);
    }

    free(pszFiltered);
}
else
{
    // No filtered text, check the last error code for more information
    DWORD dwError = GetLastError();
    _tprintf(_T("Unable to filter \"%s\", error 0x%lx\n"), pszFileName, dwError);
}
```

FilterHtmlText Function

```
INT WINAPI FilterHtmlText(
   LPCTSTR lpszInput,
   INT cchInput,
   LPTSTR lpszOutput,
   INT nMaxLength
);
```

The **FilterHtmlText** function filters HTML formatting from the input buffer and returns plain text in an output buffer.

Parameters

lpszInput

A null-terminated string which contains the HTML formatted text that will be filtered and normalized. If the ANSI version of this function is called, the input should be a null-terminated ASCII or UTF-8 encoded string. This parameter cannot be NULL and the string cannot contain embedded null characters.

cchInput

An integer which specifies the number of characters in the input string. If this parameter is -1, the length of the string will be determined by counting the number of characters up to a terminating null character. If the value is less than the length of the input string, only that number of characters will be filtered. If the value is greater than the length of the string, it will be ignored and the entire string will be filtered.

lpszOutput

A null-terminated string buffer which will contain the filtered text. The buffer must be large enough to contain the entire string and a terminating null character or the function will fail. If this parameter is NULL and the ***nMaxLength*** parameter is zero, the function will return the number of characters required to store the filtered text, not including the terminating null character.

nMaxLength

The maximum number of characters which can be copied into the ***lpszOutput*** string buffer. If this value is zero, no characters will be copied to the output buffer and the function will return the length of the filtered output, not including the terminating null character. This can be used to determine how much memory should be allocated to store the filtered text.

Return Value

If the function succeeds, it will return the number of characters copied into the output buffer, not including the terminating null character. If the ***lpszOutput*** parameter is NULL and ***nMaxLength*** is zero, the function will return the number of characters in the filtered text without copying any characters. If the function fails, or there is no text in the input buffer, the function will return zero.

Remarks

The **FilterHtmlText** function processes a string containing HTML formatted text, removes the markup and returns output suitable for display in text-only environments. HTML tags are removed and entities are converted to their canonical Unicode equivalent. When filtering markup from the text, the function will:

- Remove all leading and trailing whitespace from the text, including newlines.
- Remove script, style, and other non-visible or unsafe elements.

- Convert common tag structures, such as lists and headers, into readable plain text.
- Extract and filter hyperlinks and image alt text, ignoring internal links to other sections.
- Remove any embedded credentials in hyperlinks.
- Decode common HTML entities such as **&trade** and **&copy**, as well as numeric entites like **&#x20.**

The function will remove extraneous whitespace within the text, but will attempt to maintain the structure of ordered and unordered lists. It does not parse the style information or Javascript that may be included in the HTML content. If a paragraph uses a style that would normally prevent it from being rendered in a browser (e.g.: the visibility attribute set to "hidden"), it is ignored and the text will be included in the output. If there are sections which contain preformatted text, such as text inside **<pre>...</pre>** or **<code>...</code>** tags, individual line and paragraph breaks will be preserved.

If you are concerned that the HTML may contain obfuscated text or confusable Unicode homoglyphs, you can pass the output from this function to the **FilterUnicodeText** function. However, you should not do this if the original HTML content includes non-Latin characters or symbols because it can cause the text to become unreadable. For example, if the HTML content contains Greek text, those characters may be corrupted during the text normalization process that decomposes the Unicode characters and replaces homoglyphs with standard representations of those characters.

This function will not remove Unicode characters from the input text. If the HTML markup includes any entities which are represented as Unicode, such as **½** which represents "½", they will be returned in the output string buffer as Unicode characters. If the ANSI version of this function is called, Unicode will always be returned as UTF-8 encoded characters. If you expect the HTML to include non-ASCII characters, it is recommended that you use the Unicode version of this function.

To determine if the input string is likely to contain HTML markup before filtering it, you can use the **IsHtmlText** function.

If you wish to filter the contents of a text file which contains HTML, you can use the **FilterHtmlFile** function. That function recogizes Unicode byte order marks (BOMs) and will automatically handle any conversion between UTF-8 and UTF-16 based on whether you call the ANSI or Unicode version of the function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FilterMarkdownText Function

```
INT WINAPI FilterMarkdownText(
    LPCTSTR lpszInput,
    INT cchInput,
    LPTSTR lpszOutput,
    INT nMaxLength
);
```

The **FilterMarkdownText** function filters Markdown from the input buffer and returns plain text in an output buffer.

Parameters

lpszInput

A null-terminated string which contains the Markdown text that will be filtered and normalized. If the ANSI version of this function is called, the input should be a UTF-8 encoded string. This parameter cannot be NULL and the string cannot contain embedded null characters.

cchInput

An integer which specifies the number of characters in the input string. If this parameter is -1, the length of the string will be determined by counting the number of characters up to a terminating null character.

lpszOutput

A null-terminated string buffer which will contain the filtered text. The buffer must be large enough to contain the entire string and a terminating null character or the function will fail. If this parameter is NULL and the ***nMaxLength*** parameter is zero, the function will return the number of characters required to store the filtered text, not including the terminating null character.

nMaxLength

The maximum number of characters which can be copied into the ***lpszOutput*** string buffer. If this value is zero, no characters will be copied to the output buffer and the function will return the length of the filtered output, not including the terminating null character. This can be used to determine how much memory should be allocated to store the filtered text.

Return Value

If the function succeeds, it will return the number of characters copied into the output buffer, not including the terminating null character. If the ***lpszOutput*** parameter is NULL and ***nMaxLength*** is zero, the function will return the number of characters in the filtered text without copying any characters. If the function fails, or there is no text in the input buffer, the function will return zero.

Remarks

The **FilterMarkdownText** function processes a text string containing Markdown formatting and returns a simplified version with the formatting removed. This preserves the readable content while stripping away syntax such as headings, list markers, emphasis markers, links, and other Markdown elements that are intended for display formatting.

The function works by scanning the text from start to finish and applying a set of rules to recognize common Markdown constructs. For example, headings have their leading hash markers are removed, list markers are normalized to a simple dash or number, emphasis markers such as the asterisk and underscore are stripped, and link text is preserved with the URL shown in parentheses. Code blocks and inline code are retained without the backtick markers. Whitespace is also normalized to make the

output easier to read.

This function is intended for situations where you need plain text output from Markdown input, such as displaying content in a non-HTML context, preparing it for indexing, or passing it to other text-based utilities. It works best when you are confident that the input is actually Markdown; using it on arbitrary text may result in loss of characters that were mistaken for formatting.

The filtering is based on a set of common Markdown patterns and does not attempt to fully parse the Markdown specification. As a result, it may not recognize every possible variation of Markdown and there may be some cases where not all of the formatting is removed.

To determine if the input string is likely to contain Markdown before filtering it, you can use the **IsMarkdownText** function.

Example

```
// Basic Markdown text with an unordered list and hyperlink
LPCTSTR pszInput = _T("# Heading 1\n"
                      "\n"
                      "> A blockquote with *emphasis* and **strong text**.\n"
                      "\n"
                      "- Item 1\n"
                      "- Item 2 with a [link](https://example.com)\n"
                      "\n"
                      "Inline `code` sample.\n");

LPTSTR pszOutput = NULL;
INT cchOutput = 0;

// First, determine how many characters the filtered output will require
cchOutput = FilterMarkdownText(pszInput, -1, NULL, 0);

if (cchOutput > 0)
{
    pszOutput = (LPTSTR)malloc((cchOutput + 1) * sizeof(TCHAR));

    if (pszOutput == NULL)
        return 0; // Handle memory allocation failure

    // Filter out any Markdown in the input string
    cchOutput = FilterMarkdownText(pszInput, -1, pszOutput, cchOutput + 1);

    _tprintf(_T("Original:\n%s\nFiltered:\n%s\n"), pszInput, pszOutput);
    free(pszOutput);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FilterUnicodeText Function

```
INT WINAPI FilterUnicodeText(
    LPCTSTR lpszInput,
    INT cchInput,
    LPTSTR lpszOutput,
    INT nMaxLength
);
```

The **FilterUnicodeText** function filters text to replace confusable Unicode homoglyphs, remove symbols and trim whitespace.

Parameters

lpszInput

A null-terminated string which contains the Unicode text that will be filtered and normalized. If the ANSI version of this function is called, the input should be a UTF-8 encoded string. This parameter cannot be NULL and the string cannot contain embedded null characters.

cchInput

An integer which specifies the number of characters in the input string. If this parameter is -1, the length of the string will be determined by counting the number of characters up to a terminating null character.

lpszOutput

A null-terminated string buffer which will contain the filtered text. The buffer must be large enough to contain the entire string and a terminating null character or the function will fail. If this parameter is NULL and the ***nMaxLength*** parameter is zero, the function will return the number of characters required to store the filtered text, not including the terminating null character.

nMaxLength

The maximum number of characters which can be copied into the ***lpszOutput*** string buffer. If this value is zero, no characters will be copied to the output buffer and the function will return the length of the filtered output, not including the terminating null character. This can be used to determine how much memory should be allocated to store the filtered text.

Return Value

If the function succeeds, it will return the number of characters copied into the output buffer, not including the terminating null character. If the ***lpszOutput*** parameter is NULL and ***nMaxLength*** is zero, the function will return the number of characters in the filtered text, not including the terminating null. If the function fails, or there is no text in the input buffer, the function will return zero.

Remarks

The **FilterUnicodeText** function filters Unicode text to normalize visually confusable characters, remove symbolic or non-textual code points (such as emojis), and standardize whitespace. It is designed to produce safe, readable output by converting characters to their most recognizable and printable forms.

This function performs multi-stage normalization and filtering of Unicode text, designed to produce clean, printable output from potentially deceptive or malformed input. It applies Compatibility Decomposition (NFKD) to break down complex characters into their canonical equivalents, such as replacing ligatures or accented characters with their base ASCII forms. It also removes Unicode combining marks that could be used to visually obscure or alter text. Leading and trailing Unicode whitespace, including zero-width and non-breaking spaces, is trimmed to improve consistency.

To mitigate spoofing and visual ambiguity, it replaces confusable Unicode homoglyphs with their standard Latin counterparts. For example, the Cyrillic small letter "a" (U+0430) is replaced with the Latin "a" (U+0061). It also detects and maps mathematical alphanumeric symbols and fullwidth characters to their

ASCII equivalents. Non-textual code points, including emojis, pictographs, private-use characters, and deprecated symbols are removed from the input string. This is especially useful in security-sensitive contexts, such as sanitizing domain names, email addresses, usernames, or filenames. It can help prevent spoofing, phishing, and filter evasion through the use of homoglyphs or invisible characters.

If the ANSI version of this function is called, the input string is validated to ensure that it contains only valid UTF-8 encoding. It removes invalid character sequences such as overlong encodings, truncated multibyte sequences, illegal continuation bytes, and code points outside the valid Unicode range. You should never pass a localized ANSI string encoded using the system code page. To normalize such strings, first convert them to UTF-16 using the **MultiByteToWideChar** function, then call FilterUnicodeTextW.

If the Unicode version of this function is called, the input is validated to ensure it contains only well-formed UTF-16. This includes removing unpaired surrogates, invalid code points, unprintable control characters, and private-use characters. If the input includes malformed Unicode, embedded nulls, or arbitrary binary data, it may result in the loss of non-text content during filtering.

This function is deliberately biased toward security rather than readability and can affect the output when applied to text containing legitimate non-Latin characters. It is intended for use on text that is expected to contain only printable plaintext characters such as identifiers, URLs and file paths. For example, it will filter and normalize text containing certain Greek or Cyrillic characters that could be used to spoof ASCII letters or URL delimiters. While this helps mitigate obfuscated or malicious content, it can also make legitimate text in other languages unreadable.

Example

In this example, the input string contains visually confusable Unicode characters from the Mathematical Alphanumeric Symbols block. The **FilterUnicodeText** function maps each character to its plain ASCII equivalent, producing the expected result: "Hello!". This is particularly useful for detecting spoofed identifiers or sanitizing text used in security-sensitive contexts.

```
#ifdef UNICODE
// UTF-16 encoded version of the string "Hello!" using mathematical bold
LPCWSTR pszInput =
L"\xD835\xDC07\xD835\xDC1E\xD835\xDC25\xD835\xDC25\xD835\xDC28\x0021";
#else
// UTF-8 encoded version of the string "Hello!"
LPCSTR pszInput =
"\xF0\x9D\x90\x87\xF0\x9D\x90\x9E\xF0\x9D\x90\xA5\xF0\x9D\x90\xA5\xF0\x9D\x90\xA8\x21";
#endif

LPTSTR pszOutput = NULL;
INT cchOutput = 0;

// First, determine how many characters the filtered output will require
cchOutput = FilterUnicodeText(pszInput, -1, NULL, 0);

if (cchOutput > 0)
{
    pszOutput = (LPTSTR)malloc((cchOutput + 1) * sizeof(TCHAR));

    if (pszOutput == NULL)
        return 0; // Handle memory allocation failure

    // Convert the input to safe, normalized text; should produce "Hello!" in ASCII
    cchOutput = FilterUnicodeText(pszInput, -1, pszOutput, cchOutput + 1);

    _tprintf(_T("The string \"%s\" was filtered to \"%s\"\n"), pszInput, pszOutput);
    free(pszOutput);
}
```

GetCustomGuidValue Function

```
BOOL WINAPI GetCustomGuidValue(
    LPCGUID lpGuid,
    LPDWORD lpdwValue
);
```

The **GetCustomGuidValue** function returns the 32-bit application-defined value used to create a custom GUID.

Parameters

lpGuid

A pointer to a GUID structure which contains the custom GUID. This parameter must point to a valid v8 UUID and cannot be NULL.

lpdwValue

A pointer to a 32-bit integer that receives the application-defined value used when creating the custom GUID. This parameter cannot be NULL.

Return Value

A non-zero value is returned if the function was successful. A return value of zero indicates an error. Call the **GetLastError** function for more information about the cause of the failure.

Remarks

The **GetCustomGuidValue** function extracts the 32-bit application-defined value stored in the `Data1` field of a Version 8 UUID created by the **CreateCustomGuid** function. This value may represent a sequential counter, type identifier, process or session ID, or any other application-specific data encoded at the time the GUID was created. To ensure that the value is extracted from a compatible UUID, this function validates the version number in the GUID to ensure it is a Version 8 UUID as defined in RFC 9562.

This function is intended to be used specifically with GUIDs generated by the **CreateCustomGuid** function, where the first 32 bits (`Data1`) are defined by the application. Version 8 UUIDs are explicitly designed for application-specific use cases, and there is no standardized layout beyond the required version and variant bits. As such, UUIDs generated by other applications or libraries may encode their custom data in different parts of the structure or not at all. Using this function with a Version 8 UUID that was not generated using the same convention may produce meaningless or misleading results.

Because only the first 32 bits of the GUID are application-defined and the remaining 96 bits are created using a cryptographically secure random number generator, the likelihood of a collision between GUIDs that share the same custom value remains extremely small, even when millions or billions of GUIDs are created using the same value. For more information about collision probabilities, refer to the documentation for the **CreateCustomGuid** function.

GetFileCodePage Function

```
UINT WINAPI GetFileCodePage(
   LPCTSTR lpszFileName
);
```

The **GetFileCodePage** function attempts to determine the Windows code page used to create the file.

Parameters

lpszFileName

A null-terminated string which specifies the name of the file to examine. The file path can include environment variables surrounded by percent symbols and those variables will be automatically expanded. If you do not specify a full path, the file name will be relative to the current working directory. The file must exist, and it must be a regular file that can be opened for reading by the current process. This parameter cannot be NULL.

Return Value

A non-zero code page value is returned if the function could sucessfully determine the code page used to create the file. A value of zero indicates that the file could not be accessed, the code page could not be determined or it is not a text file. If the code page cannot be determined, the **GetLastError** function will return `ERROR_NO_UNICODE_TRANSLATION`.

Remarks

The **GetFileCodePage** function is used to determine the Windows code page used to create the text file. This is done by examining the contents of the file and checking for a byte order mark (BOM) which can identify the file. If there is no byte order mark present, it will examine the contents of the file to determine if could be a text file which uses Unicode. The following checks are performed:

- Look for the presence of a UTF-8 BOM or UTF-7 BOM.
- Look for the presence of a UTF-16LE (large endian) or UTF-16BE (big endian) BOM.
- Check if the beginning of the file contains valid UTF-8 encoding with no errors, such as invalid codepoints or overlong encoding sequences.
- Check the contents of the file to determine if there is a regular sequence of null bytes and ASCII character pairs which could indicate UTF-16 without a BOM.

The presence of a byte order marker is the most reliable method for determining if the file contains Unicode text. If there is no BOM at the beginning of the file, the function attempts to infer the possible character encoding based on what byte sequences are found near the beginning of the file. It is important to note that without a BOM, there can be false-positive detections. The following code pages may be returned:

- UTF-7 (CP_UTF7, 65000)
  An obsolete variable-length encoding designed to be more efficient than using quoted-printable encoding in combination with UTF-8. It represents Unicode text as a stream of 7-bit ASCII characters with a shift sequence to switch to 16-bit encoding for characters outside of the normal ASCII range. Byte order is not an issue, but it does have an optional BOM of **2B 2F 76**. This encoding should not be used.
- UTF-8 (CP_UTF8, 65001)

A variable-length encoding where ASCII characters (U+0000-U+007F) are stored as single bytes. Non-ASCII characters use 2-4 bytes. UTF-8 is backward-compatible with ASCII and is commonly used with various Internet protocols. Byte order is not an issue, though an optional BOM of **EF BB BF** may be used.

- UTF-16LE (1200)
  Encodes characters as 2 or 4 bytes using little-endian byte order. Often includes a BOM **FF FE** to indicate endianness. It is the native encoding for Windows Unicode text.

- UTF-16BE (1201)
  Similar to UTF-16LE, but uses big-endian byte order. Typically includes a BOM **FE FF**. This encoding is occasionally used on UNIX-based systems but is rarely used on Windows.

The code pages for UTF-16LE and UTF-16BE are defined by Microsoft, but they cannot be used with the **WideCharToMultiByte** or **MultiByteToWideChar** functions. Normally, they are only supported for use with managed applications. However, this function will recognize them as valid code pages. Unlike UTF-8 which has a defined macro **CP_UTF8**, there are no corresponding macros for UTF-16 in the Windows SDK.

Determining the ANSI code page of a text file by inspecting its contents is fundamentally unreliable because ANSI encodings lack a definitive signature, such as a byte order mark (BOM), to identify which specific code page was used. Unlike Unicode formats like UTF-8 or UTF-16, which may include a BOM or follow strict encoding rules, ANSI code pages are legacy single-byte or multibyte encodings that reuse the same byte values for different characters depending on the locale.

For instance, the byte 0xE1 maps to completely different character in Windows-1252 than it does in Windows-1251. Because many ANSI encodings overlap in the 0x80-0xFF range and are not self-describing, guessing the correct code page without additional context, such as file origin, user locale, or application metadata, is speculative and error-prone. Misidentifying the code page can lead to incorrect character rendering or data corruption. If this function cannot reliably determine the code page, it will return a code page of 0, which can either be interpreted as failure or you could attempt to render the text using the current active code page.

GetFileNameUrl Function

```
INT WINAPI GetFileNameUrl(
   LPCTSTR lpszFileName,
   LPTSTR lpszFileUrl,
   INT nMaxLength,
   DWORD dwOptions
);
```

The **GetFileNameUrl** function creates a file URL based on the name of a local file or network share.

Parameters

lpszFileName

A null-terminated string which specifies the local file name or network share. Although relative paths are supported, they are not recommended and will be automatically converted to absolute paths in the file URL. It is not necessary for the file to exist on the local system.

lpszFileUrl

A null-terminated string buffer which will contain the file URL when the function returns. If this parameter is NULL, the ***nMaxLength*** parameter should have a value of zero. In this case, the function will ignore this parameter and return the length of the URL.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer. This must include space for the terminating null character. If the maximum length is not large enough to store the entire URL, the function will fail. If the value of this parameter is zero, the function will return the number of characters required to store the URL, not including the terminating null.

dwOptions

A numeric value which determines how the file URL will be created. It may be one or more of the following values:

Value	Description
FILE_URL_DEFAULT	The file URL will be composed with default options. The case will be preserved and environment variables will not be expanded; instead they will be encoded as part of the URL. This is the same as using a value of zero (e.g.: no options).
FILE_URL_LCASE	The file URL will be returned as all lower-case letters. If this option is not specified, the case of the file as specified in ***lpszFileName*** will be preserved. This option is primarily for cosmetic consistency; file names are not case-sensitive on Windows.
FILE_URL_EXPAND	If the local file name contains any environment variables surrounded by percent (%) symbols, those variables will be expanded before composing the file URL. If this option is not specified, environment variables will be encoded as part of the URL.

Return Value

If the function succeeds, it returns the number of characters copied into the string buffer, not including the terminating null character. If you pass a value of zero as the ***nMaxLength*** parmeter, the function

will return the length of the string without copying any data. If you use this to calculate how much memory to allocate for the file URL, remember to add one to the return value for the terminating null. If the function fails, it will return zero. Call **GetLastError** to retrieve extended error information.

Remarks

The **GetFileNameUrl** function is designed to generate file URLs that conform to RFC 8089, which defines the file:// URL scheme. This can be useful for referencing local files or network shares in a standardized format that can be used in web browsers, log files, or when interoperating with systems that expect a file URL. Relative paths are automatically normalized to absolute paths based on the current working directory. The function also encodes special characters as required by the URL specification (e.g., spaces become %20). UNC paths such as `\\server\share\file.txt`) are converted into file URLs like `file:////server/share/file.txt`.

If the file name contains Unicode characters outside of the standard ASCII range, they will be included as encoded UTF-8 characters. This ensures interoperability with other platforms and allows safe transport over networks using protocols which may not support 8-bit characters. Note the encoding will always use UTF-8, regardless of whether or not you use the Unicode or ANSI (MBCS) version of this function.

File URLs do not interpret percent symbols as environment variable markers by default. Instead, the percent sign (%) is a reserved character in URL syntax and must be encoded as %25. For example, if the file path you provide contains **`%TEMP%`**, this function will encode it as **`%25TEMP%25`** in the URL. If the FILE_URL_EXPAND option is specified, environment variables will be expanded prior to encoding using the current process environment. Internally, this function uses the **ExpandEnvironmentStrings** function, which follows standard Windows conventions.

Although relative paths are supported, their use is strongly discouraged. The function internally calls **GetFullPathName**, which resolves relative paths based on the process's current working directory. This value is shared across all threads in a process and can change at any time, leading to unpredictable results or subtle bugs. For this reason, it is recommended to always provide fully qualified paths to ensure consistent behavior.

This function does not check for the existence of the file. Its sole purpose is to format the path into a valid URL format. If the application requires file validation, it should perform that check separately. If you wish to ensure the file exists, you can either use a function like **GetFileAttributes** (which will return an error if the file or folder does not exist) or you can provide the resulting file URL to the **IsValidFileUrl** function and have it perform the check.

Example

```
LPCTSTR pszFileName = _T("%PUBLIC%\\Documents\\MyProject.docx");
TCHAR szFileUrl[MAX_FILE_URL_LENGTH] = _T("");

// Expand the environment variables in the file name and return a
// file URL which conforms to the RFC 8089 standard
//
// It is recommended that file names be absolute rather than
// relative to the current working directory

INT nLength = GetFileNameUrl(
                    pszFileName,
                    szFileUrl,
                    MAX_FILE_URL_LENGTH,
                    FILE_URL_EXPAND | FILE_URL_LCASE);

if (nLength > 0)
```

```
{
    // Returns the URL file:///c:/users/public/documents/myproject.docx
    _tprintf(_T("The file URL is \"%s\"\n"), szFileUrl);
}
else
{
    _tprintf(_T("Unable to create a file URL for \"%s\"\n"), pszFileName);
}
```

GetFileTimeFromGuid Function

```
BOOL WINAPI GetFileTimeFromGuid(
   LPCGUID lpGuid,
   LPFILETIME lpFileTime
);
```

The **GetFileTimeFromGuid** function gets the timestamp from a sequential GUID and returns the value in a FILETIME structure.

Parameters

lpGuid

A pointer to a GUID structure which will contain the sequential GUID. This parameter must point to a valid v7 UUID and cannot be NULL.

lpFileTime

A pointer to a variable that receives the timestamp encoded in the GUID and converts it to a FILETIME structure. This parameter is required and cannot be NULL.

Return Value

A non-zero value is returned if the function was successful. A return value of zero indicates an error. Call the **GetLastError** function for more information about the cause of the failure.

Remarks

The **GetFileTimeFromGuid** function extracts the timestamp stored in a Version 7 UUID and populates a FILETIME structure with the value. The timestamp is stored as the number of milliseconds which have elapsed since January 1, 1970 UTC. This function converts that time value to a FILETIME structure which represents the number of 100-nanosecond intervals that have elapsed since January 1, 1601 UTC. When a sequential GUID is generated, it will typically use the system clock to create the timestamp value. If the clock was not synchronized with a time server when the GUID was created, this may cause time drift in the generated GUID.

This function requires a valid GUID which conforms to a Version 7 UUID as defined in RFC 9562 and the timestamp value embedded in the GUID must specify a legitimate time. Internally, the function will permit a certain amount of clock skew to compensate for systems where the system clock is not synchronized. However, if the timestamp represents a time more than 12 hours into the future, this function will return FALSE. Note that in this case, the FILETIME structure will contain the invalid timestamp and the last error code will be set to ST_ERROR_INVALID_TIMESTAMP.

You can use the **GetSystemTimeFromGuid** function to return the time in a SYSTEMTIME structure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib

GetLocalMachineGuid Function

```
BOOL WINAPI GetLocalMachineGuid(
    LPGUID lpGuid
);
```

The **GetLocalMachineGuid** function returns a unique identifier for the local machine.

Parameters

lpGuid

A pointer to a GUID structure which contains the unique identifier for the local machine. This parameter cannot be NULL.

Return Value

A non-zero value is returned if a unique GUID could be created for the local machine. A return value of zero indicates an error.

Remarks

The **GetLocalMachineGuid** function generates a persistent, system-specific identifier in the form of a Version 5 UUID. This GUID is intended to remain consistent across reboots and is unique to the local machine. It is generated by reading the GUID associated with the system's boot volume and combining it with a predefined namespace using a SHA-1 hash. As a result, the returned GUID will typically remain unchanged unless the system is reconfigured to boot from a different volume or the boot drive is reformatted and Windows is reinstalled.

This function can be useful in scenarios where an application needs to determine whether it is running on the same machine that initially created a configuration or data file. By storing the local machine GUID in the configuration file and later comparing it to the current system's identifier, the application can detect if the data was copied to a different system. In such cases, it may choose to revert settings to their defaults or prompt the user for reconfiguration.

If the boot volume GUID cannot be determined, the function will fall back to using the `MachineGuid` value stored in the Windows registry under `HKEY_LOCAL_MACHINE\Software\Microsoft\Cryptography`. While this value is also intended to uniquely identify a Windows installation, it is less reliable than the boot volume GUID because it can be manually modified or duplicated by cloning.

To convert the resulting GUID to a printable string suitable for display or storage, use the **CreateStringFromGuid** function. To compare two GUID string values, use **IsEqualGuidString**, which parses and compares the normalized binary form of the identifiers.

Example

```
GUID guidCurrent = GUID_NULL;
CHAR szGuidFile[MAX_PATH] = "machine.id";
CHAR szStoredGuid[40] = { 0 };
CHAR szCurrentGuid[40] = { 0 };

// Check if the stored GUID file exists
if (PathFileExistsA(szGuidFile))
{
    FILE* fp = fopen(szGuidFile, "r");
    if (fp != NULL)
    {
```

```
        if (fgets(szStoredGuid, sizeof(szStoredGuid), fp) != NULL)
        {
            // Remove newline if present
            szStoredGuid[strcspn(szStoredGuid, "\r\n")] = '\0';
        }
        fclose(fp);
     }
}

// Get the current machine GUID
if (GetLocalMachineGuid(&guidCurrent))
{
    // Convert current GUID to string
    if (CreateStringFromGuidA(&guidCurrent, szCurrentGuid, sizeof(szCurrentGuid)))
    {
        if (!IsEqualGuidStringA(szStoredGuid, szCurrentGuid))
        {
            // The GUIDs are different; likely copied from another system
            // so take appropriate action, such as reverting settings
        }
        else
        {
            // The GUIDs match, this is the same machine
        }

        // If no stored GUID exists yet, save the current one
        if (szStoredGuid[0] == '\0')
        {
            FILE* fp = fopen(szGuidFile, "w");
            if (fp != NULL)
            {
                 fprintf(fp, "%s\n", szCurrentGuid);
                 fclose(fp);
            }
         }
     }
}
else
{
     // Failed to get current machine GUID
}
```

GetMessageDigest Function

```
BOOL WINAPI GetMessageDigest(
   LPVOID lpvBuffer,
   DWORD cbBuffer,
   DWORD dwDigestOptions,
   LPTSTR lpszDigest,
   INT nMaxLength
);
```

The **GetMessageDigest** function computes a message digest for a buffer, string or data file.

Parameters

lpvBuffer

The data that will be processed by the message digest algorithm. This parameter may be NULL, in which case the standard null hash value will be returned. Depending on the options specified, this may point to a block of memory, a null-terminated string or the name of a data file.

cbBuffer

The number of bytes of data that will be processed by the message digest algorithm. If this value is zero, then the standard null hash value will be returned. If the ***lpvBuffer*** parameter is NULL, this value must be zero. If this value is -1 then ***lpvBuffer*** is considered to be a pointer to a null-terminated string.

dwDigestOptions

A numeric value which specifies the algorithm that will be used to generate the message digest, and may be combined with other option flags. The algorithm may be one of the following values:

Value	Description
MESSAGE_DIGEST_DEFAULT	Use the default message digest algorithm, which is the same as specifying MESSAGE_DIGEST_SHA256
MESSAGE_DIGEST_MD5	Use the MD5 algorithm which generates a 128-bit hash value that is returned as as 32 digit hexadecimal string. This algorithm is typically used as a checksum to verify data integrity, however it is not considered cryptographically secure and hash collision is possible.
MESSAGE_DIGEST_SHA1	Use the SHA1 algorithm which generates a 160-bit hash value that is returned as a 40 digit hexadecimal string. This algorithm is typically used as a checksum to verify data integrity, however it is not considered cryptographically secure.
MESSAGE_DIGEST_SHA256	Use the SHA-256 algorithm which generates a 256-bit hash value that is returned as a 64 digit hexadecimal string. This algorithm is used for data integrity validation and various cryptographic uses, such as password storage and document signing.
MESSAGE_DIGEST_SHA384	Use the SHA-384 algorithm which generates a 384-bit hash value that is returned as a 96 digit hexadecimal string. This is a truncated version of the SHA-512 algorithm that uses

	different initial values.
MESSAGE_DIGEST_SHA512	Use the SHA-512 algorithm which generates a 512-bit hash value that is returned as a 128 digit hexadecimal string. This algorithm is used for data integrity validation and various cryptographic uses, such as password storage and document signing.

The following values may be combined with the algorithm ID to specify options that determine how the message digest is computed and returned to the caller:

Value	Description	
0x10000	MESSAGE_DIGEST_MEMORY	The ***lpvBuffer*** parameter is a pointer to a block of memory and the ***cbBuffer*** parameter specifies how many bytes in the buffer should be used to compute the message digest. This is the default behavior if no other options are specified and the ***cbBuffer*** parameter is not -1.
0x20000	MESSAGE_DIGEST_STRING	The ***lpvBuffer*** parameter is a pointer to a null-terminated string and the ***cbBuffer*** parameter specifies how many characters in the string should be used to compute the message digest. If the ***cbBuffer*** parameter is -1 then all characters up to the terminating null byte will be used.
0x40000	MESSAGE_DIGEST_DATAFILE	The ***lpvBuffer*** parameter is a pointer to a null-terminated string that specifies the name of a data file, and the entire contents of the file will be used to compute the message digest. The ***cbBuffer*** parameter is ignored.
0x80000	MESSAGE_DIGEST_BASE64	The message digest will be returned in ***lpszDigest*** as a base64 encoded value rather than a string of hexadecimal digits. This can be useful for services that use HMAC message digests and require the hash to be in base64 format.

lpszDigest

A null-terminated string that will contain the message digest computed using the contents of the specified buffer. The digest value will consist of upper-case hexadecimal numbers, with the length varying based on the algorithm selected. The string buffer must be large enough to accommodate the entire message digest, including the terminating null character. This parameter cannot be NULL.

nMaxLength

The maximum number of characters that may be copied into the ***lpszDigest*** string buffer, including the terminating null character. This value cannot be zero, and must be large enough to accommodate the complete message digest string value. It is recommended that the string buffer be at least MAX_DIGEST_STRING characters in size.

Return Value

A non-zero value is returned if the message digest was computed and returned in the string buffer provided by the caller. A zero value indicates that the digest could not be computed, or the string

buffer provided by the caller was not large enough to contain the message digest value.

Remarks

The **GetMessageDigest** function accepts an arbitrary block of data, a null-terminated string or a data file and computes a fixed-length value (hash) that can be used to uniquely identify that content. These algorithms are designed to be one-way functions that are deterministic, have a low probability of collision and are difficult or infeasible to reverse. It should be noted that the MD5 and SHA1 algorithms are no longer considered cryptographically secure, however they are still widely used for data integrity validation to protect against accidental or unintended changes.

If the MESSAGE_DIGEST_STRING option is specified and the Unicode version of this function is called, the string will be automatically converted from UTF-16 to UTF-8 encoding, and the UTF-8 encoded text will be used to generate the message digest. If you need to generate a message digest using the UTF-16 encoded version of the string, use the MESSAGE_DIGEST_MEMORY option instead. Keep in mind that UTF-16 encoding represents each character with two bytes, so the buffer length should be twice the number of characters in the Unicode string.

If the MESSAGE_DIGEST_DATAFILE option is specified, the file contents will be processed as binary data with no special consideration given for the various end-of-line conventions used in text files, or any Unicode byte order marks in the file. It is permissible for the file to be empty (zero length), in which case the default null-hash value will be returned based on the algorithm selected by the caller.

The current thread will block while the message digest is being computed. If a large amount of data is being processed, this may cause the application to become non-responsive. In that case, it is recommended that you create a background worker thread and call this function from that worker thread, rather than from the main UI thread.

The length of the message digest string returned by this function will always be the same for a given algorithm, regardless of the size of the data buffer. For example, the length of the message digest for the SHA-256 algorithm will always be 64 characters long. Each byte of the message digest is represented by two upper-case hexadecimal numbers.

It is permitted to provide a NULL or zero-length data buffer to this function, in which case the standard null-hash value will be returned. The same null-hash value will also be returned for a zero-length string or an empty file.

Example

```
// Get a SHA-256 message digest for a string value
LPCTSTR lpszValue = _T("The quick brown fox jumps over the lazy dog");
TCHAR szDigest[MAX_DIGEST_STRING];
BOOL bSuccess;

bSuccess = GetMessageDigest(
            lpszValue,
            (DWORD)-1L,
            MESSAGE_DIGEST_SHA256 | MESSAGE_DIGEST_STRING,
            szDigest,
            MAX_DIGEST_STRING);

// Get an MD5 message digest for the contents of a data file
LPCTSTR lpszFileName = _T("testfile.zip");

bSuccess = GetMessageDigest(
            lpszFileName,
            0,
```

```
MESSAGE_DIGEST_MD5 | MESSAGE_DIGEST_DATAFILE,
szDigest,
MAX_DIGEST_STRING);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

GetTimeFromGuid Function

```
BOOL WINAPI GetTimeFromGuid(
   LPCGUID lpGuid,
   ULARGE_INTEGER* lpTimestamp
);
```

The **GetTimeFromGuid** function returns the 64-bit timestamp value from a sequential GUID.

Parameters

lpGuid

A pointer to a GUID structure which will contain the sequential GUID. This parameter must point to a valid v7 UUID and cannot be NULL.

lpTimestamp

A pointer to an unsigned 64-bit integer which receives the timestamp encoded in the GUID. This parameter is required and cannot be NULL.

Return Value

A non-zero value is returned if the function was successful. A return value of zero indicates an error. Call the **GetLastError** function for more information about the cause of the failure.

Remarks

The **GetTimeFromGuid** function extracts the timestamp stored in a Version 7 UUID and and returns it as an unsigned 64-bit integer. The timestamp is stored as the number of milliseconds which have elapsed since January 1, 1970 UTC. When a sequential GUID is generated, it will typically use the system clock to create the timestamp value. If the clock was not synchronized with a time server when the GUID was created, this may cause time drift in the generated GUID.

Although the timestamp is generally equivalent to the **__time64_t** type, is not the same as the value returned by the **_time64** function in the C standard library. The value returned by **_time64** represents the number of seconds which have elapsed since January 1, 1970 UTC. The timestamp value returned by this function represents the number of ***milliseconds*** which have elapsed.

This function requires a valid GUID which conforms to a Version 7 UUID as defined in RFC 9562 and the timestamp value embedded in the GUID must specify a legitimate time. Internally, the function will permit a certain amount of clock skew to compensate for systems where the system clock is not synchronized. However, if the timestamp represents a time more than 12 hours into the future, this function will return FALSE. Note that in this case, the ***lpTimestamp*** parameter will contain the invalid timestamp and the last error code will be set to ST_ERROR_INVALID_TIMESTAMP.

The **GetFileTimeFromGuid** function can be used to obtain the same time value in a FILETIME structure and the **GetSystemTimeFromGuid** function can be used to obtain the time in a SYSTEMTIME structure.

Requirements

GetUrlFileName Function

```
INT WINAPI GetUrlFileName(
   LPCTSTR lpszFileUrl,
   LPTSTR lpszFileName,
   INT nMaxLength,
   DWORD dwOptions
);
```

The **GetUrlFileName** function parses a file URL and returns the name of a local file or network share.

Parameters

lpszFileUrl

A null-terminated string which specifies the file URL. It is not necessary for the file URL to reference a file which exists on the local system.

lpszFileName

A null-terminated string buffer which will contain the file name when the function returns. If this parameter is NULL, the ***nMaxLength*** parameter should have a value of zero. In this case, the function will ignore this parameter and return the length of the complete file path.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer. This must include space for the terminating null character. If the maximum length is not large enough to store the entire file name, the function will fail. If the value of this parameter is zero, the function will return the number of characters required to store the URL, not including the terminating null.

dwOptions

A numeric value which determines how the file URL will be parsed. It may be one or more of the following values:

Value	Description
FILE_URL_DEFAULT	The file URL will be parsed with default options. The case will be preserved and environment variables will not be expanded. File URLs which contain certain non-standard conventions, such as using the vertical bar (|) as a drive separator will be permitted. It is generally is recommended you use this relaxed parsing mode for the broadest compatibility with most file URLs.
FILE_URL_STRICT	The file URL will be parsed with strict conformance to the standard outlined in RFC 8089. Using this option will cause the function to reject some of the older, non-standard conventions which should no longer be used. You should only use this option if you need to ensure the URLs conform to the current standard.
FILE_URL_LCASE	The file name will be returned as all lower-case letters. If this option is not specified, the case of the path and file name in ***lpszFileUrl*** will be preserved in the file name returned by the function. This option is primarily for cosmetic consistency; file names are not case-sensitive on Windows.
FILE_URL_EXPAND	If the URL contains any encoded environment variables, those

	variables will be expanded before returning the file name. If this option is not specified, environment variables will not be expanded and returned as-is. Note that because environment variables use the same percent symbol that is used for URL encoding, they must be encoded as %25NAME%25.

Return Value

If the function succeeds, it returns the number of characters copied into the string buffer, not including the terminating null character. If you pass a value of zero as the *nMaxLength* parameter, the function will return the length of the string without copying any data. If you use this to calculate how much memory to allocate for the file name, remember to add one to the return value for the terminating null. If the function fails, it will return zero. Call **GetLastError** to retrieve extended error information.

Remarks

The **GetUrlFileName** function parses a file URL and returns the equivalent absolute Windows path. This includes support for URLs that reference local files, mapped drives, and UNC network shares. The returned path is normalized to remove extraneous path delimiters and redundant components (such as . or .. directory references) and will ensure it adheres to the standard Windows path format. The file name returned by this function is always an absolute path.

The function supports both relaxed and strict parsing modes. The default behavior is to be permissive and allow certain legacy formats, such as the use of a vertical bar (|) in place of a colon to separate the drive letter (e.g., file:///C|/path). Strict parsing, enabled with the FILE_URL_STRICT flag, enforces conformance to RFC 8089 and will reject such non-standard forms. This mode is useful when input validation or standards compliance is required.

Although the file URL does not need to refer to an existing file, the returned path will always be fully qualified. If the URL contains encoded environment variables (e.g., **%25TEMP%25**), they will be expanded only if the FILE_URL_EXPAND option is specified. Unlike web URLs, file URLs on Windows are generally case-insensitive; however, the FILE_URL_LCASE flag can be used for cosmetic or consistency purposes when needed.

URL encoding ensures interoperability with other platforms and allows safe transport over networks using protocols which may not support 8-bit characters. If the file URL contains encoded UTF-8 characters they will be automatically decoded. If you use the ANSI version of this function, the file name will always be returned as a UTF-8 encoded string to prevent any possible data loss. If there is any chance the file path will contain Unicode characters, it is recommended you always use the Unicode version of this function.

File URLs do not interpret percent symbols as environment variable markers by default. Instead, the percent sign (%) is a reserved character in URL syntax and must be encoded as %25. For example, to encode **%TEMP%**, you must use **%25TEMP%25** in the URL. If the FILE_URL_EXPAND option is specified, these encoded variables will be expanded using the current process environment. Internally, this function uses **ExpandEnvironmentStrings**, which follows standard Windows conventions.

This function does not validate the file's existence or access permissions, it is solely concerned with converting a URL to a Windows-compatible file path. If validation is required, it must be performed separately after calling this function. If you wish to check that the file exists, you can use the **IsValidFileUrl** function.

It is important to note that file URLs always reference absolute paths. Some older browsers and early versions of the Java runtime supported file URLs with relative paths by omitting the authority portion of the URL; however, this function explicitly prohibits this usage because relative paths may not be

deterministic in multithreaded applications. The current working directory is stored as a global value for each process, and if one thread changes the current working directory, it will change for all other threads and can cause unpredictable behavior.

Example

```
LPCTSTR pszFileUrl = _T("file:///users/public/documents/myproject.docx");
TCHAR szFileName[MAX_PATH] = _T("");

// Return the file name for the specified URL and apply checks to
// ensure the URL conforms to the standard and does not use any
// non-standard conventions common with older browsers

INT nLength = GetUrlFileName(
                    pszFileUrl,
                    szFileName,
                    MAX_PATH,
                    FILE_URL_STRICT);

if (nLength > 0)
{
    // Returns the file C:\users\public\documents\myproject.docx
    _tprintf(_T("The file name is \"%s\"\n"), szFileName);
}
else
{
    _tprintf(_T("Unable to get the file name for \"%s\"\n"), pszFileUrl);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

IsEqualGuidString Function

```
BOOL WINAPI IsEqualGuidString(
   LPCTSTR lpszGuid1,
   LPCTSTR lpszGuid2
);
```

The **IsEqualGuidString** function compares two GUID strings and determines if they represent the same binary value.

Parameters

lpszGuid1

A null-terminated string which specifies a GUID. This parameter cannot be NULL.

lpszGuid2

A null-terminated string which specifies a GUID to be compared against the ***lpszGuid1*** parameter. This parameter cannot be NULL.

Return Value

A non-zero value is returned if the two GUIDs represent the same value. A return value of zero indicates they represent different GUIDs or at least one of the string values does not represent a valid GUID.

Remarks

The **IsEqualGuidString** function compares two serialized GUID strings and determines if they represent the same values, even if the strings themselves are not identical. When parsing the string representation of the GUID, this function will ignore leading and trailing whitespace. If the GUID is enclosed in braces or brackets, the value will be extracted from within them and other characters in the string will be ignored. The hexadecimal values in the string may be separated by a dash or spaces; however, it is not required for the GUID to include separators.

Consider these two strings:

```
"{550e8400-e29b-41d4-a716-446655440000}"
"550E8400E29B41D4A716446655440000"
```

Although these strings would be considered different using a standard string comparison function, they represent the same GUID value and the **IsEqualGuidString** function would return TRUE. If you wish to compare a string against a GUID structure, you can use the **CreateStringFromGuid** function to create a string representation of the GUID structure, which you can then pass to this function.

If one or both of the strings represents an invalid GUID, this function will return FALSE even if the strings themselves are identical. For example, if both strings are identical and have the appearance of valid GUIDs but the 4-bit version field in the GUID is invalid, this function will fail because it requires both GUIDs to represent valid values which conform to RFC 4122.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

IsHtmlText Function

```
BOOL WINAPI IsHtmlText(
   LPCTSTR lpString,
   INT nLength
);
```

The **IsHtmlText** function checks if a string appears to contain HTML formatted text.

Parameters

lpString

A null-terminated string. This parameter cannot be NULL and the string must be terminated with a null character.

nLength

An integer value which specifies the number of characters to check. If this value is -1, the length of the string is determined by counting the number of characters up to the terminating null character. This parameter cannot be zero or the function will fail with `ERROR_EMPTY`.

Return Value

A non-zero value is returned if the string contains valid HTML. A zero value indicates the string does not appear to contain any HTML formatting. On failure, call the **GetLastError** function to obtain more information about the error.

Remarks

The **IsHtmlText** function examines a text string and uses a set of simple rules to decide whether it appears to contain HTML formatting. It does not fully parse the text; instead it looks for common features such as headings, paragraphs, links and common entity names. Each feature it finds contributes to an internal score, and the function returns a positive result if the score is high enough.

This function is useful when you need to check whether text is likely to contain HTML before passing it to the **FilterHtmlText** function or another function that removes or processes formatting.

Because the detection is based on heuristics, it should be viewed as an educated guess rather than a definitive result. While it is generally accurate for typical HTML content, there may be occasional false positives, particularly for similarly structured text such as XML.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

IsMarkdownText Function

```
BOOL WINAPI IsMarkdownText(
   LPCTSTR lpString,
   INT nLength
);
```

The **IsMarkdownText** function checks if a string appears to contain text formatted using Markdown.

Parameters

lpString

A null-terminated string. This parameter cannot be NULL and the string must be terminated with a null character.

nLength

An integer value which specifies the number of characters to check. If this value is -1, the length of the string is determined by counting the number of characters up to the terminating null character. This parameter cannot be zero or the function will fail with `ERROR_EMPTY`.

Return Value

A non-zero value is returned if the string contains valid Markdown. A zero value indicates the string does not appear to contain any Markdown formatting. On failure, call the **GetLastError** function to obtain more information about the error.

Remarks

The **IsMarkdownText** function examines a text string and uses a set of simple rules to decide whether it appears to contain Markdown formatting. It does not fully parse Markdown; instead it looks for common features such as headings, lists, blockquotes, links, images, code blocks, and emphasis markers. Each feature it finds contributes to an internal score, and the function returns a positive result if the score is high enough and there is more than one type of Markdown feature present.

The detection process is designed to be fast and to avoid false positives. For example, a single numbered line will not be treated as a list unless other Markdown elements are also present. Special cases such as fenced code blocks are handled so that their contents do not trigger matches for other features.

This function is useful when you need to check whether text is likely to be Markdown before passing it to the **FilterMarkdownText** function or another function that removes or processes formatting. It works best on plain text and UTF-8 encoded strings.

Because the detection is based on heuristics, it should be viewed as an educated guess rather than a definitive result. While it is generally accurate for typical Markdown content, there may be occasional false positives or false negatives depending on the input.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

IsUnicodeConfusable Function

```
BOOL WINAPI IsUnicodeConfusable(
    LPCTSTR lpString,
    INT nLength
);
```

The **IsUnicodeConfusable** function checks if a string contains characters which can be used to obsfucate Unicode text.

Parameters

lpString

A null-terminated string. This parameter cannot be NULL.

nLength

An integer value which specifies the number of characters to check. If this value is -1, the length of the string is determined by counting the number of characters up to the terminating null character. This parameter cannot be zero.

Return Value

A non-zero value is returned if the string contains one or more characters which could be confused with another character. A zero value indicates no confusable characters were found in the string.

Remarks

The **IsUnicodeConfusable** function checks whether the input string contains Unicode characters that may be visually confused with common Latin letters, digits, or symbols. These characters are often used in phishing, obfuscation, or evasion attacks by mimicking familiar text using characters from other scripts (e.g., Cyrillic, Greek) or stylistic variants (e.g., fullwidth or mathematical alphanumerics). This check can be used to flag suspicious input, enforce stricter character policies, or warn users about potentially deceptive content.

For example, a domain name such as `paypal.com` using the Cyrillic 'p' and 'a' characters may appear visually identical to `paypal.com`, but represent a different string entirely. This function detects the presence of such characters by comparing each Unicode code point against an internal map of known homoglyphs.

The function returns a non-zero value if at least one character in the string matches a known confusable code point. It does not modify the string or perform normalization. If normalization is also required, use the **FilterUnicodeText** function instead.

This function is deliberately biased toward security and may return false positives when applied to text containing legitimate non-Latin characters. It is intended for use on text that is expected to contain only printable plaintext characters such as identifiers, URLs and file paths. For example, it will return TRUE if the text contains certain Greek or Cyrillic characters that could be used to spoof ASCII letters or URL delimiters. While this helps detect obfuscated or malicious content, it can also flag legitimate text that appears in a normal message or document.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib

IsUnicodeText Function

```
BOOL WINAPI IsUnicodeText(
   LPCTSTR lpString,
   INT nLength
);
```

The **IsUnicodeText** function checks if a string contains structurally valid Unicode text.

Parameters

lpString

A null-terminated string. This parameter cannot be NULL and the string must be terminated with a null character.

nLength

An integer value which specifies the number of characters to check. If this value is -1, the length of the string is determined by counting the number of characters up to the terminating null character. This parameter cannot be zero or the function will fail with `ERROR_EMPTY`.

Return Value

A non-zero value is returned if the string contains valid Unicode characters. A zero value indicates the string contains characters that are not valid Unicode, or the string does not contain any Unicode characters. On failure, call the **GetLastError** function to obtain more information about the error.

Remarks

There are two versions of this function, **IsUnicodeTextA** which checks a multi-byte string to ensure that it contains valid UTF-8 encoded text, and **IsUnicodeTextW** which checks a wide string to ensure it contains valid UTF-16 text.

If the value of the ***nLength*** parameter is larger than the number of characters in the string, the function will not check beyond the terminating null character. If the length of the string is unknown, specify a length of -1 and the function will check the entire contents of the string up to the terminating null character.

If the input string is empty, the function fails with the last error code set to `ERROR_EMPTY` to indicate that the operation requires actual data to validate. This is distinct from `ERROR_INVALID_DATA`, which is used for non-empty input that is structurally malformed.

If a byte-order mark (BOM) is present at the start of the buffer and no additional code units follow, the function still returns success. The BOM itself is considered valid Unicode text.

This function does not perform checks to ensure the string contains printable characters. It only validates that the Unicode string is structurally valid. The **IsUnicodeTextA** function will check to make sure there are no invalid UTF-8 encodings. The **IsUnicodeTextW** function will check to make sure the UTF-16 string does not contain any unpaired surrogates. If you wish to filter the text to include only printable characters, use the **FilterUnicodeText** function.

This function does not preserve state information and cannot be used to check the validity of a stream of text or binary data. It should only be used to validate complete Unicode strings terminated with a null character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

IsValidFileUrl Function

```
BOOL WINAPI IsValidFileUrl(
   LPCTSTR lpszFileUrl,
   BOOL bFileExists
);
```

The **IsValidFileUrl** function checks if a string represents a valid file URL.

Parameters

lpszFileUrl

A null-terminated string which specifies a file URL. This parameter cannot be NULL or point to a zero-length string.

bFileExists

An integer value which determines if the function checks to make sure the file exists. If this parameter is non-zero, the file must exist or the function will fail. If this parameter is zero, the function will succeed if the URL conforms to the standard, regardless if the file exists on the local system.

Return Value

A non-zero value is returned if the string contains a valid file URL. A zero value indicates the file URL is invalid, or if the ***bFileExists*** parameter is non-zero, the file cannot be found on the local system.

Remarks

A file URL is a special kind of Uniform Resource Identifier (URI) that uses the **file://** scheme to identify local or network files. The format is standardized in RFC 8089, but real-world usage, particularly on Windows, introduces many quirks and compatibility issues. The **IsValidFileUrl** function validates that a given string conforms to the general structure of a file URL, accounting for both the official standard and the numerous platform-specific variations commonly encountered on Windows systems. It operates in a relaxed mode by design, allowing for:

- Drive letter paths like `file:///c:/path/file.txt`
- UNC paths like `file://server/share/path/file.txt`
- Localhost and machine name authorities like `file://localhost/path/file.txt` or `file://server/share/file.txt`
- Encoded environment variables like `file:///%25TEMP%25/file.txt`
- Use of legacy syntax like C| instead of C: for drive letters
- Implicit authority names and administrative shares like `file://C$/path`

Unlike stricter parsers, this function permits more forgiving syntax to accommodate how file URLs are often generated or copy-pasted from browser address bars, log files, or third-party tools. It also automatically expands environment variables if present, allowing URLs like `file:///%25UserProfile%25/Documents/file.txt` to resolve correctly.

In addition to syntax ***bFileExists*** parameter can be used to verify that the file path resolves to an actual file on the local system or accessible network share. This is useful in scenarios where file URLs are user-provided or come from untrusted sources, such as configuration files or external input.

Validating file URLs helps prevent incorrect or malicious input, reduces the risk of referencing special device names (such as **CON**, **NUL** or **PRN**), and ensures that other functions receive well-formed URLs

that will behave as expected. To create a file URL from a local file name, you can use the **GetFileNameUrl** function which will return the complete file path as a valid URL. To parse file URLs and resolve them to a local file name, you can use the **GetUrlFileName** function.

It is important to note that file URLs always reference absolute paths. Some older browsers and early versions of the Java runtime supported file URLs with relative paths by omitting the authority portion of the URL; however, this function explicitly prohibits this usage because relative paths may not be deterministic in multithreaded applications. The current working directory is stored as a global value for each process, and if one thread changes the current working directory, it will change for all other threads and can cause unpredictable behavior.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

NormalizeUrl Function

```
INT WINAPI NormalizeUrl(
   LPCTSTR lpszUrl,
   DWORD dwFlags,
   LPTSTR lpszNormalized,
   INT nMaxLength
);
```

The **NormalizeUrl** function parses and canonicalizes a URL into a safe, navigable form. It can enforce the scheme, validate and normalize the host name, collapse and encode the path and query parameters as needed, and optionally convert local file paths to `file://` URLs.

Parameters

lpszUrl

A null-terminated string which specifies the URL to be normalized. This parameter cannot be NULL or an empty string.

dwFlags

Specifies one or more bit flags that control how the URL is normalized. A value of zero specifies that only standard normalization will be performed, such as removing any leading and trailing whitespace and ensuring the URL does not contain any illegal characters. Multiple flags may be combined using a bitwise or operator.

Value	Description
URL_FLAG_DEFAULT_HTTPS	When no URL scheme is provided and no scheme is otherwise required, select `https://` by default. If an explicit port is present, port 443 selects `https` and any other port selects `http`. Explicit input schemes are preserved.
URL_FLAG_REQUIRE_HTTP	When no scheme is provided, force `http://`. If the input already specifies a scheme, it is preserved.
URL_FLAG_REQUIRE_HTTPS	When no scheme is provided, force `https://`. If the input already specifies a scheme, it is preserved.
URL_FLAG_REJECT_LOCALHOST	Reject URLs that specify `localhost` as the host name.
URL_FLAG_REJECT_IPV4	Reject URLs that specify a numeric IPv4 address (for example, `192.0.2.1`) as the host.
URL_FLAG_REJECT_IPV6	Reject URLs that specify a bracketed IPv6 address (for example, `[2001:db8::1]`) as the host.
URL_FLAG_ASCII_HOSTNAME	Host names are checked to ensure that they only contain legal ASCII characters. Unicode host names are converted to ASCII (punycode) before validation, and the host name is normalized to lowercase.
URL_FLAG_ESCAPE_PATH	Percent-encode the path component as needed. Non-ASCII characters are encoded as UTF-8 and then percent-encoded per byte. Valid `%HH` sequences are preserved and upper-cased. The path is also normalized by removing duplicate slashes and collapsing `.` and `..` segments of the path.

URL_FLAG_ESCAPE_QUERY	Percent-encode the query and fragment tail as needed. The first **?** is treated as the start of the tail and characters commonly used in queries (such as **&**, **=**, **+**, **;**, **#**) are permitted unescaped. Non-ASCII characters are encoded as UTF-8 and then percent-encoded.
URL_FLAG_VALIDATE_UTF8	Applicable to the ANSI version only. Treat the input as UTF-8 and fail if it is not valid UTF-8. When this flag is not specified, the ANSI version attempts normalize the URL as UTF-8 first and falls back to using the system ANSI code page if the URL is not valid UTF-8.
URL_FLAG_REJECT_LOCAL_FILES	Reject absolute local and UNC paths and existing **file://** URLs. When specified, UNC paths are also rejected and unsafe file extensions are not allowed.
URL_FLAG_REJECT_UNC_PATHS	When local file normalization is permitted, reject UNC paths (for example, **\\server\share**). Files paths which use a mapped drive to a network share will be allowed.
URL_FLAG_ALLOW_UNSAFE_FILES	When converting local/UNC paths to **file://** URLs or normalizing existing **file://** URLs, permit any file extension. If this option is not specified, only a common set of safe, renderable file types are allowed. This includes HTML files, text files and common image formats.

lpszNormalized

A null-terminated string buffer which will contain the normalized URL when the function returns. This parameter may be NULL, in which case the function returns the number of characters required to store the normalized URL. If a buffer is provided, it must be large enough to contain the entire URL.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer, including the terminating null character. If this parameter is zero, the function will return the number of characters required to store the normalized URL and no characters will be copied into the buffer.

Return Value

An integer which specifies the length of the normalized URL, not including the terminating null character. A return value of zero indicates the URL could not be normalized, either due to an invalid URL or the output buffer not being large enough to store the complete URL. Call the **GetLastError** function for more information about the cause of the failure.

Remarks

The Unicode version validates the input as well-formed UTF-16. Leading and trailing whitespace is trimmed before processing, and an internal maximum is enforced to guard against excessively large inputs. The ANSI version attempts to decode the input as UTF-8 first and falls back to the active ANSI code page unless **URL_FLAG_VALIDATE_UTF8** is specified. When possible, it is recommended that you use the Unicode version of this function to ensure support for internationalized domain names. If the URL is being used for display purposes, it's not always necessary to have the function encode the host name using punycode. However, if you are passing the URL to another application or logging the URL to a text file, it's recommended that you use the **URL_FLAG_ASCII_HOSTNAME** flag to ensure the host

name is converted to a printable ASCII text format.

When local file paths are permitted, absolute drive paths such as `C:\path\file.txt` and UNC paths such as `\\server\share\file.txt` are converted to `file://` URLs. Drive paths are canonicalized, any long-path prefix is removed, backslashes are converted to forward slashes, dot-segments are resolved, and spaces are percent-encoded. If you are normalizing a URL entered by a user and want to prevent them from being able to specify a local file path, use the `URL_FLAG_REJECT_LOCAL_FILES` flag. To permit any local file type, use the `URL_FLAG_ALLOW_UNSAFE_FILES` flag. Normally you should only specify this flag if you want to check the file extension in your application rather than using the internal list of safe file types. Opening local file URLs which specify script files or executables can present a significant security risk.

Backslash characters in a path are normalized to forward slashes before parsing and any illegal characters are rejected. The input string may be a full URL with `http://` or `https://`, or scheme-relative URLs starting with `//`. The authority portion is parsed as `host[:port]` with checks for bracketed IPv6 addresses and strict port validation. This function accepts `localhost`, IPv4, and bracketed IPv6 addresses unless explicitly rejected by flags. When the `URL_FLAG_ASCII_HOSTNAME` bitflag is set, Unicode host names are always converted to IDNA (punycode) before validation and the host name is converted to lower case.

When a host name is present and the path is empty, a single `/` is inserted. The path is always normalized by removing duplicate slashes and resolving `.` and `..` segments without moving above the preserved root. When `URL_FLAG_ESCAPE_PATH` is set, Unicode characters are encoded as UTF-8 and then percent-encoded per byte; valid `%HH` pairs are preserved and uppercased, and `/` is kept as a separator. For the query and fragment portion of the URL, the `URL_FLAG_ESCAPE_QUERY` flag ensures characters are percent-encoded as needed, allowing the `&`, `=`, `+`, `;`, and `#` characters to be preserved in the URL unescaped. Note that this function will always consider the hashmark character to be the beginning of a URL fragment and will not encode it.

Scheme selection preserves any URL scheme explicitly provided by the caller. Otherwise, `URL_FLAG_REQUIRE_HTTP` or `URL_FLAG_REQUIRE_HTTPS` forces the scheme. If neither is specified and a port is present, port 443 selects `https` and any other port selects `http`. For example, the string `"example.com"` would be normalized as `http://example.com/` by default. In most cases, it is recommended you specify the `URL_FLAG_DEFAULT_HTTPS` flag to ensure host names entered without a scheme use a secure connection on port 443 rather than a standard (insecure) connection on port 80.

On success, the function sets the last error to `NO_ERROR`. Common failures include `ERROR_INVALID_PARAMETER` for malformed inputs or illegal characters, `ERROR_NO_UNICODE_TRANSLATION` for invalid UTF-16 (Unicode version) or invalid UTF-8 when validation is requested (ANSI version), and `ERROR_INSUFFICIENT_BUFFER` when the output buffer is too small. This function will never return a partial URL.

This function is primarily intended for validating and normalizing user input. Although is can be used to convert a local file path to a local file URL, the **GetFileNameUrl** function is more flexible and permits the use of environment variables in the local file path. The **GetUrlFileName** function can be used to convert a file URL back to a local file name.

Example

```
LPCTSTR pszUrlList[] = {
    _T("example.com"),
    _T("//Example.COM/../a/./b?q=1#frag"),
    _T("C:\\Docs\\Read Me.txt"),
    _T("file:///C:/Docs/Read%20Me.txt"),
```

```
    _T("about:Blank")
};

// A collection of common flags used for safe user input
const DWORD dwFlags =
    URL_FLAG_DEFAULT_HTTPS    |
    URL_FLAG_ASCII_HOSTNAME   |
    URL_FLAG_ESCAPE_PATH      |
    URL_FLAG_ESCAPE_QUERY;

for (int nIndex = 0; nIndex < ARRAYSIZE(pszUrlList); ++nIndex)
{
    TCHAR szNormalized[1024];

    if (NormalizeUrl(pszUrlList[nIndex], dwFlags, szNormalized,
_countof(szNormalized)))
    {
        _tprintf(_T("OK:     %s\n"), szNormalized);
    }
    else
    {
        DWORD dwError = GetLastError();
        _tprintf(_T("FAILED: %s (%lu)\n"), pszUrlList[nIndex], dwError);
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

UnicodeDecodeText Function

```
INT WINAPI UnicodeDecodeText(
   UINT nCodePage,
   LPCSTR lpUtf8Text,
   INT nLength,
   LPTSTR lpString,
   INT nMaxLength
);
```

The **UnicodeDecodeText** function decodes UTF-8 encoded text and returns the contents in a string buffer.

Parameters

nCodePage

A value that specifies the code page used when decoding the text. This parameter can be set to the value of any code page that is available in the operating system. It is recommended that you use CP_ACP which specifies the system default ANSI code page. This parameter is only used when decoding UTF-8 encoded text to a multi-byte string.

lpUtf8Text

A null-terminated string that contains the UTF-8 encoded text to be decoded. This parameter must always specify a pointer to an 8-bit character string, regardless if the project is configured to use the Unicode or Multi-Byte character set. This parameter cannot be NULL.

nLength

The number of bytes in the UTF-8 encoded string to be decoded. If this parameter is -1, the length of the UTF-8 encoded text is determined by counting the number of characters up to the terminating null character.

lpString

A null-terminated string buffer that will contain the decoded UTF-8 text when the function returns. The string buffer must be large enough to contain all of the encoded text, and cannot be a NULL a pointer.

nMaxLength

The maximum number of characters that can be copied into the string buffer. The contents of the ***lpString*** buffer will always be null-terminated, and the maximum size must be large enough to include the null character. This value must be greater than zero.

Return Value

If the UTF-8 encoded text is successfully decoded, the return value is the number of characters copied to the string buffer. If the text cannot be decoded, or the string buffer is not large enough to store all of the decoded text, the function will return zero. To get extended error information, call **GetLastError**.

Remarks

There are two versions of this function, **UnicodeDecodeTextA** which returns a localized multi-byte string and **UnicodeDecodeTextW** which converts the UTF-8 encoded text to UTF-16 text. Your project configuration typically determines which version of this function is used by default.

If the value of the ***nLength*** parameter is larger than the number of UTF-8 characters, the function will not check beyond the terminating null character. If the length of the ***lpUtf8Text*** string is unknown,

specify a length of -1 and the function will decode the entire contents of the string up to the terminating null character.

When calling **UnicodeDecodeTextA** to convert UTF-8 encoded text to a localized multi-byte string, it is recommended that you specify CP_ACP (zero) as the code page value unless you know it contains Unicode characters that cannot be represented using the default ANSI code page. Using CP_ACP will ensure the UTF-8 text is decoded using the current locale and language settings.

When calling **UnicodeDecodeTextW** to convert UTF-8 encoded text to UTF-16 text, the code page parameter is ignored and should always be a value of zero.

This function performs a strict check on the UTF-8 encoded text and will fail if the encoding is malformed, or in the case of being converted to a multi-byte string, if it cannot be decoded using the specified code page. It will not simply replace invalid character sequences with a default character.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csncdv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

UnicodeEncodeText Function

```
INT WINAPI UnicodeEncodeText(
   UINT nCodePage,
   LPCTSTR lpString,
   INT nLength,
   LPSTR lpUtf8Text,
   INT nMaxLength
);
```

The **UnicodeEncodeText** function encodes a string and returns UTF-8 encoded text.

Parameters

nCodePage

A value that specifies the code page used when encoding the text. This parameter can be set to the value of any code page that is available in the operating system. It is recommended that you use CP_ACP which specifies the system default ANSI code page. This parameter is only used when encoding a multi-byte string.

lpString

A null-terminated string that contains the text to be encoded. This parameter cannot be NULL.

nLength

The number of characters in the string to be encoded. If this parameter is -1, the length of the string is determined by counting the number of characters up to the terminating null character.

lpUtf8Text

A pointer to a character buffer which will contain the UTF-8 encoded text when the function returns. This parameter must always specify a pointer to an 8-bit character string, regardless if the project is configured to use the Unicode or Multi-Byte character set. This parameter cannot be NULL.

nMaxLength

The maximum number of bytes that can be copied into the UTF-8 text buffer. The contents of the ***lpUtf8Text*** buffer will always be null-terminated, and the maximum size must be large enough to include the null byte. This value must be greater than zero.

Return Value

If the string is successfully encoded, the return value is the number of characters copied to the output buffer. If the text cannot be encoded, or the output buffer is not large enough to store all of the encoded text, the function will return zero. To get extended error information, call **GetLastError**.

Remarks

There are two versions of this function, **UnicodeEncodeTextA** which converts a multi-byte string to UTF-8 encoded text, and **UnicodeEncodeTextW** which converts a UTF-16 string to a UTF-8 string. Your project configuration typically determines which version of this function is used by default.

If the value of the ***nLength*** parameter is larger than the number of characters in ***lpString***, the function will not check beyond the terminating null character. If the length of ***lpString*** is unknown, specify a length of -1 and the function will encode the entire contents of the string up to the terminating null character.

When calling **UnicodeEncodeTextA** to convert a multi-byte string to UTF-8 encoding, it is recommended that you specify CP_ACP (zero) as the code page value unless you know it contains

ANSI characters from a different code page. Using CP_ACP will ensure the string is encoded using the current locale and language settings.

This function performs a strict check on the multi-byte input string and will fail if it contains a malformed multi-byte sequence or characters that cannot be converted to UTF-8 using the specified code page. It will not simply replace invalid character sequences with a default character.

When calling **UnicodeEncodeTextW** to convert UTF-16 text to UTF-8 encoded text, the code page parameter is ignored and should always be a value of zero. The text will be normalized prior to being converted to UTF-8 using canonical composition, where decomposed characters are combined to create their canonical precomposed equivalent.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

File Transfer Protocol Client Library

Transfer files between a local and server and perform common file management functions on the server.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSFTPV12.DLL
Version	12.0.3024.1286
LibID	A86C8154-EC75-4C39-BB05-B698A87E98F1
Import Library	CSFTPV12.LIB
Dependencies	None
Standards	RFC 959, RFC 1579, RFC 2228

Overview

The File Transfer Protocol (FTP) library provides a comprehensive API which supports both high level operations, such as uploading or downloading files, as well as a collection of lower-level file I/O functions. In addition to file transfers, an application can create, rename and delete files and directories, search for files using wildcards and perform other common file management functions.

Files can be stored on the local file system or in memory, depending on the needs of your application and multiple file transfers be performed using a single function call. The library can also be used to manage files on the server and supports many of the common protocol extensions that can be used to access the remote file system. It understands a number of different directory listing formats, including those typically used with UNIX and Linux based systems, Windows servers and several other platforms.

This library supports active and passive mode file transfers, firewall compatibility options, proxy servers and secure file transfers using TLS 1.3 and SFTP (SSH 2.0). Secure file transfers support implicit and explicit TLS sessions, client certificates and 256-bit AES encryption. SFTP transfers support public/private key authentication using either RSA or OpenSSH formats.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must

have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

File Transfer Protocol Functions

Function	Description
FtpAddQueuedFile	Add a new file to the queue to be uploaded or downloaded.
FtpAddQueuedFileEx	Add a new file to the queue with additional transfer options.
FtpAllocate	Allocate the specified number of bytes on the server.
FtpAsyncConnect	Connect asynchronously to the specified server.
FtpAsyncFileList	Return an unparsed list of files in the specified directory.
FtpAsyncGetData	Copy the contents of a remote file to a local buffer.
FtpAsyncGetFile	Copy a file from the server to the local system.
FtpAsyncGetFileEx	Copy a file from the server to the local system, supporting files larger than 4 GiB.
FtpAsyncProxyConnect	Connect asynchronously to the specified proxy server.
FtpAsyncPutData	Create a file on the server using the contents of a local buffer.
FtpAsyncPutFile	Copy a file from the local system to the server.
FtpAsyncPutFileEx	Copy a file from the local system to the server, supporting files larger than 4 GiB.
FtpAttachThread	Attach the specified client handle to another thread.
FtpCancel	Cancel the current blocking operation.
FtpCancelQueuedFile	Cancel the queued file transfer.
FtpChangeDirectory	Change the current working directory on the server.
FtpChangeDirectoryUp	Change the current working directory on the server.
FtpClearQueue	Remove all files from the current transfer queue.
FtpCloseDirectory	Close the open directory on the server.
FtpCloseFile	Close the current file on the server.
FtpCommand	Send a command to the server.
FtpConnect	Establish a client connection with a server.
FtpConnectUrl	Establish a client connection using the specified URL.
FtpCreateDirectory	Create the specified directory on the server.
FtpCreateQueue	Create a new file transfer queue.
FtpCreateSecurityCredentials	Create a new security credentials structure.
FtpDeleteFile	Delete a file from the server.
FtpDeleteQueue	Delete a previously created file transfer queue.
FtpDeleteSecurityCredentials	Delete a previously created security credentials structure.
FtpDisableEvents	Disable event notification.
FtpDisableTrace	Disable logging of network function calls.
FtpDisconnect	Disconnect the client session from the server.
FtpDownloadFile	Download a file from the server to the local system.
FtpEnableEvents	Enable event notification.
FtpEnableFeature	Enable the specified feature in the client.
FtpEnableTrace	Enable logging of network function calls to a file.

FtpEndOfFile	Determine if the end-of-file has been reached.
FtpEnumFiles	Return a list of files in a directory on the server.
FtpEnumFilesEx	Return a list of files in a directory on the server, supporting files larger than 4 GiB.
FtpEnumQueuedFiles	Return a list of files in the transfer queue.
FtpEnumTasks	Return a list of asynchronous tasks.
FtpEventProc	Callback function that processes events generated by the client.
FtpFindQueuedFile	Find a file in the transfer queue which matches the search criteria.
FtpFreezeEvents	Suspend and resume event handling by the client.
FtpGetActivePorts	Return the range of local port numbers used for active transfers.
FtpGetAutoFileType	Return the file transfer type based on the file extension or content.
FtpGetBufferSize	Return the size of an internal buffer used during data transfers.
FtpGetChannelMode	Return the mode for the specified communication channel.
FtpGetClientQuota	Return quota information for the current client session.
FtpGetData	Copy the contents of a remote file to a local buffer.
FtpGetDefaultZoneId	Returns the default security zone information for downloaded files.
FtpGetDirectory	Get the current working directory on the server.
FtpGetDirectoryFormat	Get the format which is used by the server to list files.
FtpGetErrorString	Return a description for the specified error code.
FtpGetFeatures	Return the features available to the client.
FtpGetFile	Copy a file from the server to the local system.
FtpGetFileEx	Copy a file from the server to the local system, supporting files larger than 4 GiB.
FtpGetFileList	Return an unparsed list of files in the specified directory.
FtpGetFileNameEncoding	Return the character encoding used when sending a file name to the server.
FtpGetFilePathUrl	Return a normalized URL for the specified file on the server.
FtpGetFilePermissions	Return the access permissions for the specified file.
FtpGetFileSize	Return the size of a file on the server.
FtpGetFileStatus	Return file status information from the server.
FtpGetFileStatusEx	Return file status information from the server, supporting files larger than 4 GiB.
FtpGetFileTime	Return the modification time for the specified file on the server.
FtpGetFileType	Return the default file type for the current session.
FtpGetFileZoneInfo	Return file zone identifier information for the specified local file.
FtpGetFirstFile	Return the first file from the file list returned by the server.
FtpGetFirstFileEx	Return the first file from the file list returned by the server, supporting files larger than 4 GiB.
FtpGetFirstQueuedFile	Return information about the first file in the transfer queue.
FtpGetIdleTimeout	Return the idle timeout period for the control channel.
FtpGetLastError	Return the last error code.
FtpGetMultipleFiles	Copy multiple files from the server to the local system.
FtpGetNextFile	Return the next file from the file list returned by the server.
FtpGetNextFileEx	Return the next file from the file list returned by the server, supporting files larger than 4 GiB.

FtpGetNextQueuedFile	Return information about the next file in the transfer queue.
FtpGetPriority	Return the current priority for file transfers.
FtpGetProxyType	Return the proxy type selected by the client.
FtpGetQueueClient	Return the handle to the current client session.
FtpGetQueuedFile	Return information about a file queued for transfer.
FtpGetQueueStatus	Return the status of the current file transfer queue.
FtpGetQueueThread	Return a value which uniquely identifies the queue manager thread.
FtpGetResultCode	Return the result code from the previous command.
FtpGetResultString	Return the result string from the previous command.
FtpGetSecurityInformation	Return security information about the current client connection.
FtpGetSecurityZoneId	Returns the security zone identifier for the specified resource.
FtpGetServerInformation	Get system information about the server.
FtpGetServerStatus	Return system status of server.
FtpGetServerTimeZone	Return the timezone offset in seconds for the current server.
FtpGetServerType	Return the type of operating system the server is running on.
FtpGetStatus	Return the current client status.
FtpGetTaskError	Return the last error code for the specified asynchronous task.
FtpGetTaskId	Return the unique task identifier associated with the specified client session.
FtpGetText	Download the contents of a text file to a string buffer.
FtpGetThreadQueue	Return the handle to a queue associated with the specified thread.
FtpGetTimeout	Return the number of seconds until an operation times out.
FtpGetTransferStatus	Return current file transfer statistics.
FtpGetTransferStatusEx	Return current file transfer statistics, supporting files larger than 4 GiB.
FtpInitialize	Initialize the library and validate the specified runtime license key.
FtpIsBlocking	Determine if the current operation is blocked.
FtpIsConnected	Determine if the client is connected to the server.
FtpIsReadable	Determine if the client can read data from the data channel.
FtpIsWritable	Determine if the client can write data to the data channel.
FtpLogin	Login to the server.
FtpLogout	Logout from the server.
FtpNormalizePath	Normalize the specified file name returning a canonical path.
FtpNormalizeUrl	Normalize the specified URL returning a canonical path.
FtpMountStructure	Mount a structure (filesystem) on the server.
FtpOpenDirectory	Open the specified directory for reading.
FtpOpenFile	Open the specified file for reading or writing.
FtpProxyConnect	Establish a connection with a proxy server.
FtpPutData	Create a file on the server using the contents of a local buffer.
FtpPutFile	Copy a file from the local system to the server.
FtpPutFileEx	Copy a file from the local system to the server, supporting files larger than 4 GiB.

FtpPutMultipleFiles	Copy multiple files from the local system to the server.
FtpPutText	Create a text file on the server from the contents of a string buffer.
FtpRead	Read data from the server.
FtpRegisterEvent	Register an event handler for the specified event.
FtpRegisterFileType	Associate a file name extension with a specific file type.
FtpRemoveDirectory	Remove a directory from the server.
FtpRemoveQueuedFile	Remove a file from the transfer queue.
FtpRenameFile	Rename a file on the server.
FtpReset	Reset the client connection.
FtpResetQueue	Reset the internal state of file transfers in the specified queue.
FtpResumeQueue	Resume the transfer of files after queue processing has been paused.
FtpSetActivePorts	Set the range of local port numbers used for active transfers.
FtpSetBufferSize	Set the size of an internal buffer used during data transfers.
FtpSetChannelMode	Change the security mode for the specified channel.
FtpSetDefaultZoneId	Set the default security zone for downloaded files.
FtpSetDirectoryFormat	Set the format which is used by the server to list files.
FtpSetFeatures	Set the features which can be used by the client.
FtpSetFileMode	Set the current file mode.
FtpSetFileNameEncoding	Set the character encoding type used when sending a file name to the server.
FtpSetFilePermissions	Set the access permissions for the specified file.
FtpSetFileStructure	Set the current file data structure.
FtpSetFileTime	Set the modification time for the specified file on the server.
FtpSetFileType	Set the default file type for the current session.
FtpSetFileZoneInfo	Set or remove the zone indentifier associated with the specified file.
FtpSetIdleTimeout	Set the idle timeout period for the control channel.
FtpSetLastError	Set the last error code.
FtpSetPassiveMode	Set the server in passive mode.
FtpSetPriority	Set the priority for file transfers.
FtpSetTimeout	Set the number of seconds until an operation times out.
FtpStartQueue	Begin transferring the files in the specified queue.
FtpStopQueue	Stop transferring the files in the specified queue.
FtpSuspendQueue	Pause the transfer of files in the specified queue.
FtpTaskAbort	Abort the specified asynchronous task.
FtpTaskDone	Determine if an asynchronous task has completed.
FtpTaskResume	Resume execution of an asynchronous task.
FtpTaskSuspend	Suspend execution of an asynchronous task.
FtpTaskWait	Wait for an asynchronous task to complete.
FtpUninitialize	Terminate use of the library by the calling process.
FtpUploadFile	Upload a file from the local system to the server.

FtpValidateHostName	Validate the specified host name and return the resolved IP address.
FtpValidateUrl	Check the contents of a string to ensure it represents a valid URL.
FtpVerifyFile	Compare the contents of a local file against a file stored on the server.
FtpWaitForQueue	Wait for the transfer of all queued files to complete.
FtpWrite	Write data to the server.

FtpAddQueuedFile Function

```
DWORD WINAPI FtpAddQueuedFile(
   HQUEUE hQueue,
   DWORD dwQueueMode,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   UINT nFileType,
   UINT nTimeout
);
```

The **FtpAddQueuedFile** function adds a new file to the queue with additional transfer options.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An integer value which specifies if the file should be downloaded from the server or uploaded to the server. This parameter must be one of the following options and cannot have a value of zero.

Constant	Description
FTP_QUEUE_DOWNLOAD	The file should be queued for downloading from the server to the local system.
FTP_QUEUE_UPLOAD	The file should be queued for uploading from the local system to the server.

lpszLocalFile

A null-terminated string which specifies the name of the local file to be queued for transfer. This parameter cannot be NULL or point to an empty string. If the file is being queued for an upload, the file must exist on the local system or the function will fail. If the file is being downloaded, it will be created or replaced on the local system.

lpszRemoteFile

A null-terminated string which specifies the URL to the location of the file on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator and can be any of the options used with the **FtpConnect** function. If this value is zero, the default options for the queue will be used. The most common options are:

Value	Description
FTP_OPTION_PASSIVE	This option specifies the file transfer should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the

	server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the file transfer should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the file transfer should attempt to establish a secure connection with the server by default. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the file transfer should attempt to immediately establish secure TLS connection with the server by default. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the file transfer should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the file transfer should use the Secure Shell (SSH) protocol to establish the connection by default. This option will automatically be selected if the connection is established using port 22, the default port for SSH.

nFileType

An integer value which specifies the type of file being transferred. It can be one of the following values:

Value	Description
FILE_TYPE_AUTO	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the **FtpRegisterFileType** function.
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.

FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executable programs. If the type of file cannot be automatically determined, it will always be considered a binary file. If this file type is specified when uploading or downloading text files, the native end-of-line character sequences will be preserved.
FILE_TYPE_LOCAL	The file is a binary file that uses the local byte size for the server platform. On most servers, this file type is considered to be the same as FILE_TYPE_IMAGE. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.

nTimeout

The number of seconds to wait for a response from the server before failing the file transfer. If this value is zero, the default timeout period for the queue will be used.

Return Value

If the function succeeds, the return value is a unique identifier which corresponds to the queued file. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function will add a file to the current transfer queue. If successful, the value returned is a unique integer which identifies that file in the queue. To obtain information about the queued file, you can call the **FtpGetQueuedFile** function and provide this return value as the ***dwFileId*** parameter. To remove a file from the queue, use the **FtpRemoveQueuedFile** function.

Files can only be added to the queue when in an idle or paused state. If you attempt to add a file to the queue while the queue manager is transferring files, the function will fail. To determine the current state of the queue, call the **FtpGetQueueStatus** function

There are no fixed limits to the number of files which can be queued for transfer. To release the memory allocated for the queue, call the **FtpClearQueue** function. To determine the current status of the queue, including how many file transfers have been queued and how many are pending completion, call the **FtpGetQueueStatus** function.

If the local file path includes environment variables enclosed in percentage (%) symbols, those values will be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

This function will not immediately begin the process of uploading or downloading the file. It will only add the transfer request to the current queue. The file transfers are managed by a background worker thread which is created when the **FtpStartQueue** function is called.

The **FtpAddQueuedFileEx** function is an extended version of this function with additional parameters to specify a hostname, port number, user name and password. Because most file uploads require

authentication, using the extended function may be preferred to composing a URL which includes the account credentials.

Example

```
// Create a new queue
HQUEUE hQueue = FtpCreateQueue(INFINITE, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = FtpAddQueuedFile(
                     hQueue,
                     lpszLocalFile,
                     lpszRemoteFile,
                     FTP_OPTION_DEFAULT,
                     FILE_TYPE_AUTO,
                     FTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case FTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case FTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (FtpStartQueue(hQueue, FTP_QUEUE_ALL, 0, NULL, 0))
{
    FtpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    FtpStopQueue(hQueue);
}

// Remove all files from the queue
FtpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpAddQueuedFileEx Function

```
DWORD WINAPI FtpAddQueuedFileEx(
   HQUEUE hQueue,
   DWORD dwQueueMode,
   LPCTSTR lpszHostName,
   UINT nHostPort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   UINT nFileType,
   UINT nTimeout,
   LPVOID lpvReserved
);
```

The **FtpAddQueuedFileEx** function adds a new file to the queue with additional transfer options.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An integer value which specifies if the file should be downloaded from the server or uploaded to the server. This parameter must be one of the following options and cannot have a value of zero.

Constant	Description
FTP_QUEUE_DOWNLOAD	The file should be queued for downloading from the server to the local system.
FTP_QUEUE_UPLOAD	The file should be queued for uploading from the local system to the server.

lpszHostName

The name of the server to establish a connection with. This may be a fully-qualified domain name or an IP address. If this parameter is NULL or points to an empty string, the ***lpszRemoteFile*** parameter must specify a complete URL which identifies the server as well as the path to the remote file.

nHostPort

The port number which should be used when establishing the connection. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990. If this parameter is zero and a URL is specified with the ***lpszRemoteFile*** parameter, the port number included in the URL will be used as the default value.

lpszUserName

A null-terminated string which specifies the user name to be used to authenticate the connection. If this parameter is NULL or an empty string, then the login is considered to be anonymous. Note that anonymous logins are not supported for secure connections using the SSH protocol.

lpszPassword

A null-terminated string which specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

lpszLocalFile

A null-terminated string which specifies the name of the local file to be queued for transfer. This parameter cannot be NULL or point to an empty string. If the file is being queued for an upload, the file must exist on the local system or the function will fail. If the file is being downloaded, it will be created or replaced on the local system.

lpszRemoteFile

A null-terminated string which specifies the name of the file on the server. If the file is being downloaded, the file must exist on the server or the transfer will fail. If the file is being uploaded, the file will be created or replaced on the server. This parameter may specify a complete URL. Note that any values you specify as arguments to this function will override the values specified in the URL. If you want to use a URL as the remote file name, the ***lpszHostName*** parameter should be NULL and the ***nHostPort*** parameter should be zero.

dwOptions

An unsigned integer value which specifies one or more options. This parameter is constructed by using a bitwise operator and can be any of the options used with the **FtpConnect** function. If this value is zero, the default options for the queue will be used. The most common options are:

Value	Description
FTP_OPTION_PASSIVE	This option specifies the file transfer should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the file transfer should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the file transfer should attempt to establish a secure connection with the server by default. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the file transfer should attempt to immediately establish secure TLS connection with the server by default. This option is typically used when

	connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the file transfer should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the file transfer should use the Secure Shell (SSH) protocol to establish the connection by default. This option will automatically be selected if the connection is established using port 22, the default port for SSH.

nFileType

An integer value which specifies the type of file being transferred. It can be one of the following values:

Value	Description
FILE_TYPE_AUTO	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the **FtpRegisterFileType** function.
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executable programs. If the type of file cannot be automatically determined, it will always be considered a binary file. If this file type is specified when uploading or downloading text files, the native end-of-line character sequences will be preserved.
FILE_TYPE_LOCAL	The file is a binary file that uses the local byte size for the server platform. On most servers, this file type is considered to be the same as FILE_TYPE_IMAGE. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.

nTimeout

The number of seconds to wait for a response from the server before failing the file transfer. If this

value is zero, the default timeout period for the queue will be used.

lpvReserved

A reserved parameter which should always be NULL.

Return Value

If the function succeeds, the return value is a unique identifier which corresponds to the queued file. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function will add a file to the current transfer queue. If successful, the value returned is a unique integer which identifies that file in the queue. To obtain information about the queued file, you can call the **FtpGetQueuedFile** function and provide this return value as the ***dwFileId*** parameter. To remove a file from the queue, use the **FtpRemoveQueuedFile** function.

Files can only be added to the queue when in an idle or paused state. If you attempt to add a file to the queue while the queue manager is transferring files, the function will fail. To determine the current state of the queue, call the **FtpGetQueueStatus** function

There are no fixed limits to the number of files which can be queued for transfer. To release the memory allocated for the queue, call the **FtpClearQueue** function. To determine the current status of the queue, including how many file transfers have been queued and how many are pending completion, call the **FtpGetQueueStatus** function.

If the local file path includes environment variables enclosed in percentage (%) symbols, those values will be expanded based on the environment variables defined for the current user using the **ExpandEnvironmentStrings** function in the Windows API. Note that environment variable names are not case-sensitive.

This function will not immediately begin the process of uploading or downloading the file. It will only add the transfer request to the current queue. The file transfers are managed by a background worker thread which is created when the **FtpStartQueue** function is called.

Example

```
// Create a new queue
HQUEUE hQueue = FtpCreateQueue(INFINITE, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = FtpAddQueuedFileEx(
                      hQueue,
                      FTP_QUEUE_DOWNLOAD,
                      lpszHostName,
                      FTP_PORT_DEFAULT,
                      lpszUserName,
                      lpszPassword,
                      lpszLocalFile,
                      lpszRemoteFile,
                      FTP_OPTION_DEFAULT,
                      FILE_TYPE_AUTO,
                      FTP_TIMEOUT,
                      NULL);

// Display information about the queued file
```

```
if (dwFileId != 0)
{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case FTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case FTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (FtpStartQueue(hQueue, FTP_QUEUE_ALL, 0, NULL, 0))
{
    FtpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    FtpStopQueue(hQueue);
}

// Remove all files from the queue
FtpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpAllocate Function

```
INT WINAPI FtpAllocate(
   HCLIENT hClient,
   DWORD dwFileLength,
   DWORD dwRecSize
);
```

The **FtpAllocate** function instructs the server to reserve sufficient storage to accommodate the new file being transferred.

Parameters

hClient

Handle to the client session.

dwFileLength

The number of bytes to allocate storage for on the server.

dwRecSize

The maximum record or page size for the file. A value of zero indicates that the file does not have a record or page structure, and the parameter is ignored.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should be called immediately before the **FtpOpenFile** function.

This function is ignored by those servers which do not require that the maximum size of the file be declared beforehand. The most common FTP servers running under UNIX and Windows do not require that file space be pre-allocated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpAsyncConnect Function

```
HCLIENT WINAPI FtpAsyncConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **FtpAsyncConnect** function establishes a connection with the specified server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **FtpConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on. A value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990. If the secure port number is specified, an implicit TLS connection will be established by default.

lpszUserName

Points to a string that specifies the user name to be used to authenticate the current client session. If this parameter is NULL or an empty string, then the login is considered to be anonymous. Note that anonymous logins are not supported for secure connections using the SSH protocol.

lpszPassword

Points to a string that specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description

FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.
FTP_OPTION_KEEPALIVE	This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.
FTP_OPTION_VIRTUALHOST	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be

	automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the client should use the Secure Shell (SSH) protocol to establish the connection. This option will automatically be selected if the connection is established using port 22, the default port for SSH.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is

	established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members ***dwSize***, ***lpszCertStore*** and ***lpszCertName*** must be defined. Undefined structure members must be initialized to a value of zero or NULL and the ***dwSize*** member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
FTP_EVENT_CONNECT	The control connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.

FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event occurs when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event occurs when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.

To cancel asynchronous notification and return the client to a blocking mode, use the **FtpDisableEvents** function.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit TLS session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
// The Ipswitch WS_FTP server accepts the AUTH command to establish
// an explicit TLS session on the default FTP port
hClient = FtpAsyncConnect(lpszRemoteHost,
                          FTP_PORT_DEFAULT,
                          FTP_TIMEOUT,
                          FTP_OPTION_SECURE_EXPLICIT,
                          NULL,
                          hEventWnd,
                          uEventMsg);

// When the GlobalSCAPE Secure FTP server is configured in implicit
// authorization mode, it negotiates a secure session as soon as the
// connection is established and does not require a command
```

```
hClient = FtpAsyncConnect(lpszRemoteHost,
                          FTP_PORT_SECURE,
                          FTP_TIMEOUT,
                          FTP_OPTION_SECURE_IMPLICIT,
                          NULL,
                          hEventWnd,
                          uEventMsg);
```

Requirements

FtpAsyncFileList Function

```
UINT WINAPI FtpAsyncFileList(
   HCLIENT hClient,
   LPCTSTR lpszDirectory,
   DWORD dwOptions,
   LPTSTR lpszBuffer,
   INT nMaxLength,
   FTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Return an unparsed list of files in the specified directory.

Parameters

hClient

Handle to the client session.

lpszDirectory

A null-terminated string that specifies the name of a directory and/or a wildcard file mask. The format of the directory name must match the file naming conventions of the server. If this parameter is NULL or points to an empty string, the current working directory will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_LIST_DEFAULT	This option specifies the server should return a complete listing of files in the specified directory with as much detail as possible. This typically means that the file size, date, ownership and access rights will be returned to the client. Information about the files are returned in lines of text, with each line terminated by carriage return and linefeed (CRLF) characters. The exact format of the data returned is specific to the server operating system.
FTP_LIST_NAMEONLY	This option specifies the server should only return a list of file names, with no additional information about the file. Each file name is terminated by carriage return and linefeed (CRLF) characters.

lpszBuffer

A null-terminated string buffer that will contain the list of files when the function returns. This buffer should be large enough to store the complete file listing and a terminating null character. If the buffer is smaller than the total amount of data returned by the server, the data will be truncated. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more

information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpAsyncFileList** function returns a list of files in the specified directory, copying the data to a string buffer. This function is similar to the **FtpGetFileList** function, however it retrieves the list of files asynchronously using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file listing is being returned by the server.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, such as with the example listed below, then you must ensure that your code does not return from the function while the directory listing is being retrieved. In the example, this is achieved by calling the **FtpTaskWait** function. You can also perform other operation and poll the status of the task by calling the **FtpTaskDone** function. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the *lpszBuffer* parameter on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the directory listing has completed. This enables your application to know when the directory listing is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

This function can be particularly useful when the client is connected to a server that returns file listings in a format that is not recognized by the library. The application can retrieve the unparsed file listing from the server and parse the contents. Note that if you specify the FTP_LIST_NAMEONLY option, the data will only contain a list of file names and there will be no way for the application to know if they represent a regular file or a subdirectory.

This function is supported for both FTP and SFTP (SSH) connections, however the format of the data may differ depending on which protocol is used. Most UNIX based FTP servers will not list files and subdirectories that begin with a period, however most SFTP servers will return a list of all files, even those that begin with a period.

Example

```
TCHAR szFileList[MAXFILELISTSIZE];
UINT nTaskId;

nTaskId = FtpAsyncFileList(hClient,
```

```
                            NULL,
                            FTP_LIST_DEFAULT,
                            szFileList,
                            MAXFILELISTSIZE,
                            NULL, 0);

    if (nTaskId == 0)
    {
        _tprintf(_T("Unable to list files (error 0x%08lx)\n"), FtpGetLastError());
        return;
    }
    else
    {
        DWORD dwError = NO_ERROR;
        DWORD dwElapsed = 0;

        FtpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);
        _tprintf(_T("Asynchronous file listing returned in %lu milliseconds\n"),
    dwElapsed);
    }
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpAsyncGetData Function

```
UINT WINAPI FtpAsyncGetData(
   HCLIENT hClient,
   LPCTSTR lpszRemoteFile,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwReserved,
   FTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Copies the contents of a file on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the ***lpEventProc*** parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncGetData** function is used to download the contents of a remote file into a local buffer.

This function is similar to the **FtpGetData** function, however it retrieves the contents of the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being copied to the local system.

Because this function works asynchronously, it is important that the memory allocated for the buffer is not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, such as with the example listed below, then you must ensure that your code does not return from the function while the data is being downloaded. In the example, this is achieved by calling the **FtpTaskWait** function. You can also perform other operation and poll the status of the task by calling the **FtpTaskDone** function. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the ***lpvBuffer*** and ***lpdwLength*** parameters on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

The ***lpBuffer*** parameter may be specified in one of two ways, depending on the needs of the application. It can either be a pre-allocated buffer large enough to store the contents of the file or it can specify the address of a global memory handle that will contain the data. If it points to a pre-allocated buffer, the ***lpdwLength*** parameter must be initialized to the maximum number of bytes that can be copied into the buffer. If specifies the address of a global memory handle, then ***lpdwLength*** must be initialized to a value of zero. See the example code below.

Example

```
HGLOBAL hgblBuffer = NULL;
DWORD dwLength = 0;
UINT nTaskId;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter

nTaskId = FtpAsyncGetData(hClient,
                          lpszFileName,
                          &hgblBuffer,
                          &dwLength,
                          0, NULL, 0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    FtpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);

    // Lock the global memory handle, returning a pointer to the
    // contents of the file data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);
```

```
    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpAsyncGetFile Function

```
UINT WINAPI FtpAsyncGetFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   DWORD dwOffset,
   FTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Downloads the specified file from the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncGetFile** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **FtpGetFile** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the FTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = FtpAsyncGetFile(hClient,
                          lpszLocalFile,
                          lpszRemoteFile,
                          FTP_TRANSFER_DEFAULT,
                          0,
                          NULL,
                          0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;
```

```
    // Wait for the transfer to complete
    FtpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpAsyncGetFileEx Function

```
UINT WINAPI FtpAsyncGetFileEx(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   ULARGE_INTEGER uiOffset,
   FTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the

lpEventProc parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncGetFileEx** function is used to download the contents of a remote file to a file on the local system. This function is similar to the **FtpGetFileEx** function, however it retrieves the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the local system.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the FTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to download multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

FtpAsyncProxyConnect Function

```
HCLIENT WINAPI FtpAsyncProxyConnect(
   UINT nProxyType,
   LPCTSTR lpszProxyHost,
   UINT nProxyPort,
   LPCTSTR lpszProxyUser,
   LPCTSTR lpszProxyPassword,
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **FtpAsyncProxyConnect** function establishes a connection through a proxy server.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

The application should create a background worker thread and establish a connection by calling **FtpProxyConnect** within that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each client session.

Parameters

nProxyType

An identifier which specifies the type of proxy server that is being connected to. This value must be defined as one of the following values:

Value	Description
FTP_PROXY_NONE	This value specifies that no proxy server is being used. In this case, the **FtpConnect** function is called directly, ignoring the proxy parameters.
FTP_PROXY_USER	This value specifies that the client is not logged into the proxy server. The USER command is sent in the format username@ftpsite followed by the password. This is the format used with the Gauntlet proxy server.
FTP_PROXY_LOGIN	This value specifies that the client is logged into the proxy server. The USER command is then sent in the format username@ftpsite followed by the password. This is the format used by the InterLock proxy server.
FTP_PROXY_OPEN	This value specifies that the client is not logged into the proxy server. The OPEN command is sent specifying the host name, followed by the username and password.
FTP_PROXY_SITE	This value specifies that the client is logged into the server. The SITE command is sent, specifying the host name, followed by the

	username and the password.
FTP_PROXY_OTHER	This special proxy type specifies that another, undefined proxy server is being used. The client connects to the proxy host, but does not attempt to authenticate the client. The application is responsible for negotiating with the proxy server, typically using the FtpCommand function to send specific command sequences.

lpszProxyHost

The name of the proxy server to connect through; this may be a fully-qualified domain name or an IP address.

nProxyPort

The port number the proxy server is listening on; a value of zero specifies that the default port number should be used.

lpszProxyUser

The user name used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a username is required.

lpszProxyPassword

The password used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a password is required.

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990. If the secure port number is specified, an implicit TLS connection will be established by default.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the

	server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.
FTP_OPTION_KEEPALIVE	This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.
FTP_OPTION_VIRTUALHOST	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur

	when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of

	IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members ***dwSize***, ***lpszCertStore*** and ***lpszCertName*** must be defined. Undefined structure members must be initialized to a value of zero or NULL and the ***dwSize*** member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

hEventWnd

The handle to the event notification window. This window receives messages which notify the client of various asynchronous network events that occur.

uEventMsg

The message identifier that is used when an asynchronous network event occurs. This value should be greater than WM_USER as defined in the Windows header files.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

The username and password that is used to authenticate the client with the proxy server are not the same as those used to login to the target server. Once a connection has been established with the proxy server, the client must call the **FtpLogin** function to actually login to the server and begin a file

transfer.

When a message is posted to the notification window, the low word of the ***lParam*** parameter contains the event identifier. The high word of ***lParam*** contains the low word of the error code, if an error has occurred. The ***wParam*** parameter contains the client handle. One or more of the following event identifiers may be sent:

Value	Description
FTP_EVENT_CONNECT	The control connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed. The high word of the ***lParam*** parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event occurs when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event occurs when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.

To cancel asynchronous notification and return the client to a blocking mode, use the

FtpDisableEvents function.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit TLS session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpAsyncPutData Function

```
UINT WINAPI FtpAsyncPutData(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPVOID lpvBuffer,
   DWORD dwLength,
   DWORD dwReserved,
   FTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Copies the contents of the specified buffer to a file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A null-terminated string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

lpvBuffer

The data that will be copied to the server and stored in the specified file.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncPutData** function is used to upload the contents of a local buffer to the server. This function is similar to the **FtpPutData** function, however it uses a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the data is being sent to the server.

Because this function works asynchronously, it is important that the memory allocated for the buffer is

not released before the asynchronous task completes. If you provide a buffer that is allocated on the stack, ensure that your code does not return from the function while the data is being uploaded. This can be achieved by calling the **FtpTaskWait** function or periodically calling the **FtpTaskDone** function to determine if the transfer has completed. If you wish to return from the calling function immediately, then you must dynamically allocate memory for the ***lpvBuffer*** parameter on the heap and free that memory after the task has completed and the data is no longer needed.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the data transfer is about to begin, and immediately before the worker thread is terminated. The worker thread creates a secondary connection to the server with its own session handle. This ensures that the asynchronous operation will not interfere with the current client session. Your application can interact with this background worker thread using the client handle that is passed to the event handler.

If the ***lpvBuffer*** parameter is pointing to a Unicode string, it is important to note that the value of the ***dwLength*** parameter should specify the number of bytes, not the number of characters. When using UTF-16, each character is two bytes long and therefore the length of the buffer is effectively double the length of the string. Because Unicode strings can contain null characters, you must also set the current file type to FILE_TYPE_IMAGE prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpAsyncPutFile Function

```
UINT WINAPI FtpAsyncPutFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   DWORD dwOffset,
   FTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Uploads the specified file from the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the *lpEventProc* parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncPutFile** function is used to upload the contents of a local file to the server. This function is similar to the **FtpPutFile** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the FTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatus** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpAsyncPutFileEx Function

```
UINT WINAPI FtpAsyncPutFileEx(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   ULARGE_INTEGER uiOffset,
   FTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

Uploads the specified file from the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string that specifies the file that will be transferred from the local system. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. This parameter may be NULL if you do not wish to implement an event handler.

dwParam

A user-defined integer value that is passed to the callback function. This parameter is ignored if the

lpEventProc parameter is NULL.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function. The application should treat the task ID as an opaque value and never make an assumption about the sequence in which IDs are assigned to a background task.

Remarks

The **FtpAsyncPutFileEx** function is used to upload the contents of a local file to the server. This function is similar to the **FtpPutFileEx** function, however it uploads the file using a background worker thread and does not block the current working thread. This enables the application to continue to perform other operations while the file is being transferred to the server.

If the address of an event handler is provided to this function, it is guaranteed that the handler will be invoked with the FTP_EVENT_CONNECT event after the connection has been established, and the FTP_EVENT_DISCONNECT event after the transfer has completed. This enables your application to know when the file transfer is about to begin, and immediately before the worker thread is terminated. During the file transfer, the callback function will be invoked periodically with the FTP_EVENT_PROGRESS event. The client session handle is passed to the event handler, allowing you to call functions such as **FtpGetTransferStatusEx** to determine the amount of data that has been copied.

To determine when the transfer has completed without implementing an event handler, periodically call the **FtpTaskDone** function. If you wish to block the current thread and wait for the transfer to complete, call the **FtpTaskWait** function. To stop a background file transfer that is in progress, call the **FtpTaskAbort** function. This will signal the background worker thread to cancel the transfer and terminate the session.

This function can be called multiple times to upload multiple files in the background; however, most servers limit the number of simultaneous connections that can originate from a single IP address. It is recommended that you only perform two simultaneous background transfers from the same server at any one time. The application should not make any assumptions about the order in which multiple background transfers may complete or how they are sequenced. For example, it should never be assumed that a background task with a lower task ID will complete before a task with a higher ID value.

FtpAttachThread Function

```
DWORD WINAPI FtpAttachThread(
    HCLIENT hClient
    DWORD dwThreadId
);
```

The **FtpAttachThread** function attaches the specified client handle to another thread.

Parameters

hClient

Handle to the client session.

dwThreadId

The ID of the thread that will become the new owner of the handle. A value of zero specifies that the current thread should become the owner of the client handle.

Return Value

If the function succeeds, the return value is the thread ID of the previous owner. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

When a client handle is created, it is associated with the current thread that created it. Normally, if another thread attempts to perform an operation using that handle, an error is returned since it does not own the handle. This is used to ensure that other threads cannot interfere with an operation being performed by the owner thread. In some cases, it may be desirable for one thread in a client application to create the client handle, and then pass that handle to another worker thread. The **FtpAttachThread** function can be used to change the ownership of the handle to the new worker thread. By preserving the return value from the function, the original owner of the handle can be restored before the worker thread terminates.

This function should be called by the new thread immediately after it has been created, and if the new thread does not release the handle itself, the ownership of the handle should be restored to the parent thread before it terminates. Under no circumstances should **FtpAttachThread** be used to forcibly release a handle allocated by another thread while a blocking operation is in progress. To cancel an operation, use the **FtpCancel** function and then release the handle after the blocking function exits and control is returned to the current thread.

Note that the *dwThreadId* parameter is presumed to be a valid thread ID and no checks are performed to ensure that the thread actually exists. Specifying an invalid thread ID will orphan the handle until the **FtpUninitialize** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpConnect, FtpDisconnect, FtpUninitialize

FtpCancel Function

```
INT WINAPI FtpCancel(
   HCLIENT hClient
);
```

The **FtpCancel** function cancels any outstanding blocking operation in the client, causing the blocking function to fail. The application may then retry the operation or terminate the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

When the **FtpCancel** function is called, the blocking function will not immediately fail. An internal flag is set which causes the blocking operation to exit with an error. This means that the application cannot cancel an operation and immediately perform some other operation. Instead it must allow the calling stack to unwind, returning back to the blocking operation before making any further function calls.

This function may be called during a blocking file transfer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpCancelQueuedFile Function

```
BOOL WINAPI FtpCancelQueuedFile(
    HQUEUE hQueue,
    DWORD dwFileId
);
```

The **FtpCancelQueuedFile** function cancels the queued file transfer.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. If this value is zero, the function will cancel the current file transfer in progress. If queue transfers have been suspended, this parameter cannot be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

When this function is called, the queued file transfer may not immediately stop. An internal flag is set which causes the file transfer to exit with an error and the queue manager will begin processing the next file in the queue. If the queue is in an idle state, this function will fail.

It is permitted to call **FtpCancelQueuedFile** from within a queue event handler to cancel the current file transfer. In this case, the *dwFileId* parameter should be zero. If you specify a file which has not been transferred, it will be flagged as canceled and skipped by the queue manager when processing the queue. If you specify a file which has already been processed, this function will fail.

A canceled file transfer is also considered a failed transfer. When you call **FtpGetQueueStatus** after a queued file transfer is canceled, the *dwFailedFiles* member of the FTPQUEUESTATUS structure will be incremented to reflect this change. You can determine the status of an individual file transfer by calling the **FtpGetQueuedFile** function and checking the value of the *dwQueueFlags* member of the FTPQUEUEDFILE structure.

The **FtpResetQueue** function can be used to reset the state of previously canceled transfers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpChangeDirectory Function

```
INT WINAPI FtpChangeDirectory(
   HCLIENT hClient,
   LPCTSTR lpszDirectory
);
```

The **FtpChangeDirectory** function changes the current working directory for the client session.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a string that specifies the name of the directory. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the CWD command to change the current working directory. The user must have the appropriate permission to access the specified directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpChangeDirectoryUp Function

```
INT WINAPI FtpChangeDirectoryUp(
    HCLIENT hClient
);
```

The **FtpChangeDirectoryUp** function changes directory to the parent of the current working directory.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the CDUP command to the server. This command is a special case of the CWD command, and is included to simplify transferring between directory trees on those operating systems which have different syntaxes for naming the parent directory. The current user must have the appropriate permission to access the specified directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpClearQueue Function

```
BOOL WINAPI FtpClearQueue(
    HQUEUE hQueue
);
```

The **FtpClearQueue** function removes all files from the queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function can only be called when the queue is in an idle state. An error will be returned if the function is called while the queue manager is paused or actively transferring files in the queue. To determine the current state of the queue, call the **FtpGetQueueStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpCloseDirectory Function

```
INT WINAPI FtpCloseDirectory(
    HCLIENT hClient
);
```

The **FtpCloseDirectory** function closes the data socket connection to the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function must be called after all of the file information from the server has been returned. Because directory information is returned on the data channel, no file transfers can take place while a directory is being read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetDirectoryFormat, FtpGetFileStatus, FtpGetFirstFile, FtpGetNextFile, FtpOpenDirectory, FtpSetDirectoryFormat

FtpCloseFile Function

```
INT WINAPI FtpCloseFile(
   HCLIENT hClient
);
```

The **FtpCloseFile** function flushes the internal client buffers and closes the data socket connection to the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If the file is opened for writing, all buffered data is written to the server before the socket is closed. This may cause the client to block until all of the data can be written. The client application should not perform any other action until the function returns.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpCommand Function

```
INT WINAPI FtpCommand(
   HCLIENT hClient,
   LPCTSTR lpszCommand,
   LPCTSTR lpszParameter
);
```

The **FtpCommand** function sends a command to the server and returns the result code back to the caller.

Parameters

hClient

Handle to the client session.

lpszCommand

The command which will be executed by the server.

lpszParameter

An optional command parameter. If the command requires more than one parameter, then they should be combined into a single string, with a space separating each parameter. If the command does not accept any parameters, this value may be NULL.

Return Value

If the function succeeds, the return value is the result code returned by the server. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should only be used when the application needs to send a custom, site-specific command or send a command that is not directly supported by this API. This function should never be used to issue a command that opens a data channel. If the application needs to transform data as it is being sent or received, and cannot use the **FtpGetFile** or **FtpPutFile** functions, then use the **FtpOpenFile** function to open a data channel with the server.

By default, file names which are sent to the server using the **FtpCommand** function are sent as ANSI characters. If the Unicode version of the function is used, the file name will be converted from Unicode to ANSI using the current codepage. If the server supports UTF-8 encoded file names, the **FtpSetFileNameEncoding** function can be used to specify that file names with non-ASCII characters should be sent as UTF-8 encoded values. It is important to note that this option is only available if the server advertises support for UTF-8 and permits that encoding type.

Because the **FtpCommand** function communicates directly with the server using the control connection, the idle timeout period configured with **FtpSetIdleTimeout** applies to this function as well. If a session remains inactive for longer than the configured timeout, the server may close the connection before the command is sent or before a response is received. Adjusting the idle timeout can help prevent unexpected disconnects during periods of infrequent command activity, especially in interactive or long-running operations.

This function is not supported when using SFTP because that protocol does not provide a mechanism for sending arbitrary command strings. Unlike the FTP protocol, which uses a command-response model over a control channel, SFTP uses a structured binary protocol without support for custom commands. If this function is called while connected to an SFTP server, it will fail and return an error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpConnect Function

```
HCLIENT WINAPI FtpConnect(
   LPCTSTR lpszRemoteHost,
   UINT nRemotePort,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **FtpConnect** function establishes a connection with the specified server.

Parameters

lpszRemoteHost

The name of the server to connect to; this may be a fully-qualified domain name or an IP address.

nRemotePort

The port number the server is listening on; a value of zero specifies that the default port number should be used. For standard connections, the default port number is 21. For secure connections, the default port number is 990.

lpszUserName

Points to a string that specifies the user name to be used to authenticate the current client session. If this parameter is NULL or an empty string, then the login is considered to be anonymous. Note that anonymous logins are not supported for secure connections using the SSH protocol.

lpszPassword

Points to a string that specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the

	server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.
FTP_OPTION_KEEPALIVE	This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.
FTP_OPTION_VIRTUALHOST	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur

	when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the client should use the Secure Shell (SSH) protocol to establish the connection. This option will automatically be selected if the connection is established using port 22, the default port for SSH.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP

	commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members ***dwSize***, ***lpszCertStore*** and ***lpszCertName*** must be defined. Undefined structure members must be initialized to a value of zero or NULL and the ***dwSize*** member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **FtpConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit TLS session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The *dwOptions* argument can be used to specify the threading model that is used by the library when a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
// Connect to a server using a standard (non-secure) connection on
// the default port. The username and password are not encrypted.

hClient = FtpConnect(lpszRemoteHost,
                     FTP_PORT_DEFAULT,
                     lpszUserName,
                     lpszPassword,
                     FTP_TIMEOUT,
                     FTP_OPTION_DEFAULT,
                     NULL);

// Connect to a server using the default port and then initiate a
// secure connection using the AUTH TLS command

hClient = FtpConnect(lpszRemoteHost,
                     FTP_PORT_DEFAULT,
                     lpszUserName,
                     lpszPassword,
                     FTP_TIMEOUT,
                     FTP_OPTION_PASSIVE | FTP_OPTION_SECURE_EXPLICIT,
                     NULL);

// Connect to a server on port 990 and immediately initiate a
// secure connection as soon as the connection is established

hClient = FtpConnect(lpszRemoteHost,
                     FTP_PORT_SECURE,
```

```
                        lpszUserName,
                        lpszPassword,
                        FTP_TIMEOUT,
                        FTP_OPTION_PASSIVE | FTP_OPTION_SECURE_IMPLICIT,
                        NULL);

// Connect to a server on port 22 using the Secure Shell (SFTP)
// protocol to transfer files

hClient = FtpConnect(lpszRemoteHost,
                        FTP_PORT_SSH,
                        lpszUserName,
                        lpszPassword,
                        FTP_TIMEOUT,
                        FTP_OPTION_SECURE_SHELL,
                        NULL);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpConnectUrl Function

```
HCLIENT WINAPI FtpConnectUrl(
    LPCTSTR lpszUrl,
    UINT nTimeout,
    DWORD dwOptions
);
```

The **FtpConnectUrl** function establishes a connection with the specified server using a URL.

Parameters

lpszUrl

A null-terminated string which specifies the URL for the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require

	authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.
FTP_OPTION_KEEPALIVE	This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.
FTP_OPTION_VIRTUALHOST	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to

	a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies the client should use the Secure Shell (SSH) protocol to establish the connection. This option will automatically be selected if the connection is established using port 22, the default port for SSH.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is

	synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpConnectUrl** function is a high-level function that uses an FTP URL to establish a connection with a server. Unlike the other connection related functions such as **FtpConnect**, this function does more than simply connect to the server. It will also authenticate the client session, change the current working directory and set the default file transfer mode. By default, this function will always place the client in passive mode, ensuring the broadest compatibility with most servers.

The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @] hostname [:port] / [path / ...]
[filename]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. The paths in an FTP URL are relative to the home directory of the user account and are not absolute paths starting at the root directory on the server. If a file name is also specified in the URL, it will be ignored and only the file path will be used. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The **FtpConnectUrl** function is designed to provide a simpler, more convenient interface to establishing a connection with a server. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to use the lower-level connection functions. If you only need to upload or download a file using a URL, then refer to the **FtpUploadFile** and **FtpDownloadFile** functions.

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **FtpConnectUrl** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The *dwOptions* argument can be used to specify the threading model that is used by the library when

a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Example

```
HCLIENT hClient;
LPCTSTR lpszUrl = _T("ftp://ftp.sockettools.com/");

// Connect to the site specified by the URL
hClient = FtpConnectUrl(lpszUrl, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hClient == INVALID_CLIENT)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpCreateDirectory Function

```
INT WINAPI FtpCreateDirectory(
   HCLIENT hClient,
   LPCTSTR lpszDirectory
);
```

The **FtpCreateDirectory** function creates the specified directory on the server.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a string that specifies the name of the directory. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the MKD command to create the directory. The user must have the appropriate permission to create the specified directory.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

FtpCreateQueue Function

```
HQUEUE WINAPI FtpCreateQueue(
    UINT nMaxFiles,
    UINT nTimeout,
    DWORD dwOptions
);
```

The **FtpCreateQueue** function creates new file transfer queue.

Parameters

nMaxFiles

An unsigned integer which specifies the maximum number of files which can be added to the queue. The constant INFINITE can be used to specify that there is no fixed limit to the number of files in the queue.

nTimeout

An unsigned integer which specifies the default timeout for all queued file transfers. If this value is zero, a reasonable default timeout period will be used. This timeout period is used when a file is added to the queue without providing a timeout period for that specific file transfer. If a timeout period is specified for a particular file, it will override this value.

dwOptions

An unsigned integer value which specifies one or more default options for all queued files. This parameter is constructed by using a bitwise operator and can be any of the options used with the **FtpConnect** function. If transfer options are specified for a particular file, it will override this value. The most common options are:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for queued file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies queued transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies queued transfers should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an

	unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies queued file transfers should attempt to establish a secure connection with the server by default. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies queued file transfers should attempt to immediately establish secure TLS connection with the server by default. This option is typically used when connecting to a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies queued file transfers should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_SHELL	This option specifies queued file transfers should use the Secure Shell (SSH) protocol to establish the connection by default. This option will automatically be selected if the connection is established using port 22, the default port for SSH.

Return Value

If the function succeeds, the return value is a handle to the queue which can be used with subsequent function calls. If the function fails, the return value is INVALID_QUEUE. To get extended error information, call **FtpGetLastError**.

Remarks

If the *nMaxFiles* parameter is INFINITE, memory will be dynamically allocated on the process heap with no limit to the number of files which can be queued. If there is a logic error which causes the application to recursively add files to the queue, or repeatedly queue the same file, this can result in virtual memory being exhausted for the process. You can avoid this by specifying a reasonable maximum queue size, which will cause the **FtpAddQueuedFile** function to fail if that limit is exceeded.

The memory allocated for the queue will be released when the **FtpDeleteQueue** function is called.

Example

```
// Create a new queue
HQUEUE hQueue = FtpCreateQueue(INFINITE, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = FtpAddQueuedFile(
                    hQueue,
                    lpszLocalFile,
```

```
                    lpszRemoteFile,
                    FTP_OPTION_DEFAULT,
                    FILE_TYPE_AUTO,
                    FTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case FTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case FTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
        }
    }
}

// Start the queued file transfers and wait for it to complete
if (FtpStartQueue(hQueue, FTP_QUEUE_ALL, 0, NULL, 0))
{
    FtpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
    FtpStopQueue(hQueue);
}

// Remove all files from the queue
FtpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpCreateSecurityCredentials Function

```
BOOL WINAPI FtpCreateSecurityCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **FtpCreateSecurityCredentials** function allocates a new security credentials structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol should be used when establishing the connection. This is the default version of the protocol that is supported by most SSH servers.

dwOptions

A value which specifies one or more options. This value should always be zero for connections using SSH. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved

Pointer reserved for future use. Set it to NULL when using this function.

lppCredentials

Pointer to an LPSECURITYCREDENTIALS pointer. The memory for the credentials structure will be allocated by this function and must be released by calling the **FtpDeleteSecurityCredentials** function when it is no longer needed. The pointer value must be set to NULL before the function is called. It is important to note that this is a pointer to a pointer variable, not a pointer to the SECURITYCREDENTIALS structure itself.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call the **FtpGetLastError** function.

Remarks

The structure that is created by this function may be used as client credentials when establishing a secure connection. This is particularly useful for programming languages other than C/C++ which may not support C structures or pointers. The pointer to the SECURITYCREDENTIALS structure can be declared as an unsigned integer variable which is passed by reference to this function, and then passed by value to the **FtpConnect** function.

A client application only needs to call this function if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you

can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The *dwOptions* parameter should be set to CREDENTIAL_STORE_FILENAME and the *lpszCertStore* parameter should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12.These certificate files typically have an extension of .pfx or .p12. If a password was specified when the certificate was created, it must be provided in the *lpszPassword* parameter or the library will be unable to access the certificate.

Note that the *lpszUserName* and *lpszPassword* parameters are values which are used to access the certificate store or client certificate. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session. In most cases, these parameters will be NULL.

Example

```
LPCTSTR lpszCertStore = _T("HKCU:MY");   // The current user's personal certificate
store
LPCTSTR lpszCertName = _T("ClientCert"); // The client certificate name
LPSECURITYCREDENTIALS lpSecCred = NULL;

FtpCreateSecurityCredentials(SECURITY_PROTOCOL_DEFAULT,
                             CREDENTIAL_STORE_CURRENT_USER,
                             NULL,
                             NULL,
                             lpszCertStore,
                             lpszCertName,
                             NULL,
                             &lpSecCred);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: cswskv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpDeleteFile Function

```
INT WINAPI FtpDeleteFile(
   HCLIENT hClient,
   LPCTSTR lpszFileName
);
```

The **FtpDeleteFile** function deletes the specified file from the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to delete. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The current user must have the appropriate permission to delete the file, or an error will be returned by the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpDeleteQueue Function

```
BOOL WINAPI FtpDeleteQueue(
    HQUEUE hQueue
);
```

The **FtpDeleteQueue** function deletes the specified file transfer queue, releasing all memory allocated for the queued files.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function can only be called when the queue is in an idle state. If the queue manager is in the process of uploading or downloading files, the function will fail and return a value of zero. You can determine the current state of the queue by calling the **FtpGetQueueStatus** function. It is not necessary to explicitly clear the queue prior to calling this function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpCreateQueue, FtpGetQueueStatus, FtpCancelQueuedFile, FtpClearQueue, FtpStartQueue, FtpStopQueue, FtpWaitForQueue

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpDeleteSecurityCredentials Function

```
VOID WINAPI FtpDeleteSecurityCredentials(
   LPSECURITYCREDENTIALS *lppCredentials
);
```

The **FtpDeleteSecurityCredentials** function deletes an existing **SECURITYCREDENTIALS** structure.

Parameters

lppCredentials

Pointer to an **LPSECURITYCREDENTIALS** pointer. On exit from the function, the pointer will be NULL.

Return Value

None.

Example

```
if (lpSecCred != NULL)
    FtpDeleteSecurityCredentials(&lpSecCred);

FtpUninitialize();
```

Remarks

This function can be used to release the memory allocated to the client or server credentials after a secure connection has been terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpDisableEvents Function

```
INT WINAPI FtpDisableEvents(
    HCLIENT hClient
);
```

The **FtpDisableEvents** function disables the event notification mechanism, preventing subsequent event notification messages from being posted to the application's message queue.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpDisableEvents** function is used to disable event message posting for the specified client session. Although this will immediately prevent any new events from being generated, it is possible that messages could be waiting in the message queue. Therefore, an application must be prepared to handle client event messages after this function has been called.

This function is automatically called if the client has event notification enabled, and the **FtpDisconnect** function is called. The same issues regarding outstanding event messages also applies in this situation, requiring that the application handle event messages that may reference a client handle that is no longer valid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpDisableTrace Function

```
BOOL WINAPI FtpDisableTrace();
```

The **FtpDisableTrace** function disables the logging of network function calls.

Parameters

None.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, a value of zero is returned.

Remarks

This function will disable output to the log file for the current thread or process, depending on the flags used when logging was enabled. If this function is not called, the resources that were allocated for the logging session will be released when the process ends.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpDisconnect Function

```
INT WINAPI FtpDisconnect(
   HCLIENT hClient
);
```

The **FtpDisconnect** function terminates the connection with the server, closing the socket and releasing the memory allocated for the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpDownloadFile Function

```
BOOL WINAPI FtpDownloadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   UINT nTimeout
   DWORD dwOptions
   LPFTPTRANSFERSTATUS lpStatus
   FTPEVENTPROC lpEventProc
   DWORD_PTR dwParam
);
```

The **FtpDownloadFile** function downloads the specified file from the server to the local system.

Parameters

lpszLocalFile

A null-terminated string which specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions should follow Windows conventions. It is permitted to include environment variables in the local path by surrounding the variable with percent (%) symbols. Local file paths may also use standard file URLs.

lpszRemoteFile

A null-terminated string which specifies the complete URL of the file to be downloaded to the local system. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.

FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpDownloadFile** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then download the file to the local system. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @] hostname [:port] / [path / ...]
[filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be downloaded as a text or binary file. A value of "a" specifies that the file should be downloaded as a text file. A value of "i" specifies that the file should be downloaded as a binary file. If the type is not explicitly specified, the file will be downloaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **FtpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpDownloadFile** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpGetFile** to download the file.

Example

```
FTPTRANSFERSTATUS ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile = _T("ftp://ftp.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = FtpDownloadFile(lpszLocalFile,
                          lpszRemoteFile,
                          FTP_OPTION_PASSIVE,
                          &ftpStatus,
                          NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpDownloadFileEx Function

```
BOOL WINAPI FtpDownloadFileEx(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   UINT nTimeout
   DWORD dwOptions
   LPFTPTRANSFERSTATUSEX lpStatus
   FTPEVENTPROC lpEventProc
   DWORD_PTR dwParam
);
```

The **FtpDownloadFileEx** function downloads the specified file from the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the complete URL of the file to be downloaded. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an

	unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpDownloadFileEx** function provides a convenient way for an application to download a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then download the file to the local system. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @] hostname [:port] / [path / ...]
[filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be downloaded as a text or binary file. A value of "a" specifies that the file should be downloaded as a text file. A value of "i" specifies that the file should be downloaded as a binary file. If the type is not explicitly specified, the file will be downloaded as a binary file.

The ***lpStatus*** parameter can be used by the application to determine the final status of the transfer,

including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **FtpGetTransferStatusEx** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpDownloadFileEx** function is designed to provide a simpler interface for downloading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpGetFileEx** to download the file.

Example

```
FTPTRANSFERSTATUSEX ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile = _T("ftp://ftp.example.com/updates/database.mdb");
BOOL bResult;

// Download the file using the specified URL
bResult = FtpDownloadFileEx(lpszLocalFile,
                            lpszRemoteFile,
                            FTP_OPTION_PASSIVE,
                            &ftpStatus,
                            NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpEnableEvents Function

```
INT WINAPI FtpEnableEvents(
   HCLIENT hClient,
   HWND hEventWnd,
   UINT uEventMsg
);
```

The **FtpEnableEvents** function enables event notifications using Windows messages.

This function has been deprecated and may be unavailable in future releases. It was designed for use in legacy single-threaded applications and requires the application to have a message pump to process event messages. It should not be used with applications which are designed to execute as a service or those which do not have a graphical user interface.

Applications should use the **FtpRegisterEvent** function to register an event handler which is invoked when an event occurs.

Parameters

hClient

Handle to the client session.

hEventWnd

Handle to the window which will receive the client notification messages. This parameter must specify a valid window handle. If a NULL handle is specified, event notification will be disabled.

uEventMsg

The message that is received when a client event occurs. This value must be greater than 1024.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpEnableEvents** function is used to request that notification messages be posted to the specified window whenever a client event occurs. This allows an application to monitor the status of different client operations, such as a file transfer.

The *wParam* argument will contain the client handle, the low word of the *lParam* argument will contain the event ID, and the high word will contain any error code. If no error has occurred, the high word will always have a value of zero. The following events may be generated:

Value	Description
FTP_EVENT_CONNECT	The control connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed. The high word of the *lParam* parameter should be checked, since this notification message will be posted if an error has occurred.

FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event occurs when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event occurs when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.

It is not required that the client be placed in asynchronous mode in order to receive command and progress event notifications. To disable event notification, call the **FtpDisableEvents** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpEnableFeature Function

```
BOOL WINAPI FtpEnableFeature(
    HCLIENT hClient,
    DWORD dwFeature,
    BOOL bEnable
);
```

The **FtpEnableFeature** function enables or disables a specific server feature available to the client.

Parameters

hClient

Handle to the client session.

dwFeature

An unsigned integer which specifies the feature to be enabled to disabled for the current client session. Refer to the documentation for the **FtpGetFeatures** function for a list of available features.

bEnable

A boolean flag which specifies if the feature should be enabled or disabled. If the value is non-zero, the library will attempt to use that feature on the server. If the value is zero, the feature is disabled. If an application calls a function which requires a specific feature and that feature is disabled, the function will fail with an error indicating the feature is not supported.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return a value of zero. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpEnableFeature** function is used to enable or disable a specific feature for the current session. When a client connection is first established, features are enabled based on the server type and the server's response to the FEAT command. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client. An application can use the **FtpEnableFeature** function to control what commands will be sent to the server, or re-enable a command that was previously disabled.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpEnableTrace Function

```
BOOL WINAPI FtpEnableTrace(
   LPCTSTR lpszTraceFile,
   DWORD dwTraceFlags
);
```

The **FtpEnableTrace** function enables the logging of network function calls to a file.

Parameters

lpszTraceFile

A null-terminated string which specifies the name of the logfile which will be appended to or created. It is recommended that this file always specify an absolute path to avoid any ambiguity. The path can contain environment variable names surrounded by percent (%) symbols which will be expanded prior to opening or creating the file. If the file already exists, the current process must have read and write permission to access the file.

dwTraceFlags

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
TRACE_INFO	All function calls are logged, but without detailed information about the data being transmitted. This is the most basic level of logging and can be useful when debugging call sequences or return values without the additional overhead of logging the data being exchanged between the client and server.
TRACE_ERROR	Only those function calls which fail are written to the file. It is important to note that this only relates to errors at the networking level and not errors which can occur at the protocol level, such as an error response from the server because the client sends an invalid request.
TRACE_WARNING	Only those function calls which fail or return values which indicate a warning are written to the file. Warnings consist of error conditions which do not normally constitute a failure at the network level. The most common warning that can occur is a timeout while waiting for a response from the remote host.
TRACE_HEXDUMP	In addition to logging function calls, this option writes the raw data that is sent and received over the network, shown in both hexadecimal and ASCII formats. This is especially useful for debugging protocol-level issues and verifying payload contents and responses.
TRACE_TRUNCATE	If the file already exists and is not read-only, the contents will be deleted before logging begins. This option is typically used to begin a new log file each time tracing is enabled, rather than appending to an existing file. This option requires the process to have permission to read, write and delete the file in the specified folder.
TRACE_PROCESS	All function calls in the current process are logged, rather than only those functions in the current thread. This option is useful for

	multithreaded applications that are using worker threads.

Return Value

If the function succeeds, the return value is non-zero. A return value of zero indicates an error, typically because the file could not be opened or created by the current process.

Remarks

Logging is enabled and disabled at the thread or process level, depending on the flags passed to this function, and is not associated with a specific client session. When logging is enabled, the information is appended to the specified file. If the file does not exist, it will be created. To limit the size of the file, enable and disable logging only around those sections of code that you wish to debug. If you do not provide a full path to the file, it will be relative to the current working directory for the process. This can produce unexpected results in multithreaded applications because the current directory is global to the entire process and can be changed by any thread at any time.

If logging is not enabled, there is no negative impact on performance or throughput. Once enabled, application performance can degrade, especially in those situations in which there is a large amount of data being exchanged. The log file can contain detailed information about connection attempts and authentication requests, potentially exposing user credentials, authorization tokens and API keys. If you enable logging in a production release of your application, this information can also potentially reveal file structures, API endpoints and data specific to your application. Exercise caution when preserving or sharing the contents of the file.

The TRACE_HEXDUMP option can generate very large files because it includes all of the data exchanged between your application and the remote host. The TRACE_TRUNCATE option is only evaluated when logging is first enabled for a thread or process. If logging is already active, specifying this option will have no effect.

The log file has the following format:

```
APPNAME 105020 0000 INF: WSAAsyncSelect(46, 0xcc4, 0x7e9,0x27) returned 0
APPNAME 105020 0015 WRN: connect(46, 192.0.0.1:1234, 16) returned -1 [10035]
APPNAME 111535 0000 ERR: accept(46, NULL, 0x0) returned -1 [10038]
```

The first column contains the name of the process. The second column is the local time in hours, minutes and seconds. The third column is the elapsed time in milliseconds since the previous function call. The fourth column identifies if the logged event contains information, a warning, or an error. What follows is the name of the network function being called, the arguments passed to the function and the function's return value. If a warning or error is reported, the error code is appended to the record and the value is enclosed in brackets.

If function parameters are passed as integer values, they are recorded in decimal. If the parameter or return value is a memory address, it is recorded as a hexadecimal value preceded with "**0x**". Those functions which expect network addresses are displayed in one of two formats:

```
aa.bb.cc.dd:nnnn
[xxxx:xxxx:xxxxx:xxxx::xxxx]:nnnn
```

With an IPv4 address, the first four numbers separated by periods represent the IP address, and the number following the colon represents the port number in host byte order. If an IPv6 address is used instead of IPv4, the address will be a series of hexadecimal digits separated by colons and enclosed in brackets. In the second line of the above example, a connection is being made to a system with the IPv4 address 192.0.0.1 on port 1234.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpEndOfFile Function

```
BOOL WINAPI FtpEndOfFile(
   HCLIENT hClient
);
```

The **FtpEndOfFile** function is used to determine if the end-of-file has been reached while reading the contents of a remote file.

Parameters

hClient

Handle to the client session.

Return Value

If the end-of-file has been reached, the function returns a non-zero value. If the client handle is invalid, or the end-of-file has not been reached, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpEnumFiles Function

```
INT WINAPI FtpEnumFiles(
   HCLIENT hClient,
   LPCTSTR lpszDirectory,
   LPCTSTR lpszFileMask,
   DWORD dwOptions,
   LPFTPFILESTATUS lpFileList,
   INT nMaxFiles
);
```

The **FtpEnumFilesEx** function populates an array of structures that contain information about the files in a directory.

Parameters

hClient

Handle to the client session.

lpszDirectory

A null-terminated string that specifies the name of a directory on the server. If this parameter is NULL or points to an empty string, the function will return the files in the current working directory. This string cannot contain wildcard characters and must specify a valid directory name that exists on the server.

lpszFileMask

A null-terminated string that specifies a wildcard file mask that is used to return a subset of files in the directory. If this parameter is NULL or an empty string then all of the files in the directory will be returned.

dwOptions

An unsigned integer value that specifies one or more options. This parameter can be a combination of one or more of the following values:

Value	Description
FTP_ENUM_DEFAULT	The function will return both regular files and subdirectories.
FTP_ENUM_FILE	The function will return only regular files.
FTP_ENUM_DIRECTORY	The function will return only subdirectories.
FTP_ENUM_FULLPATH	The function will return the full path of the file or subdirectory.

lpFileList

A pointer to an array of FTPFILESTATUS structures which contains information about each of the files in the specified directory. This parameter cannot be NULL, and the array must be large enough to store the number of files specified by the ***nMaxFiles*** parameter.

nMaxFiles

An integer value that specifies the maximum number of files that should be returned. This value must be greater than zero and the ***lpFileList*** parameter must provide an array that is large enough to store information about each file.

Return Value

If the function succeeds, the return value is the number of files returned by the function. If the

directory is empty or there are no files that match the specified wildcard file mask, the function will return zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpEnumFiles** function provides a high-level interface for obtaining a list of available files in a directory on the server in a single function call. This is an alternative to opening a directory and returning information about each file by calling the **FtpGetNextFile** function in a loop.

This function temporarily changes the current working directory to the directory specified by the *lpszDirectory* parameter. The current working directory will be restored to its original value when the function returns. The user must have the appropriate permissions to access the directory or this function will fail.

To obtain information on a subset of files in the directory, you can specify a wildcard file mask. For FTP and FTPS (TLS) sessions, this value is passed as a parameter to the LIST command and the server performs the wildcard matching. For SFTP (SSH) sessions the wildcard matching is performed by the library, and the standard conventions for Windows file wildcards are used.

By default, the *szFileName* member for each **FTPFILESTATUS** structure will contain the base file name. If the FTP_ENUM_FULLPATH option is specified, the function will return the full path name to the file. The library must be able to automatically determine the path delimiter that is used by the server. This is done by examining how the server identifies itself, the current directory format and the path the server returns for the current working directory. For example, UNIX based servers use the forward slash as a path delimiter. If the function cannot determine what the appropriate path delimiter is, it will ignore this option and return only the base file name.

This function will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled. If the directory contains files that are larger than 4GB, the **FtpEnumFilesEx** function should be used to obtain the correct file size.

Example

```
LPFTPFILESTATUS lpFileList = new FTPFILESTATUS[MAXFILECOUNT];

// Return all of the regular files in the current working directory
INT nResult = FtpEnumFiles(hClient, NULL, NULL, FTP_ENUM_FILE,
                           lpFileList, MAXFILECOUNT);

if (nResult == FTP_ERROR)
{
    DWORD dwError = FtpGetLastError();
    _tprintf(_T("FtpEnumFiles failed, error 0x%08lx\n"), dwError);
    return;
}

_tprintf(_T("FtpEnumFiles returned %d files\n"), nResult);
for (INT nIndex = 0; nIndex < nResult; nIndex++)
{
    _tprintf(_T("file=\"%s\" size=%lu\n"), lpFileList[nIndex].szFileName,
                                           lpFileList[nIndex].dwFileSize);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h

FtpEnumFilesEx Function

```
INT WINAPI FtpEnumFilesEx(
   HCLIENT hClient,
   LPCTSTR lpszDirectory,
   LPCTSTR lpszFileMask,
   DWORD dwOptions,
   LPFTPFILESTATUSEX lpFileList,
   INT nMaxFiles
);
```

The **FtpEnumFilesEx** function populates an array of structures that contain information about the files in a directory. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszDirectory

A null-terminated string that specifies the name of a directory on the server. If this parameter is NULL or points to an empty string, the function will return the files in the current working directory. This string cannot contain wildcard characters and must specify a valid directory name that exists on the server.

lpszFileMask

A null-terminated string that specifies a wildcard file mask that is used to return a subset of files in the directory. If this parameter is NULL or an empty string then all of the files in the directory will be returned.

dwOptions

An unsigned integer value that specifies one or more options. This parameter can be a combination of one or more of the following values:

Value	Description
FTP_ENUM_DEFAULT	The function will return both regular files and subdirectories.
FTP_ENUM_FILE	The function will return only regular files.
FTP_ENUM_DIRECTORY	The function will return only subdirectories.
FTP_ENUM_FULLPATH	The function will return the full path of the file or subdirectory.

lpFileList

A pointer to an array of FTPFILESTATUSEX structures which contains information about each of the files in the specified directory. This parameter cannot be NULL, and the array must be large enough to store the number of files specified by the ***nMaxFiles*** parameter.

nMaxFiles

An integer value that specifies the maximum number of files that should be returned. This value must be greater than zero and the ***lpFileList*** parameter must provide an array that is large enough to store information about each file.

Return Value

If the function succeeds, the return value is the number of files returned by the function. If the

directory is empty or there are no files that match the specified wildcard file mask, the function will return zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpEnumFilesEx** function provides a high-level interface for obtaining a list of available files in a directory on the server in a single function call. This is an alternative to opening a directory and returning information about each file by calling the **FtpGetNextFileEx** function in a loop.

This function temporarily changes the current working directory to the directory specified by the *lpszDirectory* parameter. The current working directory will be restored to its original value when the function returns. The user must have the appropriate permissions to access the directory or this function will fail.

To obtain information on a subset of files in the directory, you can specify a wildcard file mask. For FTP and FTPS (TLS) sessions, this value is passed as a parameter to the LIST command and the server performs the wildcard matching. For SFTP (SSH) sessions the wildcard matching is performed by the library, and the standard conventions for Windows file wildcards are used.

By default, the *szFileName* member for each **FTPFILESTATUSEX** structure will contain the base file name. If the FTP_ENUM_FULLPATH option is specified, the function will return the full path name to the file. The library must be able to automatically determine the path delimiter that is used by the server. This is done by examining how the server identifies itself, the current directory format and the path the server returns for the current working directory. For example, UNIX based servers use the forward slash as a path delimiter. If the function cannot determine what the appropriate path delimiter is, it will ignore this option and return only the base file name.

This function will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled.

Example

```
LPFTPFILESTATUSEX lpFileList = new FTPFILESTATUSEX[MAXFILECOUNT];

// Return all of the regular files in the current working directory
INT nResult = FtpEnumFilesEx(hClient, NULL, NULL, FTP_ENUM_FILE,
                             lpFileList, MAXFILECOUNT);

if (nResult == FTP_ERROR)
{
    DWORD dwError = FtpGetLastError();
    _tprintf(_T("FtpEnumFilesEx failed, error 0x%08lx\n"), dwError);
    return;
}

_tprintf(_T("FtpEnumFilesEx returned %d files\n"), nResult);
for (INT nIndex = 0; nIndex < nResult; nIndex++)
{
    _tprintf(_T("file=\"%s\" size=%I64d\n"), lpFileList[nIndex].szFileName,
                                             lpFileList[nIndex].uiFileSize);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

FtpEnumQueuedFiles Function

```
LONG WINAPI FtpEnumQueuedFiles(
   HQUEUE hQueue,
   LPCTSTR lpszFileMask,
   DWORD dwQueueMode,
   DWORD dwExcludeFiles,
   LPDWORD lpFileList,
   LONG nMaxFiles
);
```

The **FtpEnumQueuedFiles** function returns a list of files in the current transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpszFileMask

A null-terminated string which specifies a file name which can include wildcards. Only those files which match this value will be enumerated. The character '?' will match against any single character, and '*' will match any number of characters. If this parameter is NULL or points to an empty string, all eligible files in the queue will be matched.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. Only those files which match the queue mode will be enumerated. This is a bitmask which may be one or more of the following values:

Constant	Description
FTP_QUEUE_ALL	Match the file name to all files in the queue.
FTP_QUEUE_DOWNLOAD	Match file names which are queued for download.
FTP_QUEUE_UPLOAD	Match file names which are queued for upload.
FTP_QUEUE_LOCAL	Match against the local file name instead of the remote file name.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the enumeration. If this value is zero, no files will be excluded; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_QUEUE_FLAG_NONE	No files should be excluded.
FTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
FTP_QUEUE_FLAG_FAILED	Exclude files which where not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.

FTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the **FtpCancelQueuedFile** function has been called and a queued file is in the process of being uploaded or downloaded.

lpFileList

A pointer to an array of unsigned integer values which will contain the unique file identifiers for each matching file in the queue. This parameter must specify an array large enough to store all of the file identifiers, otherwise the function will fail with a ST_ERROR_BUFFER_TOO_SMALL error. If this parameter is NULL, the function will return the number of matching files.

nMaxFiles

An integer value which specifies the maximum number of file identifiers which can be copied into the *lpFileList* array. If the *lpFileList* parameter is not NULL, this value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of matching files. If the queue is empty or there are no matching files, this function will return zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function populates an array of unique file identifiers which can be used to obtain information about the files in the current queue. The values returned in the *lpFileList* array can be used in conjunction with the **FtpGetQueuedFile** function. This provides an alternative to using the **FtpGetFirstQueuedFile** and **FtpGetNextQueuedFile** functions.

The application should not make any assumptions about the value of the file identifiers returned by this function. They should be considered opaque values which are only guaranteed to uniquely identify a file in the transfer queue. In particular, there is no guarantee that the file identifiers will be sequential and they should not be used as index values into an array.

Example

```
// Get the total number of files in the queue
LONG nFiles = FtpEnumQueuedFiles(hQueue, NULL, FTP_QUEUE_ALL, FTP_QUEUE_FLAG_NONE,
NULL, 0)

// Display information about the queued files
if (nFiles > 0)
{
    DWORD *pdwFileList = new DWORD[nFiles];

    nFiles = FtpEnumQueuedFiles(hQueue, NULL, FTP_QUEUE_ALL, FTP_QUEUE_FLAG_NONE,
pdwFileList, nFiles);

    for (LONG nIndex = 0; nIndex < nFiles; nIndex++)
    {
        FTPQUEUEDFILE queuedFile;

        if (FtpGetQueuedFile(hQueue, pdwFileList[nIndex], &queuedFile) == FALSE)
            break;

        switch (queuedFile.dwMode)
        {
        case FTP_QUEUE_DOWNLOAD:
```

```
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        queuedFile.dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                 break;

        case FTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        queuedFile.dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                 break;
        }
    }

    delete pdwFileList;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpEnumTasks Function

```
INT WINAPI FtpEnumTasks(
   UINT *lpTasks,
   INT nMaxTasks,
   DWORD dwOptions
);
```

Return a list of active, suspended or finished asynchronous tasks.

Parameters

lpTasks

A pointer to an array of unsigned integer values that will contain unique task identifiers when the function returns. If this parameter is NULL, the function will return the number of tasks.

nMaxTasks

An integer value that specifies the maximum number of task identifiers that may be copied into the ***lpTasks*** array. If the ***lpTasks*** parameter is NULL, this value must be zero.

dwOptions

An unsigned integer that specifies the type of asynchronous tasks that may be returned by this function. It may be a combination of the following values:

Value	Description
FTP_TASK_DEFAULT	The list of asynchronous task IDs should include both active and suspended tasks. This option is the same as specifying both the FTP_TASK_ACTIVE and FTP_TASK_SUSPENDED options.
FTP_TASK_ACTIVE	The list of asynchronous task IDs should include those tasks which are currently active. An active task represents a background connection to a server that is in the process of performing the requested action, such as uploading or downloading a file.
FTP_TASK_SUSPENDED	The list of asynchronous task IDs should include those tasks which have been suspended. A suspended task represents a background connection that has been established, but the worker thread is not scheduled for execution.
FTP_TASK_FINISHED	The list of asynchronous task IDs should include those tasks which have completed recently.

Return Value

If the function is successful, the return value is the number of task identifiers copied into the provided array. If there are no tasks which match the requested criteria, the return value is zero. A return value of FTP_ERROR indicates an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpEnumTasks** function can be used to obtain a list of numeric identifiers that represent the asynchronous tasks that have been started or those that have completed. These task IDs are used by other functions to reference the background worker thread that has been created and obtain status information for the task. For example, the **FtpTaskDone** function can be used to determine if a

particular task has completed, and the **FtpTaskWait** function can be used to wait for a task to complete and return an error status code if the background operation failed.

There is an internal limit of 128 asynchronous tasks per process that may be active at any one time. When a task completes, the status information about that task is maintained for period of time after the task has completed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpEventProc Function

```
VOID CALLBACK FtpEventProc(
   HCLIENT hClient,
   UINT nEventId,
   DWORD dwError,
   DWORD_PTR dwParam
);
```

The **FtpEventProc** function is an application-defined callback function that processes events generated by the client.

Parameters

hClient

Handle to the client session.

nEventId

An unsigned integer which specifies which event occurred. For a complete list of events, refer to the **FtpRegisterEvent** function.

dwError

An unsigned integer which specifies any error that occurred. If no error occurred, then this parameter will be zero.

dwParam

A user-defined integer value which was specified when the event callback was registered.

Return Value

None.

Remarks

An application must register this callback function by passing its address to the **FtpRegisterEvent** function. This callback function is also used by asynchronous tasks to notify the application when the task has started and completed. The **FtpEventProc** function is a placeholder for the application-defined function name. Other functions, such as **FtpStartQueue** can also use event callbacks.

If the callback function is invoked by an asynchronous task, it will execute in the context of the worker thread that is managing the client session. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself, and you should avoid calling any functions which could cause the thread to block. For example, you should not attempt to establish other network connections from within the event handler.

If your application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function for an asynchronous task. Controls should only be modified by the same UI thread that created their window. One common approach to resolve this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csftpv12.lib

FtpFindQueuedFile Function

```
DWORD WINAPI FtpFindQueuedFile(
    HQUEUE hQueue,
    LPCTSTR lpszFileName,
    DWORD dwQueueMode,
    DWORD dwExcludeFiles
);
```

The **FtpFindQueuedFile** function finds a file in the transfer queue which matches the search criteria.

Parameters

hQueue

A handle to a file transfer queue.

lpszFileName

A null-terminated string which specifies the name of the file to search for. The string may contain the wildcard character '?' to match against any single character, and '*' will match any number of characters. This parameter cannot be NULL or point to an empty string.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. This is a bitmask which may be one or more of the following values:

Constant	Description
FTP_QUEUE_ALL	Match the file name to all files in the queue.
FTP_QUEUE_DOWNLOAD	Match file names which are queued for download.
FTP_QUEUE_UPLOAD	Match file names which are queued for upload.
FTP_QUEUE_LOCAL	Match against the local file name instead of the remote file name.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the search. If this value is zero, no files will be excluded from the search; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_QUEUE_FLAG_NONE	No files should be excluded from the search.
FTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
FTP_QUEUE_FLAG_FAILED	Exclude files which where not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.
FTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the **FtpCancelQueuedFile**

	function has been called and a queued file is in the process of being uploaded or downloaded.

Return Value

If the function succeeds, the return value is a unique identifier for the file. To obtain information about the file, call the **FtpGetQueuedFile** function. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function returns a unique file identifier for the first file which matches the specified file name in the queue. If the *lpszFileName* parameter includes wildcard characters, this function will return the first file in the queue which matches the name. File name matches are not case-sensitive, even when matching against remote file names on servers which use case-sensitive naming, such as UNIX based servers.

To perform more complex searches based on the file name, or to find multiple files, you can use the **FtpGetFirstQueuedFile** and **FtpGetNextQueuedFile** functions to iterate through all queued files.

Example

```
// Find a local file in the download queue
DWORD dwFileId = FtpFindQueuedFile(
                    hQueue,
                    lpszFileName,
                    FTP_QUEUE_DOWNLOAD | FTP_QUEUE_LOCAL,
                    FTP_QUEUE_FLAG_NONE);

// Display information about the queued file
if (dwFileId != 0)
{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case FTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case FTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
        }
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csftpv12.lib

FtpFreezeEvents Function

```
INT WINAPI FtpFreezeEvents(
   HCLIENT hClient,
   BOOL bFreeze
);
```

The **FtpFreezeEvents** function is used to suspend and resume event handling by the client.

Parameters

hClient

Handle to the client session.

bFreeze

A non-zero value specifies that event handling should be suspended by the client. A zero value specifies that event handling should be resumed.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should be used when the application does not want to process events, such as when a modal dialog is being displayed. When events are suspended, all client events are queued. If events are re-enabled at a later point, those queued events will be sent to the application for processing. Note that only one of each event will be generated. For example, if the client has suspended event handling, and four read events occur, once event handling is resumed only one of those read events will be posted to the client. This prevents the application from being flooded by a potentially large number of queued events.

FtpGetActivePorts Function

```
INT WINAPI FtpGetActivePorts(
   HCLIENT hClient,
   UINT *lpnLowPort,
   UINT *lpnHighPort
);
```

The **FtpGetActivePorts** function returns the local port numbers used for active mode file transfers.

Parameters

hClient

Handle to the client session.

lpnLowPort

Points to an unsigned integer that will contain the low port number when the function returns.

lpnHighPort

Points to an unsigned integer that will contain the high port number when the function returns.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to determine the default port numbers being used for active mode file transfers. When using active mode, the client listens for an inbound connection from the server rather than establishing an outbound connection for the data transfer. In most cases, passive mode transfers are preferred because they mitigate potential compatibility issues with firewalls and NAT routers.

If active mode transfers are required, the default port range used when listening for the server connection is between 1024 and 5000. This is the standard range of ephemeral ports used by the Windows operating system. However, under some circumstances that range of ports may be too small, or a firewall may be configured to deny inbound connections on ephemeral ports. In that case, the **FtpSetActivePorts** function can be used to specify a different range of port numbers.

While it is technically permissible to assign the low and high port numbers to the same value, effectively specifying a single active port number, this is not recommended as it can cause the transfer to fail unexpectedly if multiple file transfers are performed. A minimum range of at least 1000 ports is recommended. For example, if you specify a low port value of 40000 then it is recommended that the high port value be at least 41000. The maximum port value is 65535.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetAutoFileType Function

```
UINT WINAPI FtpGetAutoFileType(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   BOOL bScanFile
);
```

The **FtpGetAutoFileType** function returns the file transfer type based on the file extension or content.

Parameters

hClient

Handle to the client session. If this parameter is INVALID_CLIENT the function will only check against the global list of default text file extensions. If the handle is valid, it will also check for any application defined file extensions.

lpszFileName

A null-terminated string which specifies the local path to the file. This parameter cannot be NULL and cannot specify a local device name or directory.

bScanFile

Specifies if the contents of the file should be scanned. A value of zero indicates that only the file extension should be used to determine the file type, while a non-zero value specifies the contents of the file should be examined if the file type cannot be determined based on its extension.

Return Value

If the function succeeds, the return value is the file transfer type. If the function fails, the return value is INVALID_FILE_TYPE. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to determine the file transfer type to be used when uploading or downloading files. This function is called internally when FILE_TYPE_AUTO is specified as the default file type. The return value may be one of the following:

Value	Description
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executable programs. If the type of file cannot be automatically determined, it will always be considered a binary file. If this file type is specified when uploading or downloading text files, the native end-of-

	line character sequences will be preserved.

If the file extension or contents are not recognized, the default file transfer type for the client session will be returned. This will usually be FILE_TYPE_IMAGE, however this can be changed by calling the **FtpRegisterFileType** function. The file type for the current client session can be explicitly set using the **FtpSetFileType** function.

If the ***bScanFile*** parameter is non-zero, the local file will be opened in a shared reading mode and up to 4,096 bytes will be examined to determine if it contains binary data. If the file is currently locked or has been opened exclusively by another process, the file type associated with the file extension will be returned instead. Text files which contain UTF-16 text will always return a file type of FILE_TYPE_IMAGE because they can contain non-ASCII characters and/or embedded null characters.

If the ***bScanFile*** parameter is non-zero and the file type cannot be determined based on the file name extension, the file specified by ***lpszFileName*** must exist and be a regular file. If the file does not exist, an error will be returned and the last error code will be set to ST_ERROR_FILE_NOT_FOUND. If the ***bScanFile*** parameter is zero, no errors will be returned if the file does not exist, the function will only check the file name extension to determine the file type. When downloading a file, the ***bScanFile*** parameter should normally be zero because the local file may not exist yet.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetBufferSize Function

```
INT WINAPI FtpGetBufferSize(
    HCLIENT hClient
);
```

The **FtpGetBufferSize** function returns the size in bytes of an internal buffer that will be used during data transfers.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the size of the internal buffer that will be used in data transfers. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The speed of data transfers, particularly on uploads, may be sensitive to network type and configuration, and the size of the internal buffer used for data transfers. The default size of this buffer will result in good performance for a wide range of network characteristics. A larger buffer will not necessarily result in better performance. For example, a value of 1460, which is the typical Maximum Transmission Unit (MTU), may be optimal in many situations.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetChannelMode Function

```
INT WINAPI FtpGetChannelMode(
    HCLIENT hClient,
    INT nChannel
);
```

The **FtpGetChannelMode** function returns the mode of the specified communications channel.

Parameters

hClient

Handle to the client session.

nChannel

An integer value which specifies which channel to return information for. It may be one of the following values:

Value	Description
FTP_CHANNEL_COMMAND	Return information about the command channel. This is the communication channel used to send commands to the server and receive command result and status information from the server.
FTP_CHANNEL_DATA	Return information about the data channel. This is the communication channel used to send or receive data during a file transfer.

Return Value

If the function succeeds, the return value is the mode for the specified channel. If the function fails, it will return FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetChannelMode** function returns a integer which may be one of the following values:

Value	Description
FTP_CHANNEL_CLEAR	The channel is not encrypted. This is the default mode for both channels when a standard, non-secure connection is established with the server.
FTP_CHANNEL_SECURE	The channel is encrypted. This is the default mode for both channels when a secure connection is established with the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetClientQuota Function

```
INT WINAPI FtpGetClientQuota(
   HCLIENT hClient,
   LPFTPCLIENTQUOTA lpClientQuota
);
```

The **GetClientQuota** function returns information about file quotas for the current client session.

Parameters

hClient

Handle to the client session.

lpClientQuota

A pointer to an FTPCLIENTQUOTA structure which contains the quota information returned by the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **GetLastError**.

Remarks

This method uses the XQUOTA command to obtain information for the current client session. If the server does not support this command, the function will fail.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetData Function

```
INT WINAPI FtpGetData(
   HCLIENT hClient,
   LPCTSTR lpszRemoteFile,
   LPVOID lpvBuffer,
   LPDWORD lpdwLength,
   DWORD dwReserved
);
```

The **FtpGetData** function transfers the contents of a file on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A null-terminated string that specifies the file on the server that will be transferred to the local system. The file naming conventions must be that of the host operating system.

lpvBuffer

A buffer which will contain the data transferred from the server, or a pointer to a global memory handle which will reference the data when the function returns.

lpdwLength

A pointer to an unsigned integer which should be initialized to the maximum number of bytes that can be copied to the buffer specified by the ***lpvBuffer*** parameter. If the ***lpvBuffer*** parameter points to a global memory handle, the length value should be initialized to zero. When the function returns, this value will be updated with the actual length of the file that was downloaded.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetData** function is used to download the contents of a remote file into a local buffer. The function may be used in one of two ways, depending on the needs of the application. The first method is to pre-allocate a buffer large enough to store the contents of the file. In this case, the ***lpvBuffer*** parameter will point to the buffer that was allocated, the value that the ***lpdwLength*** parameter points to should be initialized to the size of that buffer.

The second method that can be used is have the ***lpvBuffer*** parameter point to a global memory handle which will contain the file data when the function returns. In this case, the value that the ***lpdwLength*** parameter points to must be initialized to zero. It is important to note that the memory handle returned by the function must be freed by the application, otherwise a memory leak will occur. See the example code below.

It is important for your application to initialize the value of the ***lpdwLength*** parameter correctly. This parameter must be passed by reference and if it is not initialized properly it can cause unexpected behavior or corrupt the process heap. If an error occurs when downloading the file, the variable

passed to this function may have a value of zero when the function returns, indicating no data has been returned to the caller.

The **FtpGetText** function can be used to download a text file and store the contents in a string.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Example

```
HGLOBAL hgblBuffer = (HGLOBAL)NULL;
LPBYTE lpBuffer = (LPBYTE)NULL;
DWORD cbBuffer = 0;

// Return the file data into block of global memory allocated by
// the GlobalAlloc function; the handle to this memory will be
// returned in the hgblBuffer parameter
nResult = FtpGetData(hClient,
                     lpszRemoteFile,
                     &hgblBuffer,
                     &cbBuffer,
                     0);

if (nResult != FTP_ERROR)
{
    // Lock the global memory handle, returning a pointer to the
    // contents of the file data
    lpBuffer = (LPBYTE)GlobalLock(hgblBuffer);

    // After the data has been used, the handle must be unlocked
    // and freed, otherwise a memory leak will occur
    GlobalUnlock(hgblBuffer);
    GlobalFree(hgblBuffer);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetDefaultZoneId Function

```
BOOL WINAPI FtpGetDefaultZoneId(
    HCLIENT hClient,
    LPDWORD lpdwZoneId
);
```

The **FtpGetDefaultZoneId** function returns the default security zone for downloaded files.

Parameters

hClient

Handle to the client session.

lpdwZoneId

A pointer to an unsigned integer which is updated with the default zone ID for the client session. It may be one of the following values:

Value	Description
SECURITY_ZONE_NONE	The file does not have a zone identifier associated with it.
SECURITY_ZONE_LOCAL	The file is considered to be part of the local computer zone.
SECURITY_ZONE_INTRANET	The file originates from the local intranet zone, such as an internal corporate network.
SECURITY_ZONE_TRUSTED	The file originates from a site in the **Trusted Sites** zone.
SECURITY_ZONE_INTERNET	The file was downloaded from the Internet and is treated with caution by Windows.
SECURITY_ZONE_RESTRICTED	The file originates from a site in the **Restricted Sites** zone, which is used for untrusted content.

Return Value

If the function succeeds, the return value is non-zero and *lpdwZoneId* will be updated with the default zone identifier. If no default zone has been explicitly set, the function will still return success, and the variable *lpdwZoneId* points to will be set to `SECURITY_ZONE_NONE`. If the function fails, it returns zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetDefaultZoneId** function returns the zone identifier which was previously set using the **FtpSetDefaultZoneId** function. If no default zone has been specified for the client session, the default behavior is to not set a security zone for the file. This maintains backwards compatibility with previous versions of the library which would not create the security zone metadata for local files.

This function is typically used to confirm the currently configured zone before downloading a file, or to verify whether the default behavior has been overridden. The default zone ID is specific to the client session and does not affect other sessions or system-wide settings.

To get the security zone identifier for a local file, use the **FtpGetFileZoneInfo** function. To change or remove the security zone information for a file, use the **FtpSetFileZoneInfo** function.

For more detailed information about the zone identifiers, refer to the **FtpSetDefaultZoneId** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetDirectory Function

```
INT WINAPI FtpGetDirectory(
   HCLIENT hClient,
   LPTSTR lpszDirectory,
   INT nMaxLength
);
```

The **FtpGetDirectory** function copies the current working directory on the server to the specified buffer.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a buffer that will contain the name of the current working directory on the server. The file pathing and name conventions must be that of the server.

nMaxLength

The maximum number of characters that may be copied into the buffer, including the terminating null-character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the PWD command to the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetDirectoryFormat Function

```
INT WINAPI FtpGetDirectoryFormat(
    HCLIENT hClient
);
```

The **FtpGetDirectoryFormat** function returns an identifier which specifies what format is being used by the server to list files. By default, the library will automatically determine the appropriate format, but this value may be overridden by the **FtpSetDirectoryFormat** function.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the currently selected directory format. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Refer to the **FtpSetDirectoryFormat** function for a list of directory format types that are supported by the library. This function can be used to determine which format was selected by the library after a file listing has been retrieved.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetErrorString Function

```
INT WINAPI FtpGetErrorString(
   DWORD dwErrorCode,
   LPTSTR lpszDescription,
   INT nMaxLength
);
```

The **FtpGetErrorString** function is used to return a description of a specific error code. Typically this is used in conjunction with the **FtpGetLastError** function for use with warning dialogs or as diagnostic messages.

Parameters

dwErrorCode

The error code for which a description is returned.

lpszDescription

The buffer that will contain a description of the specified error code. This buffer should be at least 128 characters in length.

nMaxLength

The maximum number of characters that may be copied into the description buffer.

Return Value

If the function succeeds, the return value is the length of the description string. If the function fails, the return value is zero, meaning that no description exists for the specified error code. Typically this indicates that the error code passed to the function is invalid.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetLastError, FtpSetLastError

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetFeatures Function

```
DWORD WINAPI FtpGetFeatures(
    HCLIENT hClient
);
```

The **FtpGetFeatures** function returns the server features available to the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is one or more bit flags which specify the features that are available to the client. If the function fails, it will return zero. Because it is possible that no features would be enabled, a return value of zero does not always indicate an error. An application should call **FtpGetLastError** to determine if an error code has been set.

Remarks

The **FtpGetFeatures** function returns a value which may be a combination of one or more of the following bit flags:

Value	Description
FTP_FEATURE_SIZE	The server supports the SIZE command to determine the size of a file. If this feature is not enabled, the library will attempt to use the MLST or STAT command to determine the file size.
FTP_FEATURE_STAT	The server supports using the STAT command to return information about a specific file. If this feature is not enabled, the client may not be able to obtain information about a specific file such as its size, permissions or modification time.
FTP_FEATURE_MDTM	The server supports the MDTM command to obtain information about the modification time for a specific file. This command may also be used to set the file time on the server.
FTP_FEATURE_REST	The server supports restarting file transfers using the REST command. If this feature is not enabled, the client will not be able to restart file transfers and must upload or download the complete file.
FTP_FEATURE_SITE	The server supports site specific commands using the SITE command. If this feature is not enabled, no site specific commands will be sent to the server.
FTP_FEATURE_IDLE	The server supports setting the idle timeout period using the SITE IDLE command to specify the number of seconds that the client may idle before the server terminates the connection.
FTP_FEATURE_CHMOD	The server supports modifying the permissions of a specific file using the SITE CHMOD command. If this feature is not enabled, the client will not be able to set the permissions for a file.
FTP_FEATURE_AUTH	The server supports explicit TLS sessions using the AUTH

	command. If this feature is not enabled, the client will only be able to connect to a secure server that uses implicit TLS connections. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_PBSZ	The server supports the PBSZ command which specifies the buffer size used with secure data connections. If this feature is disabled, it may prevent the client from changing the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_PROT	The server supports the PROT command which specifies the protection level for the data channel. If this feature is disabled, the client will be unable to change the protection level on the data channel. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_CCC	The server supports the CCC command which returns the command channel to a non-secure mode. Changing this feature has no effect on standard, non-secure connections.
FTP_FEATURE_HOST	The server supports the HOST command which enables a client to specify the hostname after establishing a connection with a server that supports virtual hosting.
FTP_FEATURE_MLST	The server supports the MLST command which returns status information for files. If this feature is enabled, the MLST command will be used instead of the STAT command.
FTP_FEATURE_MFMT	The server supports the MFMT command which is used to change the last modification time for a file. If this command is supported, it is used instead of the MDTM command to change the modification time for a file.
FTP_FEATURE_XCRC	The server supports the XCRC command which returns the CRC-32 checksum for the contents of a specified file. This command is used for file verification.
FTP_FEATURE_XMD5	The server supports the XMD5 command which returns an MD5 hash for the contents of a specified file. This command is used for file verification.
FTP_FEATURE_LANG	The server supports the LANG command which sets the language used for the current client session. Command responses and file naming conventions will use the specified language.
FTP_FEATURE_UTF8	The server supports the OPTS UTF-8 command which specifies UTF-8 encoding when specifying filenames. This feature is typically used in conjunction with setting the default language for the client session.
FTP_FEATURE_XQUOTA	The server supports the XQUOTA command which returns quota information for the current client session.
FTP_FEATURE_UTIME	The server supports the UTIME command which is used to change the last modification time for a specified file.

When a client connection is first established, features are enabled based on the server type and the server's response to the FEAT command. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client.

For example, the first time an application calls the **FtpGetFileSize** function to determine the size of a file, the library will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the library will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the library from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetFile Function

```
INT WINAPI FtpGetFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   DWORD dwOffset
);
```

The **FtpGetFile** function transfers the specified file on the server to the local system.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string which specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions should follow Windows conventions. It is permitted to include environment variables in the local path by surrounding the variable with percent (%) symbols. Local file paths may also use standard file URLs.

lpszRemoteFile

A null-terminated string which specifies the file on the server that will be downloaded to the local system. The file naming conventions must be that of the host operating system. It is permitted to use a URL as the remote file name as long as the server name and port number match what was used to establish the connection.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetFileEx Function

```
INT WINAPI FtpGetFileEx(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   ULARGE_INTEGER uiOffset
);
```

The **FtpGetFileEx** function transfers the specified file on the server to the local system. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string which specifies the file on the local system that will be created, overwritten or appended to. The file pathing and name conventions should follow Windows conventions. It is permitted to include environment variables in the local path by surrounding the variable with percent (%) symbols. Local file paths may also use standard file URLs.

lpszRemoteFile

A null-terminated string which specifies the file on the server that will be downloaded to the local system. The file naming conventions must be that of the host operating system. It is permitted to use a URL as the remote file name as long as the server name and port number match what was used to establish the connection.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the local file exists, it will be overwritten with the contents of the downloaded file.
FTP_TRANSFER_APPEND	This option specifies that if the local file exists, the contents of file on the server is appended to the local file. If the local file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetFileList Function

```
INT WINAPI FtpGetFileList(
   HCLIENT hClient,
   LPCTSTR lpszDirectory,
   DWORD dwOptions,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **FtpGetFileList** function returns an unparsed list of files in the specified directory.

Parameters

hClient

Handle to the client session.

lpszDirectory

A null-terminated string that specifies the name of a directory and/or a wildcard file mask. The format of the directory name must match the file naming conventions of the server. If this parameter is NULL or points to an empty string, the current working directory will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_LIST_DEFAULT	This option specifies the server should return a complete listing of files in the specified directory with as much detail as possible. This typically means that the file size, date, ownership and access rights will be returned to the client. Information about the files are returned in lines of text, with each line terminated by carriage return and linefeed (CRLF) characters. The exact format of the data returned is specific to the server operating system.
FTP_LIST_NAMEONLY	This option specifies the server should only return a list of file names, with no additional information about the file. Each file name is terminated by carriage return and linefeed (CRLF) characters.

lpszBuffer

A null-terminated string buffer that will contain the list of files when the function returns. This buffer should be large enough to store the complete file listing and a terminating null character. If the buffer is smaller than the total amount of data returned by the server, the data will be truncated. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the number of bytes copied into the string buffer, not including the terminating null character. If the function fails, the return value is FTP_ERROR. To get

extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetFileList** function returns a list of files in the specified directory, copying the data to a string buffer. Unlike the other functions like **FtpEnumFiles** that parse a directory listing and return information in an **FTPFILESTATUS** structure, this function returns the unparsed file list data. The actual format of the data that is returned depends on the operating system and how the server implements file listings. For example, UNIX servers typically return the output from the **/bin/ls** command.

Some servers may not support file listings for any directory other than the current working directory. If an error is returned when specifying a directory name, try changing the current working directory using the **FtpChangeDirectory** function and then call this function again, passing NULL or an empty string as the *lpszDirectory* parameter.

This function can be particularly useful when the client is connected to a server that returns file listings in a format that is not recognized by the library. The application can retrieve the unparsed file listing from the server and parse the contents. Note that if you specify the FTP_LIST_NAMEONLY option, the data will only contain a list of file names and there will be no way for the application to know if they represent a regular file or a subdirectory.

This function is supported for both FTP and SFTP (SSH) connections, however the format of the data may differ depending on which protocol is used. Most UNIX based FTP servers will not list files and subdirectories that begin with a period, however most SFTP servers will return a list of all files, even those that begin with a period.

This function will cause the current thread to block until the file listing completes, a timeout occurs or the operation is canceled.

Example

```
TCHAR szFileList[MAXFILELISTSIZE];

nResult = FtpGetFileList(hClient, NULL, FTP_LIST_NAMEONLY,
                         szFileList, MAXFILELISTSIZE);

if (nResult != FTP_ERROR)
    _tprintf(_T("%s\n"), szFileList);
else
{
    DWORD dwError = FtpGetLastError();
    _tprintf(_T("Unable to list files (error 0x%08lx)\n"), dwError);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetFileNameEncoding Function

```
INT WINAPI FtpGetFileNameEncoding(
    HCLIENT hClient
);
```

The **FtpGetFileNameEncoding** function returns an identifier which specifies what type of encoding is being used when file names are sent to the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the type of encoding that is used. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Refer to the **FtpSetFileNameEncoding** function for a list of encoding types that are supported by the library.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetFilePathUrl Function

```
INT WINAPI FtpGetFilePathUrl(
   HCLIENT hClient,
   LPCTSTR lpszFilePath,
   LPTSTR lpszFileUrl,
   INT nMaxLength
);
```

The **FtpGetFilePathUrl** function returns a normalized URL for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFilePath

A null-terminated string which specifies the file path on the server. The path may be absolute or relative, and the path does not have to exist on the server. This parameter cannot be NULL.

lpszFileUrl

A null-terminated string buffer that will contain the URL for the specified file. If this parameter is NULL, nothing will be copied but the function will return the length of the URL, not including the terminating null character.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer. This must include space for the terminating null character. If ***lpszFileUrl*** is NULL this value should be zero.

Return Value

If the function succeeds, the return value is the number of characters copied into the ***lpszFileUrl*** buffer, not including the terminating null character. If a buffer is provided, it must be large enough to contain the entire URL or the function will fail. If the ***lpszFileUrl*** parameter is NULL, the function will return the length of the URL and nothing will be copied. If the function fails, it will return zero. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpGetFilePathUrl** function will return the URL associated with the specified file path. This can be useful if you wish to display or store URLs rather than relative paths to a file on the current server. For example, if you are connected to the server `example.com` on port 21 using a standard connection and you provide a relative file path such as `documents/invoice.pdf` this function would return a URL which looks like `ftp://example.com/documents/invoice.pdf`. For security reasons, the resulting URL will never contain user credentials.

The file path in the URL will be normalized to remove extraneous directory traversals and path separators. If the path is relative, it will be expanded to an absolute path based on the client's current working directory. If an absolute path is provided, it will be included in the URL as-is. It is not required for the file path to exist on the server at the time this function is called. For more information about path normalization, refer to the **FtpNormalizePath** function.

This function can also be used to obtain a URL which can be passed to the **FtpGetSercurityZoneId** function to determine which security zone should be assigned to the file when it is downloaded.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

Example

The following example shows how **FtpGetFilePathUrl** could be used to obtain the origin URL for a file on the server and then use that in conjunction with the **FtpGetSecurityZoneId** function to update the security zone metadata for the file if the download is successful.

```
LPCTSTR lpszLocalFile = _T("\\Users\\Public\\Documents\\Document.pdf");
LPCTSTR lpszRemoteFile = _T("files/document.pdf");

TCHAR szFileUrl[FTP_MAXURLPATHLEN] = { 0 };
DWORD dwZoneId = SECURITY_ZONE_NONE;

// Return a complete URL for the relative file path specified for the
// remote file on the server
if (FtpGetFilePathUrl(hClient, lpszRemoteFile, szFileUrl, FTP_MAXURLPATHLEN) < 1)
{
    _tprintf(_T("Unable to get URL for \"%s\"\n"), lpszRemoteFile);
    return;
}

// Check the security zone for the remote file URL
if (!FtpGetSecurityZoneId(szFileUrl, &dwZoneId))
{
    _tprintf(_T("Unable to determine a security zone for \"%s\"\n"), szFileUrl);
}

// Download the file from the server
INT nResult = FtpGetFile(hClient, lpszLocalFile, lpszRemoteFile, 0, 0);

if (nResult != FTP_ERROR)
{
    // The download was successful; if a security zone was returned for
    // the file, then update it with the zone ID and origin URL
    if (dwZoneId != SECURITY_ZONE_NONE)
    {
        if (!FtpSetFileZoneInfo(lpszLocalFile, dwZoneId, szFileUrl))
        {
            _tprintf(_T("Unable to set the security zone for \"%s\"\n"),
lpszLocalFile);
            return;
        }
    }
}
else
{
    // The download failed
    _tprintf(_T("Unable to download \"%s\" to \"%s\"\n"), lpszRemoteFile,
lpszLocalFile);
}
```

FtpGetFilePermissions Function

```
INT WINAPI FtpGetFilePermissions(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPDWORD lpdwPermissions
);
```

The **FtpGetFilePermissions** function returns information about the access permissions for a specific file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A null-terminated string which contains the name of the file that the access permissions are to be returned for. The filename cannot contain any wildcard characters.

lpdwPermissions

A pointer to an unsigned integer which will contain the access permissions for the file when the function returns. The file permissions are represented as bit flags, and may be one or more of the following values:

Value	Description
FILE_OWNER_READ	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.
FILE_OWNER_WRITE	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_OWNER_EXECUTE	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_GROUP_READ	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.
FILE_GROUP_WRITE	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_GROUP_EXECUTE	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.

FILE_WORLD_READ	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.
FILE_WORLD_WRITE	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.
FILE_WORLD_EXECUTE	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.

Return Value

If the function succeeds, the return value is a result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the STAT command to retrieve information about the specified file. On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the function will fail and value pointed to by the ***lpdwPermissions*** parameter will be zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetFileStatus, FtpSetFilePermissions

FtpGetFileSize Function

```
INT WINAPI FtpGetFileSize(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPDWORD lpdwFileSize
);
```

The **FtpGetFileSize** function returns the size of the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpdwFileSize

Points to an unsigned integer that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the SIZE command to determine the length of the specified file. Not all servers implement this command, in which case the function call will fail, and the *lpdwFileSize* parameter will be set to zero.

Note that if the file on the server is a text file, it is possible that the value returned by this method will not match the size of the file when it is downloaded to the local system. This is because different operating systems use different sequences of characters to mark the end of a line of text, and when a file is transferred in text mode, the end of line character sequence is automatically converted to a carriage return-linefeed, which is the convention used by the Windows platform.

Some FTP servers will refuse to return the size of a file if the current file type is set to FILE_TYPE_ASCII because the size of a text file on the server may not accurately reflect what the size of the file will be on the local system.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetFileSizeEx Function

```
INT WINAPI FtpGetFileSizeEx(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   ULARGE_INTEGER *lpuiFileSize
);
```

The **FtpGetFileSizeEx** function returns the size of the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpuiFileSize

Points to a ULARGE_INTEGER structure that will contain the size of the specified file in bytes.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the SIZE command to determine the length of the specified file. Not all servers implement this command, in which case the function call will fail, and the *lpdwFileSize* parameter will be set to zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetFileStatusEx, FtpOpenDirectory

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetFileStatus Function

```
BOOL WINAPI FtpGetFileStatus(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPFTPFILESTATUS lpFileStatus
);
```

The **FtpGetFileStatus** function returns information about a specific file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A null-terminated string which contains the name of the file that status information will be returned on. The file name cannot contain any wildcard characters.

lpFileStatus

A pointer to an FTPFILESTATUS structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the STAT command to retrieve information about the specified file. Unlike the **FtpGetFirstFile** and **FtpGetNextFile** functions, which read through a file list returned on the data channel, this function reads the result of a command string. For applications that need information about a specific file, using this function can be considerably faster than iterating through all of the files in a given directory. Note that not all servers support using the command in this way.

On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the FTPFILESTATUS structure members will be empty strings and zero values.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetFileStatusEx Function

```
BOOL WINAPI FtpGetFileStatusEx(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPFTPFILESTATUSEX lpFileStatus
);
```

The **FtpGetFileStatusEx** function returns information about a specific file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

A null-terminated string which contains the name of the file that status information will be returned on. The file name cannot contain any wildcard characters.

lpFileStatus

A pointer to an FTPFILESTATUSEX structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the STAT command to retrieve information about the specified file. Unlike the **FtpGetFirstFileEx** and **FtpGetNextFileEx** functions, which read through a file list returned on the data channel, this function reads the result of a command string. For applications that need information about a specific file, using this function can be considerably faster than iterating through all of the files in a given directory. Note that not all servers support using the command in this way.

On some systems, the STAT command will not return information on files that contain spaces or tabs in the filename. In this case, the FTPFILESTATUSEX structure members will be empty strings and zero values.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetFileTime Function

```
INT WINAPI FtpGetFileTime(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPSYSTEMTIME lpFileTime,
   BOOL bLocalize
);
```

The **FtpGetFileTime** function returns the modification time for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileTime

Points to a SYSTEMTIME structure that will be set to the current modification time for the remote file.

bLocalize

A boolean flag which specifies if the file time is localized to the current timezone. If this value is non-zero, then the file time is adjusted to that the time is local to the current system. If this value is zero, the file time is returned in UTC time.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetFileTime** function can be used to determine the date and time that a file was last modified on the server. The time may either be localized to the current system, or it may be returned as UTC time. If you plan on changing the values returned in the SYSTEMTIME structure and then calling **FtpSetFileTime** function to modify the file time on the server, you should do not localize the time.

This function uses the MDTM command to determine the modification time of the specified file. If the server does not support this command, the function will attempt to use the STAT command to determine the file modification time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetFileType Function

```
INT WINAPI FtpGetFileType(
   HCLIENT hClient,
   UINT *lpnFileType
);
```

The **FtpGetFileType** function returns the default file type for the current client session.

Parameters

hClient

Handle to the client session.

lpnFileType

A pointer to an unsigned integer that will identify the current file type. This parameter cannot be NULL. When the function returns it will contain one of the following values:

Value	Description
FILE_TYPE_AUTO	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the **FtpRegisterFileType** function.
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executables. If the type of file cannot be automatically determined, it will always be considered a binary file.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If this function is called when connected to an SFTP (SSH) server, the default file type will always be FILE_TYPE_IMAGE because SFTP does not differentiate between text files and binary files.

The **FtpSetFileType** function can be used to change the default file type. To determine the automatic file type for a specific file based on its extension or contents, use the **FtpGetAutoFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1

Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetFileZoneInfo Function

```
BOOL WINAPI FtpGetFileZoneInfo(
   LPCTSTR lpszLocalFile,
   LPDWORD lpdwZoneId,
   LPTSTR lpszHostUrl,
   INT nMaxLength
);
```

The **FtpGetFileZoneInfo** function returns the security zone information for a local file.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of a local file. This parameter must specify a regular file which exists on the local system and the current process must have permission to access and read from the file. If the file path includes environment variables surrounded in percent (%) symbols, the variables will be expanded. This parameter cannot be NULL.

lpdwZoneId

A pointer to an unsigned integer which will contain the zone ID assigned to the file when the function returns. It may be one of the following values:

Value	Description
SECURITY_ZONE_NONE	The file does not have a zone identifier associated with it.
SECURITY_ZONE_LOCAL	The file is considered to be part of the local computer zone.
SECURITY_ZONE_INTRANET	The file originates from the local intranet zone, such as an internal corporate network.
SECURITY_ZONE_TRUSTED	The file originates from a site in the **Trusted Sites** zone.
SECURITY_ZONE_INTERNET	The file was downloaded from the Internet and is treated with caution by Windows.
SECURITY_ZONE_RESTRICTED	The file originates from a site in the **Restricted Sites** zone, which is used for untrusted content.

lpszHostUrl

An optional pointer to a string buffer which will contain the URL used to originally download the file. This information is not always available, in which case an empty string will be returned. If this information is not required, this parameter may be NULL and the ***nMaxLength*** parameter should be specified with a value of zero.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the ***lpszHostUrl*** string including the terminating null character. If the ***lpszHostUrl*** parameter is NULL, this value should be zero. If the buffer is not large enough to contain the entire URL, the string will be truncated. The maximum allowed URL length is 2,048 characters.

Return Value

If the function succeeds, the return value is non-zero. If the function fails or zone information is not available, the function returns zero. To get extended error information, call **FtpGetLastError**.

Remarks

When a file is downloaded from the Internet or other external sources, Windows may assign a zone identifier to the file using an alternate data stream named `Zone.Identifier`. This metadata helps determine how the system treats the file with respect to security, such as whether to prompt the user with a warning before opening it.

The **FtpGetFileZoneInfo** function retrieves the zone ID associated with the specified local file, allowing an application to determine the origin and trust level of that file. This can be useful when implementing additional security measures, auditing downloaded content, or providing user warnings about potentially untrusted files.

The file name specified by the *lpszLocalFile* parameter must not reference a network location. This includes UNC paths (such as `\\server\share\file.txt`) and drive letters that are mapped to network shares. Security zone metadata cannot be read from files on network volumes because the SMB protocol does not support alternate data streams.

In addition to the zone ID, this function can optionally return the source URL used to download the file. This information, if present, is extracted from the same alternate data stream. Not all files will include this URL, as it depends on the program or browser that downloaded the file and whether it preserved this metadata. This function will not return an error if the URL stored with the security zone information is not a valid FTP URL. For example, it's possible for this function to return zone information with an HTTP URL. You can use the **FtpValidateUrl** function to determine if the host URL is a valid FTP URL.

Note that not all file systems support alternate data streams. For example, FAT32 volumes do not support them, and in such cases, zone information will not be available. Additionally, some applications may remove this metadata after download or strip it during file copy operations. The absence of zone information does not guarantee that a file is safe or originated locally.

If you wish to distinguish between a file which exists without any zone information, and an error condition where the file does not exist or could not be accessed, check the last error code. If this function returns zero and the **FtpGetLastError** function returns NO_ERROR, this indicates the file name is valid and it exists, but the `Zone.Identifier` alternate data stream does not exist.

For more detailed information about the security zone identifiers, refer to the **FtpSetDefaultZoneId** function. To change or remove the security zone metadata from a local file, use the **FtpSetFileZoneInfo** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetFirstFile Function

```
BOOL WINAPI FtpGetFirstFile(
   HCLIENT hClient,
   LPFTPFILESTATUS lpFileStatus
);
```

The **FtpGetFirstFile** function returns the first file in the directory listing returned by the server after a call to the **FtpOpenDirectory** function.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an FTPFILESTATUS structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This file list information returned by the server is cached by the library, allowing you to use this function to reposition back to the beginning of the file list.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)
{
    FTPFILESTATUS ftpFile;
    BOOL bResult;

    bResult = FtpGetFirstFile(hClient, &ftpFile);
    while (bResult)
    {
        // The ftpFile structure contains information about the file
        bResult = FtpGetNextFile(hClient, &ftpFile);
    }

    FtpCloseDirectory(hClient);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetFirstFileEx Function

```
BOOL WINAPI FtpGetFirstFileEx(
   HCLIENT hClient,
   LPFTPFILESTATUSEX lpFileStatus
);
```

The **FtpGetFirstFileEx** function returns the first file in the directory listing returned by the server after a call to the **FtpOpenDirectory** function. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an FTPFILESTATUSEX structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This file list information returned by the server is cached by the library, allowing you to use this function to reposition back to the beginning of the file list.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)
{
    FTPFILESTATUSEX ftpFile;
    BOOL bResult;

    bResult = FtpGetFirstFileEx(hClient, &ftpFile);
    while (bResult)
    {
        // The ftpFile structure contains information about the file
        bResult = FtpGetNextFileEx(hClient, &ftpFile);
    }

    FtpCloseDirectory(hClient);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetFirstQueuedFile Function

```
DWORD WINAPI FtpGetFirstQueuedFile(
   HQUEUE hQueue,
   DWORD dwQueueMode,
   DWORD dwExcludeFiles,
   LPFTPQUEUEDFILE lpFileInfo
);
```

The **FtpGetFirstQueuedFile** function returns information about the first file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An unsigned integer value which specifies if the file name should be matched against downloaded files, uploaded files or all files in the queue. It may be one of the following values:

Constant	Description
FTP_QUEUE_ALL	Return information about all files in the queue.
FTP_QUEUE_DOWNLOAD	Return information for files which are queued for download.
FTP_QUEUE_UPLOAD	Return information for files which are queued for upload.

dwExcludeFiles

An unsigned integer value which specifies which files to exclude from the search. If this value is zero, no files will be excluded from the search; otherwise, this value is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_QUEUE_FLAG_NONE	No files should be excluded.
FTP_QUEUE_FLAG_COMPLETED	Exclude files which have been transferred. This flag is set after a queued file has been uploaded or downloaded successfully.
FTP_QUEUE_FLAG_FAILED	Exclude files which where not successfully uploaded or downloaded. This flag is set when an error occurs, either when establishing a connection with the server or during the file transfer.
FTP_QUEUE_FLAG_CANCELED	Exclude files which were canceled during the file transfer. This flag is only set when the **FtpCancelQueuedFile** function has been called and a queued file is in the process of being uploaded or downloaded.

lpFileInfo

A pointer to a FTPQUEUEDFILE structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is an unsigned integer with a non-zero value which uniquely identifies the file in the queue. If there are no queued files which match the specified parameters, or the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function returns information about the first file in the current transfer queue. It is used in conjunction with the **FtpGetNextQueuedFile** function to obtain information about all queued files.

Example

```
// List all files in a file transfer queue
FTPQUEUEDFILE queuedFile;
DWORD dwFileId;

dwFileId = FtpGetFirstQueuedFile(hQueue, FTP_QUEUE_ALL, FTP_QUEUE_FLAG_NONE,
&queuedFile);

while (dwFileId != 0)
{
    switch (queuedFile.dwQueueMode)
    {
    case FTP_QUEUE_DOWNLOAD:
        _tprintf(_T("%u: download \"%s\" to \"%s\"\n"),
                 queuedFile.dwFileId,
                 queuedFile.szRemoteFile,
                 queuedFile.szLocalFile);
        break;

    case FTP_QUEUE_UPLOAD:
        _tprintf(_T("%u: upload \"%s\" to \"%s\"\n"),
                 queuedFile.dwFileId,
                 queuedFile.szRemoteFile,
                 queuedFile.szLocalFile);
        break;
    }

    dwFileId = FtpGetNextQueuedFile(hQueue, &queuedFile);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetIdleTimeout Function

```
INT WINAPI FtpGetIdleTimeout(
    HCLIENT hClient
);
```

The **FtpGetIdleTimeout** function returns the idle timeout period for the control channel.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetIdleTimeout** function returns the server-side idle timeout value that was most recently set for the control connection using the **FtpSetIdleTimeout** function. This value represents how long the server will wait during periods of inactivity before automatically closing the connection. If the idle timeout has not been explicitly set during the session, the function will return the default timeout value of 300 seconds (5 minutes).

The timeout value is only available if the server supports the non-standard `SITE IDLE` command. If the server does not support this command, this function will fail. In that case, the default timeout enforced by the server will apply, but the timeout period cannot be accessed or changed by the client. This function will also return an error if the session is using SFTP, as that protocol does not separate control and data channels and does not support idle timeout settings in the same way.

This function does not query the server for the current idle timeout value for the control channel. It simply returns the last known value that was successfully applied during the current session, if available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetLastError Function

```
DWORD WINAPI FtpGetLastError();
```

Parameters

None.

Return Value

The return value is the last error code value for the current thread. Functions set this value by calling the **FtpSetLastError** function. The Return Value section of each reference page notes the conditions under which the function sets the last error code.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. You should call the **FtpGetLastError** function immediately when a function's return value indicates that an error has occurred. That is because some functions call **FtpSetLastError**(0) when they succeed, clearing the error code set by the most recently failed function.

Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or FTP_ERROR. Those functions which call **FtpSetLastError** when they succeed are noted on the function reference page.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetMultipleFiles Function

```
INT WINAPI FtpGetMultipleFiles(
   HCLIENT hClient,
   LPCTSTR lpszLocalDirectory,
   LPCTSTR lpszRemoteDirectory,
   LPCTSTR lpszFileMask,
   DWORD dwReserved
);
```

The **FtpGetMultipleFiles** function copies one or more files from the server to the local host, using the specified wildcard.

Parameters

hClient

Handle to the client session.

lpszLocalDirectory

Pointer to a null-terminated string which specifies the local directory where the files will be downloaded to. The file pathing and name conventions should follow Windows conventions. It is permitted to include environment variables in the local path by surrounding the variable with percent (%) symbols. Local file paths may also use standard file URLs. A NULL pointer or empty string specifies that files should be copied to the current working directory.

lpszRemoteDirectory

Pointer to a null-terminated string which specifies the remote directory where the files will be downloaded from. A NULL pointer or empty string specifies that the files should be copied from the current working directory on the server.

lpszFileMask

Pointer to a string which specifies the files that are to be copied from the server to the local system. The file mask should follow the native conventions used for wildcard file matches on the server.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetMultipleFiles** function is used to transfer files from the server to the local host which match a specified wildcard file mask. This function requires that the client be able to automatically list and parse directory listings from the server, otherwise an error will be returned. All files will be transferred using the current file type as specified by the **FtpSetFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetNextFile Function

```
BOOL WINAPI FtpGetNextFile(
   HCLIENT hClient,
   LPFTPFILESTATUS lpFileStatus
);
```

The **FtpGetNextFile** function returns the next file in the directory listing returned by the server.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an FTPFILESTATUS structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetNextFile** function returns the next file in the directory listing. If the last file has been returned, the function will return zero and the client should call the **FtpCloseDirectory** function to close the directory.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)
{
    FTPFILESTATUS ftpFile;
    BOOL bResult;

    bResult = FtpGetFirstFile(hClient, &ftpFile);
    while (bResult)
    {
        // The ftpFile structure contains information about the file
        bResult = FtpGetNextFile(hClient, &ftpFile);
    }

    FtpCloseDirectory(hClient);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetNextFileEx Function

```
BOOL WINAPI FtpGetNextFileEx(
   HCLIENT hClient,
   LPFTPFILESTATUSEX lpFileStatus
);
```

The **FtpGetNextFileEx** function returns the next file in the directory listing returned by the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpFileStatus

A pointer to an FTPFILESTATUSEX structure which contains information about the file returned by the server.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetNextFileEx** function returns the next file in the directory listing. If the last file has been returned, the function will return zero and the client should call the **FtpCloseDirectory** function to close the directory.

Example

```
if (FtpOpenDirectory(hClient, _T("")) != FTP_ERROR)
{
    FTPFILESTATUSEX ftpFile;
    BOOL bResult;

    bResult = FtpGetFirstFileEx(hClient, &ftpFile);
    while (bResult)
    {
        // The ftpFile structure contains information about the file
        bResult = FtpGetNextFileEx(hClient, &ftpFile);
    }

    FtpCloseDirectory(hClient);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetNextQueuedFile Function

```
DWORD WINAPI FtpGetNextQueuedFile(
   HQUEUE hQueue,
   LPFTPQUEUEDFILE lpFileInfo
);
```

The **FtpGetNextQueuedFile** function returns information about the next file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpFileInfo

A pointer to a FTPQUEUEDFILE structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is an unsigned integer with a non-zero value which uniquely identifies the file in the queue. If there are no additional queued files which match the exclusion criteria specified with the call to **FtpGetFirstQueuedFile**, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function returns information about the next file in the current transfer queue after an initial call to **FtpGetFirstQueuedFile**. To obtain a list of all matching files in the queue, call this function repeatedly until it returns a value of zero. When information about the last file in the queue has been returned, the last error code will be set to `ST_ERROR_END_OF_QUEUE`.

Example

```
// List all files in a file transfer queue
FTPQUEUEDFILE queuedFile;
DWORD dwFileId;

dwFileId = FtpGetFirstQueuedFile(hQueue, FTP_QUEUE_ALL, FTP_QUEUE_FLAG_NONE,
&queuedFile);

while (dwFileId != 0)
{
    switch (queuedFile.dwQueueMode)
    {
    case FTP_QUEUE_DOWNLOAD:
        _tprintf(_T("%u: download \"%s\" to \"%s\"\n"),
                 queuedFile.dwFileId,
                 queuedFile.szRemoteFile,
                 queuedFile.szLocalFile);
        break;

    case FTP_QUEUE_UPLOAD:
        _tprintf(_T("%u: upload \"%s\" to \"%s\"\n"),
                 queuedFile.dwFileId,
                 queuedFile.szRemoteFile,
                 queuedFile.szLocalFile);
        break;
```

```
    }

    dwFileId = FtpGetNextQueuedFile(hQueue, &queuedFile);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetPriority Function

```
INT WINAPI FtpGetPriority(
   HCLIENT hClient
);
```

The **FtpGetPriority** function returns a value which specifies the priority of file transfers.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the current file transfer priority. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetPriority** function can be used to determine the current priority assigned to file transfers performed by the client. It may be one of the following values:

Value	Description
FTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpSetPriority

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetProxyType Function

```
INT WINAPI FtpGetProxyType(
   HCLIENT hClient
);
```

The **FtpGetProxyType** function returns the type of proxy that the client is connected to. By default, no proxy server is specified and this function returns a value of FTP_PROXY_NONE. For a list of possible proxy server types, refer to the **FtpProxyConnect** function.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value identifies the type of proxy that the client is connected to. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpConnect, FtpProxyConnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetQueueClient Function

```
HCLIENT WINAPI FtpGetQueueClient(
    HQUEUE hQueue
);
```

The **FtpGetQueueClient** function returns a handle to the current client session.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value a handle to a client session. If the function fails, it will return INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetQueueClient** function returns the handle to a client session which may be used with other functions, such as **FtpGetTransferStatus**. A valid handle will only be returned if the queue manager is currently uploading or downloading a file. If the queue is active but there are no file transfers in progress at the time this function is called, it will fail and set the last error code to `ST_ERROR_NO_QUEUED_TRANSFER`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetQueuedFile Function

```
BOOL WINAPI FtpGetQueuedFile(
   HQUEUE hQueue,
   DWORD dwFileId,
   LPFTPQUEUEDFILE lpFileInfo
);
```

The **FtpGetQueuedFile** function returns information about the specified file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. This value cannot be zero.

lpFileInfo

A pointer to a FTPQUEUEDFILE structure which will contain information about the file. This parameter cannot be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the file identifier is not valid or the file has been removed from the queue, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The file identifier can be obtained by several different functions, including **FtpEnumQueuedFiles** and **FtpGetQueueStatus,** which provides information about the current file being processed in the queue. Do not make any assumptions about the value of the identifier. Although the value is guaranteed to be unique for the specified queue, it is not guaranteed that file identifiers will be assigned in sequential order.

Example

```
// Get the number of files in the queue
LONG nFiles = FtpEnumQueuedFiles(hQueue, NULL, 0)

// Display information about the queued files
if (nFiles > 0)
{
    DWORD *pdwFileList = new DWORD[nFiles];

    nFiles = FtpEnumQueuedFiles(hQueue, pdwFileList, nFiles);

    for (LONG nIndex = 0; nIndex < nFiles; nIndex++)
    {
        FTPQUEUEDFILE queuedFile;

        if (FtpGetQueuedFile(hQueue, pdwFileList[nIndex], &queuedFile) == FALSE)
            break;

        switch (queuedFile.dwMode)
        {
        case FTP_QUEUE_DOWNLOAD:
```

```
                _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        queuedFile.dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                 break;

        case FTP_QUEUE_UPLOAD:
                _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        queuedFile.dwFileId,
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                 break;
        }
    }

    delete pdwFileList;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetQueueStatus Function

```
INT WINAPI FtpGetQueueStatus(
  HQUEUE hQueue,
  LPFTPQUEUESTATUS lpQueueStatus
);
```

The **FtpGetQueuedFile** function returns information about the specified file in the transfer queue.

Parameters

hQueue

A handle to a file transfer queue.

lpQueueStatus

A pointer to a FTPQUEUESTATUS structure which will contain information about the current state of the file transfer queue. If this parameter is NULL, the function will ignore the parameter and only return the current status of the queue.

Return Value

If the function succeeds, the return value is the current queue status. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**. The following status values may be returned:

Value	Description
FTP_QUEUE_STATUS_IDLE	The file transfer queue is idle and no files are being uploaded or downloaded. This state is returned before **FtpStartQueue** has been called or after **FtpStopQueue** has been called. The queue will also automatically enter an idle state after the last file transfer has completed and the queue manager thread exits.
FTP_QUEUE_STATUS_ACTIVE	The queue manager is active and files are currently being uploaded or downloaded.
FTP_QUEUE_STATUS_PAUSED	The queue manager is active although file transfers are currently paused. The queue enters this state after the **FtpSuspendQueue** function is called and resumes file transfers after the **FtpResumeQueue** function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetQueueThread Function

```
DWORD WINAPI FtpGetQueueThread(
    HQUEUE hQueue
);
```

The **FtpGetQueueThread** function returns a value which uniquely identifies the queue manager thread.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero and specifies a unique identifier for the queue manager thread. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetQueueThread** function can be used to obtain a unique identifier for the queue manager thread which is responsible for performing the file transfers. If the function returns zero, this indicates that either the queue handle is no longer valid, or the queue is idle and no files are currently being processed. To obtain the handle to a queue associated with a particular thread, call the **FtpGetThreadQueue** function.

You should not store the thread ID or consider it a persistent value, even during the lifetime of the process. It is only valid while the queue manager is actively processing files in the queue. The thread ID value will change every time the **FtpStartQueue** function is called.

Never use the thread ID to obtain a handle to the thread and call Windows API functions such as **SuspendThread** or **TerminateThread**. This can result inconsistency within the internal state of the queue manager and may result in incomplete or corrupted file transfers.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetResultCode Function

```
INT WINAPI FtpGetResultCode(
    HCLIENT hClient
);
```

The **FtpGetResultCode** function reads the result code returned by the server in response to a command. The result code is a three-digit numeric code, and indicates if the operation succeeded, failed or requires additional action by the client.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Result codes are three-digit numeric values returned by the server. They may be broken down into the following ranges:

Value	Description
100-199	Positive preliminary result. This indicates that the requested action is being initiated, and the client should expect another reply from the server before proceeding.
200-299	Positive completion result. This indicates that the server has successfully completed the requested action.
300-399	Positive intermediate result. This indicates that the requested action cannot complete until additional information is provided to the server.
400-499	Transient negative completion result. This indicates that the requested action did not take place, but the error condition is temporary and may be attempted again.
500-599	Permanent negative completion result. This indicates that the requested action did not take place.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetResultString Function

```
INT WINAPI FtpGetResultString(
   HCLIENT hClient,
   LPTSTR lpszResult,
   INT cbResult
);
```

The **FtpGetResultString** function returns the last message sent by the server along with the result code.

Parameters

hClient

Handle to the client session.

lpszResult

The buffer that will contain the result string returned by the server.

cbResult

The maximum number of characters that may be copied into the result string buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the length of the result string. If a value of zero is returned, this means that no result string was sent by the server.

If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetResultString** function is most useful when an error occurs because the server will typically include a brief description of the cause of the error. This can then be parsed by the application or displayed to the user. The result string is updated each time the client sends a command to the server and then calls **FtpGetResultCode** to obtain the result code for the operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetSecurityInformation Function

```
BOOL WINAPI FtpGetSecurityInformation(
   HCLIENT hClient,
   LPSECURITYINFO lpSecurityInfo
);
```

The **FtpGetSecurityInformation** function returns security protocol, encryption and certificate information about the current client connection.

Parameters

hClient

Handle to the client session.

lpSecurityInfo

A pointer to a SECURITYINFO structure which contains information about the current client connection. The *dwSize* member of this structure must be initialized to the size of the structure before passing the address of the structure to this function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to obtain security related information about the current client connection to the server. It can be used to determine if a secure connection has been established, what security protocol was selected, and information about the server certificate. Note that a secure connection has not been established, the *dwProtocol* structure member will contain the value SECURITY_PROTOCOL_NONE.

Example

The following example notifies the user if the connection is secure or not:

```
SECURITYINFO securityInfo;

securityInfo.dwSize = sizeof(SECURITYINFO);
if (FtpGetSecurityInformation(hClient, &securityInfo))
{
    if (securityInfo.dwProtocol == SECURITY_PROTOCOL_NONE)
    {
        MessageBox(NULL, _T("The connection is not secure"),
                         _T("Connection"), MB_OK);
    }
    else
    {
        if (securityInfo.dwCertStatus == SECURITY_CERTIFICATE_VALID)
        {
            MessageBox(NULL, _T("The connection is secure"),
                             _T("Connection"), MB_OK);
        }
        else
        {
            MessageBox(NULL, _T("The server certificate not valid"),
                             _T("Connection"), MB_OK);
        }
```

```
    }
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetSecurityZoneId Function

```
BOOL WINAPI FtpGetSecurityZoneId(
   LPCTSTR lpszResource,
   LPDWORD lpdwZoneId
);
```

The **FtpGetSecurityZoneId** function returns the security zone identifier for the specified resource.

Parameters

lpszResource

A null-terminated string which specifies the resource URL to check. This must be either a valid FTP URL or a local file URL.

lpdwZoneId

A pointer to an unsigned integer which is updated with the zone ID for the specified resource. It may be one of the following values when the function returns:

Value	Description
SECURITY_ZONE_NONE	The security zone for this resource cannot be determined.
SECURITY_ZONE_LOCAL	The resource is considered to be part of the local computer zone.
SECURITY_ZONE_INTRANET	The resource originates from the local intranet zone, such as an internal corporate network.
SECURITY_ZONE_TRUSTED	The resource originates from a site in the **Trusted Sites** zone.
SECURITY_ZONE_INTERNET	The resource originates from the Internet and is treated with caution by Windows.
SECURITY_ZONE_RESTRICTED	The resource originates from a site in the **Restricted Sites** zone, which is used for untrusted content.

Return Value

If the function succeeds, the return value is non-zero and ***lpdwZoneId*** will be updated with the zone identifier. If the security zone could not be determined, ***lpdwZoneId*** will be set to `SECURITY_ZONE_NONE`. If the function fails, it returns zero and the error code can be retrieved by calling **FtpGetLastError**.

Remarks

This **FtpGetSecurityZoneId** function is used to determine how a resource should be handled in terms of local security policy before performing a file transfer or download. For example, you may want to determine whether a resource originates from the Internet or local intranet before deciding whether to attach zone metadata, prompt the user, or apply additional security restrictions. It can also be used to implement policy-based rules for accepting or rejecting downloads based on their origin.

The ***lpszResource*** parameter must use the `ftp://`, `ftps://`, `ftpes://`, `sftp://` or `file://` schemes. This function will not accept URLs for other schemes such as `http://` or `https://`. While this function does not verify that the resource exists, it does require the URL to be syntatically valid. If the host name cannot be resolved to an IPv4 or IPv6 address, the function will fail. If the resource is a

local file, it must be a regular file and cannot be the name of a folder or device.

If the resource is specified using a `file://` URL that refers to a file on a network share (e.g.: `file://server/share/file.txt`), the function will attempt to access that file across the network. This may cause the application to block while Windows resolves the hostname and establishes a connection to the shared volume. If the network share is unavailable or slow to respond, the function may block until the connection succeeds or the attempt times out.

If this function returns FALSE, this indicates either the resource type is not supported or there was an internal failure when the Internet Security Manager attempted to map the resource URL to a security zone. In most default configurations, this function will return the zone `SECURITY_ZONE_INTERNET` for a valid URL unless the host has been explicitly added to the **Intranet Zone** or **Trusted Sites** list on the local system.

Security zones are used with Mark of the Web (MOTW) metadata which indicates if a file originated from an external source, such as the Internet or an untrusted network. When a file is downloaded using a web browser or other applications, it may add a `Zone.Identifier` alternate data stream to the file. This stream contains information such as `ZoneId=3`, which corresponds to the Internet Zone. Your application can use the **FtpGetFileZoneInfo** function to retrieve this information, which allows you to determine whether a file was downloaded from an external source and what zone Windows has associated with it. This metadata affects how files are handled by Windows security components such as Microsoft Defender, SmartScreen, Office Protected View, and script execution policies in Windows Explorer. If the file has no metadata, it is generally treated as coming from the Local Machine Zone (zone 0). If your application sets or clears this metadata using the **FtpSetFileZoneInfo** function, it can influence how other applications interpret the file's trust level.

It is important to note that this function is used to determine what security zone would be appropriate for a given resource, and it only performs syntactic checks and classification of the URL using the **IInternetSecurityManager** COM interface. The security zone this function returns is based on the current system and user policy, using zone assignments stored in the registry. Typically this information is managed using Windows settings or Internet options in the control panel. This function does not read the zone identifier metadata which has been assigned to a file.

For more detailed information about the zone identifiers, refer to the **FtpSetDefaultZoneId** function.

Example

```
LPCTSTR pszDownloadUrl = _T("ftp://example.com/pub/download/file.txt");
DWORD dwZoneId = SECURITY_ZONE_NONE;

if (FtpGetSecurityZoneId(pszDownloadUrl, &dwZoneId))
{
    // dwZoneId now contains SECURITY_ZONE_INTERNET
    _tprintf(_T("The security zone is: %u\n"), dwZoneId);
}
else
{
    DWORD dwError = FtpGetLastError();
    // Handle the error
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpGetServerInformation Function

```
INT WINAPI FtpGetServerInformation(
   HCLIENT hClient,
   LPTSTR lpszSystemInfo,
   INT nMaxLength
);
```

The **FtpGetServerInformation** function returns information about the server, typically including the operating system type, version and platform.

Parameters

hClient

Handle to the client session.

lpszSystemInfo

The buffer that will contain the system information returned by the server.

nMaxLength

The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SYST command to the server. The first word will identify the type of operating system. The format for the remaining information depends on the server type. Typically it is a description of the operating system version and hardware platform. For example, here are some strings commonly returned by various FTP servers:

Example	Description
UNIX Type: L8	A standard UNIX based server. This is the most common value returned by servers, and this indicates that the server supports UNIX file naming and directory listing conventions. This string may also include additional information such as the specific variant of UNIX and its version. The L8 portion of the string is a convention that lets the client know that a byte consists of 8 bits.
Windows_NT Version 5.0	A standard Windows based server, typically part of Internet Information Services (ISS). The server will use Windows file naming and directory listing conventions. The version identifies the specific release of Windows. For example, version 4.0 specifies Windows NT 4.0 and 5.0 specifies Windows 2000.
VMS V7.1 AlphaServer	A server running the VMS operating system. The server will use the standard file naming and directory listing conventions for that platform. Note that it is possible that a VMS system may also be configured to operate in a UNIX emulation mode, in which case it will return UNIX instead of VMS.
Netware	A server running the Netware operating system. The server will use the

system type	standard file naming and directory listing conventions for that platform. Note that it is possible that a Netware system may be configured to operate in a UNIX emulation mode, in which case it return UNIX instead of Netware.
WORLDGROUP Type: L8	A server running the WorldGroup software on the Windows platform. This server supports UNIX file naming and directory listing conventions. WorldGroup is a collaborative workgroup, email and file sharing service which includes an FTP server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpGetServerStatus Function

```
INT WINAPI FtpGetServerStatus(
   HCLIENT hClient,
   LPTSTR lpszStatus,
   INT nMaxLength
);
```

The **FtpGetServerStatus** function requests that the server return status information about itself.

Parameters

hClient

Handle to the client session.

lpszStatus

The buffer that will contain the system status returned by the server.

nMaxLength

The maximum number of characters that can be copied into the buffer, including the terminating null character.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the STAT command to the server. The format for the information returned depends on the server type. Typically it is a description of the server platform, version, current user and file transfer options.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetServerTimeZone Function

```
INT WINAPI FtpGetServerTimeZone(
   HCLIENT hClient,
   LPLONG lpnTimeZone
);
```

The **FtpGetServerTimeZone** function returns the timezone for the current server.

Parameters

hClient

Handle to the client session.

lpnTimeZone

A pointer to a signed long integer which will contain the timezone offset in seconds.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SITE ZONE command to the server to determine its timezone. The value returned is expressed as the number of seconds offset from Coordinated Universal Time (UTC). A positive value specifies a time west of UTC, while a negative value specifies a time east of UTC. For example, a value of 28800 would specify an offset of 8 hours west of UTC, which is the Pacific timezone.

The SIZE ZONE command is an extension that is not supported by all servers. If the server timezone cannot be determined, the function will fail and the value pointed to by the ***lpnTimeZone*** parameter will be zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetServerType Function

```
INT WINAPI FtpGetServerType(
    HCLIENT hClient
);
```

The **FtpGetServerType** function returns the type of server the client has connected to.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is a numeric value which indicates the server type. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SYST command to the server to determine the server type. The following server types are recognized by the library:

Value	Description
FTP_SERVER_UNKNOWN	The server type could not be determined by issuing the SYST command. The server may not support the command, or the command may only be allowed when issued by an authenticated user.
FTP_SERVER_UNIX	The server is running on a UNIX based operating system. This can include Linux and other variants, as well as operating systems which emulate UNIX style file pathing and directory listings.
FTP_SERVER_MSDOS	The server is running on an MS-DOS based operating system. The server expects file pathing and naming conventions according to the standard MS-DOS format and returns directory listings similar to the output of the DIR command.
FTP_SERVER_WINDOWS	The server is running on a Windows based operating system. The server expects file pathing and naming conventions according to the standard Windows long filename format, and returns directory listings similar to the output of the DIR command. Note that Windows servers may be configured to return file and directory information in a format similar to UNIX systems, in which case the system may be identified as UNIX even though it is actually running on a Windows platform.
FTP_SERVER_VMS	The server is running on a DEC VMS based operating system. The server expects file pathing and naming conventions specific to that operating system. Note that VMS servers may be configured to return file and directory information in a format similar to UNIX systems, in which case the system may be identified as UNIX even though it is actually running on a VMS platform.

FTP_SERVER_NETWARE	The server is running on a Netware based operating system. The server expects file pathing and naming conventions similar to the standard Windows long filename format, and returns directory listings that are similar to UNIX systems with the exception of the access and permissions flags for the file. Note that a Netware system may return listings in different formats based on the filesystem and site specific options specified.
FTP_SERVER_OTHER	The server type was not recognized. An attempt will be made to automatically determine the correct file pathing and naming conventions used by the server. To obtain a list of files on the server, it may be necessary to use the **FtpSetDirectoryFormat** function to specify the directory listing format.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetStatus Function

```
INT WINAPI FtpGetStatus(
   HCLIENT hClient
);
```

The **FtpGetStatus** function returns the current status of the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the client status code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetStatus** function returns a numeric code which identifies the current state of the client session. The following values may be returned:

Value	Description
FTP_STATUS_IDLE	The client is current idle and not sending or receiving data.
FTP_STATUS_CONNECT	The client is establishing a connection with the server.
FTP_STATUS_READ	The client is reading data from the server.
FTP_STATUS_WRITE	The client is writing data to the server.
FTP_STATUS_DISCONNECT	The client is disconnecting from the server.
FTP_STATUS_OPENFILE	The client is opening a data connection to the server.
FTP_STATUS_CLOSEFILE	The client is closing the data connection to the server.
FTP_STATUS_GETFILE	The client is downloading a file from the server.
FTP_STATUS_PUTFILE	The client is uploading a file to the server.
FTP_STATUS_FILELIST	The client is retrieving a file listing from the server.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session. To obtain status information about a file transfer, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetTaskError Function

```
DWORD WINAPI FtpGetTaskError(
    UINT nTaskId
);
```

Return the last error code for the specified asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed successfully, this function returns a value of zero. A non-zero return value indicates an error has occurred.

Remarks

The **FtpGetTaskError** function returns the last error code associated with the specified asynchronous task. If the task completed successfully, the return value will be zero. If the task is still active, the function will return the error ST_ERROR_TASK_ACTIVE. If the task has been suspended, the function will return ST_ERROR_TASK_SUSPENDED. Any other value indicates that the task completed, but the operation has failed and the error code will specify the cause of the failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpTaskAbort, FtpTaskResume, FtpTaskSuspend, FtpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetTaskId Function

```
UINT WINAPI FtpGetTaskId(
   HCLIENT hClient
);
```

Return the asynchronous task identifier associated with the client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is non-zero integer value that specifies a unique asynchronous task identifier. If the client handle is not associated with an asynchronous task, the function will return a value of zero.

Remarks

The **FtpGetTaskId** function will return the task ID that is associated with a client session. This is a unique unsigned integer value that references the worker thread that was created to manage the asynchronous client session. This function should only be called within an event handler that is invoked by a background task that has been started using a function such as **FtpAsyncGetFile**.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpTaskAbort, FtpTaskDone, FtpTaskResume, FtpTaskSuspend, FtpTaskWait

FtpGetText Function

```
INT WINAPI FtpGetText(
   HCLIENT hClient,
   LPCTSTR lpszRemoteFile,
   LPTSTR lpszBuffer,
   INT nMaxLength
);
```

The **FtpGetText** function copies the contents of a text file on the server to the specified string buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A null-terminated string that specifies a text file on the server. The file pathing and naming conventions must be that of the host operating system.

lpszBuffer

A null-terminated string buffer which will contain the contents of the text file when the function returns. This buffer should be large enough to store the contents of the file, including a terminating null character. This parameter cannot be NULL.

nMaxLength

An integer value that specifies the maximum number of characters that can be copied into the string buffer. This value must be larger than zero. If this value is smaller than the actual size of the text file, the data returned will be truncated.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetText** function is used to download a text file and store the contents in a string buffer. This function will always set the file type to FILE_TYPE_ASCII before downloading the file, and will restore the default file type before the method returns. Because binary files can include embedded null characters, this function should only be used with known text files.

This function has been included as a convenience for applications that need to retrieve relatively small text files and manipulate the contents as a string. If the Unicode version of this function is called, the contents of the text file is automatically converted to a Unicode string. If the size of the file is unknown or the text file is very large, it is recommended that you use the **FtpGetData** or **FtpGetFile** functions.

If you use the **FtpGetFileSize** function to determine how large the string buffer should be prior to calling this function, it is important to be aware that the actual number of characters may differ based on the end-of-line conventions used by the host operating system. For example, if you call **FtpGetFileSize** to obtain the size of a text file on a UNIX system, the value will not be large enough to store the complete file because UNIX uses a single linefeed (LF) character to indicate the end-of-line, while a Windows system will use a carriage-return and linefeed (CRLF) pair. To accommodate this difference, you should always allocate extra memory for the string buffer to store the additional end-of-line characters.

FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Example

```
LPTSTR lpszBuffer = (LPTSTR)calloc(MAXFILESIZE, sizeof(TCHAR));

if (lpszBuffer == NULL)
    return;

nResult = FtpGetText(hClient, lpszRemoteFile, lpszBuffer, MAXFILESIZE);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpChangeDirectory, FtpEnableEvents, FtpGetData, FtpGetFile, FtpGetTransferStatus, FtpPutData, FtpPutFile, FtpRegisterEvent, FtpSetBufferSize

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetThreadQueue Function

```
HQUEUE WINAPI FtpGetThreadQueue(
    DWORD dwThreadId
);
```

The **FtpGetThreadQueue** function returns a handle to the queue associated with the specified thread.

Parameters

dwThreadId

An unsigned integer value which specifies a unique identifier for the queue manager thread. If this value is zero, it will return the handle associated with the current thread.

Return Value

If the function succeeds, the return value is the handle to the queue. If the function fails, it will return INVAID_QUEUE. To get extended error information, call **FtpGetLastError**.

Remarks

All queued file transfers are handled by a queue manager which executes asynchronously in a background worker thread. This worker thread is created when the **FtpStartQueue** function is called and terminates when all files in the queue have been processed, or when the **FtpStopQueue** function is called. This function will return the queue handle associated with that worker thread.

The most common use of this function would be to obtain the handle for the queue from within a queue event handler. The application would pass in a value of zero as the thread ID and the function will return the handle to the queue which invoked the event notification.

If you call this function outside of an event handler and the ***dwThreadId*** parameter is zero, or if the queue is idle and not transferring files, this function will return INVALID_QUEUE. The thread ID is only valid while the queue manager is actively processing files in the queue.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetQueueStatus, FtpGetQueueThread, FtpStartQueue, FtpStopQueue

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpGetTimeout Function

```
INT WINAPI FtpGetTimeout(
   HCLIENT hClient
);
```

The **FtpGetTimeout** function returns the number of seconds the client will wait for a response from the server.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the timeout period in seconds. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. Once the specified number of seconds has elapsed, the blocking method will fail and return to the caller. The timeout value affects both commands issued on the control channel and file transfers using the data channel. The initial timeout value is set when establishing a connection and the default timeout period is 20 seconds.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpGetTransferStatus Function

```
INT WINAPI FtpGetTransferStatus(
   HCLIENT hClient,
   LPFTPTRANSFERSTATUS lpStatus
);
```

The **FtpGetTransferStatus** function returns information about the current file transfer in progress.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an **FTPTRANSFERSTATUS** structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetTransferStatus** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option FTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the **FTPTRANSFERSTATUS** structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small files over a fast network connection.

If you are uploading or downloading large files which exceed 4GB, you should use the **FtpGetTransferStatusEx** function which returns the size as a 64-bit value.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetTransferStatusEx Function

```
INT WINAPI FtpGetTransferStatusEx(
   HCLIENT hClient,
   LPFTPTRANSFERSTATUS lpStatus
);
```

The **FtpGetTransferStatusEx** function returns information about the current file transfer in progress. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpStatus

A pointer to an FTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpGetTransferStatusEx** function returns information about the current file transfer, including the average number of bytes transferred per second and the estimated amount of time until the transfer completes. If there is no file currently being transferred, this function will return the status of the last successful transfer made by the client.

In a multithreaded application, any thread in the current process may call this function to obtain status information for the specified client session.

If the option FTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values of the *dwTimeElapsed* and *dwTimeEstimated* members of the **FTPTRANSFERSTATUSEX** structure will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small files over a fast network connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpInitialize Function

```
BOOL WINAPI FtpInitialize(
   LPCTSTR lpszLicenseKey,
   LPVOID lpvReserved
);
```

The **FtpInitialize** function initializes the library and validates the specified license key at runtime.

Parameters

lpszLicenseKey

Pointer to a string that specifies the runtime license key to be validated. If this parameter is NULL, the library will validate the development license installed on the local system.

lpvReserved

A reserved parameter. This value should always be NULL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**. All other client functions will fail until a license key has been successfully validated.

Remarks

This must be the first function that an application calls before using any of the other functions in the library. When a NULL license key is specified, the library will only function on the development system. Before redistributing the application to an end-user, you must ensure that this function is called with a valid license key.

The *lpvReserved* parameter is maintained for backward compatibility and should always be NULL. Applications should not pass a valid pointer or reference for this parameter. For languages that do not use C-style pointers, you can typically pass a value of zero for this parameter.

Although it is only required that **FtpInitialize** be called once for the current process, it may be called multiple times; however, each call must be matched by a corresponding call to **FtpUninitialize**.

This function dynamically loads other system libraries and allocates thread local storage. If you are calling the functions in this library from within another DLL, it is important that you do not call the **FtpInitialize** or **FtpUninitialize** functions from the **DllMain** function because it can result in deadlocks or access violation errors. If the DLL is linked with the C runtime library (CRT), it will automatically call the constructors and destructors for static and global C++ objects and has the same restrictions.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpConnect, FtpDisconnect, FtpUninitialize

FtpIsBlocking Function

```
BOOL WINAPI FtpIsBlocking(
   HCLIENT hClient
);
```

The **FtpIsBlocking** function is used to determine if the client is currently performing a blocking operation.

Parameters

hClient

Handle to the client session.

Return Value

If the client is performing a blocking operation, the function returns a non-zero value. If the client is not performing a blocking operation, or the client handle is invalid, the function returns zero.

Remarks

Because a blocking operation can allow the application to be re-entered (for example, by pressing a button while the operation is being performed), it is possible that another blocking function may be called while it is in progress. Since only one thread of execution may perform a blocking operation at any one time, an error would occur. The **FtpIsBlocking** function can be used to determine if the client is already blocked, and if so, take some other action (such as warning the user that they must wait for the operation to complete).

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpIsConnected Function

```
BOOL WINAPI FtpIsConnected(
   HCLIENT hClient
);
```

The **FtpIsConnected** function is used to determine if the client is currently connected to a server.

Parameters

hClient

Handle to the client session.

Return Value

If the client is connected to a server, the function returns a non-zero value. If the client is not connected, or the client handle is invalid, the function returns zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetStatus, FtpIsBlocking, FtpIsReadable, FtpIsWritable

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpIsReadable Function

```
BOOL WINAPI FtpIsReadable(
   HCLIENT hClient,
   INT nTimeout,
   LPDWORD lpdwAvail
);
```

The **FtpIsReadable** function is used to determine if data is available to be read from the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

lpdwAvail

A pointer to an unsigned integer which will contain the number of bytes available to read. This parameter may be NULL if this information is not required.

Return Value

If the client can read data from the server within the specified timeout period, the function returns a non-zero value. If the client cannot read any data, the function returns zero.

Remarks

On some platforms, this value will not exceed the size of the receive buffer (typically 64K bytes). Because of differences between TCP/IP stack implementations, it is not recommended that your application exclusively depend on this value to determine the exact number of bytes available. Instead, it should be used as a general indicator that there is data available to be read.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpGetStatus, FtpIsBlocking, FtpIsConnected, FtpIsWritable, FtpRead

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpIsWritable Function

```
BOOL WINAPI FtpIsWritable(
   HCLIENT hClient,
   INT nTimeout
);
```

The **FtpIsWritable** function is used to determine if data can be written to the server.

Parameters

hClient

Handle to the client session.

nTimeout

Timeout for server response, in seconds. A value of zero specifies that the connection should be polled without blocking the current thread.

Return Value

If the client can write data to the server within the specified timeout period, the function returns a non-zero value. If the client cannot write any data, the function returns zero.

Remarks

Although this function can be used to determine if some amount of data can be sent to the remote process it does not indicate the amount of data that can be written without blocking the client. In most cases, it is recommended that large amounts of data be broken into smaller logical blocks, typically some multiple of 512 bytes in length.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpLogin Function

```
INT WINAPI FtpLogin(
   HCLIENT hClient,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszAccount
);
```

The **FtpLogin** function authenticates the specified user in on the server. This function must be called after the connection has been established, and before attempting to transfer files or perform any other function on the server.

Parameters

hClient

Handle to the client session.

lpszUserName

Points to a string that specifies the user name to be used to authenticate the current client session. If this parameter is NULL or an empty string, then the login is considered to be anonymous.

lpszPassword

Points to a string that specifies the password to be used to authenticate the current client session. This parameter may be NULL or an empty string if no password is required for the specified user, or if no username has been specified.

lpszAccount

Points to a string that specifies the account name to be used to authenticate the current client session. This parameter may be NULL or an empty string if no account name is required for the specified user.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Some public FTP servers support anonymous logins, where a username and password are not required to access the server. In this case, both the *lpszUserName* and *lpszPassword* parameters can be NULL or specify empty strings. In most cases, access to the server using an anonymous login is restricted, with clients only having permission to download files. Servers may also restrict the maximum number of anonymous sessions that may be logged in at one time.

This function should only be used after calling the **FtpLogout** function, enabling you to log in as another user during the same session. Not all servers will permit a client to change user credentials during the same session. In most cases, it is preferable to disconnect from the server and re-connect using the new credentials rather than using this function.

This function is not supported with secure connections using the SSH protocol.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpConnect, FtpLogout, FtpProxyConnect

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpLogout Function

```
INT WINAPI FtpLogout(
   HCLIENT hClient
);
```

The **FtpLogout** function logs out the user associated with the current client session.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpLogout** function is used when the client wants to re-authenticate using a new username and password. Before any further action may be taken, other than disconnecting from the server, the **FtpLogin** function must be called to re-authenticate the client.

It is not necessary to call this function prior to disconnecting from the server because the user current user is automatically logged out when the **FtpDisconnect** function is called.

This function is not supported with secure connections using the SSH protocol.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpMountStructure Function

```
INT WINAPI FtpMountStructure(
   HCLIENT hClient,
   LPCTSTR lpszFileSystem
);
```

The **FtpMountStructure** function mounts a different file system or other directory data structure on the server.

Parameters

hClient

Handle to the client session.

lpszFileSystem

A null-terminated string which specifies the file system to mount on the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function sends the SMNT command to the server, which may not be supported on some platforms. Use of this command typically requires that the user have administrator privileges on the server.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpNormalizePath Function

```
INT WINAPI FtpNormalizePath(
   HCLIENT hClient,
   LPCTSTR lpszFilePath,
   LPTSTR lpszNormalized,
   INT nMaxLength
);
```

The **FtpNormalizePath** function normalizes a file path on the server using the current client connection.

Parameters

hClient

A handle to the client session. This parameter may be INVALID_CLIENT to normalize the path without using the current working directory on the server.

lpszFilePath

A null-terminated string which specifies a file path on the server. This parameter cannot be NULL.

lpszNormalized

A null-terminated string buffer which will contain the normalized path when the function returns. The buffer must be large enough to contain the entire path including the terminating null character. If this parameter is NULL it will be ignored and the function will return the length of the normalized path without copying any characters.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer. If this value is zero, the ***lpszNormalized*** parameter is ignored and the function will return the length of the normalized path without copying any characters.

Return Value

This function returns the number of characters copied into the string buffer, not including the terminating null character. If the ***lpszNormalized*** parameter is NULL, it will return the length of the normalized path but will not copy any characters. If the function fails, it will return FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will accept a relative or absolute file path on the server and return a normalized version of that path. Normalization will remove extraneous path delimiters and collapse the path if there are references to parent directories. For example, if the current working directory for the user is `/home/jsmith` and the file path provided is:

```
./text/..//data//./files/filename.txt
```

This function would return the following as the normalized path:

```
/home/jsmith/data/files/filename.txt
```

Because the path is relative, the current working directory for the client would be used to create an absolute path. The extraneous path delimiters are removed (the double slashes) and the reference to the parent directory is collapsed to produce a simple, uniform path. This can be useful both for display purposes and to normalize input provided by a user.

If the ***hClient*** parameter is INVALID_CLIENT (in other words, there is no active connection to a server),

relative file paths will not be normalized as absolute paths because there is no current working directory available. This allows the function to be used without an active connection, removing any extraneous path delimiters and collapsing the path without returning an absolute path unless one was provided.

If the path specified by the ***lpszFilePath*** parameter is relative to the current directory and a client handle is not provided, the normalized path returned by the function will always be relative. For example, if the path provided is:

```
../../../../../data/filename.txt
```

This function would return the following as the normalized path:

```
data/filename.txt
```

Because the original path was relative, the normalized path is also relative and will not begin with a leading path delimiter. It is intentionally designed this way to prevent the path from "escaping" to the root directory of a file system, which can present a security risk. If the original path was absolute, the normalized path would also be absolute.

This function will accept an FTP URL and return only the normalized path and file name potion of the URL. If you need to normalize a complete URL, use the **FtpNormalizeUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpGetFilePathUrl, FtpNormalizeUrl, FtpValidateHostName FtpValidateUrl

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpNormalizeUrl Function

```
INT WINAPI FtpNormalizeUrl(
   LPCTSTR lpszUrl,
   LPTSTR lpszNormalized,
   INT nMaxLength
);
```

The **FtpNormalizeUrl** function normalizes the file path and returns a canonical URL.

Parameters

lpszUrl

A null-terminated string which specifies an FTP URL. This parameter cannot be NULL.

lpszNormalized

A null-terminated string buffer which will contain the normalized URL when the function returns. The buffer must be large enough to contain the entire URL including the terminating null character. If this parameter is NULL it will be ignored and the function will return the length of the normalized URL without copying any characters.

nMaxLength

An integer value which specifies the maximum number of characters which can be copied into the string buffer. If this value is zero, the ***lpszNormalized*** parameter is ignored and the function will return the length of the normalized URL without copying any characters.

Return Value

This function returns the number of characters copied into the string buffer, not including the terminating null character. If the ***lpszNormalized*** parameter is NULL, it will return the length of the normalized URL but will not copy any characters. If the function fails, it will return FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will accept a standard FTP, FTPS or SFTP URL and return a canonical version of that URL. Normalization will remove extraneous path delimiters and collapse the path if there are references to parent directories. If non-standard port numbers are included in the URL, they will be preserved. For example, if the follwing URL is provided to the function:

```
ftps://ftp.example.com:21/file/..//data/filename.txt
```

It will return the following as the normalized URL:

```
ftpes://ftp.example.com/data/filename.txt
```

Because the original URL specified a secure connection on port 21, this is inferred to mean the connection will use explicit TLS and not an implicit connection. This is why the scheme is changed from `ftps://` to `ftpes://` and the port number is removed, since port 21 is the default port for an explicit TLS connection. In addition, the path is collapsed and the extraneous path delimiters are removed.

This function is primarily intended to normalize URLs which may be entered by a user or read from a configuration file. It is not necessary to call this function prior to calling **FtpConnectUrl** because it will always be normalized internally prior to the connection being established. If you wish to check a URL to ensure it is valid and the server name can be resolved to an IP address, use the **FtpValidateUrl** function.

If you need to normalize a remote file path, use the **FtpNormalizePath** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpOpenDirectory Function

```
INT WINAPI FtpOpenDirectory(
   HCLIENT hClient,
   LPCTSTR lpszDirectory
);
```

The **FtpOpenDirectory** function opens the specified directory on the server.

Parameters

hClient

Handle to the client session.

lpszDirectory

Pointer to the name of the directory that will be opened. The format of the directory name must match the filename conventions used by the server. If a NULL pointer or an empty string is specified, then the current working directory is opened.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpOpenDirectory** function opens the specified directory on the server using the LIST command. The contents of the directory can be read using the **FtpGetFirstFile** and **FtpGetNextFile** functions. The directory listing is returned on the data channel in one of several different formats. The library can recognize listing formats generated by UNIX, VMS and Windows servers, as well as those of other servers which emulate one of those common formats. Once the complete directory listing has been read, the directory must be closed by calling the **FtpCloseDirectory** function.

Because the directory listing is returned on the data channel, a file transfer cannot be performed while the directory is in the process of being read by the client. Applications which need to collect a list of files to download should first open the directory, read the contents and store the file names in an array. After the directory has been closed, the application can then start transferring the files to the local system.

Some servers may not support file listings for any directory other than the current working directory. If an error is returned when specifying a directory name, try changing the current working directory using the **FtpChangeDirectory** function and then call this function again, passing NULL or an empty string as the *lpszDirectory* parameter.

To obtain a list of all files in a directory using a single function call, use the **FtpEnumFiles** function. If the server lists files in a format that is not recognized by the library, the **FtpGetFileList** function can be used to obtain an unparsed file listing from the server.

Example

```
if (FtpOpenDirectory(hClient, NULL) != FTP_ERROR)
{
    FTPFILESTATUS ftpFile;
    BOOL bResult;

    bResult = FtpGetFirstFile(hClient, &ftpFile);
    while (bResult)
```

```
    {
        // The ftpFile structure contains information about the file
        bResult = FtpGetNextFile(hClient, &ftpFile);
    }

    FtpCloseDirectory(hClient);
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpOpenFile Function

```
INT WINAPI FtpOpenFile(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   DWORD dwOpenMode,
   DWORD dwOffset
);
```

The **FtpOpenFile** function creates or opens the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to create or open. The file pathing and name conventions must be that of the server.

dwOpenMode

Specifies the type of access to the file. An application can open a file for reading, create a new file or append data to an existing file. This parameter should be one of the following values.

Value	Description
FTP_FILE_READ	The file is opened for reading on the server. A data channel is created and the contents of the file are returned to the client.
FTP_FILE_WRITE	The file is opened for writing on the server. If the file does not exist, it will be created. If it does exist, it will be overwritten.
FTP_FILE_APPEND	The file is opened for writing on the server. All data will be appended to the end of the file.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset using FTP requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Attempting to perform an action such as uploading or downloading another file while a file is currently open will result in an error. Typically this indicates that the application failed to call the **FtpCloseFile** function.

It is strongly recommended that most applications use the **FtpGetFile** or **FtpPutFile** functions to perform file transfers. These functions are easier to use, and have internal optimizations that improves the overall data transfer rate when compared to implementing the file transfer code in your own application.

When a file is created on the server, the file ownership and access rights are determined by the server. Some servers may provide a method to change these attributes through site-specific commands. Refer to the server's operating system documentation for more information about what commands may be available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpOpenFileEx Function

```
INT WINAPI FtpOpenFileEx(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   DWORD dwOpenMode,
   DWORD dwReserved,
   ULARGE_INTEGER uiOffset
);
```

The **FtpOpenFileEx** function creates or opens the specified file on the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file to create or open. The file pathing and name conventions must be that of the server.

dwOpenMode

Specifies the type of access to the file. An application can open a file for reading, create a new file or append data to an existing file. This parameter should be one of the following values.

Value	Description
FTP_FILE_READ	The file is opened for reading on the server. A data channel is created and the contents of the file are returned to the client.
FTP_FILE_WRITE	The file is opened for writing on the server. If the file does not exist, it will be created. If it does exist, it will be overwritten.
FTP_FILE_APPEND	The file is opened for writing on the server. All data will be appended to the end of the file.

dwReserved

An unsigned integer value that is reserved for future use. This parameter should always have a value of zero.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset using FTP requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

Only one file may be opened at a time for each client session. Attempting to perform an action such as uploading or downloading another file while a file is currently open will result in an error. Typically this indicates that the application failed to call the **FtpCloseFile** function.

It is strongly recommended that most applications use the **FtpGetFileEx** or **FtpPutFileEx** functions to perform file transfers. These functions are easier to use, and have internal optimizations that improves the overall data transfer rate when compared to implementing the file transfer code in your own application.

When a file is created on the server, the file ownership and access rights are determined by the server. Some servers may provide a method to change these attributes through site-specific commands. Refer to the server's operating system documentation for more information about what commands may be available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpProxyConnect Function

```
HCLIENT WINAPI FtpProxyConnect(
   UINT nProxyType,
   LPCTSTR lpszProxyHost,
   UINT nProxyPort,
   LPCTSTR lpszProxyUser,
   LPCTSTR lpszProxyPassword,
   LPCTSTR lpszRemoteHost,
   UINT nTimeout,
   DWORD dwOptions,
   LPSECURITYCREDENTIALS lpCredentials
);
```

The **FtpProxyConnect** function establishes a connection through a proxy server.

Parameters

nProxyType

An identifier which specifies the type of proxy server that is being connected to. This value must be defined as one of the following values:

Value	Description
FTP_PROXY_NONE	This value specifies that no proxy server is being used. In this case, the **FtpConnect** function is called directly, ignoring the proxy parameters.
FTP_PROXY_USER	This value specifies that the client is not logged into the proxy server. The USER command is sent in the format username@ftpsite followed by the password. This is the format used with the Gauntlet proxy server.
FTP_PROXY_LOGIN	This value specifies that the client is logged into the proxy server. The USER command is then sent in the format username@ftpsite followed by the password. This is the format used by the InterLock proxy server.
FTP_PROXY_OPEN	This value specifies that the client is not logged into the proxy server. The OPEN command is sent specifying the host name, followed by the username and password.
FTP_PROXY_SITE	This value specifies that the client is logged into the server. The SITE command is sent, specifying the host name, followed by the username and the password.
FTP_PROXY_OTHER	This special proxy type specifies that another, undefined proxy server is being used. The client connects to the proxy host, but does not attempt to authenticate the client. The application is responsible for negotiating with the proxy server, typically using the FtpCommand function to send specific command sequences.

lpszProxyHost

The name of the proxy server to connect through; this may be a fully-qualified domain name or an IP address.

nProxyPort

The port number the proxy server is listening on; a value of zero specifies that the default port number should be used.

lpszProxyUser

The user name used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a username is required.

lpszProxyPassword

The password used to authenticate the client on the proxy server. Not all proxy servers require this information; it is recommended that you consult the proxy server documentation to determine if a password is required.

lpszRemoteHost

The name of the server that you want to connect to, through the proxy server.

nTimeout

The number of seconds that the client will wait for a response from the server before failing the current operation.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_NOAUTH	This option specifies the server does not require

	authentication, or that it requires an alternate authentication method. When this option is used, the client connection is flagged as authenticated as soon as the connection to the server has been established. Note that using this option to bypass authentication may result in subsequent errors when attempting to retrieve a directory listing or transfer a file. It is recommended that you consult the technical reference documentation for the server to determine its specific authentication requirements.
FTP_OPTION_KEEPALIVE	This option specifies the client should attempt to keep the connection with the server active for an extended period of time. It is important to note that regardless of this option, the server may still choose to disconnect client sessions that are holding the command channel open but are not performing file transfers.
FTP_OPTION_VIRTUALHOST	This option specifies the server supports virtual hosting, where multiple domains are hosted by a server using the same external IP address. If this option is enabled, the client will send the HOST command to the server upon establishing a connection.
FTP_OPTION_VERIFY	This option specifies that file transfers should be automatically verified after the transfer has completed. If the server supports the XMD5 command, the transfer will be verified by calculating an MD5 hash of the file contents. If the server does not support the XMD5 command, but does support the XCRC command, the transfer will be verified by calculating a CRC32 checksum of the file contents. If neither the XMD5 or XCRC commands are supported, the transfer is verified by comparing the size of the file. Automatic file verification is only performed for binary mode transfers because of the end-of-line conversion that may occur when text files are uploaded or downloaded.
FTP_OPTION_TRUSTEDSITE	This option specifies the server is trusted. The server certificate will not be validated and the connection will always be permitted. This option only affects connections using the TLS protocol.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. This option is the same as specifying FTP_OPTION_SECURE_IMPLICIT which immediately performs the TLS protocol negotiation when the connection is established.
FTP_OPTION_SECURE_IMPLICIT	This option specifies the client should attempt to immediately establish secure TLS connection with the server. This option is typically used when connecting to

	a server on port 990, which is the default port number used for FTPS.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should establish a standard connection to the server and then use the AUTH command to negotiate an explicit secure connection. This option is typically used when connecting to the server on ports other than 990.
FTP_OPTION_SECURE_FALLBACK	This option specifies the client should permit the use of less secure cipher suites for compatibility with legacy servers. If this option is specified, the client will allow connections using TLS 1.0 and cipher suites that use RC4, MD5 and SHA1.
FTP_OPTION_TUNNEL	This option specifies that a tunneled TCP connection and/or port-forwarding is being used to establish the connection to the server. This changes the behavior of the client with regards to internal checks of the destination IP address and remote port number, default capability selection and how the connection is established. This option also forces all connections to be outbound and enables the firewall compatibility features in the client.
FTP_OPTION_KEEPALIVE_DATA	This option specifies the client should attempt to keep the control connection active during a file transfer. Normally, when a data transfer is in progress, no additional commands are issued on the control channel until the transfer completes. Specifying this option automatically enables the FTP_OPTION_KEEPALIVE option and forces the client to continue to issue NOOP commands during the file transfer. This option only applies to FTP and FTPS connections and has no effect on connections using SFTP (SSH).
FTP_OPTION_PREFER_IPV6	This option specifies the client should prefer the use of IPv6 if the server hostname can be resolved to both an IPv6 and IPv4 address. This option is ignored if the local system does not have IPv6 enabled, or when the hostname can only be resolved to an IPv4 address. If the server hostname can only be resolved to an IPv6 address, the client will attempt to establish a connection using IPv6 regardless if this option has been specified.
FTP_OPTION_FREETHREAD	This option specifies the handle returned by this function may be used by any thread, and is not limited to the thread which created it. The application is responsible for ensuring that access to the handle is synchronized across multiple threads.
FTP_OPTION_HIRES_TIMER	This option specifies the elapsed time for data transfers should be returned in milliseconds instead of seconds. This will return more accurate transfer times for smaller

	files being uploaded or downloaded using fast network connections.
FTP_OPTION_TLS_REUSE	This option specifies that TLS session reuse should be enabled for secure connections. This option is only supported on Windows 8.1 or Windows Server 2012 R2 and later platforms, and it should only be used when explicitly required by the server. This option is not compatible with servers built using OpenSSL 1.0.2 and earlier versions which do not provide Extended Master Secret (EMS) support as outlined in RFC7627.

lpCredentials

A pointer to a SECURITYCREDENTIALS structure. This parameter should be NULL if the connection is not secure or when client credentials are not required. Most servers do not require a client certificate to establish a secure connection. However, if the server does require a client certificate, the structure members ***dwSize***, ***lpszCertStore*** and ***lpszCertName*** must be defined. Undefined structure members must be initialized to a value of zero or NULL and the ***dwSize*** member must be initialized to the size of the **SECURITYCREDENTIALS** structure.

Return Value

If the function succeeds, the return value is a handle to a client session. If the function fails, the return value is INVALID_CLIENT. To get extended error information, call **FtpGetLastError**.

Remarks

This function will block the current thread until a connection has been established or the timeout period has elapsed. To prevent it from blocking the main user interface thread, the application should create a background worker thread and establish a connection by calling **FtpProxyConnect** in that thread. If the application requires multiple simultaneous connections, it is recommended you create a worker thread for each connection.

The username and password that is used to authenticate the client with the proxy server are not the same as those used to login to the target server. Once a connection has been established with the proxy server, the client must call the **FtpLogin** function to actually login to the server and begin a file transfer.

If the FTP_OPTION_KEEPALIVE option is specified, a background worker thread will be created to monitor the command channel and periodically send NOOP commands to the server if no commands have been sent recently. This can prevent the server from terminating the client connection during idle periods where no commands are being issued. However, it is important to keep in mind that many servers can be configured to also limit the total amount of time a client can be connected to the server, as well as the amount of time permitted between file transfers. If the server does not respond to the NOOP command, this option will be automatically disabled for the remainder of the client session.

If the FTP_OPTION_SECURE_EXPLICIT option is specified, the client will establish a standard connection to the server and send the AUTH TLS command to the server. If the server does not accept this command, it will then send the AUTH SSL command. If both commands are rejected by the server, an explicit TLS session cannot be established. By default, both the command and data channels will be encrypted when a secure connection is established. To change this, use the **FtpSetChannelMode** function.

The ***dwOptions*** argument can be used to specify the threading model that is used by the library when

a connection is established. By default, the handle is initially attached to the thread that created it. From that point on, until the handle is released, only the owner may call functions using that handle. The ownership of the handle may be transferred from one thread to another using the **FtpAttachThread** function.

Specifying the FTP_OPTION_FREETHREAD option enables any thread to call any function using the handle, regardless of which thread created it. It is important to note that this option disables certain internal safety checks which are performed by the library and may result in unexpected behavior unless access to the handle is synchronized. If one thread calls a function in the library, it must ensure that no other thread will call another function at the same time using the same handle.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpPutData Function

```
INT WINAPI FtpPutData(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPVOID lpvBuffer,
   DWORD dwLength,
   DWORD dwReserved
);
```

The **FtpPutData** function transfers the contents of the specified buffer to a file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A null-terminated string that specifies the file on the server that will be created, overwritten or appended to. The file naming conventions must be that of the host operating system.

lpvBuffer

The data that will be copied to the server and stored in the specified file.

dwLength

The number of bytes to copy from the buffer.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If the ***lpvBuffer*** parameter is pointing to a Unicode string, it is important to note that the value of the ***dwLength*** parameter should specify the number of bytes, not the number of characters. When using UTF-16, each character is two bytes long and therefore the length of the buffer is effectively double the length of the string. Because Unicode strings can contain null characters, you must also set the current file type to FILE_TYPE_IMAGE prior to calling this function.

The **FtpPutText** function can be used to create a text file from the contents of a string.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpPutFile Function

```
INT WINAPI FtpPutFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   DWORD dwOffset
);
```

The **FtpPutFile** function transfers the specified file on the local system to the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string which specifies the file on the local system that will be uploaded. The file pathing and name conventions should follow Windows conventions. It is permitted to include environment variables in the local path by surrounding the variable with percent (%) symbols. Local file paths may also use standard file URLs.

lpszRemoteFile

A null-terminated string which specifies the file on the server that will be created, replaced or appended to on the local system. The file naming conventions must be that of the host operating system. It is permitted to use a URL as the remote file name as long as the server name and port number match what was used to establish the connection.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

dwOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpPutFileEx Function

```
INT WINAPI FtpPutFileEx(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions,
   ULARGE_INTEGER uiOffset
);
```

The **FtpPutFileEx** function transfers the specified file on the local system to the server. This version of the function is designed to support files that are larger than 4GB.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string which specifies the file on the local system that will be uploaded. The file pathing and name conventions should follow Windows conventions. It is permitted to include environment variables in the local path by surrounding the variable with percent (%) symbols. Local file paths may also use standard file URLs.

lpszRemoteFile

A null-terminated string which specifies the file on the server that will be created, replaced or appended to on the local system. The file naming conventions must be that of the host operating system. It is permitted to use a URL as the remote file name as long as the server name and port number match what was used to establish the connection.

dwOptions

An unsigned integer that specifies one or more options. This parameter may be any one of the following values:

Value	Description
FTP_TRANSFER_DEFAULT	This option specifies the default transfer mode should be used. If the remote file exists, it will be overwritten with the contents of the uploaded file.
FTP_TRANSFER_APPEND	This option specifies that if the remote file exists, the contents of the local file is appended to the remote file. If the remote file does not exist, it is created.

uiOffset

A byte offset which specifies where the file transfer should begin. The default value of zero specifies that the file transfer should start at the beginning of the file. A value greater than zero is typically used to restart a transfer that has not completed successfully. Note that specifying a non-zero offset requires that the server support the REST command to restart transfers.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatusEx** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpChangeDirectory, FtpEnableEvents, FtpGetData, FtpGetFileEx, FtpGetMultipleFiles, FtpGetTransferStatusEx, FtpPutData, FtpPutMultipleFiles, FtpRegisterEvent, FtpSetBufferSize, FtpVerifyFile

FtpPutMultipleFiles Function

```
INT WINAPI FtpPutMultipleFiles(
   HCLIENT hClient,
   LPCTSTR lpszLocalDirectory,
   LPCTSTR lpszRemoteDirectory,
   LPCTSTR lpszFileMask,
   DWORD dwReserved
);
```

The **FtpPutMultipleFiles** function copies one or more files from the local host to the server, using the specified wildcard.

Parameters

hClient

Handle to the client session.

lpszLocalDirectory

Pointer to a null-terminated string which specifies the local directory where the files will be downloaded from. The file pathing and name conventions should follow Windows conventions. It is permitted to include environment variables in the local path by surrounding the variable with percent (%) symbols. Local file paths may also use standard file URLs. A NULL pointer or empty string specifies that files should be copied to the current working directory.

lpszRemoteDirectory

Pointer to a null-terminated string which specifies the remote directory where the files will be uploaded to. A NULL pointer or empty string specifies that the files should be copied to the current working directory on the server.

lpszFileMask

Pointer to a string which specifies the files that are to be copied from the local system to the server. The file mask should follow the Windows conventions used for wildcard file matches.

dwReserved

A reserved parameter. This value should always be zero.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpPutMultipleFiles** function is used to transfer files from the local host to the server which match a specified wildcard file mask. All files will be transferred using the current file type as specified by the **FtpSetFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpChangeDirectory, FtpGetFile, FtpGetMultipleFiles, FtpPutFile

FtpPutText Function

```
INT WINAPI FtpPutText(
   HCLIENT hClient,
   LPCTSTR lpszRemoteFile,
   LPCTSTR lpszBuffer
);
```

The **FtpPutText** function creates a text file on the server using the contents of a string buffer.

Parameters

hClient

Handle to the client session.

lpszRemoteFile

A null-terminated string that specifies the text file on the server that will be created or overwritten. The file pathing and name conventions must be that of the server.

lpszBuffer

A null-terminated string that contains the text that will be stored in the file.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpPutText** function is used to create a text file on the server from the contents of a string. If the specified file already exists on the server, its contents will be overwritten. This function will always set the file type to FILE_TYPE_ASCII before creating the file, and will restore the default file type before the method returns.

If the Unicode version of this function is called, the string will be converted to UTF-8 and then uploaded to the server. If you wish to store the contents of the string as UTF-16 Unicode on the server, you must set the current file type to FILE_TYPE_IMAGE and use the **FtpPutData** function. This function should never be used to upload binary data.

This function will cause the current thread to block until the file transfer completes, a timeout occurs or the transfer is canceled. During the transfer, the FTP_EVENT_PROGRESS event will be periodically fired, enabling the application to update any user interface controls. Event notification must be enabled, either by calling **FtpEnableEvents**, or by registering a callback function using the **FtpRegisterEvent** function.

To determine the current status of a file transfer while it is in progress, use the **FtpGetTransferStatus** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

See Also

FtpRead Function

```
INT WINAPI FtpRead(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **FtpRead** function reads the specified number of bytes from the client socket and copies them into the buffer. The data may be of any type, and is not terminated with a null character.

Parameters

hClient

Handle to the client session.

lpBuffer

Pointer to the buffer in which the data will be copied.

cbBuffer

The maximum number of bytes to read and copy into the specified buffer. This value must be greater than zero.

Return Value

If the function succeeds, the return value is the number of bytes actually read. A return value of zero indicates that the server has closed the connection and there is no more data available to be read. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

When **FtpRead** is called and the client is in non-blocking mode, it is possible that the function will fail because there is no available data to read at that time. This should not be considered a fatal error. Instead, the application should simply wait to receive the next asynchronous notification that data is available.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpRegisterEvent Function

```
INT WINAPI FtpRegisterEvent(
   HCLIENT hClient,
   UINT nEventId,
   FTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **FtpRegisterEvent** function registers an event handler for the specified event.

Parameters

hClient

Handle to the client session.

nEventId

An unsigned integer which specifies which event should be registered with the specified callback function. One of the following values may be used:

Value	Description
FTP_EVENT_CONNECT	The control connection to the server has completed.
FTP_EVENT_DISCONNECT	The server has closed the control connection to the client. The client should read any remaining data and disconnect.
FTP_EVENT_OPENFILE	The data connection to the server has completed.
FTP_EVENT_CLOSEFILE	The server has closed the data connection to the client. The client should read any remaining data and close the data channel.
FTP_EVENT_READFILE	Data is available to read by the calling process. No additional messages will be posted until the client has read at least some of the data. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_WRITEFILE	The client can now write data. This notification is sent after a connection has been established, or after a previous attempt to write data has failed because it would result in a blocking operation. This event is only generated if the client is in asynchronous mode.
FTP_EVENT_TIMEOUT	The network operation has exceeded the specified timeout period. The client application may attempt to retry the operation, or may disconnect from the server and report an error to the user.
FTP_EVENT_CANCEL	The current operation has been canceled. Under most circumstances the client should disconnect from the server and re-connect if needed. After an operation has been canceled, the server may abort the connection or refuse to accept further commands from the client.
FTP_EVENT_COMMAND	A command has been issued by the client and the server response has been received and processed. This event can be

	used to log the result codes and messages returned by the server in response to actions taken by the client.
FTP_EVENT_PROGRESS	The client is in the process of sending or receiving a file on the data channel. This event is called periodically during a transfer so that the client can update any user interface components such as a status control or progress bar.
FTP_EVENT_GETFILE	This event occurs when a file download has completed. If multiple files are being downloaded, this event will be generated for each file.
FTP_EVENT_PUTFILE	This event occurs when a file upload has completed. If multiple files are being uploaded, this event will be generated for each file.
FTP_EVENT_QUEUE	This event occurs during a queued file transfer. It only occurs when a file is being transferred using the queue management APIs and the internal state of the queue has changed. The handle passed to this event will be a handle to the queue, not a client connection to the server.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpRegisterEvent** function associates a callback function with a specific event. The event handler is an **FtpEventProc** function that is invoked when the event occurs. Arguments are passed to the function to identify the client session, the event type and the user-defined value specified when the event handler is registered. If the event occurs because of an error condition, the error code will be provided to the handler.

This function is typically used to register an event handler that is invoked while a file is being uploaded or downloaded. The FTP_EVENT_PROGRESS event will only be generated periodically during the transfer to ensure the application is not flooded with event notifications. It is guaranteed that at least one FTP_EVENT_PROGRESS notification will occur at the beginning of the transfer, and one at the end of the transfer when it has completed.

The callback function specified by the ***lpEventProc*** parameter must be declared using the **__stdcall** calling convention. This ensures the arguments passed to the event handler are pushed on to the stack in the correct order. Failure to use the correct calling convention will corrupt the stack and cause the application to terminate abnormally.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpRegisterFileType Function

```
BOOL WINAPI FtpRegisterFileType(
   HCLIENT hClient,
   LPCTSTR lpszExtension,
   UINT nFileType
);
```

The **FtpRegisterFileType** function associates a file name extension with a specific file type.

Parameters

hClient

Handle to the client session. If this parameter is INVALID_CLIENT, the file type is registered for all client sessions in the current process. If the parameter specifies a valid client session, then the association is made only for that specific session.

lpszExtension

A null-terminated string which specifies the file name extension. If this parameter is NULL or points to an empty string, the default file type will be changed for the client session.

nFileType

Specifies the type of file associated with the file extension. This parameter can be one of the following values.

Value	Description
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server.
FILE_TYPE_IMAGE	The file is a binary image and no data conversion of any type is performed on the file. This is typically the default file type for data file transfers. If the type of file that is being transferred is unknown, this file type should always be used.

Return Value

If the function succeeds, the return value non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpRegisterFileType** function is used to associate specific file types with file name extensions. The library has an internal list of standard text file extensions which it automatically recognizes. This method can be used to extend or modify that list for the client session.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpRemoveDirectory Function

```
INT WINAPI FtpRemoveDirectory(
   HCLIENT hClient,
   LPCTSTR lpszDirectory
);
```

The **FtpRemoveDirectory** function removes the specified directory on the server.

Parameters

hClient

Handle to the client session.

lpszDirectory

Points to a string that specifies the name of the directory. The file pathing and name conventions must be that of the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the RMD command to create the directory. The user must have the appropriate permission to remove the specified directory. Most servers will not permit you to remove a directory if it contains one or more files.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpRemoveQueuedFile Function

```
BOOL WINAPI FtpRemoveQueuedFile(
    HQUEUE hQueue,
    DWORD dwFileId
);
```

The **FtpRemoveQueuedFile** removes the specified file from the queue.

Parameters

hQueue

A handle to a file transfer queue.

dwFileId

An unsigned integer value which uniquely identifies the file in the queue. This value cannot be zero.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

Files can only be removed from the queue when in an idle or paused state. If you attempt to remove a file while the queue manager is in the process of uploading or download files, the function will fail.

The file identifier can be obtained by several different functions, including **FtpEnumQueuedFiles** and **FtpGetQueueStatus,** which provides information about the current file being processed in the queue. Do not make any assumptions about the value of the identifier. Although the value is guaranteed to be unique for the specified queue, it is not guaranteed that file identifiers will be assigned in sequential order.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpRenameFile Function

```
INT WINAPI FtpRenameFile(
   HCLIENT hClient,
   LPCTSTR lpszOldFileName,
   LPCTSTR lpszNewFileName
);
```

The **FtpRenameFile** function renames or moves the specified file on the server. The original file must exist and the current user must have the appropriate permissions to change the file name.

Parameters

hClient

Handle to the client session.

lpszOldFileName

A null-terminated string which specifies the name of the remote file to rename or move. This parameter cannot be NULL or a zero-length string and the file must exist on the server. The file path and name must match the conventions used on the server.

lpszNewFileName

A null-terminated string which specifies the new name for the file. This parameter cannot be NULL or a zero-length string. The file path and name must match the conventions used on the server.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

If the *lpszNewFileName* parameter specifies a file which already exists on the server, the contents of that file will be deleted and replaced by the contents of the file specified by *lpszOldFileName*. If you want to prevent this from occurring, your application can check if a file with the new name exists by calling the **FtpGetFileStatus** function. If successful, you can warn the user the rename operation would delete the contents of the new file as a consequence of renaming the original file.

If the connection was established using the standard FTP or FTPS protocols, this function causes two separate commands to be sent to the server, RNFR and RNTO. If either command fails, the function will fail and return an error code. If the connection was established using SFTP (SSH) the client will request the server rename the file atomically by specifying the internal SSH_FXF_RENAME_ATOMIC option. If the server does not support this option and *lpszNewFileName* already exists on the server, this function will attempt to delete the file and retry the rename operation.

This function can be used to move a file from one folder to another on the server, as long as the user has the appropriate permissions required to perform the operation. If the new file name includes a path, that path must already exist on the server or the function will fail.

If the old and new file names specify folders instead of regular files, the server may or may not allow the operation, depending on the access rights for those folders and the server's configuration. Some servers may allow a simple rename operation within the same parent folder, but may not permit you to move the folder to another location in the filesystem.

There is no guarantee the rename operation will be performed in an atomic fashion if multiple client sessions attempt to rename the same file at the same time. For example, it is possible that one client

could attempt to rename a file while another client is already in the process of moving the file to a new folder. In this case, the server may respond with an error indicating the file cannot be found, an access denied error or a general failure error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpReset Function

```
INT WINAPI FtpReset(
   HCLIENT hClient
);
```

The **FtpReset** function resets the client state and resynchronizes with the server. This function is typically called after an unexpected error has occurred, or an operation has been canceled.

Parameters

hClient

Handle to the client session.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The client cannot be reset while a file transfer is in progress or if the client is in a blocked state. To abort a file transfer, use the **FtpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpCancel

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpResetQueue Function

```
BOOL WINAPI FtpResetQueue(
    HQUEUE hQueue,
    DWORD dwOptions
);
```

The **FtpResetQueue** function resets the state of all file transfers in the current queue.

Parameters

hQueue

A handle to a file transfer queue.

dwOptions

An unsigned integer value which specifies which files should be reset in the queue. It may be one of the following values:

Value	Description
FTP_QUEUE_RESET_ALL	All files in the queue should be reset to their initial state.
FTP_QUEUE_RESET_COMPLETED	All files in the queue which have been successfully transferred will be reset to their initial state.
FTP_QUEUE_RESET_FAILED	All files in the queue which were not transferred will be reset to their initial state.
FTP_QUEUE_RESET_CANCELED	All files in the queue which were canceled will be reset to their initial state.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

When the **FtpStartQueue** function is called multiple times using the same queue handle, it will not attempt to transfer files which have already been successfully copied, and it will not attempt to re-transfer files if the previous transfer failed. This function resets queued files back to their initial state, prior to when the queue manager attempted to perform the transfer. The most common use would be to call the function with the FTP_QUEUE_RESET_FAILED mode and then call **FtpStartQueue** to retry failed or canceled file transfers.

Because canceled file transfers are also considered failed transfers, specifying FTP_QUEUE_RESET_FAILED will reset queued files which either encountered an error during the transfer or were explicitly canceled by calling the **FtpCancelQueuedFile** function. The FTP_QUEUE_RESET_CANCELED option will only reset the state of queued file transfers which were canceled.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpResumeQueue Function

```
BOOL WINAPI FtpResumeQueue(
    HQUEUE hQueue
);
```

The **FtpResumeQueue** function resumes transfers in the queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function signals the queue manager to resume processing files in the transfer queue after the **FtpSuspendQueue** function has been called. This function will fail if the queue is in an idle (stopped) state, and will be ignored if the queue manager is already transferring files. The **FtpGetQueueStatus** function can be called to obtain the current status of the queue.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetActivePorts Function

```
INT WINAPI FtpSetActivePorts(
   HCLIENT hClient,
   UINT nLowPort,
   UINT nHighPort
);
```

The **FtpSetActivePorts** function changes the range of local port numbers used for active mode file transfers.

Parameters

hClient

Handle to the client session.

nLowPort

An unsigned integer that specifies the low port number.

nHighPort

An unsigned integer that specifies the high port number.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function is used to modify the range of local port numbers used for active mode file transfers. When using active mode, the client listens for an inbound connection from the server rather than establishing an outbound connection for the data transfer. In most cases, passive mode transfers are preferred because they mitigate potential compatibility issues with firewalls and NAT routers.

If active mode transfers are required, the default port range used when listening for the server connection is between 1024 and 5000. This is the standard range of ephemeral ports used by the Windows operating system. However, under some circumstances that range of ports may be too small, or a firewall may be configured to deny inbound connections on ephemeral ports. In that case, the **FtpSetActivePorts** function can be used to specify a different range of port numbers.

While it is technically permissible to assign the low and high port numbers to the same value, effectively specifying a single active port number, this is not recommended as it can cause the transfer to fail unexpectedly if multiple file transfers are performed. A minimum range of at least 1000 ports is recommended. For example, if you specify a low port value of 40000 then it is recommended that the high port value be at least 41000. The maximum port value is 65535.

To determine the current range of active port numbers being used, call the **FtpGetActivePorts** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetBufferSize Function

```
INT WINAPI FtpSetBufferSize(
   HCLIENT hClient,
   INT nBufferSize
);
```

The **FtpSetBufferSize** function sets the size in bytes of an internal buffer that will be used during data transfers.

Parameters

hClient

Handle to the client session.

nBufferSize

The size of an internal buffer, in bytes. Any value greater than or equal to zero is acceptable. If ***nBufferSize*** is zero, then the default value of 4096 will be used. If ***nBufferSize*** is less than 256 bytes, the buffer size will be set to 256. The maximum value of ***nBufferSize*** is 1048576 (1Mb).

Return Value

If the function succeeds, the return value is the size of the internal buffer that will be used. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The speed of data transfers, particularly on uploads, may be sensitive to network type and configuration, and the size of the internal buffer used for data transfers. The default size of this buffer will result in good performance for a wide range of network characteristics. A larger buffer will not necessarily result in better performance. For example, a multiple of 1460, which is the typical Maximum Transmission Unit (MTU), may be optimal in many situations.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetChannelMode Function

```
INT WINAPI FtpSetChannelMode(
    HCLIENT hClient,
    INT nChannel,
    INT nMode
);
```

The **FtpSetChannelMode** function changes the security mode for the specified communication channel.

Parameters

hClient

Handle to the client session.

nChannel

An integer value which specifies which channel to return information for. It may be one of the following values:

Value	Description
FTP_CHANNEL_COMMAND	Change information for the command channel. This is the communication channel used to send commands to the server and receive command result and status information from the server.
FTP_CHANNEL_DATA	Change information for the data channel. This is the communication channel used to send or receive data during a file transfer.

nMode

An integer value which specifies the new mode for the specified channel. It may be one of the following values:

Value	Description
FTP_CHANNEL_CLEAR	Data sent and received on this channel should not be encrypted.
FTP_CHANNEL_SECURE	Data sent and received on this channel should be encrypted. Specifying this option requires that a secure connection has already been established with the server.

Return Value

If the function succeeds, the return value is the previous mode for the specified channel. If the function fails, it will return FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetChannelMode** function is used to change the default mode for the specified channel, and is typically used to control whether or not data is encrypted during a file transfer. If a standard, non-secure connection has been established with the server, an error will be returned if you specify the FTP_CHANNEL_SECURE mode for either channel.

If you have established a secure connection and then specify the FTP_CHANNEL_CLEAR mode for the command channel, the client will send the CCC command to the server to indicate that commands

should no longer be encrypted. If the server does not support this command, an error will be returned and the channel mode will remain unchanged. Once the command channel has been changed to clear mode, it cannot be changed back to secure mode. You must disconnect and re-connect to the server if you want to resume sending commands over an encrypted channel.

Changing the mode for the data channel requires that the server support the PROT command. If this command is not supported by the server, the function will fail and the channel mode will remain unchanged.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetDefaultZoneId Function

```
BOOL WINAPI FtpSetDefaultZoneId(
    HCLIENT hClient,
    DWORD dwZoneId
);
```

The **FtpSetDefaultZoneId** function sets the default security zone for downloaded files.

Parameters

hClient

Handle to the client session.

dwZoneId

An unsigned integer which specifies the default security zone identifier. It may be one of the following values:

Value	Description
SECURITY_ZONE_NONE	The file does not have a zone identifier associated with it. This typically indicates that the file was created locally or has not been marked by Windows as originating from another zone. This is the default behavior if the application does not explicitly set a default security zone.
SECURITY_ZONE_LOCAL	The file is considered to be part of the **Local Machine** zone, which includes files stored on the user's local system or removable media. This zone has the least restrictive security settings, and files are typically allowed to run without prompting or limitation. ***This zone should not be assigned to downloaded files***, as doing so can bypass security mechanisms designed to protect against potentially harmful content. Only use this setting for files that are created locally by the application itself and are known to be safe. Misuse of this setting can result in a significant security risk, especially if the file contains scripts, executables, or other active content.
SECURITY_ZONE_INTRANET	The file originates from the **Local Intranet** zone, which includes content served from internal network resources, such as shared drives, file servers, and internal web applications. This zone typically has fewer security restrictions than the Internet zone but more than the Local Machine zone. It is commonly used in enterprise environments where network resources are managed and considered relatively safe. ***This zone should not be used for files downloaded from the public Internet***, as doing so may incorrectly signal that the file is trusted within the organization. Assign this zone only to files that are retrieved from authenticated internal sources or known secure locations on the local network.
SECURITY_ZONE_TRUSTED	The file is from a site or source explicitly added to the

	Trusted Sites zone in Internet Explorer or Windows security settings. This zone is intended for domains or locations that the user or system administrator considers to be safe, such as internal applications hosted on the public Internet or third-party services with a strong reputation for safety. Files marked with this zone typically bypass certain security checks, and applications may allow active content (such as scripts or macros) to run without prompting. Use caution when assigning this zone to downloaded files, as it may override protections that would otherwise apply to untrusted content.
SECURITY_ZONE_INTERNET	The file was downloaded from the **Internet** zone, which represents untrusted or unknown sources outside the local network. This is the standard zone identifier automatically applied by web browsers, email clients, and many applications when a file is downloaded from a public website or external server. Windows uses this zone to enforce security restrictions, such as prompting the user before executing scripts, blocking active content, or displaying a warning when the file is opened. This is typically the appropriate zone to assign for any file obtained over FTP from an external site. Assigning this zone helps ensure that users are notified before opening potentially unsafe content, in accordance with Windows Attachment Manager and Group Policy settings.
SECURITY_ZONE_RESTRICTED	The file is associated with the **Restricted Sites** zone, which enforces the strictest security policies. This zone is used for content that is explicitly marked as untrusted or potentially harmful. Files tagged with this zone may be blocked from execution, prevent active content from running, or trigger warnings when accessed. Assigning this zone can be useful for sandboxing unverified downloads or limiting the risk from files obtained from questionable sources. However, it may also cause legitimate files to fail to open or operate with reduced functionality depending on system policy and application behavior.

Return Value

If the function succeeds, the return value is non-zero. If the function fails it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetDefaultZoneId** function sets the default security zone identifier that will be applied to all files downloaded during the client session. This setting controls how Windows treats downloaded files with respect to security prompts and content execution restrictions. Once the default zone ID is set, it will be automatically applied to all subsequent file downloads performed by the client session. This eliminates the need to manually set the security zone for each individual file, ensuring consistent zone tagging across the session.

When is specified, no alternate data stream is created. This

`SECURITY_ZONE_NONE` `Zone.Identifier`

causes the file to be treated as if it originated from the local system, and Windows will not apply zone-based security restrictions. This is the default behavior which maintains backwards compatibility with previous versions of the library that did not create the security zone metadata for files.

The zone ID metadata is interpreted by Windows components such as **Attachment Execution Services** and **SmartScreen** to determine whether the user should be warned when opening a file. In enterprise environments, Group Policy settings may alter how different zone IDs are handled, such as blocking scripts, macros, or unsigned executables. Developers should test zone assignment behavior in target environments when distributing files to end users.

Note that this function does not retroactively modify existing files. The default zone identifier is applied only at the time a file is downloaded using functions such as **FtpDownloadFile**.

If your application is distributed in a controlled environment, such as a corporate network with endpoint protection or user access controls, consult your organization's security policy before modifying default zone behavior. Improper zone tagging can impact file access, generate security prompts, or interfere with digital signature enforcement.

Be aware that some file operations (such as extracting from a ZIP archive, or copying files to non-NTFS volumes or across certain network shares) may strip the `Zone.Identifier` metadata. Developers should not rely solely on zone tagging as a persistent trust mechanism outside of the initial download context.

To get the security zone identifier for a local file, use the **FtpGetFileZoneInfo** function. To change or remove the security zone information for a file, use the **FtpSetFileZoneInfo** function.

Assigning `SECURITY_ZONE_LOCAL` as the default security zone identifier for downloaded files is strongly discouraged. This zone disables key Windows security features and can expose users to significant risk. This security zone should only be used with files that are generated locally by the application and are guaranteed to be safe. Never assign this zone to content obtained from the Internet or other untrusted sources.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpSetDirectoryFormat Function

```
INT WINAPI FtpSetDirectoryFormat(
    HCLIENT hClient,
    INT nFormatId
);
```

The **FtpSetDirectoryFormat** function is used to specify the format used by the server when returning a list of files. The format type is used internally by the library when parsing the file list returned by the server.

Parameters

hClient

Handle to the client session.

nFormatId

An identifier used to specify the format of the file list returned by the server. The following values are recognized:

Value	Description
FTP_DIRECTORY_AUTO	This value specifies that the library should automatically determine the format of the file lists returned by the server. It is recommended that most applications use this value and allow the library to automatically determine the appropriate file listing format used by the server.
FTP_DIRECTORY_UNIX	This value specifies that the server returns file lists in the format commonly used by UNIX servers. Note that many servers can be configured to return file listings in this format, even if they are not actually a UNIX based platform. Consult the technical reference documentation for your server for more information.
FTP_DIRECTORY_MSDOS	This value specifies that the server returns file lists in the format commonly used by MS-DOS based systems. This includes Windows IIS servers. Long file names will be returned if supported by the underlying filesystem, such as NTFS or FAT32.
FTP_DIRECTORY_VMS	This value specifies that the server returns file lists in the format commonly used by VMS servers. Note that VMS servers can be configured to return a standard UNIX style listing in additional to the default VMS format.
FTP_DIRECTORY_STERLING_1	This value specifies that the server returns file listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange) applications. This format uses a 13 byte status code.
FTP_DIRECTORY_STERLING_2	This value specifies that the server returns file listings in a proprietary format used by the Sterling server, which is used for EDI (Electronic Data Interchange) applications. This format uses a 10 byte status code.

FTP_DIRECTORY_NETWARE	This value specifies that the server returns file listings in a proprietary format used by Netware servers. The format is similar to UNIX style listings except that file access and permissions are indicated by letter codes enclosed in brackets. This is the default format selected if the server identifies itself as a Netware system.
FTP_DIRECTORY_MLSD	This value specifies that the server should return file listings in a machine-independent format as defined by RFC 3659. This format specifies file information as a sequence of name/value pairs, with the same format being used regardless of the operating system that the server is hosted on. Note that not all servers support this format, and some proxy servers may reject the command even if the remote server supports its use.

Return Value

If the function succeeds, the return value identifies the file list format used by the server. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function should only be used when the library cannot automatically determine the directory format returned by the server. To determine the format used by a server after a file list has been retrieved, use the **FtpGetDirectoryFormat** function.

The default directory format is determined both by the server's operating system and by analyzing the format of the data returned by the server. If the library is unable to automatically determine the format, it will attempt to parse the list of files as though it is a UNIX style listing.

If the FTP_DIRECTORY_MLSD format is specified, the file information returned by the server may differ from the default output of the LIST command. For example, on a UNIX based FTP server, the output of the LIST command is typically the same format that is used by the /bin/ls command, where file names are sorted and hidden files are not listed. However, the MLSD command may return an unsorted list of files that includes hidden files and directories.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetFeatures Function

```
DWORD WINAPI FtpSetFeatures(
    HCLIENT hClient,
    DWORD dwFeatures
);
```

The **FtpSetFeatures** function specifies the server features available to the client.

Parameters

hClient

Handle to the client session.

dwFeatures

An unsigned integer that specifies one or more features. Refer to the documentation for the **FtpGetFeatures** function for a list of available features.

Return Value

If the function succeeds, the return value specifies the features that were previously enabled. If the function fails, it will return zero. Because it is possible that no features were enabled, a return value of zero does not always indicate an error. An application should call **FtpGetLastError** to determine if an error code has been set.

Remarks

The **FtpSetFeatures** function is used to enable a specific set of features for the current session. When a client connection is first established, features are enabled based on the server type and the server's response to the FEAT command. However, as the client issues commands to the server, if the server reports that the command is unrecognized that feature will automatically be disabled in the client. To enable or disable a specific feature, an application can use the **FtpEnableFeature** function.

For example, the first time an application calls the **FtpGetFileSize** function to determine the size of a file, the library will try to use the SIZE command. If the server reports that the SIZE command is not available, that feature will be disabled and the library will not use the command again during the session unless it is explicitly re-enabled. This is designed to prevent the library from repeatedly sending invalid commands to a server, which may result in the server aborting the connection.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetFileMode Function

```
INT WINAPI FtpSetFileMode(
   HCLIENT hClient,
   UINT nMode
);
```

The **FtpSetFileMode** function sets the default file transfer mode for the current client session.

Parameters

hClient

Handle to the client session.

nMode

Specifies the default type of data transfer mode for files being opened or created on the server. This parameter can be one of the following values.

Value	Description
FILE_MODE_STREAM	The data is transmitted as a stream of bytes. This is the default client transfer mode.
FILE_MODE_BLOCK	The data is transmitted as a series of data blocks preceded by one or more header bytes. This transfer mode is currently not supported.
FILE_MODE_COMPRESSED	The data is transmitted in compressed form. This transfer mode is currently not supported.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The file transfer mode should be set before a file is opened or created on the server. Once the transfer mode is set, it is in effect for all files that are subsequently opened or created.

Requirements

FtpSetFileNameEncoding Function

```
INT WINAPI FtpSetFileNameEncoding(
    HCLIENT hClient,
    INT nEncoding
);
```

The **FtpSetFileNameEncoding** function specifies what type of encoding will be used when file names are sent to the server.

Parameters

hClient

Handle to the client session.

nEncoding

An integer value which specifies the encoding type. It may be one of the following values:

Value	Description
FTP_ENCODING_ANSI	File names are sent as 8-bit characters using the default character encoding for the current codepage. If the Unicode version of the functions are used, file names are converted from Unicode to ANSI using the current codepage before being sent to the server. This is the default encoding type.
FTP_ENCODING_UTF8	File names that contain non-ASCII characters are sent using UTF-8 encoding. This encoding type is only available on servers that advertise support for UTF-8 encoding and permit that encoding type to be enabled by the client.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetFileNameEncoding** function can be used to enable UTF-8 encoding of file names, which provides improved support for the use of international character sets. However, the server must provide support for UTF-8 encoding by advertising it in response to the FEAT command and it must support the OPTS command which is used to enable UTF-8 encoding. If the server does not advertise support for UTF-8, or the OPTS command fails with an error, then this function will fail with an error and the encoding type will not change.

Although it is possible to use the **FtpEnableFeature** function to explicitly enable the FTP_FEATURE_UTF8 feature, this is not recommended. If the server has not advertised support for UTF-8 encoding in response to the FEAT command, that typically indicates that UTF-8 encoding is not supported. Attempting to force UTF-8 encoding can result in unpredictable behavior when file names contain non-ASCII characters.

It is important to note that not all FTP servers support UTF-8 encoding, and in some cases servers which advertise support for UTF-8 encoding do not implement the feature correctly. For example, a server may allow a client to enable UTF-8 encoding, but once enabled will not permit the client to disable it. Some servers may advertise support for UTF-8 encoding, however if the underlying file system does not support UTF-8 encoded file names, any attempt to upload or download a file may fail

with an error indicating that the file cannot be found or created.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetFilePermissions Function

```
INT WINAPI FtpSetFilePermissions(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   DWORD dwPermissions
);
```

The **FtpSetFilePermissions** function returns information about the access permissions for a specific file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

A null-terminated string which contains the name of the file to be updated. The filename cannot contain any wildcard characters.

dwPermissions

An unsigned integer which will specify the new access permissions for the file. The file permissions are represented as bit flags, and may be one or more of the following values combined with a bitwise Or operator:

Value	Description
FILE_OWNER_READ	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.
FILE_OWNER_WRITE	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_OWNER_EXECUTE	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_GROUP_READ	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.
FILE_GROUP_WRITE	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_GROUP_EXECUTE	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.

FILE_WORLD_READ	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.
FILE_WORLD_WRITE	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.
FILE_WORLD_EXECUTE	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.

Return Value

If the function succeeds, the return value is a result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

This function uses the SITE CHMOD command to set the permissions for the file. This command is typically only supported on servers that are hosted on UNIX based systems. If the command is not supported, an error will be returned.

Users who are familiar with the UNIX operating system will recognize the **chmod** command used to change the file permissions. However, it should be noted that the numeric value used as an argument to the command is in octal, not decimal. For example, issuing the command **chmod 644 filename.txt** on a UNIX based system will make the file readable and writable by the owner, and readable by other users in the owner's group as well as all other users. The value 644 is an octal value, which is equivalent to the decimal value 420. If you were to mistakenly specify 644 as the value for the *dwPermissions* parameter, rather than the decimal value of 420, the permissions on the file would be incorrect. It is strongly recommended that you use the pre-defined constants to prevent this sort of error.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpSetFileStructure Function

```
INT WINAPI FtpSetFileStructure(
    HCLIENT hClient,
    UINT nType
);
```

The **FtpSetFileStructure** function sets the default file structure for the current client session, which indicates what type of file is being opened or created on the server.

Parameters

hClient

Handle to the client session.

nType

Specifies the default type of file structure being opened or created on the server. This parameter can be one of the following values.

Value	Description
FILE_STRUCT_NONE	The file has no inherent structure and is considered to be a stream of bytes. This is the default structure for file transfers.
FILE_STRUCT_RECORD	The file uses a record structure. This file structure is currently not supported.
FILE_STRUCT_PAGE	The file uses a page structure. This file structure is currently not supported.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The file structure should be set before a file is opened or created on the server. Once the file type is set, it is in effect for all files that are subsequently opened or created.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetFileTime Function

```
INT WINAPI FtpSetFileTime(
   HCLIENT hClient,
   LPCTSTR lpszFileName,
   LPSYSTEMTIME lpFileTime
);
```

The **FtpSetFileTime** function sets the modification time for the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszFileName

Points to a string that specifies the name of the remote file.

lpFileTime

Points to a SYSTEMTIME structure that specifies the new modification time for the remote file.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetFileTime** function will change the modification time of a file on the server. The values specified in the SYSTEMTIME structure are expected to represent UTC time, not time adjusted for the local system's timezone. If the values do represent the local time, it must be converted to UTC time prior to calling this function. To populate the SYSTEMTIME structure with the current time, use the **GetSystemTime** function.

When connected to an FTP server, this function uses the MDTM command to set the modification time for the specified file. Not all servers implement this command, in which case the function call will fail. Note that some servers only support the MDTM command to return, but not change, the file modification time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpSetFileType Function

```
INT WINAPI FtpSetFileType(
   HCLIENT hClient,
   UINT nFileType
);
```

The **FtpSetFileType** function sets the default file type for the current client session, which indicates what type of file is being opened or created on the server.

Parameters

hClient

Handle to the client session.

nFileType

Specifies the default type of file being opened or created on the server. This parameter can be one of the following values.

Value	Description
FILE_TYPE_AUTO	The file type should be automatically determined based on the file name extension. If the file extension is unknown, the file type should be determined based on the contents of the file. The library has an internal list of common text file extensions, and additional file extensions can be registered using the **FtpRegisterFileType** function.
FILE_TYPE_ASCII	The file is a text file using the ASCII character set. For those servers which mark the end of a line with characters other than a carriage return and linefeed, it will be converted to the native client format. This is the file type used for directory listings.
FILE_TYPE_EBCDIC	The file is a text file using the EBCDIC character set. Local files will be converted to EBCDIC when sent to the server. Remote files will be converted to the native ASCII character set when retrieved from the server. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.
FILE_TYPE_IMAGE	The file is a binary file and no data conversion of any type is performed on the file. This is the default file type for most data files and executable programs. If the type of file cannot be automatically determined, it will always be considered a binary file. If this file type is specified when uploading or downloading text files, the native end-of-line character sequences will be preserved.
FILE_TYPE_LOCAL	The file is a binary file that uses the local byte size for the server platform. On most servers, this file type is considered to be the same as FILE_TYPE_IMAGE. Not all servers support this file type. It is recommended that you only specify this type if you know that it is required by the server to transfer data correctly.

Return Value

If the function succeeds, the return value is the server result code. If the function fails, the return value

is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The file type should be set before a file is opened or created on the server. Once the file type is set, it is in effect for all files that are subsequently opened or created. Some functions, such as **FtpOpenDirectory** and **FtpGetText**, will temporarily change the default file type to FILE_TYPE_ASCII and then restore the current file type when they return.

Calling this function has no practical effect when connected to an SFTP (SSH) server. They do not differentiate between text and binary files and the default file type will always be FILE_TYPE_IMAGE. If your application is uploading or downloading a text file, this difference between FTP and SFTP is important because the operating system that hosts the server may have different end-of-line character conventions than the client system. For example, if you download a text file from a UNIX system using SFTP, the end-of-line is indicated by a single linefeed (LF) character. However, on the Windows platform, the end-of-line is indicated by a carriage-return and linefeed sequence (CRLF).

The **FtpGetFileType** function can be used to determine the current file type. To determine the transfer file type for a specific file, use the **FtpGetAutoFileType** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetFileZoneInfo Function

```
BOOL WINAPI FtpSetFileZoneInfo(
   LPCTSTR lpszLocalFile,
   DWORD dwZoneId,
   LPCTSTR lpszHostUrl
);
```

The **FtpSetFileZoneInfo** function sets or clears the zone identifier information for a local file.

Parameters

lpszLocalFile

A null-terminated string that specifies the name of a local file. This parameter must specify a regular file which exists on the local system and the current process must have permission to access and write to the file. If the file path includes environment variables surrounded in percent (%) symbols, the variables will be expanded. This parameter cannot be NULL.

dwZoneId

An unsigned integer which specifies the zone ID which should be assigned to the file. It may be one of the following values:

Value	Description
SECURITY_ZONE_NONE	The file does not have a zone identifier associated with it.
SECURITY_ZONE_LOCAL	The file is considered to be part of the local computer zone.
SECURITY_ZONE_INTRANET	The file originates from the local intranet zone, such as an internal corporate network.
SECURITY_ZONE_TRUSTED	The file originates from a site in the **Trusted Sites** zone.
SECURITY_ZONE_INTERNET	The file was downloaded from the Internet and is treated with caution by Windows.
SECURITY_ZONE_RESTRICTED	The file originates from a site in the **Restricted Sites** zone, which is used for untrusted content.

lpszHostUrl

An optional pointer to a string which specifies the URL used to originally download the file. If this information is not required the parameter may be a NULL pointer or an empty string. If an originating URL is provided, it must be a valid FTP URL.

Return Value

If the function succeeds, the return value is non-zero. If the function fails it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetFileZoneInfo** function enables applications to set or remove the security zone identifier metadata associated with a local file. This information is stored in an alternate data stream named `:Zone.Identifier` and is used by Windows to determine the origin and trust level of a file, potentially prompting the user with a warning before the file is opened.

The file name specified by the *lpszLocalFile* parameter must not reference a network location. This

includes UNC paths (such as `\\server\share\file.txt`) and drive letters that are mapped to network shares. Security zone metadata cannot be applied to files on network volumes because the SMB protocol does not support alternate data streams. If a file with zone metadata is copied from a local NTFS drive to a network share, any associated streams like `Zone.Identifier` will be lost.

Specifying `SECURITY_ZONE_NONE` will remove any existing zone identifier stream from the file. This has the same effect as selecting the Unblock option in the file's properties dialog in Windows Explorer. Once the stream is removed, the file will be treated as though it originated from the local computer. Note that when the `Zone.Identifier` stream is deleted from a file to remove its security zone information, Windows Explorer may not immediately reflect this change. This is because Explorer caches certain file metadata, including zone information used to display the "This file came from another computer" warning in the file's Properties dialog.

When assigning a zone ID, it is important to ensure that the value accurately reflects the source of the file. For files that have been downloaded from the Internet, it is strongly recommended to use `SECURITY_ZONE_INTERNET`. This allows Windows and other software to enforce appropriate security measures, such as requiring user confirmation before executing or opening the file.

In most scenarios, zone identifiers should only be set for files that were downloaded from untrusted or external sources. Setting an overly permissive zone (such as `SECURITY_ZONE_LOCAL`) for files obtained from the Internet or other potentially unsafe locations can expose users to security risks and circumvent built-in protections.

If a URL is provided via the *lpszHostUrl* parameter, it will be included in the zone metadata and can be retrieved later using the **FtpGetFileZoneInfo** function. This provides additional context about the origin of the file and may aid in auditing or diagnostic tasks. The URL must be a syntactically valid FTP address and should reflect the actual location from which the file was downloaded.

Not all file systems support alternate data streams. The function will fail if used on a volume (such as FAT32) that does not support this feature. Additionally, modifying zone information may fail if the file is in use, read-only, or if the current process does not have the required permissions. It is possible to disable the creation of security zone metadata through local policy settings. In this case, the function will fail and the last error code will be set to `ST_ERROR_POLICY_NO_ZONEINFO`.

For more detailed information about the security zone identifiers, refer to the **FtpSetDefaultZoneId** function.

Assigning `SECURITY_ZONE_LOCAL` as the security zone identifier for downloaded files is strongly discouraged. This zone disables key Windows security features and can expose users to significant risk. This security zone should only be used with files that are generated locally by the application and are guaranteed to be safe. Never assign this zone to content obtained from the Internet or other untrusted sources.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

FtpSetIdleTimeout Function

```
INT WINAPI FtpSetIdleTimeout(
    HCLIENT hClient,
    INT nIdleTime
);
```

The **FtpSetIdleTimeout** function sets the server-side idle timeout period for the control connection.

Parameters

hClient

Handle to the client session.

nIdleTime

The number of seconds until the control session is considered inactive. A value of zero specifies the default idle timeout period of 300 seconds (5 minutes) will be used. If the value is less than 30 seconds or greater than 7200 seconds, it will be automatically adjusted to fit within the valid range.

Return Value

If the function succeeds, the return value is the previous idle timeout period. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetIdleTimeout** function changes the idle timeout period for the control connection, which can be useful in scenarios where a file transfer session is expected to remain idle for extended periods between commands. For example, when transferring large batches of files or performing periodic synchronization, the server may automatically close the connection if no activity is detected within its default timeout period. Increasing the idle timeout helps prevent unexpected disconnects during these idle periods, reducing the need to repeatedly reconnect and re-authenticate. Conversely, reducing the timeout can be used to enforce shorter sessions in security-sensitive environments.

The `SITE IDLE` command is a non-standard extension to the FTP protocol that allows a client to query or set the server's idle timeout period for the current session. When supported, it enables the client to request how long the server should wait during periods of inactivity before automatically closing the connection. This setting does not affect the duration of data transfers, only how long the control session is kept open when idle.

Because `SITE IDLE` is not part of the official FTP specification, support for it varies between servers. If the command is not supported, the function will fail but the session will remain connected using the server's default timeout settings. The function will also return an error if a negative timeout value is specified or if the session is using SFTP, which does not support this operation.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetLastError Function

```
VOID WINAPI FtpSetLastError(
   DWORD dwErrorCode
);
```

The **FtpSetLastError** function sets the last error code for the current thread. This function is typically used to clear the last error by specifying a value of zero as the parameter.

Parameters

dwErrorCode

Specifies the last error code for the current thread.

Return Value

None.

Remarks

Error codes are unsigned 32-bit values which are private to each calling thread. Most functions will set the last error code value when they fail; a few functions set it when they succeed. Function failure is typically indicated by a return value such as FALSE, NULL, INVALID_CLIENT or FTP_ERROR. Those functions which call **FtpSetLastError** when they succeed are noted on the function reference page.

Applications can retrieve the value saved by this function by using the **FtpGetLastError** function. The use of **FtpGetLastError** is optional; an application can call the function to determine the specific reason for a function failure.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpSetPassiveMode Function

```
INT WINAPI FtpSetPassiveMode(
   HCLIENT hClient,
   BOOL bPassiveMode
);
```

The **FtpSetPassiveMode** function enables or disables passive mode file transfers for the specified client session.

Parameters

hClient

Handle to the client session.

bPassiveMode

A boolean flag which specifies that the client should enter passive mode and establish all connections with the server to transfer data.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

By default, the File Transfer Protocol uses active mode transfers, whereby the data connection is established from the server back to the local client. However, this can introduce problems for a client application that is behind a proxy server, firewall or a router which uses Network Address Translation (NAT). Enabling passive mode transfers instructs the client to create an outbound connection from the local system to the server for the data connection, similarly to how the control connection is established.

Not all servers may support passive mode, in which case an error will be returned to the client when this function is called.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetPriority Function

```
INT WINAPI FtpSetPriority(
   HCLIENT hClient,
   INT nPriority
);
```

The **FtpSetPriority** function specifies the priority for file transfers.

Parameters

hClient

Handle to the client session.

nPriority

An integer value which specifies the new priority for file transfers. It may be one of the following values:

Value	Description
FTP_PRIORITY_NORMAL	The default priority which balances resource utilization and transfer speed. It is recommended that most applications use this priority.
FTP_PRIORITY_BACKGROUND	This priority significantly reduces the memory, processor and network resource utilization for the transfer. It is typically used with worker threads running in the background when the amount of time required perform the transfer is not critical.
FTP_PRIORITY_LOW	This priority lowers the overall resource utilization for the transfer and meters the bandwidth allocated for the transfer. This priority will increase the average amount of time required to complete a file transfer.
FTP_PRIORITY_HIGH	This priority increases the overall resource utilization for the transfer, allocating more memory for internal buffering. It can be used when it is important to transfer the file quickly, and there are no other threads currently performing file transfers at the time.
FTP_PRIORITY_CRITICAL	This priority can significantly increase processor, memory and network utilization while attempting to transfer the file as quickly as possible. If the file transfer is being performed in the main UI thread, this priority can cause the application to appear to become non-responsive. No events will be generated during the transfer.

Return Value

If the function succeeds, the return value is the previous file transfer priority. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpSetPriority** function can be used to control the processor usage, memory and network

bandwidth allocated for file transfers. The default priority balances resource utilization and transfer speed while ensuring that a single-threaded application remains responsive to the user. Lower priorities reduce the overall resource utilization at the expense of transfer speed. For example, if you create a worker thread to download a file in the background and want to ensure that it has a minimal impact on the process, the FTP_PRIORITY_BACKGROUND value can be used.

Higher priority values increase the memory allocated for the transfers and increases processor utilization for the transfer. The FTP_PRIORITY_CRITICAL priority maximizes transfer speed at the expense of system resources. It is not recommended that you increase the file transfer priority unless you understand the implications of doing so and have thoroughly tested your application. If the file transfer is being performed in the main UI thread, increasing the priority may interfere with the normal processing of Windows messages and cause the application to appear to become non-responsive. It is also important to note that when the priority is set to FTP_PRIORITY_CRITICAL, normal progress events will not be generated during the transfer.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpSetTimeout Function

```
INT WINAPI FtpSetTimeout(
   HCLIENT hClient,
   INT nTimeout
);
```

The **FtpSetTimeout** function sets the number of seconds the client will wait for a response from the server.

Parameters

hClient

Handle to the client session.

nTimeout

The number of seconds to wait for a blocking operation to complete. If this value is zero, the default timeout period of 20 seconds will be used.

Return Value

If the function succeeds, the return value is zero. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The timeout value is only used with blocking client connections. Once the specified number of seconds has elapsed, the blocking function will fail and return to the caller. The timeout value affects both commands issued on the control channel and file transfers using the data channel.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpStartQueue Function

```
BOOL WINAPI FtpStartQueue(
   HQUEUE hQueue,
   DWORD dwQueueMode,
   DWORD dwReserved,
   FTPEVENTPROC lpEventProc,
   DWORD_PTR dwParam
);
```

The **FtpStartQueue** function begins transferring files in the queue.

Parameters

hQueue

A handle to a file transfer queue.

dwQueueMode

An unsigned integer which specifies which files in the queue should be transferred. It may be one of the following values:

Constant	Description
FTP_QUEUE_ALL	All files in the queue should be transferred.
FTP_QUEUE_DOWNLOAD	Transfer only those files which have been queued for download.
FTP_QUEUE_UPLOAD	Transfer only those files which have been queued for upload.

dwReserved

An unsigned integer reserved for internal use. This parameter value should always be zero.

lpEventProc

Specifies the procedure-instance address of an application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, there will be no callback notifications.

dwParam

A user-defined integer value that is passed to the callback function. If the application targets the x86 (32-bit) platform, this parameter must be a 32-bit unsigned integer. If the application targets the x64 (64-bit) platform, this parameter must be a 64-bit unsigned integer.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

Queued file transfers are performed asynchronously using a background worker thread. If you provide the address to an event callback function, that function will always be invoked in the context of the queue manager thread. You must ensure that any access to global or static variables are synchronized, otherwise the results may be unpredictable. It is recommended that you do not declare any static variables within the callback function itself and you should avoid calling any functions which could cause the thread to block. For example, you should not attempt to establish other network

connections from within the event handler.

If your application has a graphical user interface, you should never attempt to directly modify a UI control from within the callback function. Controls should only be modified by the same UI thread that created their window. One common approach to address this issue is to post a user-defined message to the main window to signal that the user interface needs to be updated. The message handler would then process the user-defined message and update the user interface as needed.

To obtain the handle to the queue from within an event handler, call the **FtpGetThreadQueue** function with the *dwThreadId* parameter set to a value of zero. This will return the handle for the current queue management session which invoked the callback function.

If a callback function is provided, the FTP_QUEUE_EVENT event notification will be invoked whenever the internal state of the queue has changed. The handle value passed to the callback function will be a handle to the queue, not to a client connection. The **FtpGetQueueStatus** function can be called within the event handler to obtain the current state of the queue. This will event will always occur when the queue manager begins processing files in the queue and after it has stopped. This event will also occur whenever the queue is suspended and then resumed.

The **FtpWaitForQueue** function can be used to wait for the queue manager to complete processing the transfer queue.

Example

```
// Create a new queue
HQUEUE hQueue = FtpCreateQueue(INFINITE, FTP_TIMEOUT, FTP_OPTION_DEFAULT);

if (hQueue == INVALID_QUEUE)
    return;

// Add a file to the queue
DWORD dwFileId = FtpAddQueuedFile(
                     hQueue,
                     lpszLocalFile,
                     lpszRemoteFile,
                     FTP_OPTION_DEFAULT,
                     FILE_TYPE_AUTO,
                     FTP_TIMEOUT);

// Display information about the queued file
if (dwFileId != 0)
{
    FTPQUEUEDFILE queuedFile;

    if (FtpGetQueuedFile(hQueue, dwFileId, &queuedFile))
    {
        switch (queuedFile.dwMode)
        {
        case FTP_QUEUE_DOWNLOAD:
               _tprintf(_T("%u: Download \"%s\" to \"%s\"\n"),
                        dwFileId,
                        queuedFile.szRemoteFile,
                        queuedFile.szLocalFile);
                break;

        case FTP_QUEUE_UPLOAD:
               _tprintf(_T("%u: Upload \"%s\" to \"%s\"\n"),
                        dwFileId,
```

```
                        queuedFile.szLocalFile,
                        queuedFile.szRemoteFile);
                break;
            }
        }
    }

    // Start the queued file transfers and wait for it to complete
    if (FtpStartQueue(hQueue, FTP_QUEUE_ALL, 0, NULL, 0))
    {
        FtpWaitForQueue(hQueue, INFINITE, &dwElapsed, &dwError);
        FtpStopQueue(hQueue);
    }

    // Remove all files from the queue
    FtpDeleteQueue(hQueue);
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpStopQueue Function

```
BOOL WINAPI FtpStopQueue(
    HQUEUE hQueue
);
```

The **FtpStopQueue** function stops transferring queued files.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

When the **FtpStopQueue** function is called and there is a file transfer in progress, it will not immediately stop the upload or download of the file. Instead, the queue manager is signaled to stop processing additional files in the queue after the transfer has completed. To wait for the current transfer to complete, call the **FtpWaitForQueue** function.

It is permitted to call **FtpStopQueue** from within a queue event handler. In this case, the current file transfer will complete and the queue manager will terminate.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpSuspendQueue Function

```
BOOL WINAPI FtpSuspendQueue(
    HQUEUE hQueue
);
```

The **FtpSuspendQueue** function pauses all file transfers for the specified queue.

Parameters

hQueue

A handle to a file transfer queue.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

If there is a file transfer in progress when this function is called, the transfer will complete normally. The queue manager will enter a suspended state after the transfer has completed and before it begins processing the next file in the queue.

It is permitted to call **FtpSuspendQueue** from within a queue event handler. In this case, the current file transfer will complete and the queue manager will stop processing additional files in the queue until it is resumed or stopped.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpTaskAbort Function

```
BOOL WINAPI FtpTaskAbort(
   UINT nTaskId,
   DWORD dwMilliseconds
);
```

Abort the specified asynchronous task.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to abort.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskAbort** function signals the background worker thread associated with the task ID to abort the current operation and terminate as soon as possible. If the *dwMilliseconds* parameter has a value of zero, the function returns immediately after the background thread has been signaled. If the *dwMilliseconds* parameter is non-zero, the function will wait that amount of time for the background thread to terminate.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock. To abort a file transfer within an event handler, use the **FtpCancel** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpTaskDone, FtpTaskResume, FtpTaskSuspend, FtpTaskWait

FtpTaskDone Function

```
BOOL WINAPI FtpTaskDone(
    UINT nTaskId
);
```

Determine if an asynchronous task has completed.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has completed, this function returns a non-zero value. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskDone** function is used to determine if the specified asynchronous task has completed. If you use this function to poll the status of a background task from within the main UI thread, you must ensure that Windows messages are processed so that the application remains responsive to the end-user. To check if a background transfer has completed, it is recommended that you use a timer to periodically call this function rather than calling it repeatedly within a loop.

To determine if the task completed successfully, the **FtpGetTaskError** function will return the last error code associated with the task. A return value of zero indicates success, while a non-zero return value specifies an error code that indicates the cause of the failure. The last error code for the task can also be retrieved using the **FtpTaskWait** function, which causes the application to wait for the asynchronous task to complete.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpTaskResume Function

```
BOOL WINAPI FtpTaskResume(
    UINT nTaskId
);
```

Resume execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskResume** function resumes execution of the background worker thread that was previously suspended using the **FtpTaskSuspend** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpTaskAbort, FtpTaskDone, FtpTaskSuspend, FtpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpTaskSuspend Function

```
BOOL WINAPI FtpTaskSuspend(
    UINT nTaskId
);
```

Suspend execution of an asynchronous task.

Parameters

nTaskId

The task identifier.

Return Value

If the asynchronous task has resumed, this function returns a non-zero value. A return value of zero indicates that an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskSuspend** function will suspend execution of the background worker thread associated with the task. Once the task has been suspended, it will no longer be scheduled for execution, however the client session will remain active and the task may be resumed using the **FtpTaskResume** function. Note that if a task is suspended for a long period of time, the background operation may fail because it has exceeded the timeout period imposed by the server.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

See Also

FtpTaskAbort, FtpTaskDone, FtpTaskResume, FtpTaskWait

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpTaskWait Function

```
BOOL WINAPI FtpTaskWait(
   UINT nTaskId,
   DWORD dwMilliseconds,
   DWORD dwReserved,
   LPDWORD lpdwElapsed,
   LPDWORD lpdwError
);
```

Wait for an asynchronous task to complete.

Parameters

nTaskId

The task identifier.

dwMilliseconds

An unsigned integer that specifies the number of milliseconds to wait for the background task to complete.

dwReserved

An unsigned integer reserved for future use. This value should always be zero.

lpdwElapsed

A pointer to an unsigned integer that will contain elapsed time in milliseconds when the function returns. If this information is not required, this parameter may be NULL.

lpdwError

A pointer to an unsigned integer that will contain the error code associated with the completed task. If this information is not required, this parameter may be NULL.

Return Value

If the function succeeds and the worker thread has terminated, the return value is non-zero. A return value of zero indicates that the worker thread is still running or an error has occurred. To get extended error information, call the **FtpGetLastError** function.

Remarks

The **FtpTaskWait** function waits for the specified task to complete. If the task is active and the ***dwMilliseconds*** parameter is non-zero, this function will cause the current working thread to block until the task completes or the amount of time exceeds the number of milliseconds specified by the caller. If the ***dwMilliseconds*** parameter is zero, then this function will poll the status of the task and return immediately to the caller.

If the specified task has already completed at the time this function is called, the function will return immediately without causing the current thread to block. If the ***lpdwElapsed*** parameter is not NULL, it will contain the number of milliseconds that it took for the task to complete. If the ***lpdwError*** parameter is not NULL, it will contain the last error code value that was set by the worker thread before it terminated. If this value is zero, that means that the background operation was successful and no error occurred. A non-zero value will indicate that the background operation has failed.

You should not call this function from the main UI thread with a long timeout period to wait for a background task to complete. Windows messages will not be processed while this function is blocked waiting for the background task to complete, and this can cause your application to appear non-

responsive to the end-user. If you have a GUI application and you need to periodically check to see if a task has completed, create a timer to periodically call the **FtpTaskDone** function. When it returns a non-zero value (indicating that the task has completed), you can safely call **FtpTaskWait** to obtain the elapsed time and last error code without blocking the current thread.

This function should never be called from within the event handler for an asynchronous task because it can cause the process to deadlock.

Example

```
UINT nTaskId;

// Begin a file transfer in the background

nTaskId = FtpAsyncGetFile(hClient,
                          lpszLocalFile,
                          lpszRemoteFile,
                          FTP_TRANSFER_DEFAULT,
                          0,
                          NULL,
                          0);

if (nTaskId != 0)
{
    DWORD dwError = NO_ERROR;
    DWORD dwElapsed = 0;

    // Wait for the transfer to complete
    FtpTaskWait(nTaskId, INFINTE, &dwElapsed, &dwError);
}
```

Requirements

FtpUninitialize Function

```
VOID WINAPI FtpUninitialize();
```

The **FtpUninitialize** function terminates the use of the library.

Parameters

There are no parameters.

Return Value

None.

Remarks

An application is required to perform a successful **FtpInitialize** call before it can call any of the other library functions. When it has finished using the library, the application must call **FtpUninitialize** to allow the library to free any resources allocated on behalf of the process. Any pending blocking or asynchronous calls in this process are canceled without posting any notification messages, and all sockets that were opened by the process are closed.

There should be a call to **FtpUninitialize** for every successful call to **FtpInitialize** made by a process. In a multithreaded environment, operations for all threads in the client are terminated.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpUploadFile Function

```
BOOL WINAPI FtpUploadFile(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   UINT nTimeout
   DWORD dwOptions
   LPFTPTRANSFERSTATUS lpStatus
   FTPEVENTPROC lpEventProc
   DWORD_PTR dwParam
);
```

The **FtpUploadFile** function uploads the specified file from the local system to the server.

Parameters

lpszLocalFile

A null-terminated string which specifies the file on the local system that will be uploaded. The file pathing and name conventions should follow Windows conventions. It is permitted to include environment variables in the local path by surrounding the variable with percent (%) symbols. Local file paths may also use standard file URLs.

lpszRemoteFile

A null-terminated string which specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_DEFAULT	Default options should be used for file transfers. This is the same as specifying that all file transfers should use passive mode when establishing a data connection with the server. It is recommended most applications use passive mode to prevent potential compatibility issues with certain types of firewalls and routers which use Network Address Translation (NAT).
FTP_OPTION_PASSIVE	This option specifies file transfers should attempt to establish the data connection with the server. If the local system is behind a firewall or a NAT router, the server may not be able to establish a data connection back to the client and the transfer will fail. This option forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.

FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUS structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpUploadFile** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then upload the file to the server. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @] hostname [:port] / [path / ...]
[filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be uploaded as a text or binary file. A value of "a" specifies that the file should be uploaded as a text file. A value of "i" specifies that the file should be uploaded as a binary file. If the type is not explicitly specified, the file will be uploaded as a binary file.

The *lpStatus* parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **FtpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpUploadFile** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpPutFile** to upload the file.

Example

```
FTPTRANSFERSTATUS ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile =
_T("ftp://update:secret@ftp.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = FtpUploadFile(lpszLocalFile,
                        lpszRemoteFile,
                        FTP_OPTION_PASSIVE,
                        &ftpStatus,
                        NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpUploadFileEx Function

```
BOOL WINAPI FtpUploadFileEx(
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   UINT nTimeout
   DWORD dwOptions
   LPFTPTRANSFERSTATUSEX lpStatus
   FTPEVENTPROC lpEventProc
   DWORD_PTR dwParam
);
```

The **FtpUploadFileEx** function uploads the specified file from the local system to the server.

Parameters

lpszLocalFile

A null-terminated string that specifies the file on the local system that will be uploaded to the server. The file pathing and name conventions must be that of the local host.

lpszRemoteFile

A null-terminated string that specifies the complete URL of the file that will be created or overwritten on the server. The URL must follow the conventions for the File Transfer Protocol and may specify either a standard or secure connection, alternate port number, username, password and optional working directory.

nTimeout

The number of seconds that the client will wait for a response before failing the operation. A value of zero specifies that the default timeout period of sixty seconds will be used.

dwOptions

An unsigned integer that specifies one or more options. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
FTP_OPTION_PASSIVE	This option specifies the client should attempt to establish the data connection with the server. When the client uploads or downloads a file, normally the server establishes a second connection back to the client which is used to transfer the file data. However, if the local system is behind a firewall or a NAT router, the server may not be able to create the data connection and the transfer will fail. By specifying this option, it forces the client to establish an outbound data connection with the server. It is recommended that applications use passive mode whenever possible.
FTP_OPTION_FIREWALL	This option specifies the client should always use the host IP address to establish the data connection with the server, not the address returned by the server in response to the PASV command. This option may be necessary if the server is behind a router that performs Network Address Translation (NAT) and it returns an

	unreachable IP address for the data connection. If this option is specified, it will also enable passive mode data transfers.
FTP_OPTION_SECURE	This option specifies the client should attempt to establish a secure connection with the server. Note that the server must support secure connections using the TLS protocol.
FTP_OPTION_SECURE_EXPLICIT	This option specifies the client should use the AUTH command to negotiate an explicit secure connection. Some servers may only require this when connecting to the server on ports other than 990.

lpStatus

A pointer to an FTPTRANSFERSTATUSEX structure which contains information about the status of the current file transfer. If this information is not required, a NULL pointer may be specified as the parameter.

lpEventProc

Specifies the procedure-instance address of the application defined callback function. For more information about the callback function, see the description of the **FtpEventProc** callback function. If this parameter is NULL, the callback for the specified event is disabled.

dwParam

A user-defined integer value that is passed to the callback function.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpUploadFileEx** function provides a convenient way for an application to upload a file in a single function call. Based on the connection information specified in the URL, it will connect to the server, authenticate the session, change the current working directory if necessary and then upload the file to the server. The URL must be complete, and specify either a standard or secure FTP scheme:

```
[ftp|ftps|sftp]://[username : password] @] hostname [:port] / [path / ...]
[filename] [;type=a|i]
```

If no user name and password is provided, then the client session will be authenticated as an anonymous user. If a path is specified as part of the URL, the function will attempt to change the current working directory. Note that the path in an FTP URL is relative to the home directory of the user account and is not an absolute path starting at the root directory on the server. The URL scheme will always determine if the connection is secure, not the option. In other words, if the "ftp" scheme is used and the FTP_OPTION_SECURE option is specified, that option will be ignored. To establish a secure connection, either the "ftps" or "sftp" scheme must be specified.

The optional "type" value at the end of the file name determines if the file should be uploaded as a text or binary file. A value of "a" specifies that the file should be uploaded as a text file. A value of "i" specifies that the file should be uploaded as a binary file. If the type is not explicitly specified, the file will be uploaded as a binary file.

The ***lpStatus*** parameter can be used by the application to determine the final status of the transfer, including the total number of bytes copied, the amount of time elapsed and other information related

to the transfer process. If this information isn't needed, then this parameter may be specified as NULL.

The *lpEventProc* parameter specifies a pointer to a function which will be periodically called during the file transfer process. This can be used to check the status of the transfer by calling **FtpGetTransferStatus** and then update the program's user interface. For example, the callback function could calculate the percentage for how much of the file has been transferred and then update a progress bar control. The *dwParam* parameter is used in conjunction with the event handler and specifies a user-defined value that is passed to the callback function. One common use in a C++ program is to pass the *this* pointer as the value, and then cast it back to an object pointer inside the callback function. If no event handler is required, then a NULL pointer can be specified as the value for *lpEventProc* and the *dwParam* parameter will be ignored.

The **FtpUploadFileEx** function is designed to provide a simpler interface for uploading a file. However, complex connections such as those using a proxy server or a secure connection which uses a client certificate will require the program to establish the connection using **FtpConnect** and then use **FtpPutFileEx** to upload the file.

Example

```
FTPTRANSFERSTATUSEX ftpStatus;
LPCTSTR lpszLocalFile = _T("c:\\temp\\database.mdb");
LPCTSTR lpszRemoteFile =
_T("ftp://update:secret@ftp.example.com/updates/database.mdb");
BOOL bResult;

// Upload the file using the specified URL
bResult = FtpUploadFileEx(lpszLocalFile,
                          lpszRemoteFile,
                          FTP_OPTION_PASSIVE,
                          &ftpStatus,
                          NULL, 0);

if (!bResult)
{
    TCHAR szError[128];

    // Display a message box that describes the error
    FtpGetErrorString(FtpGetLastError(), szError, 128);
    MessageBox(NULL, szError, NULL, MB_ICONEXCLAMATION|MB_TASKMODAL);
    return;
}
```

FtpValidateHostName Function

```
BOOL WINAPI FtpValidateHostName(
   LPCTSTR lpszHostName,
   LPTSTR lpszAddress,
   INT nMaxLength
);
```

The **FtpValidateHostName** function determines if the specified host name is valid and returns its IP address.

Parameters

lpszHostName

A null-terminated string which specifies the host name. The function will fail If this parameter is NULL or an empty string.

lpszAddress

A null-terminated string buffer which will contain the IP address of the host. If specified, this string must be large enough to store the complete IP address, including the terminating null character. If this parameter is NULL or the ***nMaxLength*** parameter is zero, it will be ignored and the IP address will not be returned.

nMaxLength

An integer value that specifies the maximum number of characters which can be copied into the ***lpszAddress*** string buffer. The buffer must be large enough to store the complete address. Because this function can return either an IPv4 or IPv6 address, it is recommended the minimum length for the buffer to be 46 characters. If this parameter is zero, the ***lpszAddress*** parameter will be ignored.

Return Value

If the function succeeds, the host name is valid and the return value will be non-zero. If the function fails, the host name could not be resolved to an IP address and the return value will be zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpValidateHostName** function provides a convenient way to determine if a host name is valid by attempting to resolve the name into an IP address. If the Unicode version of this function is used, any non-ASCII characters in the host name will be automatically encoded into a compatible format and then resolved to an IP address. If you are unsure if an internationalized domain name will be specified as the host name, it is recommended you use the Unicode version.

If the ***lpszHostName*** parameter specifies a valid IPv4 or IPv6 address string instead of a host name, this function will return a copy of that IP address in the buffer provided by the caller. This allows the function to be used in cases where a user may input either a host name or IP address.

If you wish to validate a complete FTP URL instead of a host name, use the **FtpValidateUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpConnectUrl, FtpValidateUrl

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FtpValidateUrl Function

```
BOOL WINAPI FtpValidateUrl(
    LPCTSTR lpszUrl
);
```

The **FtpValidateUrl** function determines if a string represents a valid FTP URL.

Parameters

lpszUrl

A null-terminated string that specifies the URL to validate.

Return Value

If the specified URL is valid and the host name can be resolved to an IP address, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpValidateUrl** function will check the value of a string to ensure that it represents a complete, valid URL using either a standard or secure FTP scheme. This function will not establish a connection with the server to verify that it exists, it will only attempt to resolve the host name to an IP address. If the remote host is specified as an IP address, this function will check to make sure that the address is formatted correctly. Note that if you wish to specify an IPv6 address, you must enclose the address in brackets.

To establish a connection with a server using a URL, use the **FtpConnectUrl** function.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpVerifyFile Function

```
BOOL WINAPI FtpVerifyFile(
   HCLIENT hClient,
   LPCTSTR lpszLocalFile,
   LPCTSTR lpszRemoteFile,
   DWORD dwOptions
);
```

The **FtpVerifyFile** function attempts to verify that the contents of a file on the local system are the same as the specified file on the server.

Parameters

hClient

Handle to the client session.

lpszLocalFile

A null-terminated string which specifies the file on the local system the remote file will be validated against. The file pathing and name conventions should follow Windows conventions. It is permitted to include environment variables in the local path by surrounding the variable with percent (%) symbols. Local file paths may also use standard file URLs.

lpszRemoteFile

A null-terminated string which specifies the file on the server that will be validated. The file naming conventions must be that of the host operating system. It is permitted to use a URL as the remote file name as long as the server name and port number match what was used to establish the connection.

dwOptions

Specifies the options that may be used when comparing the files. This parameter may be one or more of the following values:

Value	Description
FTP_VERIFY_DEFAULT	File verification should use the best option available based on the available server features. If the server supports the XSHA1 or XMD5 command, the function will calculate an SHA-1 or MD5 hash of the local file contents and compare the value with the file on the server. If the server does not support either hash algorithm, but it does support the XCRC command, the function will calculate a CRC32 checksum of the local file contents and compare the value with the file on the server. If the server does not support any hash or checksum commands, the function will compare the size of the local and remote files.
FTP_VERIFY_SIZE	Files are verified by comparing the number of bytes of data in the local and remote files. This is the least reliable option, and should only be used if the server does not support either the XSHA1, XMD5 or XCRC commands.
FTP_VERIFY_CRC32	Files are verified by calculating a CRC32 checksum of the local file contents and comparing it with the value returned by the server in response to the XCRC command. This option should only be used if the server does not support the XSHA1 or XMD5 commands.

FTP_VERIFY_MD5	Files are verified by calculating an MD5 hash of the local file contents and comparing it with the value returned by the server in response to the XMD5 command. This option should only be used if the server does not support the XSHA1 command.
FTP_VERIFY_SHA1	Files are verified by calculating an SHA-1 hash of the local file contents and comparing it with the value returned by the server in response to the XSHA1 command. This is the preferred option for performing file verification.

Return Value

If the function succeeds, the return value is non-zero. If the function fails, the return value is zero. To get extended error information, call **FtpGetLastError**.

Remarks

The **FtpVerifyFile** function will attempt to verify that the contents of the local and remote files are identical using one of several methods, based on the features that the server supports. Preference will be given to the most reliable method available, using either an SHA-1 hash, MD5 hash, a CRC32 checksum or comparing the size of the file, in that order.

The method used to verify a file's contents determines how confidently it can be said that the local and remote files are identical. This function supports several algorithms, listed below in order of preference based on reliability and availability:

- SHA-1 is a cryptographic hash function that produces a 160-bit (20-byte) hash value. It is the most reliable option supported by this function and is preferred for verifying file contents. Although no longer recommended for cryptographic security due to potential collision attacks, it remains well-suited for file integrity checks where the threat of intentional tampering is low.
- MD5 generates a 128-bit (16-byte) hash and is faster than SHA-1. It offers a reasonable balance between performance and reliability for non-security-critical applications such as file verification. However, it is less resistant to collisions and should be used only if SHA-1 is not supported by the server.
- CRC32 is a non-cryptographic checksum algorithm that produces a 32-bit value. It is designed for detecting accidental data corruption rather than verifying content integrity. CRC32 is significantly faster but also far more prone to collisions, and should only be used when stronger methods like SHA-1 or MD5 are unavailable.
- If none of the supported hash or checksum commands are available, the function falls back to comparing the local and remote file sizes. This is the least reliable method and can only detect differences in file length, not in actual content.

It is not recommended that you use this function with text files because of the different end-of-line conventions used by different operating systems. For example, a text file on a Windows system uses a carriage-return and linefeed pair to indicate the end of a line of text. However, on a UNIX system, a single linefeed is used to indicate the end of a line. This can cause the **FtpVerifyFile** function to indicate the files are not identical, even though the only difference is in the end-of-line characters that are used.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpWaitForQueue Function

```
BOOL WINAPI FtpWaitForQueue(
   HQUEUE hQueue,
   DWORD dwMilliseconds,
   LPDWORD lpdwElapsed,
   LPDWORD lpdwError
);
```

The **FtpWaitForQueue** function waits for the specified queue to complete the file transfers.

Parameters

hQueue

A handle to a file transfer queue.

dwMilliseconds

An unsigned integer value which specifies the number of milliseconds to wait for the queue to complete processing. If this value is zero, the function will return immediately. If this value is INFINITE (0xFFFFFFFF), the function will block indefinitely until all files in the queue have been processed.

lpdwElapsed

A pointer to an unsigned integer which will contain the number of milliseconds the queue manager has been active when the function returns. If this information is not needed, this parameter can be NULL. If this parameter is not NULL, it will always be initialized to a value of zero.

lpdwError

A pointer to an unsigned integer which will contain the last error code set if a file transfer has failed or was canceled. If this information is not needed, this parameter can be NULL. If this parameter is not NULL, it will always be initialized to a value of zero.

Return Value

If the function succeeds, the return value is non-zero, which means the queue manager has completed transferring all queued files. If the function fails, or the timeout period elapses, it will return zero. To get extended error information, call **FtpGetLastError**.

Remarks

This function will cause the current thread to block until either the queue manager has completed processing all files in the queue, or until the specified number of milliseconds have elapsed. It is important to note that Windows messages will not be processed during this time. If you call this function within the main UI thread, it can potentially cause the application to become non-responsive. To determine the current state of the queue without blocking the current thread, call the **FtpGetQueueStatus** function.

If the *dwMilliseconds* parameter is non-zero and file transfers have not completed within the specified amount of time, the function will return zero and the last error code will be set to `ST_ERROR_OPERATION_TIMEOUT`.

If an event callback function has been specified when starting the queue, you should never call this function within the event handler. Attempting to do so can potentially create a situation which will cause the application to become non-responsive. The function will return zero if it determines it's being called within the context of the queue manager thread and will set the last error code to `ST_ERROR_THREAD_DEADLOCK`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FtpWrite Function

```
INT WINAPI FtpWrite(
   HCLIENT hClient,
   LPBYTE lpBuffer,
   INT cbBuffer
);
```

The **FtpWrite** function sends the specified number of bytes to the server.

Parameters

hClient

Handle to the client session.

lpBuffer

The pointer to the buffer which contains the data that is to be sent to the server.

cbBuffer

The number of bytes to send from the specified buffer.

Return Value

If the function succeeds, the return value is the number of bytes actually written. If the function fails, the return value is FTP_ERROR. To get extended error information, call **FtpGetLastError**.

Remarks

The return value may be less than the number of bytes specified by the ***cbBuffer*** parameter. In this case, the data has been partially written and it is the responsibility of the client application to send the remaining data at some later point. For non-blocking clients, the client must wait for the next asynchronous notification message before it resumes sending data.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FTPCLIENTQUOTA

The **FTPCLIENTQUOTA** structure provides information about the file quota for the current client session.

```
typedef struct _FTPCLIENTQUOTA
{
    DWORD   dwFileCount;
    DWORD   dwFileLimit;
    DWORD   dwDiskUsage;
    DWORD   dwDiskLimit;
} FTPCLIENTQUOTA, *LPFTPCLIENTQUOTA;
```

Members

dwFileCount

An unsigned integer value which specifies the number of files that the user has created. If file quotas have not been enabled for the current user, this value will be zero.

dwFileLimit

An unsigned integer value which specifies the maximum number of files that may be created by the user. If file quotas have not been enabled for the current user, this value will be zero.

dwDiskUsage

An unsigned integer value which specifies the number of bytes of disk storage that has been allocated by the current user. If file quotas have not been enabled for the current user, this value will be zero.

dwDiskLimit

An unsigned integer value which specifies the maximum number of bytes of disk storage that may be allocated by the current user. If file quotas have not been enabled for the current user, this value will be zero.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FTPFILESTATUS

This structure is used by the **FtpEnumFiles**, **FtpGetFirstFile** and **FtpGetNextFile** functions to return information about files on the server.

```
typedef struct _FTPFILESTATUS
{
    TCHAR        szFileName[FTP_MAXFILENAMELEN];
    TCHAR        szFileOwner[FTP_MAXOWNERNAMELEN];
    TCHAR        szFileGroup[FTP_MAXGROUPNAMELEN];
    BOOL         bIsDirectory;
    DWORD        dwFileSize;
    DWORD        dwFileLinks;
    DWORD        dwFileVersion;
    DWORD        dwFilePerms;
    SYSTEMTIME   stFileDate;
} FTPFILESTATUS, *LPFTPFILESTATUS;
```

Members

szFileName

A string buffer which contains the name of the file on the server.

szFileOwner

A string buffer which contains the name of the user that owns the file on the server. Note that not all server types support the concept of file ownership by a user. Some UNIX systems will not provide this information if an anonymous login was used. For the proprietary Sterling directory formats, the "mailbox" is stored in this member.

szFileGroup

A string buffer which contains the name of the group that owns the file on the server. Note that not all server types support the concept of file ownership by a group. For the proprietary Sterling directory formats, the "batch number" is stored in this member, with the character # prepended for the format FTP_DIRECTORY_STERLING_2.

bIsDirectory

A boolean flag which specifies if the file is actually a subdirectory.

dwFileSize

The size of the file in bytes on the server. Servers that return file information in an MS-DOS format will always set this value to zero if the file refers to a subdirectory. If the file is a text file, the file size on the server may be different than the size on the local host if different end-of-line character conventions are used. It should be noted that under VMS, the file size is reported in 512 byte blocks, so the size should be considered approximate on that platform.

dwFileLinks

The number of links to the file. Note that not all server types support the concept of file links, in which case this value will be zero.

dwFileVersion

The number of revisions made to the file. Note that not all server types support the concept of file versioning, in which case this value will be zero. Currently this value will only be non-zero for VMS platforms.

dwFilePerms

The permissions associated with the file. This value is actually a combination of bits that specify the

individual permissions for the file owner, group and world (all other users). For those familiar with UNIX, the file permissions are the same as those used by the chmod command. For the proprietary Sterling directory formats, a bit map representing the status codes and transfer protocol of the file is stored in this member.

stFileDate

A SYSTEMTIME structure which specifies the date that the file was created or last modified.

File Permissions

Value	Description
FILE_OWNER_READ	The owner has permission to open the file for reading. If the current user is the owner of the file, this grants the user the right to download the file to the local system.
FILE_OWNER_WRITE	The owner has permission to open the file for writing. If the current user is the owner of the file, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_OWNER_EXECUTE	The owner has permission to execute the contents of the file. The file is typically either a binary executable, script or batch file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_GROUP_READ	Users in the specified group have permission to open the file for reading. If the current user is in the same group as the file owner, this grants the user the right to download the file.
FILE_GROUP_WRITE	Users in the specified group have permission to open the file for writing. On some platforms, this may also imply permission to delete the file. If the current user is in the same group as the file owner, this grants the user the right to replace the file. If this permission is set for a directory, this grants the user the right to create and delete files.
FILE_GROUP_EXECUTE	Users in the specified group have permission to execute the contents of the file. If this permission is set for a directory, this may also grant the user the right to open that directory and search for files in that directory.
FILE_WORLD_READ	All users have permission to open the file for reading. This permission grants any user the right to download the file to the local system.
FILE_WORLD_WRITE	All users have permission to open the file for writing. This permission grants any user the right to replace the file. If this permission is set for a directory, this grants any user the right to create and delete files.
FILE_WORLD_EXECUTE	All users have permission to execute the contents of the file. If this permission is set for a directory, this may also grant all users the right to open that directory and search for files in that directory.

Sterling Status Codes

Bits 0-25 correspond to letters of the alphabet, most of which have distinct meanings in the Sterling formats.

Letter code	Bit position	Hexadecimal value

A	0	1h
B	1	2h
C	2	4h
n-th letter of alphabet	n-1	2 to the (n-1) power
Z	25	2000000h

For the proprietary Sterling directory formats, bits 26-31 represent the transfer protocol associated with the file:

Protocol	Bit position	Hexadecimal value	Constant
TCP	26	4000000h	FTP_STERLING_STATUS_TCP
FTP	27	8000000h	FTP_STERLING_STATUS_FTP
BSC	28	10000000h	FTP_STERLING_STATUS_BSC
ASC	29	20000000h	FTP_STERLING_STATUS_ASC
FTS	30	40000000h	FTP_STERLING_STATUS_FTS
other	31	80000000h	FTP_STERLING_STATUS_OTHER

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

Copyright © 2026 Catalyst Development Corporation. All rights reserved.

FTPFILESTATUSEX

This structure is used by the **FtpEnumFilesEx**, **FtpGetFirstFileEx** and **FtpGetNextFileEx** functions to return information about files on the server. This structure is designed for use with extended functions that support files larger than 4GB.

```
typedef struct _FTPFILESTATUSEX
{
    TCHAR          szFileName[FTP_MAXFILENAMELEN];
    TCHAR          szFileOwner[FTP_MAXOWNERNAMELEN];
    TCHAR          szFileGroup[FTP_MAXGROUPNAMELEN];
    BOOL           bIsDirectory;
    ULARGE_INTEGER uiFileSize;
    DWORD          dwFileLinks;
    DWORD          dwFileVersion;
    DWORD          dwFilePerms;
    DWORD          dwFileFlags;
    SYSTEMTIME     stFileDate;
} FTPFILESTATUSEX, *LPFTPFILESTATUSEX;
```

Members

szFileName

A string buffer which contains the name of the file on the server.

szFileOwner

A string buffer which contains the name of the user that owns the file on the server. Note that not all server types support the concept of file ownership by a user. FTPQUEUEDFILE

This structure is used by the **FtpGetFirstQueuedFile**, **FtpGetNextQueuedFile** and **FtpGetQueuedFile** functions to return information about a file in the transfer queue.

```
typedef struct _FTPQUEUEDFILE
{
    DWORD          dwFileId;
    DWORD          dwQueueMode;
    DWORD          dwQueueFlags;
    DWORD          dwTimeElapsed;
    DWORD          dwLastError;
    ULARGE_INTEGER uiBytesCopied;
    TCHAR          szLocalFile[FTP_MAXFILENAMELEN];
    TCHAR          szRemoteName[FTP_MAXURLPATHLEN];
} FTPQUEUEDFILE, *LPFTPQUEUEDFILE;
```

Members

dwFileId

An unsigned integer which specifies a unique identifier for the queued file. The application should not make any assumptions about the value of the file identifiers. They should be considered opaque values which are only guaranteed to uniquely identify a file in the transfer queue. In particular, there is no guarantee that the file identifiers will be sequential and they should not be used as index values into an array.

dwQueueMode

An unsigned integer value which specifies how the file was queued for transfer. It may be one of the following values:

Constant	Description
FTP_QUEUE_DOWNLOAD	The file was queued for download.
FTP_QUEUE_UPLOAD	The file was queued for upload.

dwQueueFlags

An unsigned integer which specifies one or more bit flags which provides information about the status of the file transfer. It may be one or more of the following values:

Constant	Description
FTP_QUEUE_FLAG_NONE	The file is pending transfer in queue.
FTP_QUEUE_FLAG_COMPLETED	The file has been transferred successfully. If this flag is set, no errors were encountered during the upload or download.
FTP_QUEUE_FLAG_FAILED	The file transfer failed. If this flag is set, the *dwError* member of this structure will contain the error code associated with the failed transfer.
FTP_QUEUE_FLAG_CANCELED	The file transfer was canceled. This flag is only set when the **FtpCancelQueuedFile** function has been called and a queued file is in the process of being uploaded or downloaded.

dwTimeElapsed

An unsigned integer which specifies the number of milliseconds required to complete the transfer. This value will be zero unless the file has been transferred successfully.

dwLastError

An unsigned integer which specifies the last error code for a failed transfer. If the file was transferred successfully, this value will be zero.

uiBytesCopied

A value which specifies the number of bytes which were copied during the file transfer. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

szLocalFile

A null-terminated string which specifies the full path to the local file being transferred.

szRemoteFile

A null-terminated string which specifies the complete URL to the remote file being transferred.

Remarks

It is possible that the ***szLocalFile*** and ***szRemoteFile*** structure members will be different than the values passed to the **FtpAddQueuedFile** function. Those values are normalized, with any relative paths converted to absolute paths. Internationalized domain names will be encoded and the URL paths will be collapsed, removing any extraneous path information. For example, if the remote file name is specified as `ftp://ftp.server.tld/folder1/../folder2/filename.txt` it would be normalized as `ftp://ftp.server.tld/folder2/filename.txt`.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib
Unicode: Implemented as Unicode and ANSI versions

FTPQUEUESTATUS

This structure is used by the **FtpGetQueueStatus** function to return information about the current status of the file transfer queue.

```
typedef struct _FTPQUEUESTATUS
{
    DWORD dwStatus;
    DWORD dwThreadId;
    DWORD dwQueuedFiles;
    DWORD dwPendingFiles;
    DWORD dwCopiedFiles;
    DWORD dwFailedFiles;
    DWORD dwTimeElapsed;
    DWORD dwCurrentFile;
    DWORD dwLastError;
    ULARGE_INTEGER uiBytesCopied;
    ULARGE_INTEGER uiBytesTotal;
} FTPQUEUESTATUS, *LPFTPQUEUESTATUS;
```

Members

dwStatus

An unsigned integer which specifies the current status of the queue. It can be one of the following values:

Value	Description
FTP_QUEUE_STATUS_IDLE	The file transfer queue is idle and no files are being uploaded or downloaded. This state is returned before **FtpStartQueue** has been called or after **FtpStopQueue** has been called. The queue will also automatically enter an idle state after the last file transfer has completed and the queue manager thread exits.
FTP_QUEUE_STATUS_ACTIVE	Files in the queue are being uploaded or downloaded. The *dwCurrentFile* member of this structure identifies the file which is currently being transferred.
FTP_QUEUE_STATUS_PAUSED	File transfers are currently paused. The queue enters this state after the **FtpSuspendQueue** function is called and resumes file transfers after the **FtpResumeQueue** function is called.

dwThreadId

An unsigned integer which specifies the thread ID for the queue manager which is performing the file transfers. All file transfers are performed asynchronously in a background worker thread. If this structure member is zero, the queue is idle and not performing file transfers. The application should not use the thread ID to obtain a handle to suspend or terminate the thread. This can potentially result in unexpected behavior or instability within the application.

dwQueuedFiles

An unsigned integer which specifies the total number of queued files. This value includes pending and completed file transfers.

dwPendingFiles

An unsigned integer which specifies the number of files which are queued to be transferred.

dwCopiedFiles

An unsigned integer which specifies the number of files which have been successfully transferred. This value reflects the total number of files which have the FTP_QUEUE_FLAG_COMPLETED status.

dwFailedFiles

An unsigned integer which specifies the number of files which have failed to transfer or the file transfer has been canceled. This value reflects the total number of files which have the FTP_QUEUE_FLAG_FAILED status.

dwTimeElapsed

An unsigned integer which specifies the total amount of time, in milliseconds, the queue manager has been active performing a file transfer. If the queue is idle, this value will reflect the total run time for the previously active queue. A value of zero indicates the queue was never active or the queue state has been reset with a call to **FtpResetQueue**.

dwCurrentFile

An unsigned integer which specifies the unique identifier for the current file being transferred. If no file transfer is in progress, this member will have a value of zero. If the value is non-zero, it can be passed to the **FtpGetQueuedFile** function to obtain information about the queued file.

dwLastError

An unsigned integer which specifies the last error code for a failed file transfer. If there have been no errors, this value will be zero.

uiBytesCopied

A value which specifies the number of bytes which were copied during the current or last transfer. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

uiBytesTotal

A value which specifies the total number of bytes which were copied during the current queue run. The ULARGE_INTEGER type is a union of a structure and a 64-bit value which can be used on both 32-bit and 64-bit systems. For languages other than C/C++ you can define this structure member as an unsigned 64-bit integer type.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftpv12.lib

FTPTRANSFERSTATUS

This structure is used by the **FtpGetTransferStatus** function to return information about a file transfer in progress.

```
typedef struct _FTPTRANSFERSTATUS
{
   DWORD   dwBytesTotal;
   DWORD   dwBytesCopied;
   DWORD   dwBytesPerSecond;
   DWORD   dwTimeElapsed;
   DWORD   dwTimeEstimated;
   TCHAR   szLocalFile[FTP_MAXFILENAMELEN];
   TCHAR   szRemoteFile[FTP_MAXFILENAMELEN];

} FTPTRANSFERSTATUS, *LPFTPTRANSFERSTATUS;
```

Members

dwBytesTotal

The total number of bytes that will be transferred. If the file is being copied from the server to the local host, this is the size of the remote file. If the file is being copied from the local host to the server, it is the size of the local file. If the file size cannot be determined, this value will be zero.

dwBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the file transfer is completed. This is based on the average number of bytes transferred per second.

szLocalFile

A null-terminated string which specifies the local file that is being copied to or from the server.

szRemoteFile

A null-terminated string which specifies the remote file that is being copied to or from the local system.

Remarks

If the option FTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values returned in the ***dwTimeElapsed*** and ***dwTimeEstimated*** members will be in milliseconds instead of seconds. You can use this option to obtain more accurate elapsed times when uploading or downloading small files over a fast network connection.

If you are uploading or downloading large files which exceed 4GB, you should use the **FTPTRANSFERSTATUSEX** structure which uses 64-bit integers for the file size.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

Header File: cstools12.h

FTPTRANSFERSTATUSEX

This structure is used by the **FtpGetTransferStatusEx** function to return information about a file transfer in progress. This structure is designed for use with extended functions that support files larger than 4GB.

```
typedef struct _FTPTRANSFERSTATUSEX
{
   ULARGE_INTEGER dwBytesTotal;
   ULARGE_INTEGER dwBytesCopied;
   DWORD          dwBytesPerSecond;
   DWORD          dwTimeElapsed;
   DWORD          dwTimeEstimated;
   DWORD          dwReserved;
   TCHAR          szLocalFile[FTP_MAXFILENAMELEN];
   TCHAR          szRemoteFile[FTP_MAXFILENAMELEN];
} FTPTRANSFERSTATUSEX, *LPFTPTRANSFERSTATUSEX;
```

Members

uiBytesTotal

The total number of bytes that will be transferred. If the file is being copied from the server to the local host, this is the size of the remote file. If the file is being copied from the local host to the server, it is the size of the local file. If the file size cannot be determined, this value will be zero.

uiBytesCopied

The total number of bytes that have been copied.

dwBytesPerSecond

The average number of bytes that have been copied per second.

dwTimeElapsed

The number of seconds that have elapsed since the file transfer started.

dwTimeEstimated

The estimated number of seconds until the file transfer is completed. This is based on the average number of bytes transferred per second.

dwReserved

This structure member is reserved for future use.

szLocalFile

A null-terminated string which specifies the local file that is being copied to or from the server.

szRemoteFile

A null-terminated string which specifies the remote file that is being copied to or from the local system.

Remarks

If the option FTP_OPTION_HIRES_TIMER has been specified when connecting to the server, the values returned in the ***dwTimeElapsed*** and ***dwTimeEstimated*** members will be in milliseconds instead of seconds. SECURITYCREDENTIALS

The **SECURITYCREDENTIALS** structure specifies the information needed by the library to specify additional security credentials, such as a client certificate or private key, when establishing a secure connection.

```
typedef struct _SECURITYCREDENTIALS
{
    DWORD    dwSize;
    DWORD    dwProtocol;
    DWORD    dwOptions;
    DWORD    dwReserved;
    LPCTSTR  lpszHostName;
    LPCTSTR  lpszUserName;
    LPCTSTR  lpszPassword;
    LPCTSTR  lpszCertStore;
    LPCTSTR  lpszCertName;
    LPCTSTR  lpszKeyFile;
} SECURITYCREDENTIALS, *LPSECURITYCREDENTIALS;
```

Members

dwSize

Size of this structure. If the structure is being allocated dynamically, this member must be set to the size of the structure and all other unused structure members must be initialized to a value of zero or NULL.

dwProtocol

A bitmask of supported security protocols. The value of this structure member is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_SSL	Either SSL 2.0 or SSL 3.0 should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, TLS will be excluded from the list of supported protocols. Both SSL 2.0 and 3.0 have been deprecated and will never be used unless explicitly specified. It is not recommended that you enable either of these protocols for secure connections because it will cause most servers to reject your connection request, even if a version of TLS is also specified.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only

	protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol should be used when establishing the connection. This is the default version of the protocol that is supported by most SSH servers.

dwOptions

A value which specifies one or options. This value should always be zero for connections using SSH. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library

	will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

dwReserved

This structure member is reserved for future use and should always be initialized to zero.

lpszHostName

A null-terminated string which specifies the hostname that will be used when validating the server certificate. If this member is NULL, then the server certificate will be validated against the hostname used to establish the connection.

lpszUserName

A null-terminated string which identifies the owner of client certificate. Currently this member is not used by the library and should always be initialized as a NULL pointer.

lpszPassword

A null-terminated string which specifies the password needed to access the certificate. Currently this member is only used if the CREDENTIAL_STORE_FILENAME option has been specified. If there is no password associated with the certificate, then this member should be initialized as a NULL pointer.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The library will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the library will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the library will return an error indicating that the certificate could not be found. If the SECURITY_PROTOCOL_SSH

protocol has been specified, this member should be NULL.

lpszKeyFile

A null-terminated string which specifies the name of the file which contains the private key required to establish the connection. This member is only used for SFTP (SSH) connections and should always be NULL when establishing a secure connection using FTPS (FTP+TLS). If the member is NULL, then no private key is used. The private key file must be in the standard PEM format defined in RFC 1422. Both the standard RSA private key format and the proprietary OpenSSH format are supported.

Remarks

A client application only needs to create this structure if the server requires that the client provide a certificate as part of the process of negotiating the secure session. If a certificate is required, note that it must have a private key associated with it. Attempting to use a certificate that does not have a private key will result in an error during the connection process indicating that the client credentials could not be established.

If you are using a local certificate store, with the certificate and private key stored in the registry, you can explicitly specify whether the certificate store for the current user or the local machine (all users) should be used. This is done by prefixing the certificate store name with "HKCU:" for the current user, or "HKLM:" for the local machine. For example, a certificate store name of "HKLM:MY" would specify the personal certificate store for the local machine, rather than the current user. If neither prefix is specified, then it will default to the certificate store for the current user. You can manage these certificates using the CertMgr.msc Microsoft Management Console (MMC) snap-in.

It is possible to load the certificate from a file rather than from current user's certificate store. The ***dwOptions*** member should be set to CREDENTIAL_STORE_FILENAME and the ***lpszCertStore*** member should specify the name of the file that contains the certificate and its private key. The file must be in Private Information Exchange (PFX) format, also known as PKCS #12. These certificate files typically have an extension of .pfx or .p12. Note that if a password was specified when the certificate file was created, it must be provided in the ***lpszPassword*** member or the library will be unable to access the certificate.

Note that the ***lpszUserName*** and ***lpszPassword*** members are values which are used to access the certificate store or private key file. They are not the credentials which are used when establishing the connection with the remote host or authenticating the client session.

The ***lpszKeyFile*** path can use environment variables enclosed in percent symbols, and the path to the private key file will be normalized. It is recommended you always use an absolute path to the private key file. If you do not include a path, it will use the current working directory for the process. This can produce inconsistent results with multithreaded applications because the current working directory for a process is a global value and it can be changed by any thread at any time.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1

SECURITYINFO

The **SECURITYINFO** structure contains security related information about the connection, including the protocol, cipher suite and certificate.

```
typedef struct _SECURITYINFO
{
   DWORD        dwSize;
   DWORD        dwProtocol;
   DWORD        dwCipher;
   DWORD        dwCipherStrength;
   DWORD        dwHash;
   DWORD        dwHashStrength;
   DWORD        dwKeyExchange;
   DWORD        dwCertStatus;
   SYSTEMTIME   stCertIssued;
   SYSTEMTIME   stCertExpires;
   LPCTSTR      lpszCertIssuer;
   LPCTSTR      lpszCertSubject;
   LPCTSTR      lpszFingerprint;
} SECURITYINFO, *LPSECURITYINFO;
```

Members

dwSize

Specifies the size of the data structure. This member must always be initialized to the size of the structure in bytes prior to passing the address of this structure to the function. If this this member is not initialized, an error will be returned indicating that an invalid parameter has been passed to the function.

dwProtocol

A numeric value which specifies the security protocol selected when establishing the connection.

Value	Description
SECURITY_PROTOCOL_NONE	The connection is not secure. This value indicates a standard connection was established and all other structure members will have a value of zero.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol was selected when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol was selected when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol was selected when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.
SECURITY_PROTOCOL_SSH2	The Secure Shell 2.0 protocol was selected. This protocol will only be used when connecting to an SSH server and is not supported with any other application protocol. Version 1.0 of the protocol is no longer considered secure and is not supported.

dwCipher

A numeric value which specifies the cipher that was selected when establishing the secure connection.

Value	Description
SECURITY_CIPHER_AES	The Advanced Encryption Standard cipher is a fixed block size cipher which use a key size of 128, 192 or 256 bits.
SECURITY_CIPHER_DES	The Data Encryption Standard block cipher was selected. This is a fixed key length cipher, using 56-bit keys.
SECURITY_CIPHER_DES3	The Triple DES block cipher was selected. This cipher encrypts the data three times using different keys, effectively providing a 168-bit length key.
SECURITY_CIPHER_DESX	A variant of the DES block cipher which XORs an extra 64-bits of the key before and after the plaintext has been encrypted, increasing the key size to 184 bits.
SECURITY_CIPHER_RC4	The RC4 stream cipher was selected. This is a variable key length cipher which supports keys between 40 and 128 bits, in 8-bit increments.
SECURITY_CIPHER_RC5	The RC5 block cipher was selected. This is a variable key length cipher which supports keys up to 2040 bits, in 8-bit increments.

dwCipherStrength

A numeric value which specifies the strength (the length of the cipher key in bits) of the cipher that was selected. Typically this value will be 128 or 256. 40-bit and 56-bit key lengths are considered weak encryption, and subject to brute force attacks. 128-bit and 256-bit key lengths are considered to be secure, and are the recommended key length for secure communications.

dwHash

A numeric value which specifies the hash algorithm which was selected.

Value	Description

SECURITY_HASH_MD5	The MD5 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA1	The SHA-1 algorithm was selected. Its use has been deprecated and is no longer considered to be cryptographically secure.
SECURITY_HASH_SHA256	The SHA-256 algorithm was selected.
SECURITY_HASH_SHA384	The SHA-384 algorithm was selected.
SECURITY_HASH_SHA512	The SHA-512 algorithm was selected.

dwHashStrength

A numeric value which specifies the strength (the length in bits) of the message digest that was selected.

dwKeyExchange

A numeric value which specifies the key exchange algorithm which was selected.

Value	Description
SECURITY_KEYEX_RSA	The RSA public key algorithm was selected.
SECURITY_KEYEX_KEA	The Key Exchange Algorithm (KEA) was selected. This is an improved version of the Diffie-Hellman public key algorithm.
SECURITY_KEYEX_DH	The Diffie-Hellman key exchange algorithm was selected.
SECURITY_KEYEX_ECDH	The Elliptic Curve Diffie-Hellman key exchange algorithm was selected. This is a variant of the Diffie-Hellman algorithm which uses elliptic curve cryptography.

dwCertStatus

A numeric value which specifies the status of the certificate returned by the secure server.

Value	Description
SECURITY_CERTIFICATE_VALID	The certificate is valid.
SECURITY_CERTIFICATE_NOMATCH	The certificate is valid, but the domain name does not match the common name in the certificate.
SECURITY_CERTIFICATE_EXPIRED	The certificate is valid, but has expired.
SECURITY_CERTIFICATE_REVOKED	The certificate has been revoked and is no longer valid.
SECURITY_CERTIFICATE_UNTRUSTED	The certificate or certificate authority is not trusted on the local system.
SECURITY_CERTIFICATE_INVALID	The certificate is invalid. This typically indicates that the internal structure of the certificate has been damaged.

stCertIssued

A structure which contains the date and time that the certificate was issued by the certificate authority. If the issue date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values. This member only has meaning for connections using the TLS

protocol.

stCertExpires

A structure which contains the date and time that the certificate expires. If the expiration date cannot be determined for the certificate, the SYSTEMTIME structure members will have zero values.

lpszCertIssuer

A null-terminated string which contains information about the organization that issued the certificate. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate issuer could not be determined, this member may be NULL. This member only has meaning for connections using the TLS protocol.

lpszCertSubject

A null-terminated string which contains information about the organization that the certificate was issued to. This string consists of one or more comma-separated tokens. Each token consists of an identifier, followed by an equal sign and a value. If the certificate subject could not be determined, this member may be NULL. This member only has meaning for connections using the TLS protocol.

lpszFingerprint

A null-terminated string which contains a sequence of hexadecimal values that uniquely identify the server. This member may be NULL.

Remarks

The size of this structure is typically determined using the **sizeof** operator in C/C++ and most other languages have a similar method for obtaining the size of a data structure or user-defined type. It is important to note the size of this structure will be different on 32-bit and 64-bit platforms due to the difference in the length of the structure members which are pointers.

When evaluating structure members which are string pointers, such as ***lpszCertIssuer*** and ***lpszCertSubject***, you should always check to ensure their values are not NULL (zero) before attempting to dereference them. If those values are undefined, it is not guaranteed they will point to zero-length strings.

There are additional protocols and ciphers defined which are not listed above because they are considered insecure and are no longer supported. It is important to note that most servers will reject attempts to use unsupported protocols such as SSL 3.0 and will either abort the connection or issue an error message and then immediately disconnect.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h

SYSTEMTIME

The **SYSTEMTIME** structure represents a date and time using individual members for the month, day, year, weekday, hour, minute, second, and millisecond.

```
typedef struct _SYSTEMTIME
{
    WORD wYear;
    WORD wMonth;
    WORD wDayOfWeek;
    WORD wDay;
    WORD wHour;
    WORD wMinute;
    WORD wSecond;
    WORD wMilliseconds;
} SYSTEMTIME, *LPSYSTEMTIME;
```

Members

wYear

Specifies the current year. The year value must be greater than 1601.

wMonth

Specifies the current month. January is 1, February is 2 and so on.

wDayOfWeek

Specifies the current day of the week. Sunday is 0, Monday is 1 and so on.

wDay

Specifies the current day of the month

wHour

Specifies the current hour.

wMinute

Specifies the current minute

wSecond

Specifies the current second.

wMilliseconds

Specifies the current millisecond.

File Transfer Protocol Server Library

Implements a server that enables the application to send and receive files using the File Transfer Protocol.

Reference

- Functions
- Data Structures
- Error Codes

Library Information

File Name	CSFTSV12.DLL
Version	12.0.3024.1286
LibID	BB27183D-4826-4F44-9EF7-128EADE765D4
Import Library	CSFTSV12.LIB
Dependencies	None
Standards	RFC 959, RFC 1579, RFC 2228

Overview

This library provides an interface for implementing an embedded, lightweight server that can be used to exchange files with a client using the standard File Transfer Protocol. The server can accept connections from any third-party application or a program developed using the SocketTools FTP client API.

The application specifies an initial server configuration and then responds to events that are raised by the API when the client sends a request to the server. An application may implement only minimal handlers for most events, in which case the default actions are performed for most standard FTP commands. However, an application may also use the event mechanism to filter specific commands or to extend the protocol by providing custom implementations of existing commands or add entirely new commands.

The server supports active and passive mode file transfers, has compatibility options for NAT router and firewall support, and provides support for secure file transfers using explicit TLS. Secure connections require a valid security certificate to be installed on the system.

Requirements

The SocketTools Library Edition libraries are compatible with any programming language which supports calling functions exported from a standard dynamic link library (DLL). You should install all updates for your development tools and have the current Windows SDK installed. The minimum supported version of Visual Studio is Visual Studio 2010 with Service Pack 1 (SP1) installed. The SocketTools header files are designed to be compatible with all modern C/C++ compilers and we also provide function definitions for several additional languages such as Object Pascal and Visual Basic.

This library is supported on Windows 7, Windows Server 2008 R2 and later versions of the desktop and server platforms. If you are deploying applications to Windows 7, you must have Service Pack 1 (SP1) installed as a minimum requirement. If you are deploying applications to Windows 8, you must have the 8.1 update installed. If you are targeting the Windows on ARM platform, the minimum

required version is Windows 10 build 1709.

SocketTools includes support for both 64-bit and 32-bit Windows platforms. All current versions of Windows are 64-bit, and we include 32-bit x86 libraries to maintain compatibility with legacy development tools. SocketTools also provides native ARM64 libraries for systems running Windows on ARM. Note that 32-bit applications on ARM use x86 emulation, and Microsoft no longer supports native 32-bit ARM (ARM32) applications. Embarcadero's C++Builder and Delphi compilers (as of version 12.3) do not support building native ARM64 applications for Windows. For developing applications targeting the Windows on ARM platform, we recommend using Visual Studio 2019 or later.

The import libraries included with SocketTools are provided in several different formats. The most commonly used format is COFF, which is available for x64, x86 and native ARM64 platforms. For compatibility with older Borland (Embarcadero) compilers, we also provide OMF libraries for x86 platforms and ELF libraries for x64 platforms. If you are using Visual Studio, you will want to use the standard COFF import libraries. Note that some languages may not require import libraries and will link to the exported functions in the DLL based on the function declaration itself.

Distribution

When you distribute your application that uses this library, it is recommended that you install the file in the same folder as your application executable. If you install the library into a shared location on the system, it is important that you distribute the correct version for the target platform and it should be registered as a shared DLL. This is a standard Windows dynamic link library, not an ActiveX component, and does not require COM registration.

File Transfer Protocol Server Functions

Function	Description
FtpAddVirtualUser	Add a new virtual user for the specified server
FtpAuthenticateClient	Authenticate the client and assign access rights for the session
FtpChangeClientDirectory	Change the current working directory for the client session
FtpCreateServerCredentials	Create a new server security credentials structure
FtpDeleteServerCredentials	Delete a previously created security credentials structure
FtpDeleteVirtualUser	Delete a virtual user from the specified server
FtpDisconnectClient	Disconnect the specific client session, closing the control channel and aborting any file transfer
FtpEnableClientAccess	Enable or disable access rights for the specified client session
FtpEnableCommand	Enable or disable a specific server command
FtpEnumServerClients	Returns a list of active client sessions established with the specified server
FtpGetActiveClient	Return the client ID for the active client session associated with the current thread
FtpGetClientAccess	Return the access rights that have been granted to the client session
FtpGetClientAddress	Return the IP address of the specified client session
FtpGetClientCredentials	Return the credentials for the specified client session
FtpGetClientDirectory	Return the current working directory for a client session
FtpGetClientFileType	Return the current file type used for transfers by the specified client
FtpGetClientHomeDirectory	Return the home directory for an authenticated client session
FtpGetClientIdentity	Return the identity of the specified client session
FtpGetClientIdleTime	Return the idle timeout period for the specified client
FtpGetClientLocalPath	Return the full local path for the specified virtual path
FtpGetClientServer	Return the handle to the server that created the specified client session
FtpGetClientThreadId	Returns the thread ID associated with the specified client session
FtpGetClientUserName	Return the user name associated with the specified client session
FtpGetClientVirtualPath	Return the virtual path for a local file on the server
FtpGetCommandFile	Return the full path to the local file name or directory specified by the client
FtpGetCommandLine	Return the complete command line issued by the client
FtpGetCommandName	Return the name of the last command issued by the client
FtpGetCommandParam	Return the value of the specified parameter for the command issued by the client
FtpGetCommandParamCount	Return the number of parameters to the current command issued by the client
FtpGetCommandResult	Return the result code and a description of the last command processed by the server
FtpGetCommandUsage	Return the number of times a specific command has been issued by all clients
FtpGetProgramExitCode	Return the exit code of the last program executed by the client
FtpGetProgramName	Return the name of the last program executed by the client
FtpGetProgramOutput	Return a copy of the standard output from the last program executed by the client
FtpGetProgramText	Return a copy of the standard output from the last program in a string buffer
FtpGetRenamedFile	Return the original name of a file being renamed by the client
FtpGetServerAddress	Return the IP address for the server

FtpGetServerDirectory	Return the full path to the root directory assigned to the specified server
FtpGetServerError	Return information about the last server error that occurred
FtpGetServerIdentity	Return the identity and version information for the specified server
FtpGetServerLogFile	Return the current log file format and full path for the file
FtpGetServerMemoryUsage	Return the amount of memory allocated for the server and all client sessions
FtpGetServerName	Return the host name assigned to the server or specified client session
FtpGetServerOptions	Return the configuration options for the specified server
FtpGetServerPriority	Return the current priority assigned to the specified server
FtpGetServerStackSize	Return the initial size of the stack allocated for threads created by the server
FtpGetServerTransferInfo	Return information about the current file transfer for the client session
FtpGetServerUuid	Return the UUID assigned to the specified server
FtpGetServerUuidString	Return the UUID assigned to the server as a printable string
FtpIsClientAnonymous	Determine if the specified client has authenticated as an anonymous user
FtpIsClientAuthenticated	Determine if the specified client session has been authenticated
FtpIsCommandEnabled	Determine if the specified command is currently enabled or disabled
FtpRegisterProgram	Register a program for use with the SITE EXEC command
FtpRenameServerLogFile	Rename or delete the current log file being updated by the server
FtpSendResponse	Send a result code and optional message to the client in response to a command
FtpServerAsyncNotify	Enable or disable asynchronous notification of changes in server status
FtpServerDisableTrace	Disable logging of network function calls
FtpServerEnableTrace	Enable logging of network function calls to a file
FtpServerInitialize	Initialize the library and validates the specified license key at runtime
FtpServerProc	Callback function used to process server events
FtpServerRestart	Restart the server, terminating all active client sessions
FtpServerResume	Resume accepting client connections on the specified server
FtpServerStart	Start the server and begin accepting client connections
FtpServerStop	Stop the server and terminate all active client connections
FtpServerSuspend	Suspend accepting client connections on the specified server
FtpServerThrottle	Limit the number of active client connections, connections per address and connection rate
FtpServerUninitialize	Terminate use of the library by the application
FtpSetClientAccess	Change the access rights associated with the specified client session
FtpSetClientFileType	Change the current file type used for transfers by the specified client
FtpSetClientIdentity	Change the identity string associated with the specified client session
FtpSetClientIdleTime	Change the idle timeout period for the specified client session
FtpSetCommandFile	Change the name of the local file or directory that is the target of the current command
FtpSetServerAddress	Change the IP address that the server will use with passive data connections
FtpSetServerError	Set the last error code for the specified server session
FtpSetServerIdentity	Change the identity and version information for the specified server
FtpSetServerLogFile	Change the current log format, level of detail and file name
FtpSetServerName	Change the hostname assigned to the specified server or client session

FtpSetServerPriority	Change the priority assigned to the specified server
FtpSetServerStackSize	Change the initial size of the stack allocated for threads created by the server

FtpAddVirtualUser Function

```
BOOL WINAPI FtpAddVirtualUser(
   HSERVER hServer,
   UINT nHostId,
   DWORD dwUserAccess,
   LPCTSTR lpszUserName,
   LPCTSTR lpszPassword,
   LPCTSTR lpszDirectory
);
```

Add a new virtual user for the specified server.

Parameters

hServer

The server handle.

nHostId

An integer value which identifies the virtual host. This parameter is reserved for future use and must always have a value of zero.

dwUserAccess

An integer value which specifies the access clients will be given when authenticated as this user. For a list of user access permissions, see User Access Constants.

lpszUserName

A null-terminated string which specifies the user name. The maximum length of a username is 63 characters and it is recommended that names be limited to alphanumeric characters. Whitespace, control characters and certain symbols such as path delimiters and wildcard characters are not permitted. If an invalid character is included in the name, the function will fail with an error indicating the username is invalid. This parameter cannot be NULL and the name must be at least three characters in length. Usernames are not case sensitive.

lpszPassword

A null-terminated string which specifies the user password. The maximum length of a password is 63 characters and is limited to printable characters. Whitespace and control characters are not permitted. If an invalid character is included in the password, the function will fail with an error indicating the password is invalid. This parameter cannot be NULL and must be at least one character in length. Passwords are case sensitive.

lpszDirectory

A null-terminated string which specifies the directory that will be the virtual user's home directory. If the server was started in multi-user mode, this directory will be relative to the user directory created by the server, otherwise it will be relative to the server root directory. If the directory does not exist, it will be created the first time that the virtual user successfully logs in to the server. If this parameter is NULL or an empty string, a default home directory will be created for the virtual user.

Return Value

If the function succeeds, the return value is non-zero. If the server handle is invalid or the virtual host ID does not specify a valid host, the function will return zero. If the function fails, the last error code will be updated to indicate the cause of the failure.

Remarks

The **FtpAddVirtualUser** function adds a virtual user that is associated with the specified virtual host. When a client connects with the server and provides authentication credentials, the server will check if the username has been created using this function. If a match is found, the client access rights will be updated.

If you wish to modify the information for a user, it is not necessary to delete the username first. If this function is called with a username that already exists, that record is replaced with the values passed to this function. You cannot use this function to create a virtual user named "anonymous".

The virtual users created by this function exist only as long as the server is active. If you wish to maintain a persistent database of users and passwords, you are responsible for its implementation based on the requirements of your specific application. For example, a simple implementation would be to store the user information in a local XML or INI file and then read that configuration file after the server has started, calling this function for each user that is listed.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpAuthenticateClient Function

```
BOOL WINAPI FtpAuthenticateClient(
    HSERVER hServer,
    UINT nClientId,
    DWORD dwUserAccess,
    BOOL bCreateHome,
    LPCTSTR lpszDirectory
);
```

Authenticate the client and assign access rights for the session.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

dwUserAccess

An unsigned integer which specifies one or more user access rights. For a list of user access rights that can be granted to the client, see User Access Constants.

bCreateHome

An integer value that specifics if the server should create the home directory for the authenticated client if it does not already exist. If this value is non-zero, the home directory will be created. If value is zero, the home directory will not be created and if it does not exist, this function will fail.

lpszDirectory

A null-terminated string that specifies the home directory for the user. If an absolute path is specified, it will be relative to the server root directory. If a relative path is specified, it will be a subdirectory of the home directory for the server instance. If this parameter is NULL or an empty string, a home directory will be assigned based on the server home directory and the user name.

Return Value

If the client session could be authenticated, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the client has already been authenticated, this function will return zero.

Remarks

The **FtpAuthenticateClient** function is used to authenticate a specific client session, typically in response to an FTP_CLIENT_USERAUTH event that indicates a client has requested authentication. This function is also used internally to automatically grant the appropriate access rights to local user and anonymous client sessions.

It is recommended that most applications specify FTP_ACCESS_DEFAULT as the ***dwUserAccess*** value for a client session, since this allows the server automatically grant the appropriate access based on the server configuration options for normal and anonymous users. If the server is going to be publicly accessible or third-party FTP clients will be used to access the server, you should always grant the FTP_ACCESS_LIST permission to clients. Many client applications will not function correctly if they are unable to obtain a list of files in the user's home directory.

If FTP_ACCESS_RESTRICTED is specified and the server was started in multi-user mode, the client

session will be effectively locked to its home directory and cannot navigate to the server root directory. By default, restricted client sessions are also limited to only downloading files and requesting directory listings. If a client session is not restricted, the client can access files outside of its home directory. Regardless of this option, a client cannot access files outside of the server root directory.

If FTP_ACCESS_RESTRICTED or FTP_ACCESS_ANONYMOUS is specified, the client session will be authenticated in a restricted mode and the access rights for the session will persist until the client disconnects from the server. Unlike regular users, the access rights for a restricted client cannot be changed by the server at a later point. This restriction is designed to prevent the inadvertent granting of rights to an untrusted client that could compromise the security of the server.

If the *lpszDirectory* parameter is NULL or an empty string and the server has been started in multi-user mode, each user is assigned their own home directory based on their username. If the server has not been started in multi-user mode, then the default home directory will be the server root directory and is shared by all users. The **FtpGetClientHomeDirectory** function will return the full path to the home directory for an authenticated client.

If the FTP_ACCESS_EXECUTE permission is granted to the client session, it can execute external programs using the SITE EXEC command. Because the program is executed in the context of the server process, it is recommended that you limit access to this functionality and ensure that the programs being executed do not introduce any security risks to the operating system. This permission is never granted by default, and the SITE EXEC command will return an error if the client session is anonymous, regardless of whether this permission is granted or not.

This function is should only be used for custom authentication schemes and is not necessary if you have used the **FtpAddVirtualUser** function to create virtual users.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpChangeClientDirectory Function

```
BOOL WINAPI FtpChangeClientDirectory(
    HSERVER hServer,
    UINT nClientId,
    LPCTSTR lpszDirectory
);
```

Change the current working directory for the specified client.

Parameters

hServer

The server handle.

nClientId

An unsigned integer which uniquely identifies the client session.

lpszDirectory

A null-terminated string which specifies the new current working directory for the client session. If this parameter is NULL or an empty string, the current working directory will be changed to the client home directory. If this parameter is not NULL, it must specify a directory that exists and is accessible by the server process.

Return Value

If the current working directory was changed, the return value is non-zero. If the server handle and client ID do not specify a valid client session, or the directory is invalid, this function will return zero.

Remarks

The **FtpChangeClientDirectory** function will change the current working directory for the specified client session. This function is called internally when the client sends the CWD or CDUP commands, however it may be explicitly used by the application to change the client's working directory in response to a server event.

This function cannot be used to change the current working directory for a client to an arbitrary directory outside of the server root directory. If the *lpszDirectory* parameter specifies a relative path (i.e.: a path that does not begin with a drive letter or leading path delimiter) then the new working directory will be relative to the current working directory. If an absolute path is specified, the absolute path must include the complete path to either the server root directory or the user's home directory, based on the permissions granted to the client session. If a path outside of the server root directory is specified, this function will fail with an access denied error.

Use caution when calling this function to override the directory specified by the client when it sends the CWD or CDUP commands. If your application changes the current working directory to one not specified by the client, it may cause unpredictable behavior in the client application because the actual path of the current working directory will not match the directory that was requested.

If this function is used to change the current working directory in response to the CWD command, you should not call the **FtpGetCommandParam** function and pass the command parameter as an argument to this function. You must use the **FtpGetCommandFile** function to obtain the directory name provided by the client prior to calling this function.

The application should never call the **SetCurrentDirectory** function in the Windows API to change the current directory for the process to the working directory of a client session. Because the server is

multithreaded and each client session is managed in its own thread, an application using this library should avoid using relative paths.

Requirements

Minimum Desktop Platform: Windows 7 Service Pack 1
Minimum Server Platform: Windows Server 2008 R2 Service Pack 1
Header File: cstools12.h
Import Library: csftsv12.lib
Unicode: Implemented as Unicode and ANSI versions

FtpCreateServerCredentials Function

```
BOOL WINAPI FtpCreateServerCredentials(
  DWORD dwProtocol,
  DWORD dwOptions,
  LPCTSTR lpszUserName,
  LPCTSTR lpszPassword,
  LPCTSTR lpszCertStore,
  LPCTSTR lpszCertName,
  LPVOID lpvReserved,
  LPSECURITYCREDENTIALS *lppCredentials
);
```

The **FtpCreateServerCredentials** function creates a SECURITYCREDENTIALS structure.

Parameters

dwProtocol

A bitmask of supported security protocols. This parameter is constructed by using a bitwise operator with any of the following values:

Value	Description
SECURITY_PROTOCOL_DEFAULT	The default security protocol will be used when establishing a connection. This option will always request the latest version of the preferred security protocol and is the recommended value. Currently the default security protocol is TLS 1.2.
SECURITY_PROTOCOL_TLS	Either the TLS 1.2 or 1.3 protocol should be used when establishing a secure connection. The correct protocol is automatically selected, based on what version of the protocol is supported by the server. If this is the only protocol specified, SSL will be excluded from the list of supported protocols. This may be necessary for some servers which reject any attempt to use the older SSL protocol and require that only TLS be used.
SECURITY_PROTOCOL_TLS10	The TLS 1.0 protocol should be used when establishing a secure connection. This version is supported on all Windows platforms, however some servers may reject connections using version 1.0 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.
SECURITY_PROTOCOL_TLS11	The TLS 1.1 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. Some servers may reject connections using version 1.1 in favor of using version 1.2. This version should only be used for backwards compatibility with older servers that have not been updated to use the current version of TLS.

SECURITY_PROTOCOL_TLS12	The TLS 1.2 protocol should be used when establishing a secure connection. This version is supported on Windows 7 and later desktop platforms, and Windows Server 2008 R2 and later server platforms. This version of TLS offers the broadest compatibility with most servers.
SECURITY_PROTOCOL_TLS13	The TLS 1.3 protocol should be used when establishing a secure connection. This is the newest version of the protocol and is only supported on Windows 11, Windows Server 2022 and later versions of Windows. If this version is not supported by the operating system, TLS 1.2 will be used instead.

dwOptions

A value which specifies one or options. This member is constructed by using a bitwise operator with any of the following values:

Value	Description
CREDENTIAL_STORE_CURRENT_USER	The library will attempt to open a store for the current user using the certificate store name provided in this structure. If no options are specified, then this is the default behavior.
CREDENTIAL_STORE_LOCAL_MACHINE	The library will attempt to open a local machine store using the certificate store name provided in this structure. If this option is specified, the library will always search for a local machine store before searching for the store by that name for the current user.
CREDENTIAL_STORE_FILENAME	The certificate store name is a file that contains the certificate and private key that will be used.

lpszUserName

A null-terminated string which specifies the certificate owner's username. A value of NULL specifies that no username is required. Currently this parameter is not used and any value specified will be ignored.

lpszPassword

A null-terminated string which specifies the certificate owner's password. A value of NULL specifies that no password is required. This parameter is only used if a PKCS #12 (PFX) certificate file is specified and that certificate has been secured with a password. This value will be ignored the current user or local machine certificate store is specified.

lpszCertStore

A null-terminated string which specifies the name of the certificate store to open. A certificate store is a collection of certificates and their private keys, typically organized by how they are used. If this value is NULL or points to an empty string, the default certificate store "MY" will be used.

Store Name	Description
CA	Certification authority certificates. These are certificates that are issued by

	entities which are entrusted to issue certificates to other individuals or organizations. Companies such as Comodo and DigiCert act as certification authorities.
MY	Personal certificates and their associated private keys for the current user. This store typically holds the client certificates used to establish a user's credentials. This corresponds to the "Personal" store that is displayed by the certificate manager utility and is the default store used by the library.
ROOT	Certificates that have been self-signed by a certificate authority. Root certificates for a number of different certification authorities such as Comodo and DigiCert are installed as part of the operating system and periodically updated by Microsoft.

lpszCertName

A null-terminated string which specifies the name of the certificate to use. The function will first search the certificate store for a certificate with a matching "friendly name"; this is a name for the certificate that is assigned by the user. Note that the name must match completely, but the comparison is not case sensitive. If no matching certificate is found, the function will then attempt to find a certificate that has a matching common name (also called the certificate subject). This comparison is less stringent, and the first partial match will be returned. If this second search fails, the function will return an error indicating that the certificate could not be found.

lpvReserved
